1. INTRODUCTION

Complex hyperbolic *n*-ball \mathbb{B}^n is a higher dimensional analogue of the unit 1-ball \mathbb{B}^1 in hyperbolic geometry. It is the domain $\mathbb{B}^n = \{z \in \mathbb{C}^n : |z| < 1\}$, or equivalently $\mathbb{P}V_-$ the projectivization of the negative cone $V_- = \{u \in V : h(u, u) < 0\}$ for $V \cong \mathbb{C}^{n+1}$ equipped with a hermitian form *h* with signature (n, 1). In this paper we study the following compact arithmetic quotient of \mathbb{B}^2 . We start from $K = \mathbb{Q}(\sqrt{D})$ a quadratic field with discriminant D > 0 and a CM extension $F = K(\sqrt{\alpha})$ for some totally negative $\alpha \in K$. We have 2 pairs of embeddings of $F \to \mathbb{C}$: $\sigma_1, \bar{\sigma}_1, \sigma_2, \bar{\sigma}_2$. Consider (V, h) where $V \cong F^{\oplus 3}$ is an *F*-vector space equipped with a hermitian form *h* with signature (2, 1) under the first pair of embeddings and definite under the other pair of embeddings. Then the special unitary group $\Gamma := SU(h^{\sigma_1}, \mathcal{O}_F)$ that preserves *h* and has entries in \mathcal{O}_F gives an arithmetic lattice, and its action on $(F \otimes \mathbb{C}, h^{\sigma_1})$ induces a compact arithmetic quotient of \mathbb{B}^2 . Denote D' to be the norm of the relative discriminant of the CM extension F/K. We proved the following.

Theorem 1.1. For any genus g, there exists $D_0(g) > 0$ and $D'_0 > 0$ such that for $D > D_0(g)$ and $D' > D'_0$, the corresponding $\Gamma \setminus \mathbb{B}^2$ defined as above has no complex curves of genus g.

This also has a moduli interpretation in terms of abelian sixfolds with \mathcal{O}_{F} endomorphism. See Section 5.2 for detail. We say that a skew-Hermitian form T over \mathbb{C} has signature (m, n) if the Hermitian form $i^{-1}T$ has signature (m, n).

Theorem 1.2. Fix a skew-Hermitian form T over F such that T is of signature (2,1) under a pair of complex embeddings of F and is definite under the other pair. For any complex curve C of genus g, consider abelian schemes $f : \mathcal{A} \to C$ of dimension 6 with \mathcal{O}_F -endomorphism of type (\mathcal{O}_F^3, T) . Then there exists $D_0(g) > 0$ and $D'_0 > 0$ such that for $D > D_0(g)$ and $D' > D'_0$, such type of abelian schemes must be isotrivial.

The proof uses the method of volume estimates, which has been used in, for example, [HT02, HT12, BT13, BT18, BT19] to prove interesting results in algebraic geometry. In contrast to existing literature, we use it to understand the geometry of quotient singularities. Compared to similar objects such as Hilbert modular surfaces, notable new phenomena for arithmetic quotient of 2-balls include the existence of 1-dimensional quotient singularities given by some special curves, and non-cyclic quotient singularities at the intersection of these curves. This requires a volume estimate to give a bound on the intersection number between these stacky special curves and any other complex curves. Compared to the volume estimates in [Mem23], our work focuses on the geometry near the quotient singularities instead of the boundaries.

2. Background

2.1. Complex Hyperbolic 2-ball. In this section we define complex hyperbolic *n*-balls and summarize useful facts about the n = 2 case. See [Gol99] or [Par03] for detail.

2.1.1. The projective model. The unit ball in \mathbb{C}^n and the Bergman metric, which is a natural metric with constant negative holomorphic sectional curvature, give a model for complex hyperbolic *n*-space \mathbb{B}^n . When n = 1, this is the usual Poincaré unit disc model of the hyperbolic plane. We now give a brief review of \mathbb{B}^n , especially the case where n = 2.

A Hermitian form on \mathbb{C}^n is a \mathbb{C} -valued \mathbb{R} -bilinear form $h : \mathbb{C}^n \times \mathbb{C}^n \to \mathbb{C}$ such that for any fixed $w \in \mathbb{C}^n$, $v \mapsto h(v, w)$ is \mathbb{C} -linear, and for any $v, w \in \mathbb{C}^n$, $h(v, w) = \overline{h(w, v)}$. Alternatively, if we fix a basis of \mathbb{C}^n , so v, w can be considered as column vectors, then a Hermitian form h is given by $(v, w) \mapsto v^H J_h w$ for some Hermitian matrix J_h . Here the superscript H means the Hermitian conjugate, i.e. the transpose of the element-wise complex conjugation of the matrix, and thus a matrix J is Hermitian if $J = J^H$.

Let V be \mathbb{C}^{n+1} equipped with a Hermitian form $\langle \cdot, \cdot \rangle$ of signature (n, 1). One example is the standard Hermitian form $h_{std}(u, v) = u_1 \bar{v}_1 + \cdots + u_n \bar{v}_n - u_{n+1} \bar{v}_{n+1}$. Since $\langle u, u \rangle$ is real for any $u \in V$, we can define subsets:

negative	$V_{-} = \{ u \in V : \langle u, u \rangle < 0 \}$
null	$V_0 = \{ u \in V \setminus \{0\} : \langle u, u \rangle = 0 \}$
positive	$V_+ = \{ u \in V : \langle u, u \rangle > 0 \}$

and for $u \in V$ we denote u < 0 (resp. u > 0) if $u \in V_-$ (resp. V_+). Since $\langle \lambda u, \lambda u \rangle = |\lambda|^2 \langle u, u \rangle$ for any scalar $\lambda \in \mathbb{C}^*$ and any $u \in V$, the projectivization map $\mathbb{P} : \mathbb{C}^{n+1} \to \mathbb{P}^n_{\mathbb{C}}$ preserves the sign of $\langle u, u \rangle$ and thus $\mathbb{P}V_-$, $\mathbb{P}V_0$, and $\mathbb{P}V_+$ are

well-defined. The projective model of complex hyperbolic *n*-space \mathbb{B}^n is defined to be the negative lines in V, i.e. $\mathbb{B}^n := \mathbb{P}V_-$. Thus, its boundary $\partial \mathbb{B}^n = \mathbb{P}V_0$.

We can define a natural metric on \mathbb{B}^n called the Bergman metric. First we denote the "tance" function for any $u, v \in V_- \cup V_+$:

$$ta(u,v) := \frac{\langle u, v \rangle \langle v, u \rangle}{\langle u, u \rangle \langle v, v \rangle} \in \mathbb{R}$$

It has the following useful properties:

- (i) ta(u, v) = ta(v, u) for any $u, v \in V_- \cup V_+$;
- (ii) $ta(\lambda u, v) = ta(u, v)$ for any $\lambda \in \mathbb{C}^*$ and $u, v \in V_- \cup V_+$, so $ta(\cdot, \cdot)$ is well-defined on $\mathbb{P}V_- \cup \mathbb{P}V_+$;
- (iii) $\operatorname{ta}(u,v) \ge 1$ if $u, v \in V_-$; $\operatorname{ta}(u,v) \ge 0$ if $u, v \in V_+$; $\operatorname{ta}(u,v) \le 0$ if $u \in V_+$ and $v \in V_-$.

For the proof, only $ta(u, v) \ge 1$ for $u, v \in V_{-}$ is not trivial. It can be explicitly proved in the case of the standard Hermitian form and then extended to the general case by Cayley transforms which will be defined below. Now the distance function $d(\cdot, \cdot)$ on \mathbb{B}^{n} given by the Bergman metric is defined to be

$$\cosh^2\left(\frac{d(u,v)}{2}\right) := \operatorname{ta}(u,v) := \frac{\langle u,v \rangle \langle v,u \rangle}{\langle u,u \rangle \langle v,v \rangle}$$

for $u, v \in \mathbb{B}^n$, or alternatively,

$$ds^{2} = \frac{-4}{\langle u, u \rangle^{2}} \det \begin{pmatrix} \langle u, u \rangle & \langle u, du \rangle \\ \langle du, u \rangle & \langle du, du \rangle \end{pmatrix}$$

The -4 normalizes its holomorphic sectional curvature to be -1.

The Bergman metric is invariant to the choice of the Hermitian form in the sense that for different choices of Hermitian forms, the complex hyperbolic *n*-spaces are isometric. More specifically, we have the standard Hermitian form $h_{std}(u, v) =$ $u_1\bar{v}_1 + \cdots + u_n\bar{v}_n - u_{n+1}\bar{v}_{n+1}$ corresponding to the diagonal matrix J_{std} with diagonal entries $1, \cdots, 1, -1$. Then consider J any Hermitian matrix of signature (n, 1), so J can be unitarily diagonalized with real eigenvalues, i.e. we can find a matrix $T \in \operatorname{GL}_{n+1}(\mathbb{C})$ such that $J = T^H J_{std} T$. Then we have an isometry called Cayley transform $(\mathbb{C}^{n+1}, J) \to (\mathbb{C}^{n+1}, J_{std}), \quad u \mapsto Tu$. When we consider $h_{std}(u, v) =$ $u_1\bar{v}_1 + \cdots + u_n\bar{v}_n - u_{n+1}\bar{v}_{n+1}$, any point $[u_1, \cdots, u_{n+1}] \in \mathbb{P}V_-$ corresponds to a point $(u_1/u_{n+1}, \cdots, u_n/u_{n+1})$ inside the open unit ball in \mathbb{C}^n , so we also call \mathbb{B}^n the complex hyperbolic *n*-ball.

2.1.2. Isometries. Consider $V \cong \mathbb{C}^{n+1}$ equipped with a Hermitian form $h(\cdot, \cdot) = \langle \cdot, \cdot \rangle$ of signature (n, 1). If we fix a basis of V, the Hermitian form is represented by a Hermitian matrix J, and linear transformations M on V preserving the Hermitian form satisfy:

$$\langle Mu, Mv \rangle = v^H M^H J M u = \langle u, v \rangle = v^H J u.$$

for any $u, v \in V$, so it is equivalent to requiring $M^H J M = J$. Thus they define the unitary group:

$$U(J) := \{ M \in M_{n+1}(\mathbb{C}) : \langle Mu, Mv \rangle = \langle u, v \rangle \ \forall u, v \in V \} \cong U(n, 1).$$

The last isomorphism is induced by Cayley transform $T: U(J) \to U(J_{std}) =:$ $U(n, 1), \quad M \mapsto TMT^{-1}$. Since $\det(M^H JM) = \det(J)$, we also have $|\det(M)| = 1$. Since scalar multiplication λI_{n+1} for any $\lambda \in \mathbb{C}^*$ commutes with any $M \in U(J)$, U(J) is well-defined on $\mathbb{P}V$, and the kernel of this action on $\mathbb{P}V$ is $\{\lambda I : |\lambda| = 1\} \cong$ $U(1) \subset U(J)$. Then, we define the projective unitary group

$$\mathbb{P}U(J) := U(J)/\{\lambda \cdot id : |\lambda| = 1\} = SU(J)/\{\lambda \cdot id \in SU(J) : |\lambda| = 1\}$$

whose element always has a representative with determinant 1 in SU(J). Indeed, \mathbb{B}^n is homogeneous:

Lemma 2.1 (Lemma 3.1.3 of [Gol99]). $\mathbb{P}U(J)$ acts transitively on \mathbb{B}^n .

Then we focus on the case n = 2 and list some results about the classification of isometries on \mathbb{B}^2 . In the literature they are mostly proved for the case where $J = J_{std}$, but the statements also apply to the general case since they do not depend on the choice of basis.

To state the classification, we first have the following trichotomy:

Definition 2.2. A holomorphic complex hyperbolic isometry is

- (i) *loxodromic* if it fixes exactly two points of $\partial \mathbb{B}^2$;
- (ii) *parabolic* if it fixes exactly one point of $\partial \mathbb{B}^2$;
- (iii) *elliptic* if it fixes at least one point of \mathbb{B}^2 .

For $M \in SU(J)$, we have the following restriction on its characteristic polynomial, which is a consequence of $M^H J M = J$.

Lemma 2.3 (Lemma 6.2.5 of [Gol99]). If $M \in SU(J)$ and λ_0 is an eigenvalue of M, then $\bar{\lambda}_0^{-1}$ is also an eigenvalue of M. Therefore, if we denote t := tr(M), then the characteristic polynomial of M is $\lambda^3 - t\lambda^2 + \bar{t}\lambda - 1$.

Now we can state the classification of isometries.

Theorem 2.4 (Theorem 6.2.4 of [Gol99]). Consider $M \in SU(J)$.

