Abstract: Scoring functions constructed by transforming the realization and prediction variables of (strictly) consistent scoring functions have been widely studied empirically, yet their theoretical foundations remain unexplored. To address this gap, we establish formal characterizations of (strict) consistency for these transformed scoring functions and their elicitable functionals. Our analysis focuses on two interrelated cases: (a) transformations applied exclusively to the realization variable, and (b) bijective transformations applied jointly to both realization and prediction variables. We formulate analogous characterizations for (strict) identification functions. The resulting theoretical framework is broadly applicable to statistical and machine learning methodologies. When applied to Bregman and expectile scoring functions, our framework shows how it enables two critical advances: (a) rigorous interpretation of prior empirical findings from models trained with transformed scoring functions, and (b) systematic construction of novel identifiable and elicitable functionals, specifically the g -transformed expectation and g -transformed expectile. By unifying theoretical insights with practical applications, this work advances principled methodologies for designing scoring functions in complex predictive tasks.

Keywords: consistent scoring function; elicitable functional; loss function; machine learning; point forecasting

1. Introduction

Predictive modeling requires evaluating predictions from machine learning algorithms to assess their adequacy or facilitate comparisons. The adequacy of predictions is evaluated

using identification functions (Nolde and Ziegel 2017), while models are generally compared via scoring functions (also referred to as loss or objective functions) for point predictions (Gneiting 2011) or scoring rules for probabilistic predictions (Gneiting and Raftery 2007). This work focuses specifically on identification/scoring functions.

The use of scoring functions for model comparison is well-established in statistical literature (Gneiting 2011) and machine learning (Tyrakis and Papacharalampous 2024). Driven by domain-specific requirements, disciplines such as environmental science and technology have independently developed scoring functions-often referred to as performance metrics or error metrics-tailored to their needs (Moriassi et al. 2007; Bennett et al. 2013; Jackson et al. 2019). These needs emphasize evaluating models' ability to predict phenomena such as extreme events or highly skewed variables. To address these challenges, scoring functions of the form $S(g(z), g(y))$, where $S(z, y)$ evaluates a prediction z against a realized outcome y , and g is a bijection, are applied (Pushpalatha et al. 2012; Thirel et al. 2024). While empirical assessments of such transformations are well-documented (Pushpalatha et al. 2012; Thirel et al. 2024), their theoretical foundations remain unexplored, hindering broader implementation across disciplines.

Modelers typically train their models by minimizing average (realized) scores but often evaluate performance using multiple metrics that may not align with the scoring function employed during training (Gneiting 2011). From a statistical perspective, this training process can be interpreted as an application of M -estimation (Huber 1967; Newey and McFadden 1994) within a regression framework. Specifically, parameters are estimated by minimizing the average value of a scoring function that quantifies the discrepancy between model predictions and observations.

Thus, scoring functions serve a dual purpose: parameter estimation and prediction evaluation. Dimitriadis et al. (2024a) bridge these procedures, demonstrating that an M -estimator for a regression model is consistent if and only if the scoring function used by the M -estimator is consistent for the target functional. A scoring function is (strictly) consistent for a statistical functional (property), if its expected value is (uniquely) minimized when the modeler follows the directive to predict the statistical functional (Gneiting 2011). Common examples include the mean, median, quantiles (Koenker and Bassett Jr 1978) and expectiles (Newey and Powell 1987). These functionals are also identifiable, meaning that there exist (strict) identification functions whose expected value (uniquely) equals 0, when the modeler follows the directive to predict the functional

(Gneiting 2011; Fissler and Ziegel 2016).

In machine learning, model comparisons are best achieved by disclosing the scoring function a priori or specifying a statistical functional to predict for the dependent variable (Gneiting 2011). However, even when targeting a specific functional, different scoring functions consistent for the functional can lead to different model rankings in practice (Patton 2020). Consequently, specifying both the desired functional and a consistent scoring function for evaluation is critical (Patton 2020).

Motivated by these considerations, we aim to bridge the gap between machine learning practices involving transformed predictions/realizations and statistical literature on consistent scoring functions. We contribute in two ways:

a. Characterization of identification and consistent scoring functions: Building on Osband’s (1985) revelation principle for transformed predictions and new theoretical results for transformed realizations (Theorems 3-4), we characterize identification/consistent scoring functions for transformed predictions and realizations (Remark 1).

b. Specific functional families: We characterize families of (strict) identification and (strictly) consistent scoring functions; including quantile and expectile cases. These results yield new identifiable and elicitable functionals based on the squared-error and expectile scoring function. They also explain empirical findings for transformed squared error scoring functions (Pushpalatha et al. 2012 and Thirel et al. 2024).

