Abstract

Retrieval-Augmented Large Language Models (LLMs), which integrate external knowledge into LLMs, have shown remarkable performance in various medical domains, including clinical diagnosis. However, existing RAG methods struggle to effectively assess task difficulty to make retrieval decisions, thereby failing to meet the clinical requirements for balancing efficiency and accuracy. So in this paper, we propose FIND (Fine-grained Information Density Guided Adaptive RAG), a novel framework that improves the reliability of RAG in disease diagnosis scenarios. FIND incorporates a fine-grained adaptive control module to determine whether retrieval is necessary based on the information density of the input. By optimizing the retrieval process and implementing a knowledge filtering module, FIND ensures that the retrieval is better suited to clinical scenarios. Experiments on three Chinese electronic medical record datasets demonstrate that FIND significantly outperforms various baseline methods, highlighting its effectiveness in clinical diagnosis tasks.

1 Introduction

Large Language Models (LLMs) (Achiam et al., 2023; Saab et al., 2024) have shown exceptional performance in various medical tasks, including clinical diagnosis (Zhou et al., 2024). However, their adoption in high-stakes areas is hindered by challenges such as hallucination, where models generate plausible but incorrect information (Maynez et al., 2020; Huang et al., 2023b), and the resource-intensive nature of updating their knowledge base (Zhang et al., 2023b; Kasai et al., 2024). Retrieval-augmented generation (RAG) (Lewis et al., 2020) has emerged as a potential solution, reducing hallucinations and ensuring up-to-date information by integrating trustworthy documents.

Figure 1: Illustration of three different RAG paradigms for solving clinical diagnosis task.

Despite its promise, applying RAG to clinical diagnostics presents unique challenges. In realworld medical scenarios, balancing efficiency and accuracy is crucial. While LLMs can accurately diagnose simple or well-defined problems without retrieval, traditional RAG methods, which retrieve information for every query, incur unnecessary computational costs and risk misleading LLM reasoning with irrelevant data (Figure 1.a).

To address these issues, researchers have proposed the Adaptive-RAG paradigm (Jeong et al., 2024; Su et al., 2024; Yao et al., 2024), which performs retrieval only when necessary through specific input judgment conditions or smaller classification models. However, existing Adaptive-RAG methods face limitations (Figure 1.b). First, relying solely on LLM outputs to decide retrieval is superficial, as LLMs are prone to hallucinations (Yona et al., 2024; Yao et al., 2024) and may confidently generate incorrect content despite lacking relevant knowledge (Huang et al., 2023a; Xu et al., 2024).

Corresponding Author. Email: jwduan@csu.edu.cn.

Second, while training small classification models to evaluate queries is feasible, they struggle with long, complex, and redundant input contexts. These models often fail to accurately capture query structures and distinctions, exhibiting biases toward query length or phrasing.

Unlike single-hop or multi-hop questionanswering tasks, disease diagnosis tasks cannot directly retrieve the correct answer in a single step. Instead, they require progressively narrowing down the most likely disease by assessing the relevance between patient information and knowledge base documents. This necessitates that retrieval information must be both critical and useful; otherwise, irrelevant data may lead to retrieval failure. Additionally, the input for disease diagnosis tasks, often lengthy and semantically discontinuous, makes it challenging to directly retrieve matching documents from knowledge bases. Most existing adaptive-RAG methods overly focus on whether to perform retrieval, neglecting the filtering of retrieval information and optimization of the retrieval process, resulting in suboptimal performance for disease diagnosis tasks.

To address these issues, we propose FIND (Fine-Grained Information Density Guided Adaptive RAG), a novel framework that improves the reliability of RAG in disease diagnosis scenarios. As illustrated in Figure 2, Our framework incorporates a fine-grained adaptive control module to determine whether retrieval is necessary based on the information density of the input. This module segments long and complex input into fine-grained units and trains a classifier to predict the importance of each unit. Based on the classification results, we calculate the information density of the input and decide whether retrieval is necessary. Additionally, we introduce a differential diagnosis guided knowledge filtering module to enhance the quality of the retrieval process by filtering out irrelevant information and retaining the most useful documents.

Our main contributions are as follows:

- We propose FIND, a framework for adaptive retrieval-augmented disease diagnosis without the need for tuning backbone LLMs.
- We desgined a novel data annotation methodology that employs masking operations to elicit varied responses from LLMs, thereby acquiring label information. Concurrently, we have optimized the retrieval process to better

accommodate clinical scenarios with complex context.

• We conducted extensive experiments on three Chinese EMR datasets to demonstrate the effectiveness of our FIND framework.

2 Related Work

2.1 RAG in Clinical Disease Diagnosis

To improve diagnostic accuracy, model reliability, and reduce hallucination issues without retraining, recent studies widely adopt Retrieval-Augmented Generation (RAG) to integrate external medical knowledge (Wen et al., 2023; Wu et al., 2024; Shi et al., 2023; Thompson et al., 2023; Zhao et al., 2024b). Most research uses basic retrieval methods (Ge et al., 2024; Shi et al., 2023; Zhang et al., 2023a; Zhao et al., 2024b; Oniani et al., 2024), typically leveraging embedding models to encode external knowledge and task queries into vector representations. Relevant knowledge is retrieved via vector similarity and used in LLMs through tailored prompts for diagnosis generation. Besides, knowledge graphs are also widely employed (Wen et al., 2023; Wu et al., 2024; Gao et al., 2023).