(i) M is loxodromic if and only if one of the eigenvalues λ has $|\lambda| \neq 1$. In this case, if we denote $\lambda = re^{i\theta}$ for $r, \theta \in \mathbb{R}$, then the three eigenvalues are $re^{i\theta}$, $r^{-1}e^{i\theta}$, $e^{-2i\theta}$. If they have eigenvectors u, v, w respectively, then

 $\langle u, u \rangle = \langle v, v \rangle = \langle u, w \rangle = \langle v, w \rangle = 0, \quad \langle w, w \rangle > 0, \quad \langle u, v \rangle \neq 0.$

- (ii) M is parabolic if and only if it has a repeated eigenvalue whose eigenspace is spanned by one null vector. It is called pure parabolic (resp. screw parabolic) if the dimension of this eigenspace is 3 (resp. 2).
- (iii) M is elliptic if and only if it can diagonalized and all the eigenvalues have norm 1. We have the following cases:
 - (a) M only has one fixed point in \mathbb{B}^2 . In this case, let the fixed point be given by a negative eigenvector u with eigenvalue λ_1 . Then either we have a repeated eigenvalue $\lambda_2 = \lambda_3 \neq \lambda_1$ corresponding to an eigenspace spanned by two positive vectors, or all eigenvalues $\lambda_1, \lambda_2, \lambda_3$ are distinct and each of λ_2, λ_3 corresponds to a positive eigenspace. M is called a complex reflection about a point in the first case, and is regular elliptic in the second case.

- (b) *M* is called a complex reflection about a line or boundary elliptic when the fixed points in \mathbb{B}^2 form a complex line. In this case, this line corresponds to a 2-dimensional eigenspace spanned by both positive and negative vectors. In other words, we can find eigenvectors u, v, w corresponding to eigenvalues $\lambda_1 = \lambda_2 \neq \lambda_3$ with u < 0 and v, w > 0.
- (c) The last case is where M corresponds to scalar multiplication by a third root of unity.

By Lemma 2.3, the trace of an isometry determines the characteristic polynomial, so we have the following by computation of the resultant.

Theorem 2.5 (Theorem 6.2.4 of [Gol99]). Let $f(\tau) = |\tau|^4 - 8\text{Re}(\tau^3) + 18|\tau|^2 - 27$. Let $M \in SU(J)$. Then

- (i) M is loxodromic if and only if f(tr(M)) > 0;
- (ii) M has distinct eigenvalues if and only if f(tr(M)) < 0;
- (iii) M has repeated eigenvalues if and only if f(tr(M)) = 0.

When $M \in SU(J)$ is diagonalizable, we can pick some eigenvectors as a basis of \mathbb{C}^3 . Using the orthogonal relations above we have the following useful identities.

Corollary 2.6. Consider $M \in SU(J)$.

(i) When M is loxodromic, denote the three eigenvalues to be $re^{i\theta}$, $r^{-1}e^{i\theta}$, $e^{-2i\theta}$ and their respective eigenvectors v_1, v_2, v_3 . Then for any $u \in (\mathbb{C}^3, J)$,

$$u = \frac{\langle u, v_2 \rangle}{\langle v_1, v_2 \rangle} v_1 + \frac{\langle u, v_1 \rangle}{\langle v_2, v_1 \rangle} v_2 + \frac{\langle u, v_3 \rangle}{\langle v_3, v_3 \rangle} v_3.$$
(2.7)

and thus

$$1 = \frac{\langle u, v_2 \rangle \langle v_1, u \rangle}{\langle v_1, v_2 \rangle \langle u, u \rangle} + \frac{\langle u, v_1 \rangle \langle v_2, u \rangle}{\langle v_2, v_1 \rangle \langle u, u \rangle} + \frac{\langle u, v_3 \rangle \langle v_3, u \rangle}{\langle v_3, v_3 \rangle \langle u, u \rangle} =: w + \bar{w} + \operatorname{ta}(u, v_3)$$
(2.8)

if we denote $w := \frac{\langle u, v_2 \rangle \langle v_1, u \rangle}{\langle v_1, v_2 \rangle \langle u, u \rangle}$

(ii) When M is regular elliptic or a complex reflection about a point (resp. boundary elliptic), we can find eigenvectors v_1, v_2, v_3 corresponding to eigenvalues $\lambda_1, \lambda_2, \lambda_3$ respectively such that $\lambda_1 \neq \lambda_2$ and $\lambda_1 \neq \lambda_3$ (resp. $\lambda_1 = \lambda_2 \neq \lambda_3$), and

$$\langle v_1, v_1 \rangle < 0, \quad \langle v_2, v_2 \rangle, \langle v_3, v_3 \rangle > 0, \quad \langle v_1, v_2 \rangle = \langle v_1, v_3 \rangle = \langle v_2, v_3 \rangle = 0$$

and consequently, for any $u \in (\mathbb{C}^3, J)$,

$$u = \frac{\langle u, v_1 \rangle}{\langle v_1, v_1 \rangle} v_1 + \frac{\langle u, v_2 \rangle}{\langle v_2, v_2 \rangle} v_2 + \frac{\langle u, v_3 \rangle}{\langle v_3, v_3 \rangle} v_3.$$
(2.9)

and thus

$$1 = \frac{\langle u, v_1 \rangle \langle v_1, u \rangle}{\langle v_1, v_1 \rangle \langle u, u \rangle} + \frac{\langle u, v_2 \rangle \langle v_2, u \rangle}{\langle v_2, v_2 \rangle \langle u, u \rangle} + \frac{\langle u, v_3 \rangle \langle v_3, u \rangle}{\langle v_3, v_3 \rangle \langle u, u \rangle} =: \sum_{j=1}^3 \operatorname{ta}(u, v_j)$$
(2.10)

2.1.3. Complex Lines and Distance Formulas. One can classify the totally geodesic subspaces of \mathbb{B}^n using the general theory of symmetric spaces:

Theorem 2.11 (Section 3.1.11 of [Gol99]). The only totally geodesic subspaces of \mathbb{B}^n are either complex linear subspaces or totally real totally geodesic submanifolds.

When n = 2, they are complex lines and totally real Lagrangian planes. Complex lines are the usual complex lines in \mathbb{C}^2 that intersect the open unit 2-ball when we consider \mathbb{B}^2 as the open unit 2-ball. Equivalently, a complex line $L \subset \mathbb{B}^2$ is the projectivization of the intersection between a 2-dimensional linear subspace of $V = (\mathbb{C}^3, J)$ and the negative cone V_- . Therefore, it can be determined by its polar vector: $L = \{z \in \mathbb{B}^2 : \langle z, n \rangle = 0\}$ for some $n \in V_+$. Totally real Lagrangian planes are embedded copies of the real hyperbolic space $\mathbb{H}^2_{\mathbb{R}}$. When we consider the standard Hermitian form, they are the images under a $\mathbb{P}U(J_{std})$ -action of the space given by those points in \mathbb{B}^2 with real coordinates.

Then we list some distance formulas related to complex lines.

Proposition 2.12 (Corollary 6.7 of [Par03]). Let L be a complex line with polar vector n. For any $z \in \mathbb{B}^2$, the distance d(z, L) from z to L is given by

$$\cosh^2\left(\frac{d(z,L)}{2}\right) = 1 - \operatorname{ta}(z,n) \ge 1.$$

Proposition 2.13 (Section 3.3.2 of [Gol99] or Proposition 6.8 of [Par03]). Let L_1, L_2 be complex lines with polar vector n_1, n_2 . Then

(i) If $ta(n_1, n_2) > 1$, then L_1 and L_2 do not intersect in $\mathbb{B}^2 \cup \partial \mathbb{B}^2$ (which is called ultraparallel) and

$$\cosh^2\left(\frac{d(L_1, L_2)}{2}\right) = \operatorname{ta}(n_1, n_2) > 1.$$

- (ii) If $ta(n_1, n_2) = 1$, then L_1 and L_2 intersect on $\partial \mathbb{B}^2$ (which is called asymptotic) or coincide.
- (iii) If $ta(n_1, n_2) < 1$, then L_1 and L_2 intersect in \mathbb{B}^2 .

2.2. Arithmetic Quotient of Type I. Let K be a totally real number field of degree m. Consider a CM extension $F := K(\sqrt{\alpha})$ for some totally negative $\alpha \in K$. The embeddings come in complex conjugate pairs: $\sigma_1, \bar{\sigma}_1, \dots, \sigma_m, \bar{\sigma}_m$. Then, take a Hermitian form $h(\cdot, \cdot) = \langle \cdot, \cdot \rangle$ in n + 1 variables with coefficients in F, i.e.

$$\langle z, w \rangle := w^H J z, \ z, w \in F^{n+1}$$

for some Hermitian matrix $J = J^H \in M_{n+1}(F)$, such that for the first pair of embeddings $(\sigma_1, \bar{\sigma}_1)$, h^{σ_1} and $h^{\bar{\sigma}_1}$ are of signature (n, 1), and for all other pairs of embeddings $(\sigma, \bar{\sigma}) = (\sigma_2, \bar{\sigma}_2), \cdots, (\sigma_m, \bar{\sigma}_m)$, h^{σ} and $h^{\bar{\sigma}}$ are definite. Then under the first pair of embeddings, these define an arithmetic lattice $\Gamma := SU(h^{\sigma_1}, \mathcal{O}_F) :=$ $SU(h^{\sigma_1}) \cap SL_3(\mathcal{O}_F)$ and the Shimura variety $X := \mathbb{B}^n / \Gamma$. We will focus on the case where $K = \mathbb{Q}(\sqrt{D})$ is a real quadratic field with discriminant D > 0. We identify F with $\sigma_1(F)$.

The lattices constructed in this way are cocompact since SU(n + 1) is compact and then we can apply [McR11, Theorem 5.2] or [MR13, Lemma 8.1.3]. Therefore, by Godement's compactness criterion, Γ has no nontrivial unipotent elements. Furthermore, this implies that there is no parabolic element in Γ by Theorem 2.5.

3. Geometry of Elliptic Points

Now we will focus on the situation in the main theorem. We fix the setting and notation as follows:

 $K := \mathbb{Q}(\sqrt{D}) \text{ with discriminant } D > 0. \quad F := K(\sqrt{\alpha}) \text{ a } CM \text{ extension}$ with the norm of the relative discriminant $D_2 > D'_0$ for some fixed D'_0 such that there is no non-totally real integer $z \in \mathcal{O}_F$ with $|z| \leq 3$ in all embeddings. Denote its complex embeddings $\sigma_1, \bar{\sigma}_1, \sigma_2, \bar{\sigma}_2$. Take a Hermitian form $h(\cdot, \cdot) = \langle \cdot, \cdot \rangle$ represented by a matrix J on F^3 with coefficients in F such that h^{σ_1} and $h^{\bar{\sigma}_1}$ are of signature (2, 1), and h^{σ_2} and $h^{\bar{\sigma}_2}$ are definite. Consider the arithmetic lattice $\Gamma := SU(h^{\sigma_1}, \mathcal{O}_F) :=$ $SU(h^{\sigma_1}) \cap SL_3(\mathcal{O}_F)$ and the arithmetic quotient $X := \Gamma \setminus \mathbb{B}^2$.

3.1. **Repulsion of Elliptic Points.** This section is dedicated to show repulsion of elliptic points, for example, isolated elliptic points tend to be far apart when the discriminant D of the real quadratic field defining the space is big. Such repulsion phenomena for Shimura varieties have been shown in certain cases in terms of level structures. For instance, [BT16] showed the repulsion of cusps and special subvarieties for products of modular curves in terms of the level structure, and [BT18] proved similar results for cusps and points of Hilbert modular varieties.

Note that in this section we are showing the repulsion of the preimages of elliptic points of X in \mathbb{B}^2 , i.e. the points in \mathbb{B}^2 stabilized by some elements in Γ . The repulsion can descend to X since the action of Γ is properly discontinuous, and it is useful when we derive the multiplicity bounds in Section 4.

Now, we call points (resp. complex lines) in \mathbb{B}^2 (or their images in X) stabilized by an elliptic element inside the arithmetic lattice *elliptic points* (resp. *elliptic complex lines*), and an elliptic point u is an *isolated elliptic point* if for some elliptic element M inside its stabilizer group, u is an isolated point in the locus that M stabilizes. The precise statement of repulsion of isolated elliptic points is the following.

Proposition 3.2. Follow the notation in (3.1). For any given R > 0, there exists $D_0(R) > 0$ such that when $D > D_0(R)$, if u and v are distinct isolated elliptic points on \mathbb{B}^2 , then their distance $d_{\mathbb{B}^2}(u, v) > R$.

We first assume that u and v are stabilized by M_1 and M_2 in Γ respectively, where M_1 and M_2 have the same set of eigenvalues. First we identify possible orders of elliptic elements in this context.

Lemma 3.3. For $K := \mathbb{Q}(\sqrt{D})$ with discriminant D > 0 and $F := K(\sqrt{\alpha})$ a CM extension, the maximal possible order of elliptic elements is 18 if D > 21. If we further assume that $F \neq K(\sqrt{\alpha})$ for $\alpha = -1, -2, -3, -7$, then the only possible triples of eigenvalues are $(1, -1, -1), (1, \omega, \omega^2), (1, i, -i), (1, -\omega, -\omega^2)$.

