Abstract

We discuss how desirable it is that Large Language Models (LLMs¹) be able to adapt or align² their language behavior with users who may be diverse in their language use. User diversity may come about among others due to i) age differences; ii) gender characteristics, and / or iii) multilingual experience, and associated differences in language processing and use. We consider potential consequences for usability, communication, and LLM development.

1 Introduction

Language processing is increasingly viewed as modulated in real time by characteristics of human language users (e.g., their age and associated decline in processing speed, gender cues in someone's voice, literacy, or their bi- and multilingual language background, Federmeier and Kutas, 2005; Ito et al., 2018; Mishra et al., 2012; Münster and Knoeferle, 2018; Salthouse, 1996; Van Berkum et al., 2008). Given this diversity, the present paper asks to what extent it is desirable that LLMs align with the user in language behavior (reducing distance and thus potentially facilitating communication), and to what extent it is desirable that human users align with an LLM's language output. We review research on age-, gender-related, and multilingual diversity in language performance (Section 2; due to length restrictions, we review selected findings only). Following this review, we discuss the pros and cons of linguistic and other alignment between humans and LLMs (Section 3) and present conclusions in Section 4.

2 Diversity in language processing / use

2.1 Age-related changes

For language use and production, for instance, older (vs. younger) adults seem to use more pronouns: Hendriks et al. (2008) compared younger and older adults' production in an elicitation task (picture stories) and in a comprehension task (written stories). For production, older (vs. younger) adults produced more pronouns in referencing an old topic in the context of a new topic. For the comprehension task, by contrast, no significant between-group differences emerged. The authors interpreted their findings as reflecting age-related changes: Younger adults will use a definite noun phrase instead of a pronoun to avoid ambiguity. But older adults' more limited processing capacities may produce more often ambiguous pronouns instead of unambiguous full noun phrases, perhaps due to limits in their cognitive resources for taking the hearer's perspective. Abrams and Farrell (2011) reported more difficulty in language production than comprehension for older adults (Burke et al., 2000); one example was more frequent tip-ofthe-tongue production in older than younger adults (James and Burke, 2000, but note also some ageinvariant dimensions of phonological processing related to reducing tip-of-the tongue phenomena by presenting phonologically-related words).

For language processing, age-related changes seem to occur at many linguistic levels: Semantic interpretation, for instance, was slowed in older adults (Federmeier and Kutas, 2005), perhaps be-

¹We mean by 'LLM' fully trained models like ChatGPT4 that can be accessed by users via a web interface.

²We use the term 'alignment', as it is used in (psycho-)linguistics, to mean sharing of mental representations between interlocutors from the phonological to the lexical, morphosyntactic, syntactic, semantic and situation model levels (see Pickering and Garrod, 2004). Earlier work in social psychology has coined the term 'adaptation' (Giles et al., 1991, 1973): It refers to individuals adjusting their communication styles to accommodate their interlocutors. For instance, people modify their verbal and nonverbal behavior (e.g., to reduce or emphasize differences), often based on factors like social identity, context, or relationships. Note that in the context of LLMs, the term 'alignment' has been debated and there seems to be a lack of clarity as to what 'alignment' means, whether it is 'functional alignment' (e.g., improving instruction following) or 'worldview or social value alignment' (based on the argument that humans share values) (Kirk et al., 2023, p. 3)

cause general processing speed declines with age (Salthouse, 1996). Vocabulary knowledge changes with age, too, such that older adults may have difficulty in deriving unfamiliar word meanings from context. For instance, they were more likely to produce generalized interpretations of the word meaning and selected fewer exact definitions than younger adults. Older adults may thus have special difficulties in deriving the meaning of unfamiliar words from context (McGinnis and Zelinski, 2000). Differences also emerged in audio-visual comprehension when relating, for instance, verbs to action depictions, where effects of grounding occurred earlier in young than older adults (Maquate and Knoeferle, 2021)³. For naturalistic communication, Dikker et al. (2022) reviewed the literature on age-related changes in inter-brain synchrony and concluded that "Older adults may have a harder time aligning and coupling due to factors including increased variability in neural firing (neural 'noise'), difficulty sustaining dynamic patterns, sensory changes that result in lost fidelity of the signals that are important for alignment, and/or difficulties with attention and executive control that are critical for regulating neural patterns that are critical for accommodation to a conversation partner or adaptive behavior to a communicative context." (p. 55).