2.2 Adaptive-RAG

Adaptive Retrieval-Augmented Generation (RAG) dynamically determines whether a large language model (LLM) requires external knowledge retrieval to mitigate inaccuracies. FLARE (Jiang et al., 2023b) and DRAGIN (Su et al., 2024) activate search engines when the LLM generates low-confidence tokens. Wang et al. (Wang et al., 2024a) use a prompting mechanism for LLMs to autonomously decide on retrieval. Self-Awareness-Guided Generation (Wang et al., 2023b) trains a classifier to assess output authenticity, while Adaptive-RAG (Jeong et al., 2024) evaluates query complexity to determine retrieval necessity. Mallen et al. (Mallen et al., 2023) propose activating retrieval based on entity frequency in queries, though this may fail for complex, multi-step reasoning tasks. Asai et al. introduce Self-RAG (Asai et al., 2023), which trains a model to dynamically retrieve, critique, and generate text.

3 Methods

In this section, we first present the formal definition of disease diagnosis task and the task settings for adaptive-RAG-based disease diagnosis. Then we

Figure 2: The overall architecture of our proposed framework FIND. FIND consists of two stages. Stage(a) involves inference & Retrieval Decision Making Based on Fine-Grained Information Density. Stage (b) focuses on knowledge retrieval and integration. Note that Stage (b) is activated only when the score computed in Stage (a) falls below a predefined threshold.

will introduce the details of each components of our proposed FIND framework.

3.1 Preliminaries

Direct Disease Diagnosis via LLM: Let LLM denote a large language model that maps an input token sequence $\mathbf{x} = [x_1, x_2, \dots, x_n]$ to an output sequence $\mathbf{y} = [y_1, y_2, \dots, y_n]$, formalized as $\mathbf{y} = \text{LLM}(\mathbf{x})$. For disease diagnosis, \mathbf{x} represents patient information \mathcal{Q} , and \mathbf{y} corresponds to the generated diagnosis $\hat{a}: \mathcal{Q} = \mathbf{x}$ and $\hat{a} = \mathbf{y}$.

RAG-based Disease Diagnosis: External knowledge d, containing clinical information, is retrieved from a source \mathcal{D} (e.g., encyclopedia, knowledge base, or graph) using a retrieval model Retriever. This process is formalized as d =Retriever(\mathcal{Q} ; \mathcal{D}), where $d \in \mathcal{D}$.

Adaptive-RAG-based Disease Diagnosis: Proposed by (Jeong et al., 2024), this method employs a classifier Classifier to evaluate query complexity: o = Classifier(q). Based on o, the retrieval function is selectively activated.

3.2 Fine-grained Adaptive Control Module

We propose a fine-grained adaptive control paradiagm. In this section, we first describe the adaptive mechanism of our framework (Figure 2-Stage(a)), followed by the strategy for generating training data (Figure 3).

3.2.1 Fine-grained Information Density Assessment

While smaller models can assess query complexity and make retrieval decisions (Jeong et al., 2024), they are limited to short, simple inputs (e.g., single or multi-hop QA tasks). Medical diagnostic tasks, however, involve long, complex contexts with extensive information. Standard-sized language models struggle to process such inputs fully, risking biases (e.g., relying on document length or term frequency) rather than understanding structure. Training larger models (e.g., (Asai et al., 2023)) for this purpose is costly and contradicts our goal of tuning-free RAG solutions.

To address this, we segment long and complex input Q into fine-grained units(in this paper we use sentences): $Q = \{s_i\}_{i=1}^n$ and then train a language model Classifer to predict each unit's importance

Figure 3: Details of our proposed annotation strategy. During the annotation process, we adopt different annotation strategies based on the responses generated by the LLM.

individually.

$$p_i = \mathsf{Classifier}(s_i) \quad \forall i \in \{1, 2, ..., n\} \quad (1)$$

This approach simplifies the task of understanding long documents by converting it into a sentencelevel text understanding task, avoiding the limitations of directly modeling entire documents with small language models. Following (Jeong et al., 2024), each segmented text unit s_i is assigned one of three labels {A, B, C}. Here, A denotes critical importance for diagnostic decision-making, B indicates usefulness as a retrieval source despite not directly yielding a correct result, and C marks irrelevance to diagnosis, allowing discarding during retrieval.

Based on the classification results, we calculate the information density of the current input Q as follows:

$$I(\mathcal{Q}) = \sum_{i=1}^{n} \left(\alpha \cdot \mathbb{I}(l_i = \mathsf{A}) + \beta \cdot \mathbb{I}(l_i = \mathsf{B}) + \gamma \cdot \mathbb{I}(l_i = \mathsf{C}) \right)$$
(2)

$$I_{\text{norm}}(\mathcal{Q}) = \frac{I(\mathcal{Q})}{\alpha \cdot n} \tag{3}$$

where l_i denotes the classification result of sentence s_i , α , β , and γ are weights for the three category

labels, and $\mathbb{I}(\cdot)$ is the indicator function returning 1 if the condition is true and 0 otherwise. The denominator $\alpha \cdot n$ represents the information density when all sentences are classified as A, used for normalization.