Proof. Since Γ acts properly discontinuously, the order n of an elliptic element $M \in \Gamma$ is finite, and the eigenvalues $\{\lambda_1, \lambda_2, \lambda_3\}$ of M are n-th roots of unity. Therefore, the splitting field $F(\{\lambda_j\}_j)$ of the characteristic polynomial of M over F should include the n-th cyclotomic field, but the possible values of $[F(\{\lambda_j\}_j) : \mathbb{Q}]$ are 4,8,12, so n can only be a divisor of them and now there are only finitely many cases. When

 $[F(\{\lambda_j\}_j):\mathbb{Q}]$ is 8 or 12, $F(\{\lambda_j\}_j) = \mathbb{Q}(\zeta_n)$ must contain $K := \mathbb{Q}(\sqrt{D})$, which is impossible when D > 21 (n = 21 is the maximal odd integer with $[\mathbb{Q}(\zeta_n):\mathbb{Q}] \leq 12$). Assuming $[\mathbb{Q}(\zeta_n):\mathbb{Q}]$ is 4 or 6 and D > 9, $\mathbb{Q}(\zeta_n)$ adjoining \sqrt{D} will be a nontrivial field extension and it must give $F(\{\lambda_j\}_j)$, so $\mathbb{Q}(\zeta_n)$ must contain $\sqrt{\alpha}$. Now we can check each case: n cannot be 5 or 10 as $\mathbb{Q}(\zeta_5)$ contains no imaginary quadratic field; n can be 8 only when $F = K(\sqrt{-2})$ or K(i); n can be 12 only when F = $K(\sqrt{-3})orK(i)$; n can be 7 or 14 only when $F = K(\sqrt{-7})$; n can be 9 or 18 only when $F = K(\sqrt{-3})$.

Thus, when $F \neq K(\sqrt{\alpha})$ for $\alpha = -1, -2, -3, -7$, the only possible values of n are 2,3,4,6. Applying $\lambda_1 \lambda_2 \lambda_3 = 1$ and $\lambda_1 + \lambda_2 + \lambda_3 \in \mathcal{O}_F$, we finish the classification of possible triples of eigenvalues.

From 2.1.2, we know that when the triple of eigenvalues is (1, -1, -1) and there is a negative eigenvector corresponds to eigenvalue -1, the elliptic element will stabilize a complex line given by the (-1)-eigenspace. Except this case, the other types of elliptic elements correspond to isolated elliptic points.

Come back to the setting of Proposition 3.2. By Theorem 2.4, we can let $\{u_j\}_{j=1,2,3} \in F(\{\lambda_j\}_{j=1,2,3})$ (resp. $\{v_j\}_{j=1,2,3}$) be the pairwise orthogonal eigenvectors of the elliptic element M_1 (resp. M_2), and $\{\lambda_j\}_{j=1,2,3}$ (resp. $\{\tilde{\lambda}_j\}_{j=1,2,3}$) are the corresponding eigenvalues. The arithmetic of the Hermitian form gives the following.

Lemma 3.4. Follow the notation in (3.1). For any given R > 0, there exists $D_0(R) > 0$ such that when $D > D_0(R)$, $|\operatorname{tr}(M_1M_2)|^2$ and $2\operatorname{Re}(\operatorname{tr}(M_1M_2))$ are rational integers, and $\operatorname{Re}(\operatorname{tr}(M_1M_2)) \leq |\operatorname{tr}(M_1M_2)| \leq 3$.

Proof. Since $\{u_j\}_{j=1,2,3}$ (resp. $\{v_j\}_{j=1,2,3}$) give a pairwise orthogonal basis, we can apply (2.7) to v_k (resp. u_k) to get the following useful equation for any fixed $k \in \{1,2,3\}$:

$$\sum_{j=1}^{3} \operatorname{ta}(v_k, u_j) = \sum_{j=1}^{3} \frac{\langle v_k, u_j \rangle \langle u_j, v_k \rangle}{\langle u_j, u_j \rangle \langle v_k, v_k \rangle} = 1 \quad \left(\operatorname{resp.} \sum_{j=1}^{3} \operatorname{ta}(u_k, v_j) = \sum_{j=1}^{3} \frac{\langle u_k, v_j \rangle \langle v_j, u_k \rangle}{\langle v_j, v_j \rangle \langle u_k, u_k \rangle} = 1 \right)$$

$$(3.5)$$

To compute $tr(M_1M_2)$, first note that the orthogonal relations give the following:

$$(u_1 \ u_2 \ u_3)^H J(u_1 \ u_2 \ u_3) = \begin{pmatrix} \langle u_1, u_1 \rangle & & \\ & \langle u_2, u_2 \rangle & \\ & & \langle u_3, u_3 \rangle \end{pmatrix}$$
$$\implies (u_1 \ u_2 \ u_3)^{-1} = \begin{pmatrix} 1/\langle u_1, u_1 \rangle & & \\ & 1/\langle u_2, u_2 \rangle & \\ & & 1/\langle u_3, u_3 \rangle \end{pmatrix} (u_1 \ u_2 \ u_3)^H J$$

Using this we can rewrite the diagonalized M_1 and M_2 and get:

$$\operatorname{tr}(M_{1}M_{2})$$

$$=\operatorname{tr}\left(\left(u_{1}\ u_{2}\ u_{3}\right)\begin{pmatrix}\lambda_{1}\\\lambda_{2}\\\lambda_{3}\end{pmatrix}\left(u_{1}\ u_{2}\ u_{3}\right)^{-1}\left(v_{1}\ v_{2}\ v_{3}\right)\begin{pmatrix}\tilde{\lambda}_{1}\\\tilde{\lambda}_{2}\\\tilde{\lambda}_{3}\end{pmatrix}\left(u_{1}\ u_{2}\ u_{3}\right)^{-1}\right)$$

$$=\operatorname{tr}\left(\left(\begin{pmatrix}\frac{\lambda_{1}}{\langle u_{1},u_{1}\rangle}\\\frac{\lambda_{2}}{\langle u_{2},u_{2}\rangle}\\\frac{\lambda_{3}}{\langle u_{3},u_{3}\rangle}\end{pmatrix}\left(u_{1}\ u_{2}\ u_{3}\right)^{H}J\left(v_{1}\ v_{2}\ v_{3}\right)\right)$$

$$\left(\begin{pmatrix}\frac{\tilde{\lambda}_{1}}{\langle v_{1},v_{1}\rangle}\\\frac{\tilde{\lambda}_{2}}{\langle v_{2},v_{2}\rangle}\\\frac{\tilde{\lambda}_{3}}{\langle v_{3},v_{3}\rangle}\end{pmatrix}\left(v_{1}\ v_{2}\ v_{3}\right)^{H}J\left(u_{1}\ u_{2}\ u_{3}\right)\right)$$

$$=\sum_{j,k=1}^{3}\lambda_{j}\tilde{\lambda}_{k}\operatorname{ta}(u_{j},v_{k})$$

$$(3.6)$$

Until the end of this lemma, let u_3 (resp. v_3) denote the negative eigenvector, so the other two eigenvectors are positive, and $ta(u_3, v_3)$ gives the distance between the elliptic points. This gives:

$$|\operatorname{tr}(M_1 M_2)| = \left| \sum_{j,k=1}^3 \lambda_j \tilde{\lambda}_k \operatorname{ta}(u_j, v_k) \right| \le \sum_{j,k=1}^3 |\operatorname{ta}(u_j, v_k)|$$

= $\operatorname{ta}(u_3, v_3) + \sum_{j,k=1}^2 \operatorname{ta}(u_j, v_k) - \sum_{j=1}^2 (\operatorname{ta}(u_j, v_3) + \operatorname{ta}(u_3, v_j))$
= $\operatorname{ta}(u_3, v_3) + (\operatorname{ta}(u_3, v_3) + 1) - 2(1 - \operatorname{ta}(u_3, v_3))$ by (3.5)
= $4\operatorname{ta}(u_3, v_3) - 1$

In our setting, we can extend the embeddings $F \hookrightarrow \mathbb{C}$ to $F(\lambda_j) \hookrightarrow \mathbb{C}$ while fixing the embeddings of the eigenvalues, and we use the same notation for these extended embeddings. Then the argument above fits into the embedding σ_2 that gives the definite hermitian form:

$$\left| \operatorname{tr}(M_1 M_2)^{\sigma_2} \right| = \left| \sum_{j,k=1}^3 \lambda_j \tilde{\lambda}_k \operatorname{ta}^{\sigma_2}(u_j^{\sigma_2}, v_k^{\sigma_2}) \right| \le \sum_{j,k=1}^3 \left| \operatorname{ta}^{\sigma_2}(u_j^{\sigma_2}, v_k^{\sigma_2}) \right| = 3$$

where the last equality is due to (3.5).

Since $\operatorname{ta}(u_3, v_3)$ is bounded by $\cosh^{-1}(R/2)$, $|\operatorname{tr}(M_1M_2)|^2$ is an integral element in $\mathcal{O}_{\mathbb{Q}(\sqrt{D})}$ with both embeddings in \mathbb{R} nonnegative and bounded by fixed numbers. When D is big, this is possible only when $|\operatorname{tr}(M_1M_2)|^2 \in \mathbb{Z}$, and thus $|\operatorname{tr}(M_1M_2)|^2 = |\operatorname{tr}(M_1M_2)^{\sigma_2}|^2 \leq 9$. The same argument applies to $2\operatorname{Re}(\operatorname{tr}(M_1M_2))$.

Further investigation of $tr(M_1M_2)$ will finish the proof.

Proof of Proposition 3.2. Since $|\operatorname{tr}(M_1M_2)|^2$ is a rational integer bounded by 9, when the norm of the relative discriminant of F/K is large enough to make sure there is no non-totally real integer $z \in \mathcal{O}_F$ with $|z| \leq 3$ in all embeddings, $\operatorname{tr}(M_1M_2)$ will be real. Note that this can be independent from D. We first look at the case where $(\lambda_1, \lambda_2, \lambda_3) = (\tilde{\lambda}_1, \tilde{\lambda}_2, \tilde{\lambda}_3) = (\lambda, \bar{\lambda}, 1)$ for $e^{i\theta} = \lambda \notin \mathbb{R}$. Denote $t = \lambda + \bar{\lambda}$. Since $\operatorname{ta}(u_j, v_k) \in \mathbb{R}$ for j, k = 1, 2, 3, $\operatorname{tr}(M_1M_2) \in \mathbb{R}$ means:

$$Im (tr(M_1M_2)) = \sum_{j,k=1}^{3} Im (\lambda_j \tilde{\lambda}_k) ta(u_j, v_k)$$

= sin(\theta)(ta(u_1, v_3) + ta(u_3, v_1)) - sin(\theta)(ta(u_2, v_3) + ta(u_3, v_2))
+ sin(2\theta)ta(u_1, v_1) - sin(2\theta)ta(u_2, v_2)
= sin(\theta)(cos(\theta) - 1)(ta(u_1, v_1) - ta(u_2, v_2)) = 0

Since $\lambda \notin \mathbb{R}$, this implies that $a := \operatorname{ta}(u_1, v_1) = \operatorname{ta}(u_2, v_2)$. Apply the same argument to $\operatorname{Im}(\operatorname{tr}(M_1^{-1}M_2)) = 0$, we obtain $b := \operatorname{ta}(u_1, v_2) = \operatorname{ta}(u_2, v_1)$. Therefore, $\operatorname{ta}(u_j, v_3)$ and $\operatorname{ta}(u_3, v_j)$ are all equal to 1 - a - b.