2.2 Age and foreign-accented speech as input

There are interactions between aging and foreign language comprehension, too. Older adults experienced, for instance, difficulty in semantic interpretation of foreign-accented speech: Native-accented semantic errors elicited the expected N400 effect (a negativity in brain amplitude averages that increases with increases in semantic processing difficulty). By contrast, for foreign-accented speech, such a differential brain response (larger N400 for semantically felicitous vs. infelicitous stimuli) was absent in older adults. By comparison, grammatical errors were not processed differently depending on native or foreign-language accent (Abdollahi et al., 2021). The state of the art is somewhat controversial though and further studies reported no such age differentiation in adaptation to foreignaccented speech (e.g., Bieber and Gordon-Salant, 2017; Burda et al., 2003; Hau et al., 2020). Regarding alignment, the slow-down and problems in understanding unfamiliar words or accents in

older than younger adults could be counteracted with suitable LLM alignment.

2.3 Gender/sex and language use / processing

There is good evidence that knowledge of gender (stereotypes) can rapidly influence language processing. For instance, activation of genderstereotypical role names in online spoken language comprehension (in Finnish) occurred rapidly (Pyykkönen et al., 2009): Listeners activated gender stereotypes in story contexts where this information was not needed to establish coherence. Gender stereotypes further elicited expectations in that when participants listened to passive-voice sentences like *The wood is being painted*... they anticipated the agent of the action. That effect was larger for female than for male-stereotypical contextual information but was not modulated by participants' gender attitudes (Guerra et al., 2021).

Prior research also assessed sex/gender differences in language use. Newman et al. (2008) reported clear gender differences: Women used more words concerning psychological and social processes (more pronouns, verbs, and social words also related to the home); men referred more often to impersonal topics (current concerns) and object properties and used more swear words. These gender differences seemed larger for tasks with fewer constraints (e.g., when participants were asked to track their thoughts and feelings, p. 222 ff.). The finding that women used more pronouns and "certainty words" (Newman et al., 2008, p. 230) could relate to earlier findings such as women using more intensive adverbs, perhaps suggesting tentativeness in women's language use (e.g., Biber, 1998; Mehl and Pennebaker, 2003; Mulac et al., 2000, 2001, as cited in Newman et al., 2008). Newman et al. also replicated more frequent use of numbers, articles, long words, and swear words in men than women (e.g., Gleser et al., 1959; Mehl and Pennebaker, 2003; Mulac et al., 1986). These differences notwithstanding, some stereotypes failed to be confirmed: Mehl et al. (2007) assessed whether women were more talkative than men (daily word use for six samples from 210 women and 186 men, mostly university students in the US and Mexico, p. 82). They reported comparable word frequency among the two genders (women: 16215; men: 15669 words on average per day).

Overall, the picture of quantitative gender differences in language use reveals nuanced differences, perhaps requiring complementary qualitative analy-

³While LLMs are currently often used in the written modality, user diversity regarding speech will likely become more relevant as LLMs are developed further.

sis. Regarding alignment, an interesting point is to what extent the differences in language use would implicate limits on the extent of (real-time) alignment in language processing of human language users from different genders and LLMs.