If I_{norm} exceeds θ_1 , the information is sufficient for the LLM to independently diagnose. If I_{norm} lies between θ_1 and θ_2 , retrieval is activated. If I_{norm} falls below θ_2 , a warning signals insufficient information.

This approach determines retrieval necessity while filtering irrelevant information, enhancing retrieval quality and accuracy. By training a small classifier, these functions are achieved without additional computational overhead.

3.2.2 Automatic Annotation and Training Strategy

Due to the lack of annotated datasets meeting the aforementioned requirements, we propose a simple yet effective strategy for automatically constructing and annotating a training dataset.

Inspired by the Rationale paradigm in interpretability (Jiang et al., 2023a), we determine the importance of each segment by sequentially masking them. For a given input Q (e.g., medical records or diagnostic questions) with the physician's diagnostic result *a* as the golden label, we split Q into sentences $Q = [s_1, s_2, \ldots, s_n]$. Each segment s_i is masked to obtain $Q' = [s_1, s_2, \ldots, s_{i-1}, s_{i+1}, \ldots, s_n]$. The LLM then performs diagnostic reasoning on both Q and Q', yielding predictions:

$$\hat{a} = \mathsf{LLM}(\mathcal{Q}, \mathsf{prompt})$$
 (4)

$$\hat{a'} = \mathsf{LLM}(\mathcal{Q}', \mathsf{prompt})$$
 (5)

If $\hat{a} \approx a$, the model's capability is sufficient. By comparing \hat{a} and $\hat{a'}$, we assess the importance of s_i . The annotation strategy is as follows:

(1). $\hat{a} \approx a$: If $\hat{a'} = \hat{a}$, s_i is labeled C as noncritical. If $\hat{a'}$ significantly changes, causing diagnostic errors, s_i is labeled A as crucial.

Notably, even if the LLM predicts correctly without s_i , s_i may still provide supplementary information. To avoid losing important details (Sohn et al., 2024), we introduce an additional retrieval step for label = C. If s_i retrieves relevant information, its label is updated to B.

(2). $\hat{a} \neq a$: In this case, the LLM alone is unable to make an effective diagnosis, indicating the need to activate the retrieval augmentation module. Here, we use s_i as retrieval query and employ the BM25 retrieval method to query the knowledge base. If relevant content is retrieved, s_i is considered indirectly useful for diagnosis and is assigned the label label = B. Otherwise, s_i is deemed relatively unimportant and is assigned the label label = C.

Figure 3 shows the data annotation process. This automatic method generates a classification dataset from the LLM's predictions, which trains a classifier. This approach ensures the model evaluates input text importance effectively, integrating only relevant information into the LLM, and mitigates the scarcity of medical annotated data by using model-generated labels instead of manual annotations.

3.3 RAG Pipeline for Complex Clinical Context

In this section, we introduce our proposed RAG pipeline tailored for complex clinical input contexts. Inspired by (Zhao et al., 2024a), we preprocess the documents in the knowledge base by segmenting them into chunks prior to retrieval. Specifically, we impose a length constraint on the chunks, using sentences as the minimal segmentation unit. Details can be found in appendix.

3.3.1 Chunk-Sentence Level Knowledge Retrieval

Given an input query $Q = \{s_i\}_{i=1}^n$ consisting of n sentences, our retrieval algorithm operates through two sequential phases: chunk-level retrieval and document-level reranking. The complete process can be formally described as follows:

For each sentence $s_i \in Q$, we use it as a query to retrieve the top-*m* relevant chunks from the document collection. This is achieved by a retriever function Retriever, which maps a query s_i to a set of chunks $C_i = \{c_{i,k}\}_{k=1}^m$, where $c_{i,k}$ denotes the *k*-th chunk retrieved for query s_i . The retrieval process can be formally expressed as:

$$\mathcal{C}_i = \mathsf{Retriever}(s_i, m) \quad \forall i \in \{1, 2, \dots, n\}$$
(6)

After processing all sentences in Q, we obtain a combined set of chunks $C = \bigcup_{i=1}^{n} C_i$.

Each chunk $c \in C$ is then mapped back to its original document $D_j \in D$. For each document D_j , we maintain a score S_j that counts the number of chunks retrieved from it. Formally, the score S_j is computed as:

$$S_j = \sum_{c \in \mathcal{C}} \mathbb{I}(c \in \mathcal{D}_j) \tag{7}$$

where $\mathbb{I}(\cdot)$ is the indicator function that returns 1 if *c* belongs to \mathcal{D}_i and 0 otherwise.

Finally, the documents are re-ranked based on their scores S_j , and the top-k documents with the highest scores are selected as the final retrieval result. The ranked documents are denoted as:

$$\mathcal{D}^* = \{\mathcal{D}_{(1)}, \mathcal{D}_{(2)}, \dots, \mathcal{D}_{(k)}\}$$

where $\mathcal{D}_{(l)}$ represents the document with the *l*-th highest score.

3.3.2 Differential Diagnosis Guided Knowledge Filtering

Despite an optimized retrieval process, retrieved documents may not always be useful, particularly in clinical diagnosis tasks requiring complex reasoning and long contexts. To filter irrelevant information, retain useful documents, and leverage large language models (LLMs), we introduce a filtering algorithm inspired by **differential diagnosis** in clinical medicine. We design a prompt template prompt_{diff} to guide the LLM in identifying conflicts between patient information (e.g., symptoms, medical history, examination results) and retrieved

documents, determining whether to retain a document.