Now we check each case of possible pairs of negative eigenvectors. First, (u_1, v_3) cannot be both negative, since otherwise $ta(u_1, v_3) = ta(u_2, v_3) = 1 - a - b$ should have opposite signs by definition, but they cannot be 0 as $ta(u_1, v_3) \ge 1$. This also applies to (u_2, v_3) , (u_3, v_1) , and (u_3, v_2) . Then, suppose that (u_1, v_1) are negative eigenvectors. It means that $a = ta(u_1, v_1) \ge 1$, b < 0, $ta(u_3, v_3) = 2a + 2b - 1 \ge 0$, and $ta(u_1, v_3) = ta(u_2, v_3) = 1 - a - b$ should have opposite signs. Thus, 1 - a - b = 0, and we have

$$tr(M_1^{-1}M_2) = ta(u_3, v_3) + ta(u_1, v_1) + ta(u_2, v_2) + \bar{\lambda}^2 ta(u_1, v_2) + \lambda^2 ta(u_2, v_1)$$

= $(2a + 2b - 1) + 2a + (\bar{\lambda}^2 + \lambda^2)(1 - a)$
= $(t^2 - 1) + (4 - t^2)a$
 $\geq (t^2 - 1) + (4 - t^2) = 3$

Since $|\operatorname{tr}(M_1^{-1}M_2)| \leq 3$, we have $\operatorname{tr}(M_1^{-1}M_2) = 3$ and thus $M_1^{-1}M_2 = I$. This argument also applies to (u_1, v_2) , (u_2, v_1) , and (u_2, v_2) . The last case left is when (u_3, v_3) are negative eigenvectors. Then

$$\begin{aligned} \operatorname{tr}(M_1 M_2) &+ \operatorname{tr}(M_1^{-1} M_2) + \operatorname{tr}(M_1 M_2^{-1}) + \operatorname{tr}(M_1^{-1} M_2^{-1}) \\ &= 4\operatorname{ta}(u_3, v_3) + 2t(\operatorname{ta}(u_1, v_3 + \operatorname{ta}(u_2, v_3) + \operatorname{ta}(u_3, v_1) + \operatorname{ta}(u_3, v_2)) \\ &+ (\bar{\lambda}^2 + \lambda^2 + 2)(\operatorname{ta}(u_1, v_1) + \operatorname{ta}(u_2, v_2) + \operatorname{ta}(u_1, v_2) + \operatorname{ta}(u_2, v_1)) \quad \text{by (3.6)} \\ &= 4\operatorname{ta}(u_3, v_3) + 4t(1 - \operatorname{ta}(u_3, v_3)) + t^2(\operatorname{ta}(u_3, v_3) + 1) \quad \text{by (3.5)} \\ &= (t - 2)^2 \operatorname{ta}(u_3, v_3) + t^2 + 4t \end{aligned}$$

Since u_3 and v_3 correspond to eigenvalue 1, $\operatorname{ta}(u_3, v_3) \in F$. Moreover, the computation above shows that $(t-2)^2 \operatorname{ta}(u_3, v_3) \in \mathcal{O}_F \cap \mathbb{R} = \mathcal{O}_K$ and it is bounded in both real embeddings of $K = \mathbb{Q}(\sqrt{D})$, so when D is big, $(t-2)^2 \operatorname{ta}(u_3, v_3) \in \mathbb{Z}$. However, this means that $1 \leq \operatorname{ta}(u_3, v_3) = \operatorname{ta}^{\sigma_2}(u_3^{\sigma_2}, v_3^{\sigma_2}) \leq 1$, so $\operatorname{ta}(u_3, v_3) = 1$. In conclusion, in all the possible cases, both negative eigenvectors in fact represent the same point.

Now the only case left is the case where $(\lambda_1, \lambda_2, \lambda_3) = (\tilde{\lambda}_1, \tilde{\lambda}_2, \tilde{\lambda}_3) = (-1, -1, 1)$ and $u_3, v_3 < 0$, but then

$$\operatorname{tr}(M_1 M_2) = \operatorname{ta}(u_3, v_3) + \sum_{j,k=1}^2 \operatorname{ta}(u_j, v_k) - \sum_{j=1}^2 (\operatorname{ta}(u_j, v_3) + \operatorname{ta}(u_3, v_j))$$

= $\operatorname{ta}(u_3, v_3) + (\operatorname{ta}(u_3, v_3) + 1) - 2(1 - \operatorname{ta}(u_3, v_3))$
= $4\operatorname{ta}(u_3, v_3) - 1$
 $\geq 4 - 1 = 3$ (3.7)

so $|\operatorname{tr}(M_1M_2)| \leq 3$ gives that $M_1M_2 = I$.

Now we have proved the case where the respective stabilizers M_1 and M_2 for u and v have the same set of eigenvalues. For the general case, we first obtain the bound $D_0(R)$ of D such that the distance between isolated elliptic points with conjugate stabilizers has a lower bound 2R. Then for isolated elliptic points u and v with stabilizers M_1 and M_2 , since $2R < d(v, M_1v) \le d(v, u) + d(u, M_1v) = 2d(u, v)$, we have d(u, v) > R.

The proposition above only applies to isolated elliptic points. For distinct elliptic elements which stabilize complex lines, it is possible that these two stacky lines intersect. This happens in one of the simplest examples: consider $J = diag(1, 1, -\sqrt{D})$ and elliptic elements $M_1 = diag(1, -1, -1)$ and $M_2 = diag(-1, 1, -1)$ representing flipping over the two coordinate axes, and then the loci stabilized by them intersect at the origin [0, 0, 1]. This example also shows that the isotropy groups are not necessarily cyclic in this context. However, we still have the following repulsion result in this case.

Proposition 3.8. Follow the notation in (3.1). For any given R > 0, there exists $D_0(R) > 0$ such that when $D > D_0(R)$, if M_1 and M_2 are elliptic elements with eigenvalues (-1, -1, 1) stabilizing distinct complex lines, then either their distance $d_{\mathbb{B}^2}(L_1, L_2) > R$, or they intersect at an isolated elliptic point.

Proof. Denote L_1, L_2 the complex lines stabilized by M_1, M_2 respectively. We can assume that $(\lambda_1, \lambda_2, \lambda_3) = (\tilde{\lambda}_1, \tilde{\lambda}_2, \tilde{\lambda}_3) = (-1, -1, 1)$ and $u_1, v_1 < 0$.

If $L_1 \cap L_2 \neq \emptyset$, then we can pick $u_1 = v_1$ to be the intersection point. Note that M_1M_2 should stabilize u_1 , and the corresponding eigenvalue is $(-1)^2 = 1$. Thus, M_1M_2 is either the identity which means $M_1 = M_2^{-1} = M_2$, or an elliptic element stabilizing an isolated elliptic point.

If $L_1 \cap L_2 = \emptyset$, then since the space is compact, they cannot be asymptotic and thus $\operatorname{ta}(u_3, v_3) > 1$. However, $\operatorname{ta}(u_3, v_3)^{\sigma_2} \leq 1$, so $\operatorname{ta}(u_3, v_3) \notin \mathbb{Q}$. From (3.7) and Lemma 3.4 we see that $\operatorname{8ta}(u_3, v_3) = 2\operatorname{tr}(M_1M_2) + 2 \in \mathcal{O}_F \cap \mathbb{R} = \mathcal{O}_K$. Thus,

 $8 \tan(u_3, v_3) \in \mathcal{O}_K \setminus \mathbb{Z}. \text{ Then if we pick } D_0 \text{ with } \sqrt{D_0} \ge 8 \cosh^2(R/2), \text{ then} \\ 8 \cosh^2\left(\frac{d(L_1, L_2)}{2}\right) = 8 \tan(u_3, v_3) > 8 \tan(u_3, v_3) - 8 \tan(u_3, v_3)^{\sigma_2} \ge \sqrt{D} > 8 \cosh^2\left(\frac{R}{2}\right).$

As a corollary, the proofs of Proposition 3.2 and 3.8 above give strong restrictions on possible stabilizer groups:

Corollary 3.9. Follow the notation in (3.1). Then for any given R > 0, there exists $D_0(R) > 0$ such that when $D > D_0(R)$, the order of possible stabilizer groups of an isolated elliptic point is no more than 48.

Proof. We first summarize what we got in the proof of Proposition 3.2 in this situation: for $M_1, M_2 \in \Gamma$ stabilizing $u \in \mathbb{B}^2$ with the same triple of eigenvalues $(\lambda, \overline{\lambda}, 1)$ where $\lambda \in \{-1, \omega, i, -\omega\}$:

- (1) When $\lambda \neq -1$, the eigenvalues of M_1, M_2 corresponding to u cannot be respectively 1 and λ (or $\bar{\lambda}$). (*)
- (2) If eigenvalues of M_1, M_2 corresponding to u are the same non-real number (resp. complex conjugate non-real numbers), then $M_1 = M_2$ (resp. $M_1 = M_2^{-1}$).
- (3) When both eigenvalues of M_1, M_2 corresponding to u are 1, nothing was proved.

Now we generalize these to the case where $M_1, M_2 \in \Gamma$ stabilizing $u \in \mathbb{B}^2$ with probably different triples of eigenvalues. Let the eigenvalues of M_1, M_2 corresponding to u be λ_1, λ_2 respectively.

- (1) λ_1, λ_2 cannot be respectively 1 and λ for $\lambda \neq \pm 1$: otherwise, note that M_1M_2 and M_2 are elliptic elements whose eigenvalue corresponding to u is λ , so by (*), $M_1M_2 = M_2$ and thus $M_1 = I$.
- (2) When one of λ_1, λ_2 is not real, M_1, M_2 should be in the same cyclic group. Let λ_j be a primitive n_j -th root of unity for j = 1, 2. We check each case as follows. If $(n_1, n_2) = (3, 4)$ or (4, 6), then M_1M_2 is an elliptic element of order at least 12, which contradicts Lemma 3.3. If $(n_1, n_2) = (2, 4)$, then M_1M_2 and M_2^{-1} are elliptic elements with the same eigenvalue corresponding to u, so by $(*), M_1M_2 = M_2^{-1}$, and M_1 is in the cyclic group generated by M_2 . Similar argument also works when $(n_1, n_2) = (2, 6), (3, 6), (2, 3)$.
- (3) When $\lambda_1, \lambda_2 \in \{\pm 1\}, M_1, M_2$ may not be in the same cyclic group. However, consider $u^{\perp} := \{v \in V : \langle u, v \rangle = 0\}$. The restriction of the hermitian form on u^{\perp} is positive definite, so the subgroup G_1 consisting of elliptic elements whose eigenvalues corresponding to u are 1 now descends to lie in a copy of SU(2) given by $(u^{\perp}, \langle \cdot, \cdot \rangle)$. By the classification of finite subgroup of SU(2) and our constraints on orders of elements, G_1 must be among cyclic groups $\mathbb{Z}/n\mathbb{Z}$ for n = 2, 3, 4, 6, dihedral groups D_n of order 2n for n = 2, 3, 4, 6, tetrahedral group A_4 , and octahedral group S_4 . For the full stabilizer group G of u, if $G \setminus G_1$ is nonempty, it should consist of elliptic elements whose eigenvalues corresponding to u are -1, i.e. they stabilize complex lines passing through u. In this case, for any $M \in G \setminus G_1, M^2 = I$

and $M^{-1}G_1M$ consists of elliptic elements whose eigenvalues corresponding to u are 1, so $M^{-1}G_1M = G_1$. Therefore, the index of G_1 in G is at most 2.

In conclusion, if $u \in \mathbb{B}^2$ has a nontrivial stabilizer group, then it is either a cyclic group of order n whose eigenvalues corresponding to u are those n-th roots of unity for $n \in \{2, 3, 4, 6\}$, or it is isomorphic to a finite subgroup of SU(2) of order at most 24 (or its extension of index 2).

For a specific choice of the CM extension $F = K(\alpha)$, this bound may be improved by further analysis on possible finite subgroups of SU(2). See [Bea09] for detail.

For stabilizer groups of an elliptic complex line, this classification is trivial in our case: if two nontrivial elliptic elements stabilize the same complex line, then they have the same 2-dimensional (-1)-eigenspace and thus the same orthogonal 1-eigenspace, so they have to be the same.

3.2. Injectivity Radius. Recall that the injectivity radius $\rho_X(x)$ of a point $x \in X$ is defined as half of the length of the shortest closed geodesic through x. In our setting, we do not have a uniform lower bound of injectivity radii since the closed geodesics of points close to an elliptic point can be arbitrarily small. However, if we only consider loxodromic elements, we do have the following lower bound of injectivity radii.

Proposition 3.10. Follow the notation in (3.1). Let the injectivity radius of a point $x \in X$ given by loxodromic elements be

$$\rho_X^{Lox}(x) := \min_{\text{M loxodromic}} d(x, Mx)/2.$$

Then there exists $D_0 > 0$ such that when $D > D_0$, $\rho_X^{Lox}(x) \ge \cosh^{-1}\left(\frac{D^{1/4}-1}{2}\right)$.

Proof. For a loxodromic element M, by Theorem 2.4 we write its eigenvalues as λ , $\bar{\lambda}^{-1}$ and $\bar{\lambda}/\lambda$ with $|\lambda| > 1$, and if their respective eigenvectors are v_1, v_2, v_3 , then $1 = w + \bar{w} + \operatorname{ta}(u, v_3)$ for any $u \in V \setminus V_0$ and $w := \frac{\langle u, v_2 \rangle \langle v_1, u \rangle}{\langle v_1, v_2 \rangle \langle u, u \rangle}$. Suppose that $x \in X$ is represented by $u \in V_-$. Since $u \in V_-$ and $v_3 \in V_+$, $\operatorname{ta}(u, v_3) \leq 0$, and thus $\operatorname{Re}(w) \geq 1/2$.