The remainder of the manuscript is structured as follows. Section 2 reviews notation, identifiable/elicitable functionals, and strict identification/strictly consistent scoring functions. Section 3 presents new theoretical results (Theorems 3, 4, Remark 1) and their application to specific identification/consistent scoring function classes. Sections 4 and 5 discuss implications and conclude.

2. Notation and theory of consistent scoring functions

This section outlines the theory of consistent scoring functions and identification functions. Theoretical results are accompanied by practical examples. The discussion is limited to results essential for understanding the theoretical framework in Section 3, while we do not intend to provide a comprehensive overview of the topic. Appendix A introduces the notation and definitions for vector calculus used consistently throughout the manuscript.

2.1 Random variables and statistical functionals

Let \underline{y} be a random variable. Hereinafter, random variables will be underlined. A materialization of \underline{y} will be denoted by y . We write $\underline{y} \sim F$ to indicate that \underline{y} has cumulative distribution function (CDF) F , i.e.

$$F(y) := P(\underline{y} \leq y) \quad (2.1)$$

A k -dimensional statistical functional (or simply a functional) T (Gneiting 2011) is a mapping

$$T: \mathcal{F} \rightarrow \mathcal{P}(D), F \mapsto T(F) \subseteq D \quad (2.2)$$

where \mathcal{F} is a class of probability distributions. The functional maps each probability distribution $F \in \mathcal{F}$ to a subset $T(F)$ of the domain $D \subseteq \mathbb{R}^k$, that is an element of the power set $\mathcal{P}(D)$. $T(F)$ can be single-valued or set-valued.

Running example 1.1: An example of a single valued one-dimensional statistical functional is the mean of a probability distribution. It is defined by

$$E^{1/2}(F) := \mathbb{E}_F[\underline{y}], \quad (2.3)$$

where $\mathbb{E}_F[\cdot]$ is the expectation of a random variable \underline{y} with CDF F . The mean functional is a special case of the expectile functional $E^\tau(F)$ for $\tau = 1/2$; see Section 2.8.2. Another example of a one-dimensional statistical functional is the τ -quantile $Q^\tau(F)$ (or quantile at level τ , Koenker and Bassett Jr 1978), which is a mapping:

$$Q^\tau: \mathcal{F} \rightarrow \mathcal{P}(D), D \subseteq \mathbb{R} \quad (2.4)$$

and is defined by:

$$Q^\tau(F) = \{z \in D: \lim_{y \uparrow z} F(y) \leq \tau \leq F(z)\}, D \subseteq \mathbb{R}, \tau \in (0,1), F \in \mathcal{F} \quad (2.5)$$

The τ -quantile $Q^\tau(F)$ is generally a set-valued functional (Fissler et al. 2021), since it is a closed bounded interval of \mathbb{R} (Taggart 2022). If F is a strictly increasing function in \mathbb{R} , then $Q^\tau(F)$ is single-valued. ■

2.2 Strictly consistent scoring functions

Let $\mathbf{y} \in I \subseteq \mathbb{R}^d$ be a realization of a variable $\underline{\mathbf{y}}$ and $\mathbf{z} \in D \subseteq \mathbb{R}^k$ be a k -dimensional functional prediction. Predictions can be issued by either a time series model, a machine learning algorithm, or a physics-based model among others. Then a scoring function S is a mapping

$$S: D \times I \rightarrow \mathbb{R} \quad (2.6)$$

that assigns a penalty (loss) $S(\mathbf{z}, \mathbf{y})$ to a prediction \mathbf{z} when \mathbf{y} realizes. In the following, scoring functions will be negatively oriented, i.e. the lower the penalty, the better the prediction. An appealing property of a scoring function is strict consistency.

Definition 1 (Murphy and Daan 1985, p. 391; Gneiting 2011): The scoring function S is \mathcal{F} -consistent for the functional T if

$$\mathbb{E}_F[S(\mathbf{t}, \underline{\mathbf{y}})] \leq \mathbb{E}_F[S(\mathbf{z}, \underline{\mathbf{y}})] \quad \forall F \in \mathcal{F}, \mathbf{t} \in T(F), \mathbf{z} \in D \quad (2.7)$$

It is strictly \mathcal{F} -consistent if it is \mathcal{F} -consistent and equality in eq. (2.7) implies that $\mathbf{z} \in T(F)$. ■

The definition states that if a modeler receives a directive to predict a functional, and uses an \mathcal{F} -consistent scoring function to evaluate its prediction, then the scoring function is minimized in expectation when the prediction is optimal (i.e. equal to the value of the functional). If the scoring function is strictly \mathcal{F} -consistent, then it is uniquely minimized in expectation at the optimal prediction.