Specifically, given a set of retrieved documents $\mathcal{D}^* = \{\mathcal{D}_1, \mathcal{D}_2, \dots, \mathcal{D}_k\}$, the filtering process is formalized as follows: For each document $\mathcal{D}_i \in \mathcal{D}^*$, the LLM evaluates whether the document supports the diagnosis based on prompt_{diff}. The filtering function $V(\mathcal{Q}, \mathcal{D}_i, \text{prompt}_{diff})$ is defined as:

$$V(\mathcal{Q}, \mathcal{D}_i, \text{prompt}_{\text{diff}}) = \begin{cases} \text{True}, & \text{if } \langle \text{support} \rangle \\ \text{False}, & \text{otherwise} \end{cases}$$
(8)

where $\langle \text{support} \rangle$ indicates that the LLM determines the document \mathcal{D}_i is critical and useful for the diagnosis. And the final set of filtered documents $\mathcal{D}_{\text{filtered}}$ is obtained by retaining only the documents for which $V(\cdot, \mathcal{D}_i, \cdot) = \text{True:}$

$$\mathcal{D}_{\text{filtered}} = \{ \mathcal{D}_i \in \mathcal{D}^* \mid V(\mathcal{Q}, \mathcal{D}_i, \text{prompt}_{\text{diff}}) = \text{True} \}$$
(9)

3.3.3 Knowledge Augmented Diagnosis Generation

The final RAG-based diagnosis process can be formulated as follows:

$$Preds = LLM(Q, \mathcal{D}_{filtered}, prompt_{rag})$$
(10)

where prompt_{rag} denotes the default RAG-based diagnosis prompt template.

4 Experimental Setup

4.1 Datasets

We evaluated our framework using three Chinese EMR datasets: CMEMR (Jia et al., 2025), ClinicalBench (Yan et al., 2024), and CMB-Clin (Wang et al., 2023a), to assess its ability in analyzing complex clinical information and making accurate diagnoses.

CMEMR (Jia et al., 2025) is derived from a Chinese medical website¹, focusing on real-world clinical diagnosis challenges. **ClinicalBench** (Yan et al., 2024) includes data from Grade 3A hospitals in China, spanning various medical departments and diseases. **CMB-Clin** (Wang et al., 2023a) consists of 74 high-quality, complex EMRs, each containing multiple medical QA pairs.

For consistency with our task, we simplified the diverse medical tasks in ClinicalBench and CMB-Clin to focus solely on disease diagnosis.

4.2 Baseline Methods

We compare our approach with three categories of methods:

Non-Retrieval methods: We include Chain-of-Thought (CoT) (Wei et al., 2022) and Atypical Prompting (Qin et al., 2024), a method designed for the medical domain that enhances reasoning by focusing on atypical factors like scenarios and symptoms.

Vanilla-Retrieval methods: Following (Su et al., 2024), we include three classic RAG methods: SR-RAG, FL-RAG, and FS-RAG. Details are in the appendix.

Adaptive-Retrieval methods: This paradigm improves retrieval flexibility and controllability by presetting conditions or introducing other models. We include Adaptive-RAG (Jeong et al., 2024), DRAGIN (Su et al., 2024), SEAKR (Yao et al., 2024), and RAG² (Sohn et al., 2024). Details are in Appendix A.

4.3 Evaluation Metric

Following (Fan et al., 2024), we use the International Classification of Diseases (ICD-10) (Percy et al., 1990) to standardize disease terminologies. We extract disease entities from diagnostic results and EMR labels, then perform fuzzy matching with a threshold of 0.5 to link them to ICD-10, creating normalized sets $S_{\hat{D}}$ and $S_{\mathcal{R}}$. These sets are used to calculate Precision, Recall, and F1-score. Details are in Appendix C.

4.4 Implementation Details

We choose qwen2.5-7B-instruct as the backbone model for inference in our experiments by default. For the classifier we choose Mengzi-T5-base (Zhang et al., 2021). During retrieval we use BM25 as default retriever. FOr the external knowledge corpus we use CMKD (Clinical Medicine Knowledge Database)². Detailed settings of each module and hyperparameters are provided in Appendix B.

5 Results and Analyses

5.1 Overall Performance

Our experiments evaluate the framework against baselines on three Chinese EMR datasets. Table 1 highlights key findings: (1) Our framework significantly outperforms Non-Retrieval methods, demon-

Table 1: Experimental results on CMEMR, ClinicalBench and CMB-Clin datasets. Bold indicates the best performances and the second-best performances are underlined. *w/o* denotes the removal of the corresponding module in the ablation experiment.

strating the value of the RAG module. (2) Vanillaretrieval methods do not consistently surpass Non-Retrieval methods, as uncontrolled retrieval often degrades performance, especially in challenging tasks. (3) Our approach outperforms other Adaptive-RAG methods, attributed to our finegrained adaptive module and optimized retrieval process, which previous methods overlooked. (4) FIND shows stable performance across datasets, particularly excelling on CMEMR and Clinical-Bench, highlighting its clinical diagnostic capability.