Before we compute the injectivity radius, first note that when the discriminant D grows, $|\lambda|$ will become large as follows: $\operatorname{tr}(M) = \lambda + \overline{\lambda}^{-1} + \overline{\lambda}/\lambda$ satisfies $\operatorname{tr}(M) \in \mathcal{O}_F$ and $|\operatorname{tr}(M)^{\sigma_2}| \leq 3$ since $M^{\sigma_2} \in U(3)$ only has eigenvalues of norm 1. Thus, $|\operatorname{tr}(M)|^2$ is either a rational integer bounded by 9, or an integer in $\mathcal{O}_K \setminus \mathbb{Z}$, but by the proof of Proposition 3.2, the first case implies that M is elliptic, so $|\operatorname{tr}(M)|^2 \in \mathcal{O}_K \setminus \mathbb{Z}$. This gives that $|\operatorname{tr}(M)|^2 = (|\operatorname{tr}(M)|^2 - |\operatorname{tr}(M)^{\sigma_2}|^2) + |\operatorname{tr}(M)^{\sigma_2}|^2 \geq \sqrt{D}$.

Now we compute the injectivity radius. Note that
$$\operatorname{ta}(u, Mu) = \frac{\langle Mu, u \rangle \langle u, Mu \rangle}{\langle Mu, Mu \rangle \langle u, u \rangle} = \left| \frac{\langle Mu, u \rangle}{\langle u, u \rangle} \right|^2$$
. Then since $Mu = \lambda \frac{\langle u, v_2 \rangle}{\langle v_1, v_2 \rangle} v_1 + \bar{\lambda}^{-1} \frac{\langle u, v_1 \rangle}{\langle v_2, v_1 \rangle} v_2 + \frac{\bar{\lambda}}{\lambda} \frac{\langle u, v_3 \rangle}{\langle v_3, v_3 \rangle} v_3$,
 $\left| \frac{\langle Mu, u \rangle}{\langle u, u \rangle} \right| = \left| \lambda w + \bar{\lambda}^{-1} \bar{w} + \bar{\lambda} / \lambda (1 - w - \bar{w}) \right|$
 $\geq \left| |\lambda w + \bar{\lambda}^{-1} \bar{w}| - |\bar{\lambda} / \lambda (1 - w - \bar{w})| \right| = |\lambda w + \bar{\lambda}^{-1} \bar{w}| - (w + \bar{w} - 1)$
 $\geq \operatorname{Re}(|\lambda|w + |\bar{\lambda}^{-1}|\bar{w}) - (w + \bar{w} - 1) = \operatorname{Re}(w)(|\lambda| + |\lambda|^{-1} - 2) + 1$
 $\geq (|\operatorname{tr}(M)| - 3)/2 + 1$
 $\geq \frac{D^{1/4} - 1}{2}$.

If the closed geodesics of a point given by an elliptic element fixing one single point is small, then this point should be close to this isolated elliptic point. This geometric intuition can be made precise as follows.

Proposition 3.11. For any given R > 0, if $d_{\mathbb{B}^2}(u, Mu) < R$ for some $u \in \mathbb{B}^2$ and some elliptic element M of order 2, 3, 4, or 6, with isolated fixed point $v_1 \in \mathbb{B}^2$, then $d_{\mathbb{B}^2}(u, v_1) < R$.

Proof. Let v_1, v_2, v_3 be pairwise orthogonal eigenvectors of M and $\lambda_1, \lambda_2, \lambda_3$ be their corresponding eigenvalues. Apply (2.7) to u and we have

$$Mu = \lambda_1 \frac{\langle u, v_1 \rangle}{\langle v_1, v_1 \rangle} v_1 + \lambda_2 \frac{\langle u, v_2 \rangle}{\langle v_2, v_2 \rangle} v_2 + \lambda_3 \frac{\langle u, v_3 \rangle}{\langle v_3, v_3 \rangle} v_3$$

and then

$$\left|\frac{\langle Mu, u \rangle}{\langle u, u \rangle}\right| = \left|\lambda_1 \operatorname{ta}(u, v_1) + \lambda_2 \operatorname{ta}(u, v_2) + \lambda_3 \operatorname{ta}(u, v_3)\right|$$
$$\geq \left|\operatorname{Re}\left(\operatorname{ta}(u, v_1) + \lambda_2/\lambda_1 \operatorname{ta}(u, v_2) + \lambda_3/\lambda_1 \operatorname{ta}(u, v_3)\right)\right|$$

Since $\sum_{j=1}^{3} \operatorname{ta}(u, v_j) = 1$, $\operatorname{ta}(u, v_2)$, $\operatorname{ta}(u, v_3) \leq 0$ and $|\lambda_2/\lambda_1| = |\lambda_3/\lambda_1| = 1$, we have $\operatorname{Re}(\operatorname{ta}(u, v_1) + \lambda_2/\lambda_1 \operatorname{ta}(u, v_2) + \lambda_3/\lambda_1 \operatorname{ta}(u, v_3)) \geq \operatorname{ta}(u, v_1) + \operatorname{ta}(u, v_2) + \operatorname{ta}(u, v_3) = 1$. Thus,

$$\left|\frac{\langle Mu, u \rangle}{\langle u, u \rangle}\right| \ge \operatorname{Re}\left(\operatorname{ta}(u, v_1) + \lambda_2/\lambda_1 \operatorname{ta}(u, v_2) + \lambda_3/\lambda_1 \operatorname{ta}(u, v_3)\right)$$
$$= \operatorname{ta}(u, v_1) + \operatorname{Re}\left(\lambda_2/\lambda_1\right) \operatorname{ta}(u, v_2) + \operatorname{Re}\left(\lambda_3/\lambda_1\right) \operatorname{ta}(u, v_3)$$
$$\ge (1 - k) \operatorname{ta}(u, v_1) + k$$

where k is the largest real part of nontrivial n-th roots of unity, i.e. k = -1, -1/2, 0, 1/2for n = 2, 3, 4, 6 respectively. Therefore,

$$\cosh(d_{\mathbb{B}^2}(u, v_1)) = 2\operatorname{ta}(u, v_1) - 1 \le 2\frac{\left|\frac{\langle Mu, u \rangle}{\langle u, u \rangle}\right| - k}{1 - k} - 1 < 4\operatorname{cosh}(R/2) - 3 \le \operatorname{cosh}(R).$$

Similarly, we have the following for elliptic complex lines.

Proposition 3.12. For any given R > 0, if $d_{\mathbb{B}^2}(u, Mu) < R$ for some $u \in \mathbb{B}^2$ and some elliptic element M stabilizing a complex line L with normal vector n, then $d_{\mathbb{B}^2}(u, L) < R/2$.

Proof. Let v_1, v_2, n be pairwise orthogonal eigenvectors of M and -1, -1, 1 be their corresponding eigenvalues. Then

$$\frac{\langle Mu, u \rangle}{\langle u, u \rangle} = \left| -\operatorname{ta}(u, v_1) - \operatorname{ta}(u, v_2) + \operatorname{ta}(u, n) \right| = 1 - 2\operatorname{ta}(u, n) < \operatorname{cosh}(R/2).$$

Thus,

$$\cosh^2\left(\frac{d_{\mathbb{B}^2}(u,L)}{2}\right) = 1 - \operatorname{ta}(u,n) < \frac{\cosh(R/2) + 1}{2} = \cosh^2\left(\frac{R}{4}\right).$$

4. Multiplicity Bounds

In this section, we will conclude two kinds of multiplicity bounds for any curve $C \subset X = \Gamma \setminus \mathbb{B}^2$ inside our compact quotient of the hyperbolic 2-ball. The first one is the multiplicity bound of C at a point $x \in C \subset X$ in terms of the volume of C in a geodesic ball centered at x. This is a corollary of a theorem by Hwang and To in [HT02]:

Theorem 4.1. Follow the notation in (3.1). Then for any complex analytic curve $C \subset X$ and an isolated elliptic point $x \in C$ with stabilizer group G_x , let $B_{x,r}$ be the geodesic ball centered at x with radius r. Then there exists $D_0(r) > 0$ such that when $D > D_0(r)$,

$$\operatorname{vol}(C \cap B_{x,r}) \ge \frac{4\pi}{|G_x|} \operatorname{sinh}^2\left(\frac{r}{2}\right) \operatorname{mult}_x(C).$$

Proof. [HT02, Theorem 1] says that, for any complex analytic curve $\tilde{C} \subset \mathbb{B}^2$ and any point $\tilde{x} \in \tilde{C}$, the geodesic ball $\tilde{B}_{\tilde{x},r}$ centered at \tilde{x} with radius r satisfies

$$\operatorname{vol}(\tilde{C} \cap \tilde{B}_{\tilde{x},r}) \ge 4\pi \sinh^2\left(\frac{r}{2}\right) \operatorname{mult}_{\tilde{x}}(\tilde{C}).$$

Now we use Proposition 3.2 for R = 3r to pick the D_0 , i.e. for $D > D_0$, distances between distinct isolated elliptic points are greater than 3r. Then for $C \subset X$ and $x \in C$, consider $\tilde{x} \in \mathbb{B}^2$ a preimage of x under the quotient map $\tilde{\phi} : \mathbb{B}^2 \to X$. Now the restriction $\phi = \tilde{\phi}|_{\tilde{B}_{\tilde{x},r}} : \tilde{B}_{\tilde{x},r} \to B_{x,r}$ is a surjection. For any $p \in B_{x,r} \setminus \{x\}$, consider $\phi^{-1}(p)$. When D is large, $\tilde{p}, M\tilde{p} \in \tilde{B}_{\tilde{x},r}$ implies that M is not loxodromic by Proposition 3.10. If M is elliptic, $\tilde{p}, M\tilde{p} \in \tilde{B}_{\tilde{x},r}$ implies that $d(\tilde{p}, M\tilde{p}) < 2r$, and then by Proposition 3.11 and $D > D_0$, M is in the stabilizer group of x. Therefore, $|\phi^{-1}(p)|$ is at most the order of the isotropic group of x, which is bounded by 48 by Corollary 3.9.

The other one is a multiplicity bound for the intersection of any curve C with an elliptic complex line $L \subset X$ in terms of a geodesic tubular neighborhood of L. Most of the rest of this section is dedicated to prove the following theorem, while we will derive a relative version at the end of this section.

Theorem 4.2. Follow the notation in (3.1). For any complex analytic curve $C \subset X$ and a set of elliptic complex line $\{L_j \subset X\}_j$, let $W_{L,r} = \{p \in X : d(p,L) < r\}$ be the geodesic tubular neighborhood of L with radius r. Then for any r, there exists $D_0(r) > 0$ such that when $D > D_0(r)$,

$$\operatorname{vol}(C \cap \cup_j W_{L_j,r}) \ge \frac{\pi}{6} \sinh^2\left(\frac{r}{2}\right) \sum_j (C \cdot L_j)$$

The proof will use the idea in [HT12, Theorem 1], where a similar bound was proved for the intersection between any curve and the diagonal inside a product of hyperbolic curves. The idea here is to find a semi-positive (1,1)-form defined in the neighborhood of the complex line L, such that its integration against L over $W_{L,r}$ is bounded by the volume of L and its potential function is plurisubharmonic with desired pole orders along L. Then this gives a multiplicity bound through computation of the Lelong numbers.

Before we derive a result about the quotient space, we will first do the computation on $\tilde{W}_{\tilde{L},r}$ for one elliptic complex line $\tilde{L} \subset \mathbb{B}^2$. The statement on \mathbb{B}^2 we will prove is the following:

Proposition 4.3. Follow the notation in (3.1). For any complex analytic curve $\tilde{C} \subset \mathbb{B}^2$ and an elliptic complex line $\tilde{L} \subset \mathbb{B}^2$, let $\tilde{W}_{\tilde{L},r} = \{p \in \mathbb{B}^2 : d_{\mathbb{B}^2}(p,\tilde{L}) < r\}$ be the geodesic tubular neighborhood of \tilde{L} with radius r. Then for any r, there exists $D_0(r) > 0$ such that when $D > D_0(r)$,

$$\operatorname{vol}(\tilde{C} \cap \tilde{W}_{\tilde{L},r}) \ge 4\pi \sinh^2\left(\frac{r}{2}\right)(\tilde{C} \cdot \tilde{L}).$$

By Proposition 2.12, let

$$\tilde{\mu}(p) = \tanh^2\left(\frac{d(p,\tilde{L})}{2}\right) = \frac{-\mathrm{ta}(p,n)}{1-\mathrm{ta}(p,n)}$$

where n is a normal vector of L, and the tubular neighborhood in \mathbb{B}^2 is

$$\tilde{W}_{L,r} = \{ p \in \mathbb{B}^2 : d(p,L) < r \} = \{ p \in \mathbb{B}^2 : \tilde{\mu}(p) < 2 \tanh^2(r/2) \}.$$

Since the metric is invariant to different choices of hermitian forms, it suffices to prove the case for J = diag(1, 1, -1). We can also assume the complex line \tilde{L} has normal vector $n = [1, 0, 0] \in \mathbb{P}V^+$ as the $\mathbb{P}U(2, 1)$ -action is transitive on \mathbb{B}^2 . Consider $p = (z, w) = [z, w, 1] \in \mathbb{P}V^-$. Then we have

$$\tilde{\mu} = \frac{|z|^2}{1 - |w|^2}.$$

We first conclude a criterion for plurisubharmonic function when $\log \tilde{\mu}$ is the input.