2.4 Multilingual language processing

For production, Sell et al. (2023) examined task-based conversations of L1 and L2 (secondlanguage) speakers of German and compared articulation rate, vowel duration, and vowel space when German L1 (first-language) speakers talked to L1 versus L2 German speakers. The addressee type did not influence vowel duration in production, but the articulation rate was slower in talking to non-native (vs. native) addressees (no matter their proficiency). Concerning processing, substantial individual variability seems to exist and this variability can even affect learning outcomes (see Ingvalson et al., 2014, for a review), and thus arguably also linguistic alignment to the language of humans or technical systems. Second language proficiency can modulate comprehension: In Ito et al. (2018), both L1 (English) and L2 (L1 Japanese, L2 English) speakers visually anticipated a target (a picture of a cloud given a context of the sun going behind...); L2 comprehenders though were comparatively slower in looking at the cloud, perhaps echoing the delays observed in processing for older (vs. younger) adults. L1 (but not L2) speakers anticipated a competitor object for *cloud* (a clown). This suggests phonological information can enable expectations in comprehenders' first but less so in their non-native language. Another difference concerns local structural ambiguity resolution: Pozzan and Trueswell (2016) reported that L2 adults resembled native adults in their disambiguation eye-gaze pattern but their behavior in an act-out task indicated difficulty revising the interpretation much like in 5-year-old natives (e.g., Trueswell et al., 1999). The authors interpreted this as reflecting learners' increased cognitive effort in processing an L2 such that less cognitive control was available (see Kotz, 2009, on syntactic processing).

A slow-down in real-time anticipation of upcoming content can also come from negative transfer of constraints (from L1 to L2): Ito et al. (2023) had participants with different language backgrounds (group 1: L1 Vietnamese who are late bilinguals of German L2; group 2: heritage speakers of Vietnamese in Germany) listen to Vietnamese sentences while viewing four objects. Both groups anticipated an object compatible with verb or classifier meaning upon hearing verb / classifier respectively. But when the verb constraints differed (e.g., distinct Vietnamese verbs for wearing a shirt vs. earrings; the same verb *tragen* 'wear' in German), then heritage speakers were distracted by the earrings matching the German (but not the Vietnamese) verb. When language mapping was distinct across an L1 and an L2, it thus interfered with heritage speakers' expectations during comprehension (Hopp, 2022, for related review).

Differences in bilingual language knowledge and processing also concern semantic representations (would bilinguals have separate or the same representations for semantic information from different languages?). Chen et al. (2024a) employed functional magnetic resonance imaging (fMRI) and recorded proficient Chinese-English speakers' brain responses during the reading of English and Chinese narratives. A comparison of their brain activity suggested that semantic representations seem largely shared for English and Chinese but with subtle shifts by language. It's possible that such subtle differences in knowledge and processing would be important to consider for the alignment of LLMs to bi- and multi-lingual language users.

2.5 Interim summary

Related to aging and bi- or multilingualism, cognitive resources seem to play an important role in processing differences. Understanding unfamiliar words / accents (in older age) and interference from the native language (for L2) may cause subtle challenges in communication. For gender, results point to clear, albeit nuanced, differences in language use. Tailoring linguistic performance to linguistically diverse language users (see Ostrand and Berger, 2024) may have advantages in terms of greater ease of communication – when an LLM aligns with the user, or vice versa (for relevant research see Giles et al., 1991, 1973; Pickering and Garrod, 2004; Pickering and Gambi, 2018).

3 LLM-to-human alignment: Beneficial for ease of communication?

One motivation for alignment focus relates to usability: LLMs as tools may align with users (e.g., by tracking user input across time in a user model). Following the logic that adaptation and alignment facilitate communication, human users should find it easier to interact with a personalized than nonadapted LLM. Such adaptation may and should go beyond simple increases in communication effectiveness and efficiency by the model assuming context (common tasks / interests) from a user's prior interaction with the model.