5.2 Analysis of Adaptive-Control Module

We validate the classifier in our Adaptive Control module by comparing it with Adaptive-RAG and RAG². Figure 4 shows our classifier's accuracy significantly surpasses the baselines, confirming our fine-grained approach better models complex clinical texts. The confusion matrix reveals label B is more often misclassified as label A, while label C is rarely misclassified, indicating challenges in distinguishing decisive from important information, thereby providing a direction for our future improvement efforts.

Figure 4: Classification accuracy comparison between FIND and other two baseline methods Adaptive-RAG (Jeong et al., 2024) and RAG² (Sohn et al., 2024). We also provide the confusion matrix across three labels (Right).

5.3 Ablation Study

We conducted an ablation study on the CMEMR dataset, with results shown at the bottom of Table 1. The findings indicate: (1) Removing the fine-grained adaptive module, chunk-sentence level knowledge retrieval module, or the differential diagnosis guided knowledge filtering module all degrade performance, highlighting their importance in handling complex clinical reasoning and retrieval tasks. (2) Removing both the fine-grained adaptive module and the chunk-sentence level knowledge retrieval module causes significant performance degradation. This is because, without the fine-grained adaptive module, many samples that the LLM could accurately diagnose independently are forced into retrieval, increasing the risk of irrelevant information leading to errors. Additionally, the low semantic correlation in clinical texts renders the knowledge retrieval module ineffective without the chunk-sentence level retrieval module, as it becomes nearly impossible to accurately match relevant documents.

5.3.1 The Effects of Different Retrievers

To further investigate our retrieval module design, we compared our method with other RAG methods using four retrievers: the sparse retriever BM25 (our default), and three dense retrievers: E5 (Wang et al., 2024b), BGE-m3 (Xiao et al., 2024), and CoROM (Long et al., 2022). Results in Table 2 show that our method achieves optimal and consistent performance across retrievers, demonstrating our retrieval module design and demonstrating the reduced retrieval difficulty due to the Fine-Grained Adaptive Module's sentence-level classification and filtering.

Methods	bm25	BGE	E5	CoROM
SR-RAG	44.19	45.55	41.73	44.21
FL-RAG	45.04	46.94	43.21	44.26
FS-RAG	43.27	45.08	44.32	42.45
Adaptive-RAG	48.73	49.65	45.33	48.06
RAG^2	45.69	42.80	46.64	44.97
DRAGIN	47.00	45.51	47.62	42.25
SEAKR	46.62	41.94	44.31	45.18
FIND(ours)	50.25	48.51	49.12	50.73

Table 2: Performance comparison (in F1-score) of using different retrievers on CMEMR dataset. Bold indicates the best performances.

5.3.2 Performance Analysis Across Different LLMs for Inference

Table 3 shows the performance of various reasoning LLMs on all held-out datasets. The reasoning capabilities of the LLMs significantly affect diagnostic performance in three aspects: 1) Model size: For the same Qwen2.5 model, increasing the size from 7B to 14B improves performance by 10% on the CMEMR dataset. 2) Model type: The proportion of pre-training data also significantly impacts the LLM's reasoning abilities for specific language tasks. Since our medical records are in Chinese, the Qwen series consistently outperforms the LLaMA series. 3) Instruction-following ability: Although FIND can be integrated seamlessly into any backbone LLM, its performance largely depends on the backbone LLM's ability to follow instructions. This explains why ChatGLM3-6B, despite similar parameter sizes, performs noticeably worse than several other models.

Backbone	Р	R	F1	
Qwen2.5-7B	52.50	48.20	50.25	
Qwen2.5-14B	55.72	50.53	53.00	
Chatglm3-6B	41.33	32.13	36.15	
Glm4-9B	43.46	42.51	42.98	
Llama3-8B	46.77	38.83	42.43	
Llama3.1-8B	45.67	47.59	46.61	

Table 3: Performance comparison of different inference LLMs on CMEMR dataset. Bold indicates the best performances.

5.4 Case Study

Table 4 in Appendix D presents representative case studies demonstrating the practicality of our proposed FIND. The results show that FIND conducts fine-grained importance assessment of patient information, accurately determining if the current data suffices for diagnosis and initiating retrieval when appropriate. Unlike previous Adaptive-Retrieval methods, our approach warns when I_{norm} falls below a threshold, indicating potential diagnostic failure. This meets clinical requirements for balancing accuracy and reliability, highlighting practical significance.

6 Conclusion

In this paper, we proposed FIND, a novel framework that improves the reliability of RAG in disease diagnosis scenarios. Our framework incorporates a fine-grained adaptive control module to determine whether retrieval is necessary based on the information density of the input. By optimizing the retrieval process and implementing a knowledge filtering module, FIND ensures that the retrieval is better suited to clinical scenarios. Our experiments on three Chinese EMR datasets demonstrate the effectiveness of FIND in clinical diagnosis tasks. Future work may explore further optimization of the retrieval process and the application of FIND to other medical tasks.

Limitations

Although our classification data annotation strategy is straightforward and effective, it still exhibits certain shortcomings in practical application. Due to the potential presence of repetitive content within the input patient information, LLMs may still arrive at a correct diagnosis even after masking a critical sentence. This can result in inaccurate annotation labels, necessitating manual inspection and revision on top of our proposed automatic annotation strategy. Moreover, clinical medical texts, particularly EMRs, often contain abbreviations, synonyms, and aliases. And the manner in which identical patient information is recorded can vary significantly among different physicians, leading to a high degree of inconsistency. This issue to some extent hampers the search accuracy of our retrieval system. In the future, we aim to explore more effective preprocessing strategies for medical texts to enhance retrieval quality.