Lemma 4.4. For any given $r_* > 0$, let $s_* := \log(\tanh^2(r_*/2))$. Then for any C^2 function $f : [-\infty, s_*] \to \mathbb{R}$, the function $f \circ (\log \tilde{\mu})$ is plurisubharmonic on $\tilde{W}_{\tilde{L},r} \setminus \tilde{L}$ if $f''(s), f'(s) \ge 0$ for $s < s_*$.

Proof. It suffices to check that $i\partial\bar{\partial}(f(\log \tilde{\mu}))$ is semipositive. We can check this by writing down the (1,1)-form in coordinates (z,w): we say that a (1,1)-form ω on

 \mathbb{B}^2 is represented by a matrix M if

$$M = \begin{pmatrix} \omega \left(\frac{\partial}{\partial z}, \frac{\partial}{\partial \bar{z}} \right) & \omega \left(\frac{\partial}{\partial z}, \frac{\partial}{\partial \bar{w}} \right) \\ \omega \left(\frac{\partial}{\partial w}, \frac{\partial}{\partial \bar{z}} \right) & \omega \left(\frac{\partial}{\partial w}, \frac{\partial}{\partial \bar{w}} \right) \end{pmatrix} \Big|_{(z,w)}$$

Then $i\partial \bar{\partial} \tilde{\mu}$ and $i\partial \tilde{\mu} \wedge \bar{\partial} \tilde{\mu}$ are respectively represented by:

$$\begin{pmatrix} \frac{1}{1-|w|^2} & \frac{\bar{z}w}{(1-|w|^2)^2} \\ \frac{z\bar{w}}{(1-|w|^2)^2} & \frac{|z|^2(1+|w|^2)}{(1-|w|^2)^3} \end{pmatrix} \text{ and } \tilde{\mu} \cdot \begin{pmatrix} \frac{1}{1-|w|^2} & \frac{\bar{z}w}{(1-|w|^2)^2} \\ \frac{z\bar{w}}{(1-|w|^2)^2} & \frac{|z|^2|w|^2}{(1-|w|^2)^3} \end{pmatrix}.$$
(4.5)

Since

$$i\partial\bar{\partial}(f\circ\log\tilde{\mu}) = \frac{f'(\log\tilde{\mu})}{\tilde{\mu}} \cdot i\partial\bar{\partial}\tilde{\mu} + \frac{f''(\log\tilde{\mu}) - f'(\log\tilde{\mu})}{\tilde{\mu}^2} \cdot i\partial\tilde{\mu} \wedge \bar{\partial}\tilde{\mu},$$

it is represented by

$$\begin{split} & \frac{f'(\log\tilde{\mu})}{\tilde{\mu}} \cdot \begin{pmatrix} \frac{1}{1-|w|^2} & \frac{\bar{z}w}{(1-|w|^2)^2} \\ \frac{z\bar{w}}{(1-|w|^2)^2} & \frac{|z|^2(1+|w|^2)}{(1-|w|^2)^3} \end{pmatrix} + \frac{f''(\log\tilde{\mu}) - f'(\log\tilde{\mu})}{\tilde{\mu}^2} \cdot \tilde{\mu} \cdot \begin{pmatrix} \frac{1}{1-|w|^2} & \frac{\bar{z}w}{(1-|w|^2)^2} \\ \frac{z\bar{w}}{(1-|w|^2)^2} & \frac{|z|^2|w|^2}{(1-|w|^2)^3} \end{pmatrix} \\ = & f''(\log\tilde{\mu}) \cdot \begin{pmatrix} \frac{1}{|z|^2} & \frac{\bar{z}w}{|z|^2(1-|w|^2)} \\ \frac{z\bar{w}}{|z|^2(1-|w|^2)} & \frac{|w|^2}{(1-|w|^2)^2} \end{pmatrix} + f'(\log\tilde{\mu}) \cdot \begin{pmatrix} 0 & 0 \\ 0 & \frac{1}{(1-|w|^2)^2} \end{pmatrix}, \end{split}$$

and it is positive semidefinite when $f'(s), f''(s) \ge 0$ since the two matrices in the last row have zero determinants and positive traces.

In the following we will consider the function $F(s) = -2\log(1 - e^s)$. It can be constructed following the idea by Hwang and To in [HT12]. We first verify that $\tilde{\omega}_F := i\partial\bar{\partial}(F \circ \log \tilde{\mu})$ is semipositive and bounded by the volume form in our setting.

Lemma 4.6. $\tilde{\omega}_F := i\partial \bar{\partial} (F \circ \log \tilde{\mu})$ satisfies $0 \leq \tilde{\omega}_F \leq \omega_{\mathbb{B}^2}$, where $\omega_{\mathbb{B}^2}$ is the Kähler form given by the Bergman metric.

Proof. Since $s \in [-\infty, 0)$,

$$F'(s) = \frac{2e^s}{1 - e^s}, \quad F''(s) = \frac{2e^s}{(1 - e^s)^2},$$

are nonnegative and by Lemma 4.4, $\tilde{\omega}_F$ is semipositive. The Kähler form $\omega_{\mathbb{B}^2}$ is represented by

$$\frac{2}{(1-|z|^2-|w|^2)^2} \begin{pmatrix} 1-|w|^2 & \bar{z}w\\ z\bar{w} & 1-|z|^2 \end{pmatrix}.$$

We plug F into the computation in the proof of Lemma 4.4 and we get that $\tilde{\omega}_F$ is represented by

$$\begin{aligned} \frac{2|z|^2(1-|w|^2)}{(1-|z|^2-|w|^2)^2} \cdot \begin{pmatrix} \frac{1}{|z|^2} & \frac{\bar{z}w}{|z|^2(1-|w|^2)} \\ \frac{z\bar{w}}{|z|^2(1-|w|^2)} & \frac{|w|^2}{(1-|w|^2)^2} \end{pmatrix} + \frac{2|z|^2}{1-|z|^2-|w|^2} \cdot \begin{pmatrix} 0 & 0 \\ 0 & \frac{1}{(1-|w|^2)^2} \end{pmatrix} \\ = \frac{2}{(1-|z|^2-|w|^2)^2} \cdot \begin{pmatrix} 1-|w|^2 & \bar{z}w \\ z\bar{w} & \frac{|z|^2(1-|z|^2-|w|^2)}{(1-|w|^2)^2} \end{pmatrix}. \end{aligned}$$
Since $1-|z|^2-|w|^2 > 0, \ \frac{|z|^2(1-|z|^2-|w|^2)}{(1-|w|^2)^2} < \frac{1-|z|^2-|w|^2}{1-|w|^2} \le \frac{1-|z|^2-|w|^2+|z|^2|w|^2}{1-|w|^2} = 1-|z|^2,$ and thus $\tilde{\omega}_F \le \omega_{\mathbb{B}^2}.$

Similar to Lemma 21 in [BT16], we have the following.

Lemma 4.7. $\frac{1}{2\sinh^2(r/2)} \int_{\tilde{C} \cap \tilde{W}_{\tilde{L},r}} \tilde{\omega}_F$ is an increasing function of r.

Proof. By Stokes' theorem,

$$\int_{\tilde{C}\cap\tilde{W}_{\tilde{L},r}} \tilde{\omega}_F = F'(\log \tanh^2(r/2)) \int_{\tilde{C}\cap\tilde{W}_{\tilde{L},r}} i\partial\bar{\partial}\log\tilde{\mu}$$
$$= 2\sinh^2(r/2) \int_{\tilde{C}\cap\tilde{W}_{\tilde{L},r}} i\partial\bar{\partial}\log\tilde{\mu}$$

because we can approximate F by a linear function of slope $F'(\log \tanh^2(r/2))$ at the boundary of $\tilde{W}_{\tilde{L},r}$ without changing the integral of the interior. Moreover, applying Lemma 4.4 to f(s) = s shows that $\log \tilde{\mu}$ is plurisubharmonic, and then the claim follows.

Now we can conclude the proof as in the proof of Theorem 19(b) in [BT16].

Proof of Proposition 4.3. By Lemma 4.6 and Lemma 4.7, we have

$$\int_{\tilde{C}\cap\tilde{W}_{\tilde{L},r}} \omega_{\mathbb{B}^2} \ge \int_{\tilde{C}\cap\tilde{W}_{\tilde{L},r}} \tilde{\omega}_F \ge 2\sinh^2(r/2) \cdot \lim_{r\to 0} \int_{\tilde{C}\cap\tilde{W}_{\tilde{L},r}} i\partial\bar{\partial}\log\tilde{\mu}$$

We can bound the limit by a local calculation of Lelong numbers the same as in [HT12] with minor modifications: for points in a small polydisc neighborhood U_j of each intersection point $(0, w_j) \in \tilde{C} \cap \tilde{L}$, $\tilde{\mu} = \frac{|z|^2}{1-|w|^2} \leq \lambda |z|^2$ for some fixed $\lambda > 1$ as there are only finitely many U_j , and this constant term λ will have no impact when we take the limit to compute the Lelong number. The same as in [HT12], we can conclude that

$$\lim_{r \to 0} \int_{\tilde{C} \cap \tilde{W}_{\tilde{L},r}} i \partial \bar{\partial} \log \tilde{\mu} \ge 2\pi \cdot (\tilde{C} \cdot \tilde{L}).$$

Now we continue to prove Theorem 4.2, i.e. descend Proposition 4.3 to the quotient space $X = \Gamma \setminus \mathbb{B}^2$ and consider a finite set of elliptic complex lines $\{L_j \subset X\}_j$. For each L_j , pick a preimage $\tilde{L}_j \subset \mathbb{B}^2$, so all the preimages of L_j are given by $\Gamma \cdot \tilde{L}_j$.

For an elliptic complex line $\tilde{L} \subset \mathbb{B}^2$, let $\Gamma_{\tilde{L}} \subset \Gamma$ be the stabilizer group of \tilde{L} . Since \tilde{L} is determined by its normal vector n, the stabilizer is in fact $\Gamma_{\tilde{L}} = \{M \in \Gamma : M \cdot n = \lambda n \text{ for some } \lambda \in \mathbb{C}^*\}$ if we consider $n \in V_+$. Note that $\tilde{W}_{\tilde{L},r}$ is invariant under the action of $M \in \Gamma_{\tilde{L}}$ since $\operatorname{ta}(M \cdot p, n) = \operatorname{ta}(p, M^{-1} \cdot n) = \operatorname{ta}(p, n)$.

To derive a result on $\cup_j \tilde{W}_{L_j,r}$, we consider the covering given by the disjoint union of tubular neighborhoods of $\{\tilde{L}_j\}_j$, and we will show that the sizes of the fibers are bounded.

Lemma 4.8. Follow the notation in (3.1). For any given r > 0, there exists $D_0 > 0$ such that the number of elements in the fibers of the quotient map

$$\tilde{\pi}: \sqcup_j \tilde{W}_{\tilde{L}_j, r} \to \cup_j W_{L_j, r}$$

is at most 24 for any $D > D_0$.

Proof. Assume that it is not injective at $p \in \bigcup_j W_{L_j,r}$. It means that by rewriting the indices we can assume that p has a preimage $\tilde{p} \in \tilde{W}_{\tilde{L}_1,r}$ such that there is either a distinct $\tilde{p}_0 \in \tilde{W}_{\tilde{L}_1,r}$ with $M \cdot \tilde{p} = \tilde{p}_0$ for $M \in \Gamma$, or a not necessarily distinct $\tilde{p}_0 \in \tilde{W}_{\tilde{L}_2,r}$ with $M \cdot \tilde{p} = \tilde{p}_1$ for $M \in \Gamma$. In the first case, $\tilde{p}_0 \neq \tilde{p}$ means that $M \notin \Gamma_{\tilde{L}_1}$, so $M^{-1} \cdot \tilde{L}_1$ is a distinct elliptic complex line in \mathbb{B}^2 , and $\tilde{p} = M^{-1} \cdot \tilde{p}_0 \in \tilde{W}_{\tilde{L}_1,r} \cap \tilde{W}_{M^{-1} \cdot \tilde{L}_1,r}$. In the second case, since \tilde{L}_1 and \tilde{L}_2 have distinct images in $X, M \cdot \tilde{L}_1$ and \tilde{L}_2 are distinct in \mathbb{B}^2 , and we have $\tilde{p}_0 = M \cdot \tilde{p} \in \tilde{W}_{\tilde{L}_2,r} \cap \tilde{W}_{M \cdot \tilde{L}_1,r}$.