Human users might, in turn, align with LLM style which means aligning with performance derived from statistical averaging across many instances. If so, human users may converge over time to an LLM-inspired style (if it exists), maybe even losing much of the linguistic diversity that exist due to someone's age, their gender, or their multilingual background. But maybe that is also okay in a human-machine setting. One might argue that the challenge is to improve user experience without sacrificing linguistic diversity (Rehm, 2023; Rehm and Way, 2023). This may create tension between aligning software with a language user's values or language characteristics (e.g., their pronunciation, knowledge of words and languages, syntactic structures, experience in the world) versus foregrounding training on English as 'lingua franca' (in an increasingly English-speaking world) with normed pronunciation, grammar and typical semantic and world knowledge.

3.1 Alignment in human communication

The original alignment account was motivated by the observation of semantic priming between human interlocutors (e.g., Garrod and Anderson, 1987a; Garrod and Doherty, 1994; Garrod and Anderson, 1987b), and by the finding that speakers repeat both their own and their interlocutor's linguistic structures (e.g., Bühler, 1934; Lashley, 1951). Priming effects have been observed at the phonological (e.g., Bard et al., 2000), lexico-semantic (e.g., Brennan and Clark, 1996; Clelland and Pickering, 2003; Garrod and Anderson, 1987b), structural (e.g., Bock, 1986, 1989; Bock and Loebell, 1990; Branigan et al., 1995, 2000, 2005; Clelland and Pickering, 2003; Levelt and Kelter, 1982), as well as situation-model levels (e.g., Clark and Wilkes-Gibbs, 1986; Garrod and Anderson, 1987b), as reviewed in Pickering and Garrod (2004).

Later studies have provided insights into the mechanism of structural priming by examining its sensitivity to verb repetition. When the verb was identical between prime and target, participants produced approximately eighty percent of target picture descriptions with the same syntactic structure as the previous prime sentence; by contrast, when the verb differed between prime and target, this percentage decreased to 65 percent (Branigan et al., 2000). The increased priming through lexical boost has been extended to relation priming of noun-noun combinations (Raffray et al., 2007). Participants were more likely to interpret *dog scarf* as a scarf that had pictures of a dog on it (*dog* describes the object scarf) than as a scarf worn by a dog (the dog owns the scarf) after a preceding interpretation of a descriptive (vs. possessive) relation. Priming increased with (vs. without) repetition of one of the two words in the target (e.g., *rabbit scarf* or *dog T-shirt*, see also Clelland and Pickering, 2003). These results suggest that structural priming can be modulated by lexical content, corroborating alignment of different levels of linguistic structure.

Structural priming extends to triadic dialogues and diverse dialogue roles. In a study involving triadic dialogues, a confederate and a naive participant took turns in describing cards (e.g., depicting a pirate handing a cake to a sailor) either to one another or to the experimenter (Branigan et al., 2007). Speakers tended to produce descriptions with the same syntactic structure as a previous speaker both when they were an addressee and a side participant. These findings were taken as evidence that syntactic alignment in dialogue is pervasive and not limited to speakers and addressee. However, prior addressees aligned more than side-participants, suggesting that participant role (and associated tasks) can modulate the extent of alignment.

Alignment extends to unrehearsed story telling: A speaker's neural activity was spatially and temporally coupled with the listener's neural activity, which disappeared when participants could not communicate (Stephens et al., 2010). Coupling was found in areas associated with production and comprehension (e.g., early auditory area, superior temporal gyrus, angular gyrus, temporoparietal junction, parietal lobule, inferior frontal gyrus, and the insula) and in areas known to subserve semantic and social processing (e.g., the precuneus, dorsolateral prefrontal cortex, orbito- frontal cortex, striatum, and medial prefrontal cortex). This coupling predicted comprehension success. While it is unclear at which precise levels of representations the speaker and listener aligned, their neural activity was both temporally and spatially coordinated in a way that linked to comprehension success (see also Garrod and Pickering, 2008; Hurley, 2008).