A Details of Baseline Methods

In this section, we provide a detailed introduction to two categories of baseline methods, namely Vanilla-Retrieval methods and Adaptive-Retrieval methods, including their methodological descriptions and implementation details.

A.1 Vanilla-Retrieval methods

SR-RAG(Single-round RAG): Relevant passages are retrieved from an external corpus based on the initial question. The retrieved passages are then added into the LLM's input.

FL-RAG(Fixed Length RAG) (Khandelwal et al., 2019; Borgeaud et al., 2022; Ram et al., 2023): A multi-round retrieval augmentation method that triggers the retrieval module every n tokens. The tokens generated in the previous token window are utilized as the query.

FS-RAG(Fixed Sentence RAG) (Trivedi et al., 2023): A multi-round retrieval augmentation method that triggers the retrieval module every sentence. The last generated sentence are utilized as the query.

A.2 Adaptive-Retrieval methods

Adaptive-RAG (Jeong et al., 2024) trains a filtering model with labels obtained from correctly answered queries with and without RAG.

DRAGIN (Su et al., 2024) evaluating the uncertainty of each token to activate the retrieval model. **SEAKR** (Yao et al., 2024) introduce self-aware uncertainty to decide whether activating the retrieval model based on its value.

 \mathbf{RAG}^2 (Sohn et al., 2024) does not incorporate a pre-retrieval judgment mechanism; instead, it trains a filtering model based on perplexity labels to filter the retrieved documents.

A.3 Settings of Baseline Methods

To ensure a fair comparison, we implement all baseline methods using the same backbone LLM, retriever, and external knowledge corpus by default. For baseline methods that require training a classifier (RAG² (Sohn et al., 2024) and Adaptive-RAG (Jeong et al., 2024)), we adopt the same language model as used in our framework, namely Mengzi-T5-base (Zhang et al., 2021).

B Implementation Details

B.1 Details of External Knowledge Corpus

We employ the CMKD (Clinical Medicine Knowledge Database) as the external knowledge corpus. Knowledge documents for all 5,200 diseases were obtained from the official website. An example is provided in Chinese (Figure 5) and English (Figure 6) version. Following (Zhao et al., 2024a), we preprocess the documents in the knowledge base by segmenting them into chunks prior to retrieval.

Specifically, we impose a length constraint on the chunks, using sentences as the minimum segmentation unit. A sliding window is then applied to extend the context by merging overlapping content from the end of the previous sentence, thereby preventing semantic discontinuity at truncation points. Short chunks at the end of a document are merged with preceding chunks to ensure better semantic coherence. Furthermore, since the knowledge documents for each disease are inherently semi-structured, containing fixed fields such as "Etiology," "Clinical Manifestations," "Laboratory Tests," and "Other Auxiliary Examinations," we terminate the current chunk at the end of the text corresponding to each field during the segmentation process. By default, we set the chunk size to 200 words after segmenting the documents of CMKD.

B.2 Details of the Classifier

We adopt Mengzi-T5-base (Zhang et al., 2021) as our base model of Classifier. Specifically, the classifier is trained using the epoch that shows the best performance until 100 training iterations from the validation set, with the learning rate of 3e-5 and the AdamW (Loshchilov and Hutter, 2019) as an optimizer. For the training data of the classifier, we sampled and annotated 5% of the EMR samples from each department across the three datasets. Note that these EMR samples used for training the classifier are excluded from the evaluation set during experiment.

B.3 HyperParameters

During inference, we set the maximum generation length of the LLM to 256. To ensure reproducibility, we set do_sample to False by default.

When calculating the information density based on the classifier's predictions, the weights α , β , and γ for labels A, B, and C are set to 1.0, 0.5, and 0.1, respectively. The thresholds θ_1 and θ_2 are set to 0.6 and 0.3, respectively.

For the retrieval process, the number of chunks m retrieved for each sentence s_i is set to 100, and the number of documents k after chunk-todocument mapping and re-ranking is set to 5. During retrieval, chunks with a similarity score below 50% to the given query s_i are discarded.

C Evaluation Metrics Calculation

Firstly, for the disease entities in the diagnosis results \hat{D} and the reference diagnosis results \mathcal{R} in the medical records, we used a fuzzy matching process (with a predefined threshold of 0.5) to associate these disease entities with ICD-10 terms, thus mapping \hat{D} and \mathcal{R} to two standardized disease sets $S_{\hat{D}}$ and $S_{\mathcal{R}}$ respectively. We then define: **True Positives (TP):** The number of disease entities in the predicted result $S_{\hat{D}}$ that correspond correctly with the reference diagnosis $S_{\mathcal{R}}$.

False Positives (FP): The number of disease entities that appear in the predicted result $S_{\hat{D}}$ but do not match correctly with the reference diagnosis $S_{\mathcal{R}}$.

False Negatives (FN): The number of disease entities in the reference diagnosis $S_{\mathcal{R}}$ that do not appear in the predicted result $S_{\hat{\mathcal{T}}}$.