In both cases, \tilde{p} is now in the intersection of tubular neighborhoods of two distinct elliptic complex lines. Let \tilde{L}_a , \tilde{L}_b denote these two elliptic complex lines and let their nontrivial stabilizers in Γ be M_a and M_b respectively. By Proposition 3.8, when Dis large, disjoint elliptic complex lines should be far apart and thus $\tilde{W}_{\tilde{L}_a,r} \cap \tilde{W}_{\tilde{L}_b,r}$ is empty. If these two elliptic complex lines intersect, then by Proposition 3.8, the intersection point is an isolated elliptic point stabilized by $M_a M_b$. Note that $\tilde{p}_0 \in \tilde{W}_{\tilde{L}_b,r}$ implies $d(M_b \cdot \tilde{p}, \tilde{p}) < 2r$, and then by $d(\tilde{p}, L_a) < r$, $M_b \cdot \tilde{p} \in \tilde{W}_{\tilde{L}_a,3r}$. Then,

$$d(\tilde{p}, M_a M_b \cdot \tilde{p}) \le d(\tilde{p}, M_b \cdot \tilde{p}) + d(M_b \cdot \tilde{p}, M_a M_b \cdot \tilde{p})$$

$$< 2r + 6r$$

$$= 8r.$$

Then by Proposition 3.11, \tilde{p} is inside the ball centered at the intersection point of radius 8r. Now by Proposition 3.2, when D is large enough to make sure that distances between distinct isolated elliptic points are more than 16r, \tilde{p} can at most lie in a unique hyperbolic ball centered at an isolated elliptic point.

In conclusion, we have shown that when $D > D_0$ for some D_0 only depending on r, for any $p \in \bigcup_j W_{L_j,r}$ with a preimage $\tilde{p} \in \bigsqcup_j \tilde{W}_{\tilde{L}_j,r}$, \tilde{p} is at most in a unique hyperbolic ball centered at an isolated elliptic point, and any additional preimage of p will generate an additional distinct elliptic complex line going through this isolated elliptic point. By Corollary 3.9, an isolated elliptic point can lie on at most 24 distinct elliptic complex lines, so p can at most have 24 preimages in $\bigsqcup_j \tilde{W}_{\tilde{L}_j,r}$. \Box

Proof of Theorem 4.2. Let ω_X denote the volume form on X. By Proposition 4.3 and Lemma 4.8, we have

$$\operatorname{vol}(C \cap \cup_{j} W_{L_{j},r}) = \int_{\cup_{j} W_{L_{j},r}} [C] \wedge \omega_{X}$$
$$\geq \frac{1}{24} \sum_{j} \int_{\tilde{W}_{\tilde{L}_{j},r}} [\tilde{C}] \wedge \omega_{\mathbb{B}^{2}}$$
$$\geq \frac{\pi}{6} \operatorname{sinh}^{2} \left(\frac{r}{2}\right) \sum_{j} (C \cdot L_{j}).$$

Similar to [BT16, Proposition 23], we can derive the following relative version.

Proposition 4.9. Follow the notation in (3.1). Then for any given 0 < r < R, there exists $D_0(R) > 0$ such that when $D > D_0(R)$,

$$\operatorname{vol}(C \cap W_{L,R}) \ge \frac{\cosh^2(R/2)}{24 \cosh^2(r/2)} \operatorname{vol}(C \cap W_{L,r}).$$

Proof. We will first show that $\frac{1}{\cosh^2(r/2)} \int_{\Gamma_{\tilde{L}} \setminus (\tilde{C} \cap \tilde{W}_{\tilde{L},r})} \omega_{\mathbb{B}^2}$ is a nondecreasing func-

tion of r, where \tilde{L} is given by z = 0. Consider $f(t) = \log\left(\frac{t}{1-t}\right)$ and by Lelong-Poincaré we have:

$$\begin{split} i\partial\bar{\partial}(f\circ\tilde{\mu}) &= i\partial\bar{\partial}\log|z|^2 - i\partial\bar{\partial}\log(1-|z|^2 - |w|^2)\\ &= \pi[\tilde{L}] + \frac{1}{2}\omega_{\mathbb{B}^2}. \end{split}$$

By Stokes' theorem, we have:

$$\begin{split} \frac{1}{2} \int_{\Gamma_{\tilde{L}} \setminus (\tilde{C} \cap \tilde{W}_{\tilde{L},r})} \omega_{\mathbb{B}^2} + \pi \cdot (\tilde{L} \cdot \tilde{C}) &= \int_{\Gamma_{\tilde{L}} \setminus (\tilde{C} \cap \tilde{W}_{\tilde{L},r})} i \partial \bar{\partial} (f \circ \tilde{\mu}) \\ &= f' (\log(\tanh^2(r/2))) \int_{\Gamma_{\tilde{L}} \setminus (\tilde{C} \cap \tilde{W}_{\tilde{L},r})} i \partial \bar{\partial} \log \tilde{\mu}. \end{split}$$

By Lemma 4.4, $\log \tilde{\mu}$ is plurisubharmonic, so $\int_{C \cap W_{L,r}} i \partial \bar{\partial} \log \tilde{\mu}$ is a nondecreasing function of r. $f'(\log(\tanh^2(r/2))) = \cosh^2(r/2)$ is an increasing function of r, so $\frac{1}{\cosh^2(r/2)} \int_{\Gamma_{\tilde{L}} \setminus (\tilde{C} \cap \tilde{W}_{\tilde{L},r})} \omega_{\mathbb{B}^2}$ is a nondecreasing function of r and we obtain an inequality in $\Gamma_{\tilde{L}} \setminus \tilde{W}_{\tilde{L},R}$ by plugging in 0 < r < R. When D is big, by Lemma 4.8 the degree of the quotient map $\Gamma_{\tilde{L}} \setminus \tilde{W}_{\tilde{L},R} \to W_{L,R}$ is bounded by 24, so the inequality descends to $W_{L,R}$ if we add a factor of 24.

Similarly, we have the relative version for volume estimates for a point.

Proposition 4.10. Follow the notation in (3.1). Then for any given 0 < r < R and any isolated elliptic point $x \in X$, there exists $D_0(R) > 0$ such that when $D > D_0(R)$,

$$\operatorname{vol}(C \cap B_{x,R}) \ge \frac{\cosh^2(R/2)}{48 \cosh^2(r/2)} \operatorname{vol}(C \cap B_{x,r}).$$

Proof. It suffices to show that $\frac{1}{\cosh^2(r/2)} \int_{C \cap \tilde{B}_{x,r}} \omega_{\mathbb{B}^2}$ is a nondecreasing function of r for the case where x is $[0,0,1] \in \mathbb{B}^2$. Now for any $p = [z,w,1] \in \mathbb{B}^2$, we have $\cosh^2(d(x,p)/2) = \operatorname{ta}(x,p) = 1/(1-|z|^2-|w|^2)$. Now consider $g(t) = -\log(1-t)$, and thus $g'(|z|^2 + |w|^2) = 1/(1-|z|^2-|w|^2) = \cosh^2(d(x,p)/2)$. Then by Stokes' theorem:

$$\int_{C\cap\tilde{B}_{x,r}} \omega_{\mathbb{B}^2} = \int_{C\cap\tilde{B}_{x,r}} 2i\partial\bar{\partial}(-\log(1-|z|^2-|w|^2))$$
$$= \cosh^2(r/2) \int_{C\cap\tilde{B}_{x,r}} 2i\partial\bar{\partial}(|z|^2+|w|^2)$$

Note that $p = [z, w, 1] \mapsto |z|^2 + |w|^2$ is plurisubharmonic, so we finish the proof. \Box

5. Proof of Main Theorems

5.1. **Proof of Theorem 1.1.** Consider any irreducible curve $C \subset X$ of genus g. The idea of the proof is to derive two contradictory inequalities in terms of the volume and the genus of the curve when the discriminant D is large. We will first show the case where C does not have generic stacky-ness, i.e. it is not a component of an elliptic complex line. The other case will follow using the same strategy.

Step 1. An upper bound of $vol_X(C)$ when C is not a component of an elliptic complex line

Let $U \subset C$ be the open subset of C with all elliptic points removed. Then U can be uniformized by \mathbb{H} . Apply Schwarz's lemma to the hyperbolic metric on X and the uniformized metric on \mathbb{H} of constant curvature -1, and then by Gauss-Bonnet we have

$$\frac{1}{4\pi} \operatorname{vol}_X(C) \le -\chi(C) \le 2g - 2 + \#\{\text{elliptic points}\}$$
(5.1)

where $\chi(C)$ is the orbifold Euler characteristic. This inequality will become an upper bound of $\operatorname{vol}_X(C)$ if we can show that $\#\{\text{elliptic points}\} < c \cdot \operatorname{vol}_X(C)$ for some small constant $c < \frac{1}{4\pi}$. Now we will first show a bound of $\#\{\text{elliptic points}\}$ for a fixed number R > 0, and later we can see how to pick R in terms of the genus g.

Step 1.1. an upper bound of numbers of elliptic points on C given by elliptic complex lines

Consider all elliptic complex lines $\{L_j\}_j$ in X that intersect C. Then by Theorem 4.2 when D is large we have:

#{elliptic points given by elliptic complex lines}
$$\leq \sum_{j} (C \cdot L_j) \leq \frac{\operatorname{vol}_X(C)}{\frac{\pi}{6} \operatorname{sinh}^2(\frac{r}{2})}.$$

Step 1.2. an upper bound of numbers of elliptic points on C given by isolated elliptic points

By Theorem 4.1 and Proposition 3.2, when D is large, the balls of radius r centered at isolated elliptic points are disjoint, and thus

#{isolated elliptic points counted by multiplicity}
$$\leq \frac{\operatorname{vol}_X(C)}{\frac{\pi}{12}\sinh^2\left(\frac{r}{2}\right)}$$

In conclusion, we have

$$\frac{1}{4\pi} \operatorname{vol}_X(C) \le 2g - 2 + \frac{\operatorname{vol}_X(C)}{\frac{\pi}{18} \operatorname{sinh}^2\left(\frac{r}{2}\right)}$$

and when $\sinh^2\left(\frac{r}{2}\right) > 72$, we obtain an upper bound of $\operatorname{vol}_X(C)$.

Step 2. In the meantime, consider any point p on C. By Theorem 4.1, we have a lower bound of $\operatorname{vol}_X(C)$ in terms of the injectivity radius of this point. We want this lower bound to be larger than the upper bound we just obtained when D is large, which will imply that such C cannot exist. If a point on C with injectivity radius $r = R_1$ can lead to such a contradiction, it suffices to find a point on C whose distance to any isolated elliptic points is greater than $2R_1$ and to any elliptic lines is greater than R_1 when D is big by Proposition 3.10, 3.11 and 3.12.

Suppose we cannot, i.e. the whole curve C is contained in a union of hyperbolic balls of radius $2R_1$ and tubes of radius R_1 . C is compact so this cover can be finite. Denote the centers of these balls x_1, \dots, x_{m_1} and complex lines for these tubes L_1, \dots, L_{m_2} . The relative versions of the volume inequalities (Proposition 4.10 and 4.9) give that for some $R_2 > R_1$ we have

$$\operatorname{vol}(C \cap B_{x,2R_2}) \ge 26\operatorname{vol}(C \cap B_{x,2R_1})$$
$$\operatorname{vol}(C \cap W_{L,R_2}) \ge 26\operatorname{vol}(C \cap W_{L,R_1})$$

By Proposition 3.2 and 3.8, when D grows we can make sure each point in the union for R_2 is covered by at most 1 ball and 24 tubes. Then, we have

$$26 \operatorname{vol}_X(C) \le 26 \left(\sum_{j=1}^{m_1} \operatorname{vol}(C \cap B_{x_j,2R_1}) + \sum_{j=1}^{m_2} \operatorname{vol}(C \cap W_{L_j,R_1})\right)$$
$$\le \sum_{j=1}^{m_1} \operatorname{vol}(C \cap B_{x_j,2R_2}) + \sum_{j=1}^{m_2} \operatorname{vol}(C \cap W_{L_j,R_2})$$
$$\le 25 \operatorname{vol}_X(C)$$

which is a contradiction. Therefore, there is no curves of genus g when D is large if this curve is not an elliptic complex line.

Step 3. When C is a component of an elliptic complex line, this is similar: we still have (5.1) except there is a factor of 1/2 on the right hand side because of the generic quotient singularity of the line, and the order of the elliptic points might be different, but it is bounded by the original order. Since intersection points of elliptic complex lines are isolated elliptic points, we only have to consider isolated elliptic points on the curve. Consequently, (5.1) becomes:

$$\frac{1}{4\pi} \operatorname{vol}_X(C) \le \frac{1}{2} \left[2g - 2 + \frac{\operatorname{vol}_X(C)}{\frac{\pi}{12} \operatorname{sinh}^2\left(\frac{r}{2}\right)} \right]$$

and gives an upper bound of $\operatorname{vol}_X(C)$ for large D. For the lower bound of $\operatorname{vol}_X(C)$, the same idea applies except that we do not need to consider tubular neighborhood by Proposition 3.8.