Overall, the interactive alignment account received support from numerous findings that suggest interlocutors in a dialogue converge on the same names for things, develop the same reference frame, share assumptions about referent identity, and tend to use the same syntactic structures. In the original proposal 'alignment' referred to similar mental representation in human-human dialogue (Pickering and Garrod, 2004; Garrod and Pickering, 2004). Alignment phenomena appear, however more pervasive than that, including even nonlinguistic representations. The framework has also been discussed in the context of embodied as well as social perspectives on cognition (see Garrod and Pickering, 2009; Pickering and Garrod, 2009).

3.2 Alignment in human-computer interaction and personalization of LLMs

Priming facilitation appears more pronounced in human-computer interaction, especially when the technical system is "simple" compared to "advanced" in terms of attributed (not real) communicative abilities (Branigan et al., 2011). That is, adaptation seems to be motivated by beliefs about the interlocutor (Shen and Wang, 2023). In interacting with spoken dialog systems, some older users seemed more "social" in treating the dialog system like a human and thus failing to follow a systeminitiative dialog strategy; however other older users behaved more factual and used short commands, following the system's dialog strategy (Wolters et al., 2009). Using user simulations, Kallirroi et al. (2010) showed that such behavioral differences can be used to learn dialog strategies for older users.

Related to the notion in psycholinguistics, what is meant by 'alignment' in artificial intelligence research, is personalization of the LLM to user values and expectations, or improvements in how well it follows prompts (see Kirk et al., 2023, for discussion and Footnote 2). By contrast, in psycholinguistics, we mean the alignment of linguistic behavior and implicated representations. Below we review AI-focused alignment but highlight the need for also considering linguistic alignment (see Ostrand and Berger, 2024).

For evolving language technology, one challenge is to make it benefit users. This involves applying features of quality of experience and user experience from the evaluation of diverse software e.g., Möller and Raake, 2014; Möller et al., 2007 to the evaluation of new technologies, including checking facts (Mohtaj et al., 2024) or avoiding biases (e.g., related to political discourse in LLMs, Bleick et al., 2024). For gender, for instance, biases have been uncovered dependent on the size, multilingualism, and training data of the models (Caglidil et al., 2024). While such model characteristics can be controlled, avoiding or mitigating biases, challenges remain in conceptualizing (to) what (extent) alignment is desirable between LLMs and language users also as a function of the task at hand (e.g., writing / correcting personal user emails versus formulating legal texts) and user characteristics.

Alignment of technology towards user characteristics may help to improve usability. Wolters et al. (2010) investigated the usefulness of help prompts for older vs. younger users of a smart-home assistant, and how this changed linguistic alignment. While the timing of help prompts did not affect the interaction style of younger users, early taskspecific help supported older users in adapting their interaction style to the system's capabilities. The authors concluded that "well-placed help prompts can significantly increase the usability of spoken dialogue systems for older people." (p. 311).

Wang et al. (2024) examined how users engage with LLMs like GPT. They focused on user behavior, preferences, and expectations in various contexts and developed a taxonomy of 7 user intentions in LLM interactions (based on analysis of interaction logs and human verification). Further measures were usage frequency, user experience and concerns in engaging with LLMs, LLM response accuracy, personalization, and transparency. Challenges such as biases remained and can negatively affect user experience. The paper emphasizes the need for better design frameworks to improve user experience in LLM interactions. They highlight alignment with user needs and expectations also across different tool uses.

Relatedly, Kirk et al. (2023) examined to how adapting LLMs to individual preferences would make them better suited to individual users. They discussed (unclear) definitions of alignment, the problem of companies imposing their own ideas of preferences and the influence of crowd workers whose backgrounds may not be well-documented. As **benefits** of personalized LLMs, they identified enhanced user experience, better alignment with values and norms, reduced generalization issues, increased user satisfaction, and adaptability to specific tasks. As risks of personalizing LLMs by means of, for instance, alignment, they list bias amplification, social echo chambers (only hearing one's own views), ethical concerns (e.g., when biases lead to toxic speech or misinformation), difficulties as to what constitutes socially-acceptable

personalization, and lack of transparency and accountability (e.g., missing documentation). In summary, aligning LLMs with human moral and ethical expectations positively affects user experience; but such alignment could create echo chambers and biases in LLM output that may reinforce the users' own preferences only. Striking a balance between these aspects of user experience - also for political views - seems key from a societal viewpoint (see Bansal et al., 2023; Chen et al., 2024b; Shen et al., 2023; Wang et al., 2023; Wolf et al., 2024).