Based on the above statistical values, we calculate the following evaluation metrics:

Recall (R) :
$$R = \frac{\text{TP}}{\text{TP} + \text{FN}}$$
 (11)

Precision (P) :
$$P = \frac{TP}{TP + FP}$$
 (12)

F1 Score (F1) :
$$F = \frac{2 \times P \times R}{P + R}$$
 (13)

E Prompt Templates

Document Example (Chinese)

【疾病名】:病毒性心肌炎

【英文名】: Viral Myocarditis

【ICD号】: I41.0*

【分类】:心血管内科

概述:病毒性心肌炎(viral myocarditis)是一种与病毒感染有关的局限性或弥漫性炎症性心肌疾病,是最常见的感染性心肌炎。近年来随着检测技术的提高,发现多种病毒可引起心肌炎,其发病率呈逐年增高趋势,是遍及全球的常见病和多发病。

流行病学: ... 病毒性心肌炎可发生于各个年龄段,但从临床发病情况看以儿童和40岁以 下成人居多。由于许多病毒感染具有明显的季节分布特点,如流感病毒感染多发生在冬季,而肠道病毒感染则多发生于夏秋季,因此,病毒性心肌炎的发病也具有明显的季节 特征,夏秋季发病率较高,冬春季较少。...

病因: ...目前已证实能引起心肌炎的病毒包括:(1)小核糖核酸病毒:肠道病毒如柯萨奇(Coxsackie)、埃可(ECHO)、脊髓灰质炎病毒、鼻病毒等;(2)虫媒病毒:如黄热病毒、登革热病毒、白蛉热病毒、流行性出血热病毒等;...

临床表现: ... 在临床就诊的患者中,90%左右以心律失常为主诉或首发症状,常诉心悸、 乏力、胸闷、头晕等,严重者可出现晕厥或阿-斯综合征。部分患者可有程度不一的胸 痛,其原因可能有: ...

实验室检查: ...血清心肌肌钙蛋白I(cTnI)或肌钙蛋白T(cTnT)增高(以定量测定为准)有较大价值。...

其他辅助检查: ...X线检查约1/4病人有不同程度心脏扩大, 搏动减弱, 其扩大程度与心肌损害程度一致, 有时可见心包积液(病毒性心肌心包炎), 严重病例因左心功能不全有肺淤血或肺水肿征象。...

鉴别诊断: 1.风湿性心肌炎有典型风湿热表现者,则两者鉴别不难,一般可从以下几点作鉴别:风湿性心肌炎常有扁桃体炎或咽峡炎等链球菌感染史,抗"O"增高,血沉降多明显 增快,C反应蛋白(CRP)阳性,心电图改变以P-R间期延长较常见,咽拭物培养常有链球 菌生长,且多有大关节炎,鉴于风湿性心肌炎常有心内膜炎,因此二尖瓣反流性收缩期 杂音多较明显,且可因瓣膜水肿、炎症出现舒张期杂音(Carey Coombs杂音),若心脏扩大 不明显,而杂音较响亮,则风湿性可能性更大。...

治疗:(1)应用改善心肌细胞营养与代谢药物:该类药物包括维生素C、维生素B、辅酶A 50~100U或肌苷200~400mg,每天肌内注射或静脉注射1~2次;细胞色素C 15~30mg,每天静脉注射1~2次,该药应先皮试,无过敏者才能注射。...

Figure 5: A document example from CMKD (in Chinese).

Data Example (English)

[Disease Name]: Viral Myocarditis [English Name]: –

[ICD Code]: I41.0*

[Classification]: Cardiovascular Medicine

Overview: Viral myocarditis is a localized or diffuse inflammatory myocardial disease associated with viral infections, and it is the most common infectious myocarditis. In recent years, with the improvement of detection techniques, it has been found that various viruses can cause myocarditis, and its incidence has been increasing year by year, making it a common and frequently occurring disease worldwide.

Epidemiology: ... Viral myocarditis can occur in all age groups, but clinically, it is more common in children and adults under 40 years old. Since many viral infections have distinct seasonal distribution characteristics, such as influenza virus infections occurring mostly in winter and enterovirus infections occurring mostly in summer and autumn, the incidence of viral myocarditis also has obvious seasonal characteristics, with higher incidence in summer and autumn and lower incidence in winter and spring....

Etiology: ... It has been confirmed that viruses that can cause myocarditis include: (1) Picornaviruses: enteroviruses such as Coxsackie, ECHO, poliovirus, rhinovirus, etc.; (2) Arboviruses: such as yellow fever virus, dengue virus, sandfly fever virus, epidemic hemorrhagic fever virus, etc.;...

Clinical Manifestations: ... Among patients who seek clinical consultation, about 90% report arrhythmia as their main complaint or initial symptom, often complaining of palpitations, fatigue, chest tightness, dizziness, etc. In severe cases, syncope or Adams-Stokes syndrome may occur. Some patients may experience varying degrees of chest pain, which may be due to:...

Laboratory Tests: ... Elevated serum cardiac troponin I (cTnI) or troponin T (cTnT) (based on quantitative measurements) is of significant value....

Other Auxiliary Examinations: ... X-ray examination shows that about 1/4 of patients have varying degrees of cardiac enlargement and weakened pulsations, with the degree of enlargement consistent with the degree of myocardial damage. Sometimes pericardial effusion (viral myopericarditis) can be seen, and severe cases may show signs of pulmonary congestion or pulmonary edema due to left heart dysfunction....