5.2. Moduli interpretation. In this section we will prove Theorem 1.2. We will first describe the Hodge structures the compact ball quotient parametrizes and their correspondence with the abelian varieties in the theorem.

To describe the Hodge structures we want, first note that *n*-balls parametrize \mathbb{C} -Hodge structures: an element $v \in \mathbb{P}V_{-}$ defines a 1-dimensional subspace of V, and the Hermitian form h polarizes the decomposition $V = \mathbb{C}v \oplus v^{\perp}$ as it is negative definite on $\mathbb{C}v$ and positive definite on v^{\perp} . This can be extended to an integral Hodge structure using the arithmetic of the lattices as follows.

Consider a \mathbb{Z} -lattice $H_{\mathbb{Z}} \cong \mathcal{O}_F^3$ of rank 12 equipped with an \mathcal{O}_F -action, so $H_{\mathbb{C}} = \mathbb{C} \otimes_{\mathbb{Z}} H_{\mathbb{Z}}$ can be decomposed into a direct sum of eigenspaces of the \mathcal{O}_F -action $H_{\mathbb{C}} \cong H^{\sigma_1} \oplus H^{\overline{\sigma}_1} \oplus H^{\overline{\sigma}_2} \oplus H^{\overline{\sigma}_2}$ where the \mathcal{O}_F -action on each component is given by the corresponding complex embedding of $F \subset \mathbb{C}$. For each embedding $\sigma : F \to \mathbb{C}$, consider $\pi_{\sigma} : H_{\mathbb{C}} = \mathbb{C} \otimes_{\mathbb{Z}} H_{\mathbb{Z}} \to \mathbb{C}_{\sigma} \otimes_{\mathcal{O}_F} H_{\mathbb{Z}} \cong \mathbb{C}^3$ given by identity map, where \mathbb{C}_{σ} emphisizes that the \mathcal{O}_F action on \mathbb{C} is given by σ . For any embedding $\sigma' : F \to \mathbb{C}$,

any $t \in \mathcal{O}_F$, and $v \in H^{\sigma'}$, $\sigma'(t)\pi_{\sigma}(v) = \pi_{\sigma}(\sigma'(t)v) = \pi_{\sigma}(t \cdot v) = \sigma(t)\pi_{\sigma}(v)$, which implies that $\pi_{\sigma}(v) = 0$ when $\sigma \neq \sigma'$. Therefore, π_{σ} is indeed a projection onto the σ -eigenspace and it gives a canonical way to identify the σ -eigenspace. For example, $1 \otimes v \in H_{\mathbb{C}} = (\sigma_1(v), \bar{\sigma}_1(v), \sigma_2(v), \bar{\sigma}_2(v))$ for $v \in H_{\mathbb{Z}}$.

Note that under this identification, the complex conjugation in $H_{\mathbb{C}}$ is not given by complex conjugation in each eigenspace. In fact, consider $\sum_j b_j \otimes v_j \in H^{\sigma} \subset \mathbb{C} \otimes H_{\mathbb{Z}}$. Then the action of $t \in \mathcal{O}_F$ gives $\sum_j \sigma(t)b_j \otimes v_j = \sum_j b_j \otimes tv_j$. Taking complex conjugation of the coefficients we can see that $\sum_j \bar{b}_j \otimes v_j$ is in the eigenspace corresponding to $\bar{\sigma}$. Consequently, for $x = (x_1, x_2, x_3, x_4) \in H_{\mathbb{C}} \cong H^{\sigma_1} \oplus H^{\bar{\sigma}_1} \oplus H^{\sigma_2} \oplus H^{\bar{\sigma}_2}, \ \bar{x} = (\bar{x}_2, \bar{x}_1, \bar{x}_4, \bar{x}_3).$

Now for each $v \in \mathbb{P}V_{-}^{\sigma_1}$, we can define a polarized integral Hodge structure on $H_{\mathbb{C}}$ of weight w = -1 by picking the negative and positive definite parts respectively for each pair of complex embeddings of F. Concretely, fix a nonzero element $\alpha \in \mathcal{O}_F \cap i\mathbb{R}$ with $\operatorname{Im}(\sigma_1(\alpha)) < 0$. Without loss of generality we assume the hermitian form $-i\alpha h$ is positive definite under σ_2 , and then we define

$$H^{-1,0} = \mathbb{C}v \oplus \bar{v}^{\perp_{\bar{\sigma}_1}} \oplus 0 \oplus H^{\bar{\sigma}_2}.$$

and $H^{0,-1} = \overline{H^{-1,0}}$ gives

$$H^{0,-1} = v^{\perp_{\sigma_1}} \oplus \mathbb{C}\bar{v} \oplus H^{\sigma_2} \oplus 0$$

so we do have the Hodge decomposition $H_{\mathbb{C}} = H^{0,-1} \oplus H^{-1,0}$. Now we can polarize this Hodge structure using αh : for $x, y \in H_{\mathbb{C}} \cong V^{\sigma_1} \oplus V^{\bar{\sigma}_1} \oplus V^{\bar{\sigma}_2} \oplus V^{\bar{\sigma}_2}$,

$$Q: H_{\mathbb{C}} \otimes \bar{H}_{\mathbb{C}} \to \mathbb{C}(1) \quad (x, \bar{y}) \mapsto \sum_{\sigma} \sigma(\alpha) h^{\sigma}(\pi_{\sigma}(x), \pi_{\sigma}(y)),$$

and by construction it does define a polarization on the real structure. To see that it takes integer values on $H_{\mathbb{Z}}$, consider $u, v \in H_{\mathbb{Z}}$, and then $Q(u, \bar{v}) = Q(u, v) =$ $\operatorname{tr}_{F/\mathbb{Q}}(\alpha h(u, v)) \in \mathbb{Z}$.

Now we summarize the moduli interpretation of our compact quotient of hyperbolic 2-balls as follows. Fix any Hermitian form $h: F^3 \times F^3 \to F$ with coefficients in \mathcal{O}_F such that it is of signature (2, 1) under the first pair of complex embeddings and definite under the other pair of embeddings, and also fix a nonzero element $\alpha \in \mathcal{O}_F \cap i\mathbb{R}$ with $\operatorname{Im}(\sigma_1(\alpha)) < 0$. Then for any $v \in \mathbb{B}^2$ we have constructed an integral Hodge structure for a \mathbb{Z} -lattice $H_{\mathbb{Z}} \cong \mathcal{O}_F^3$ of rank 12, polarized by Q defined above. Since polarized integral Hodge structures of weight -1 correspond to abelian varieties by taking $H_{\mathbb{C}}/(H^{0,-1}+H_{\mathbb{Z}})$, we can state the moduli interpretation in terms of abelian varieties. For an abelian variety A with \mathcal{O}_F -multiplication $\mathcal{O}_F \hookrightarrow \operatorname{End}(A)$, $H_1(A, \mathbb{Z})$ has an induced \mathcal{O}_F -module structure, and we say that A has a polarization given by a skew-Hermitian form T defined over F if $E(u, v) = \operatorname{tr}_{F/\mathbb{Q}}(T(u, v))$ is a Riemann form that polarizes A.

Lemma 5.2. When $D' > D'_0$, the compact quotient $X = \mathbb{B}^2/SU(h^{\sigma_1}, \mathcal{O}_F)$ is the moduli space for abelian varieties A of dimension 6 with \mathcal{O}_F -endomorphism that have $H_1(A, \mathbb{Z}) \cong \mathcal{O}_F^3$ and admit a polarization given by $-\alpha h$.

Proof. To continue the construction above, note that the associated positive definite Hermitian form on $H^{-1,0}$ is $i^{-1}Q$, so taking its imaginary part we obtain the Riemann

form in the language of abelian varieties, which is equal to $\operatorname{tr}_{F/\mathbb{Q}}(-\alpha h)$ if we restrict the pairing to the lattice.

For any abelian variety A of dimension 6 with \mathcal{O}_F -endomorphism whose $H_1(A, \mathbb{Z}) \cong \mathcal{O}_F^3$ under the induced \mathcal{O}_F -action, the \mathcal{O}_F -action extends to $H_{\mathbb{C}} = H_1(A, \mathbb{Z}) \otimes_{\mathbb{Z}} \mathbb{C}$ and gives an eigenspace decomposition of $H_{\mathbb{C}}$. We then further assume that A admit a polarization given by $-\alpha h$. By the assumption on the signature of h, the projection of its $H^{-1,0}$ onto the σ_1 -eigenspace is 1-dimensional and determines an element $v \in \mathbb{B}^2$.

Thus, \mathbb{B}^2 parametrizes this type of abelian varieties with a choice of frames $H_1(A,\mathbb{Z}) \cong \mathcal{O}_F^3$. For two choices of $H_1(A,\mathbb{Z}) \cong \mathcal{O}_F^3$, the transition matrix T preserves $-\alpha h$ and, therefore, the hermitian form h, i.e. $T \in U(h)$. Since we are considering the basis of \mathcal{O}_F^3 , the entries of T has to be in \mathcal{O}_F . By our assumption $D' > D'_0$ on the field F, $|\det T| = 1$ means $\det T = \pm 1$. When $\det T = -1$, note that -1 acts trivially and -T has determinant 1. Thus, for two elements in \mathbb{B}^2 parametrizing the same abelian variety, the transition matrix between them for some choices of frames can be chosen in $SU(h, \mathcal{O}_F)$. Therefore, $\mathbb{B}^2/SU(h^{\sigma_1}, \mathcal{O}_F)$ is the moduli space for the type of abelian varieties described here.

Before we restate Theorem 1.1, note that the existence of a polarization given by a skew-Hermitian form defined over F is automatic for an abelian variety with \mathcal{O}_{F} -action:

Lemma 5.3. An abelian variety A of dimension 6 over \mathbb{C} with \mathcal{O}_F -endomorphism admits a polarization given by a skew-Hermitian form defined over F.

Proof. The \mathcal{O}_F -action on A makes $H_1(A, \mathbb{Z}) \otimes \mathbb{Q}$ an F-vector space of dimension $2 \cdot 6/4 = 3$. Fix an isomorphism $\eta : F^3 \to H_1(A, \mathbb{Z}) \otimes \mathbb{Q}$. Let E be a Riemann form that polarizes A. Then any $u, v \in F^3$ define a \mathbb{Q} -linear map $F \to \mathbb{Q}$, $t \mapsto (\eta^* E)(t \cdot u, v)$. By the nondegeneracy of $\operatorname{tr}_{F/\mathbb{Q}}$, there is an $h(u, v) \in F$ such that $(\eta^* E)(t \cdot u, v) = \operatorname{tr}_{F/\mathbb{Q}}(th(u, v))$. Since Rosati involution is the adjoint operator with respect to E and F is a CM field, $h: F^3 \times F^3 \to F$ is skew-Hermitian with respect to the F-action.

Now we restate Theorem 1.1 in terms of families of abelian varieties over a complex curve. For a complex curve C and an abelian schemes $f : \mathcal{A} \to C$ with \mathcal{O}_{F} endomorphism, $\mathbb{V} := (R^1 f_* \mathbb{Z})^{\vee}$ has an induced \mathcal{O}_F -module structure. We say that \mathcal{A} is of type (M, T) for an \mathcal{O}_F -module M and a skew-Hermitian form T defined over F, if there exists a global polarization $\mathcal{Q} : \mathbb{V} \times \mathbb{V} \to \mathbb{Z}$ such that for any $c \in C$ its restriction \mathcal{Q}_c to fiber \mathbb{V}_c gives a Hodge isometry $(\mathbb{V}_c, \mathcal{Q}_c(u, v)) \cong (M, \operatorname{tr}_{F/\mathbb{Q}}(T(u, v)))$. We say that a skew-Hermitian form h over \mathbb{C} has signature (m, n) if the Hermitian form $i^{-1}h$ has signature (m, n). To apply Lemma 5.2, note that for any skew-Hermitian form T defined over F that gives a polarization, we always have $nT = -\alpha h$ for some $n \in \mathbb{Z}, \alpha \in \mathcal{O}_F \cap i\mathbb{R}$, and h a Hermitian form over \mathcal{O}_F , so we only need to check the signature of the skew-Hermitian form.

Theorem 5.4 (Theorem 1.2). Fix a skew-Hermitian form T over F such that T is of signature (2, 1) under a pair of complex embeddings of F and is definite under the other pair. For any complex curve C of genus g, consider abelian schemes $f : \mathcal{A} \to C$ of dimension 6 with \mathcal{O}_F -endomorphism of type (\mathcal{O}_F^3, T). Then there

exists $D_0(g) > 0$ and $D'_0 > 0$ such that for $D > D_0(g)$ and $D' > D'_0$, such type of abelian schemes must be isotrivial.