From a societal viewpoint, alignment regarding language and culture is interesting, too: AlKhamissi et al. (2024), for instance, investigated the cultural alignment of LLMs and assessed to what extent these models reflect culture-specific knowledge in the World Views Survey (version 7, 2017-2021). They also considered language and hypothesized that prompting with different languages might elicit different responses to similar queries (the training data might encode different facts across different languages). Using the native (vs. a foreign) language of a specific culture would, according to the authors, elicit greater cultural alignment (e.g., alignment to the survey conducted in Egypt may be higher if an LLM is asked in Arabic than English). They pre-trained models with proportionally more data from a specific culture and also examined the alignment of the LLM when it impersonated specific personas (e.g., a working-class individual who may be digitally underrepresented vs. a more educated person). A further hypothesis was that alignment in both Arabic and English tests would be lower for a working-class persona that is digitally underrepresented compared to an upper-middle-class persona in Egypt's capital. The results showed better cultural alignment of the LLM with survey participants from the United States than the Egypt survey, replicating prior results. Prompts in a country's dominant language elicited increased alignment for GPT-3.5 and AceGPT-Chat (e.g., Arabic vs. English prompts elicited more alignment with the Egypt survey). For another model, the multilingual mT0-XXL, despite training with a more balanced language distribution, "the curse of multilinguality" (Pfeiffer et al., 2022) may have caused inferior cultural alignment with the US survey when prompted with English compared to Arabic. Further results suggested that alignment (of model to survey) improved: i) from lower to higher social class and level of education (suggesting that more

marginalized populations are less well reflected in the model); ii) when the LLM impersonated male than female users / survey respondents; and iii) for older than younger age groups (Section 5 in AlKhamissi et al. (2024)).

3.3 Foregrounding linguistic alignment

What seems to be more neglected than alignment to non-linguistic biases, however, is alignment to the user's specific phonology, morphosyntax, syntax, semantics, and world / situation knowledge. Concerning alignment to the user in much more subtle linguistic ways, we may ask, as have others (Ostrand and Berger, 2024, p. 3) why AI development should heed cognitive properties and linguistic expectations of LLM users. Ostrand and Berger (2024) argue that attention to language issues is key for ensuring continued usage: "If researchers and developers do not investigate factors that influence users' perceptions of a model's conversational responses or task performance, it is harder to be sure that the model will work as intended." (p. 3). Foregrounding linguistic alignment could lead to reduced cognitive effort for the user, inspire engineers to develop new benchmarks and evaluation tasks, affect (pre-)training and fine-tuning of models, and help develop new multi-modal data sets (p. 3 top right, e.g., including human cognitive factors). This seems relevant given the finding that many of the differences related to age or multilingualism at least for real-time processing may have to do with (the availability /increased recruitment of) cognitive resources and executive control. Additionally, one could consider user choice in the degree of alignment e.g., to have LLMs on-demand as language teacher (prescriptive usage of a chosen language and register) or as a human-like conversation partner (when ease or a sense of social connection is desired). Similarly, it could be interesting for users to know they have a choice of interacting with an LLM as a sparring partner or as a political ally in discussing societal and political issues.

4 Conclusion

We note both substantial benefits and risks in personalizing LLMs via alignment to individual (groups of) users. While much of the existing LLM research focuses on alignment of values, we foreground the need to consider linguistic alignment in consensus with Ostrand and Berger (2024).