Differential Diagnosis: 1. Rheumatic myocarditis: For those with typical rheumatic fever manifestations, the differentiation is not difficult. Generally, the following points can be used for differentiation: rheumatic myocarditis often has a history of streptococcal infections such as tonsillitis or pharyngitis, elevated anti-streptolysin O (ASO), significantly increased erythrocyte sedimentation rate (ESR), positive C-reactive protein (CRP), and common ECG changes such as prolonged P-R interval. Throat swab cultures often grow streptococci, and there is often polyarthritis. Since rheumatic myocarditis often involves endocarditis, the systolic murmur of mitral regurgitation is usually more pronounced, and diastolic murmurs (Carey Coombs murmur) may appear due to valve edema and inflammation. If the heart is not significantly enlarged but the murmur is loud, rheumatic myocarditis is more likely....

Treatment: (1) Use of drugs that improve myocardial cell nutrition and metabolism: These drugs include vitamin C, vitamin B, coenzyme A $50\sim100$ U, or inosine 200 ~400 mg, administered intramuscularly or intravenously once or twice daily; cytochrome C $15\sim30$ mg, administered intravenously once or twice daily. This drug should be skin-tested first, and only those without allergies can be injected....

Figure 6: A data example from CMEMR(translated).

Case 1: Non-retrieval

[Patient Info]:

<Chief Complaint>: Pain in the right upper abdomen for 2 days... <History of Present Illness>: ...Persistent pain with paroxysmal exacerbation, accompanied by nausea and vomiting (vomitus consisted of gastric contents), as well as abdominal distension and poor appetite... <Physical Examination>: ...No abdominal muscle tension or palpable masses... <Auxiliary Examination>: ...Color ultrasound indicates gallbladder sludge and stones...

 $[I_{norm}]$: 0.63[Activate_Retreival]: False[Raise_Warning]: False[LLM Diagnosis]: Gallstones and acute cholecystitis (\checkmark)

Case 2: Retrieval

[Patient Info]:

...<History of Present Illness>: ...Previously treated at a local hospital with enteric-coated aspirin tablets and isosorbide mononitrate, but no significant improvement was observed...<Physical Examination>: ...The heart rhythm is regular, and no pathological murmurs are heard in any of the valve auscultation areas... <Auxiliary Examination>: ...During the Bruce protocol exercise test, at 2 minutes and 14 seconds, tall tent-shaped T waves appeared in the precordial leads, accompanied by upsloping ST-segment elevation in the corresponding leads (Figure 2). Simultaneously, the patient experienced chest tightness...

[*I*_{norm}]: 0.47 [Activate_Retreival]: True [Raise_]

[Raise_Warning]: False

[**Retrieved Documents**]: ...Transient episodes of chest pain induced by exercise or other conditions that increase myocardial oxygen demand... In some patients with spontaneous angina, transient ST-segment elevation occurs during episodes, known as variant angina. New-onset exertional angina, worsening exertional angina, and spontaneous angina are often collectively referred to as "unstable angina."...

[LLM Diagnosis]: Coronary heart disease, unstable angina (\checkmark)

Case 3: Warning

[Patient Info]:

<Chief Complaint>: Recurrent pain in both knees for 8 years, worsening over the past month.... <Past Medical History> Previously healthy, preoperative blood tests and coagulation function tests were normal, and color Doppler ultrasound of the arteries and veins of both lower limbs showed no abnormalities. <Physical Examination>: ...No localized redness or swelling in the bilateral knee joints, with normal muscle tone....

 $[I_{norm}]$: 0.27[Activate_Retreival]: True[Raise_Warning]: True[Retrieved Documents]: Knee synovitis: The common sites of disease are the knee and hipjoints, and the general symptoms are joint pain and significant limitation of movement...[LLM Diagnosis]: Knee synovitis (\times)

Table 4: Case Study. For clarity, only part of the key information of the selected samples is presented.

You are an outstanding AI medical expert. You can perform a preliminary disease diagnosis based on the patient's Information.

[Role]<USR>

Below is a medical record summary of a patient from the \${department}.

[Medical Record Summary]:

###

\${summary}

###

Based on the above, you tried to search in the medical knowledge base and retrieved the following document from the knowledge base:

\${External Knowledge Documents}

[The Conception of Differential Diagnosis]

When analyzing the given documents, you may refer to the method of "differential diagnosis" in clinical medicine: by analyzing the degree of concordance between the patient's onset cause, presenting symptoms, examination indicators, and the characteristics of the diseases described in the current document, you can determine the relevance of the document for reference. Additionally, you need to compare whether there are contradictions or significant inconsistencies between the patient's condition and the descriptions in the document. If such inconsistencies exist, you should consider that the current document may not provide accurate diagnostic guidance.

[Requirements]:

Your task is to match the patient's condition with the description in the knowledge base document, analyzing any content that matches or conflicts. Then, use your knowledge to think critically and ultimately determine whether the knowledge base document is valuable for diagnosis. If you think it is valuable, select "True"; if you think it is misleading or irrelevant, select "False".

Please output in the following JSON format and do not output anything else: {"status": "the value of status"}

Table 7: The default prompt template for LLM filtering the retrieved document via differential diagnosis prompt. The presence of a "\$" symbol indicates a placeholder variable that needs to be filled with specific content.