The following theorem demonstrates the relationship between finding optimal predictions and evaluating predictions. It states that the classes of consistent scoring functions for a specified functional and of scoring functions under which the functional is an optimal prediction are identical (Gneiting 2011).

Theorem 1 (Gneiting 2011): The scoring function S is \mathcal{F} -consistent for the functional T if and only if, given any $F \in \mathcal{F}$, any $\mathbf{z} \in T(F)$ is an optimal point prediction under S . ■

The following definition of elicibility of a functional explains the correspondence between specific functionals and scoring functions.

Definition 2 (Osband 1985; Lambert et al. 2008; Gneiting 2011): The functional T is elicitable relative to the class \mathcal{F} if there exists a scoring function S that is strictly \mathcal{F} -consistent for T . ■

For some of the following results, the assumption that the scoring function $S(\mathbf{z}, \mathbf{y})$ is bounded below is required (Gneiting 2011). We can assume nonnegativity of the scoring function S without loss of generality, since properties are transferrable to any lower bounded function. The properties of a consistent scoring function do not change if multiplied with a positive constant and a function of \mathbf{y} is added (Gneiting 2011).

Scoring functions with the property of homogeneity are appealing.

Definition 3 (Gneiting 2011): A scoring function S is homogeneous of order b if

$$S(cz, cy) = |c|^b S(z, y) \quad \forall z \in D, y \in I, c \in \mathbb{R} \quad (2.8)$$

■.

Homogeneity order describes a function's scaling behavior. For example, functions of order 0 ignore scale and measurement units, of order 1 scale linearly, and of order 2 penalize large discrepancies more (Fissler et al. 2023).

Running example 1.2: The mean is an elicitable functional for the class \mathcal{F} of probability distributions with finite second moment. A strictly \mathcal{F} -consistent scoring function for the mean functional is the squared error scoring function

$$S_{SE}(z, y) := (z - y)^2 \quad (2.9)$$

A simple proof is given below:

$$\begin{aligned} \mathbb{E}_F[S_{SE}(z, \underline{y})] - \mathbb{E}_F[S_{SE}(\mathbb{E}_F[\underline{y}], \underline{y})] &= (z^2 - 2z\mathbb{E}_F[\underline{y}] + \mathbb{E}_F^2[\underline{y}] - \mathbb{E}_F^2[\underline{y}] + 2\mathbb{E}_F^2[\underline{y}] - \\ \mathbb{E}_F^2[\underline{y}]) &\Rightarrow \end{aligned} \quad (2.10)$$

$$\mathbb{E}_F[S_{SE}(z, \underline{y})] - \mathbb{E}_F[S_{SE}(\mathbb{E}_F[\underline{y}], \underline{y})] = (z - \mathbb{E}_F[\underline{y}])^2 \quad (2.11)$$

Therefore,

$$\mathbb{E}_F[S_{SE}(\mathbb{E}_F[\underline{y}], \underline{y})] \leq \mathbb{E}_F[S_{SE}(z, \underline{y})] \quad \forall F \in \mathcal{F}, z \in \mathbb{R} \quad (2.12)$$

and

$$\mathbb{E}_F[S_{SE}(z, \underline{y})] = \mathbb{E}_F[S_{SE}(\mathbb{E}_F[\underline{y}], \underline{y})] \Leftrightarrow z = \mathbb{E}_F[\underline{y}] \quad (2.13)$$

that completes the proof.

The median functional, i.e. the $1/2$ -quantile $Q^{1/2}(F)$ is also elicitable relative to the class \mathcal{F} of probability distributions with finite first moment (Gneiting 2011). A strictly \mathcal{F} -consistent scoring function for the median functional is the absolute error scoring function

$$S_{AE}(z, y) = |z - y| \quad (2.14)$$

■.

2.3 Identification functions

We assume that there exists a function (Gneiting 2011; Fissler and Ziegel 2016):

$$V: D \times I \rightarrow \mathbb{R} \quad (2.15)$$

Definition 4 (Gneiting 2011; Fissler and Ziegel 2016): V is said to be an \mathcal{F} -identification

function for the functional $T(F)$ if

$$\mathbb{E}_F[V(T(F), \underline{\mathbf{y}})] = 0 \quad (2.16)$$

It is a strict \mathcal{F} -identification function for the functional $T(F)$ if

$$\mathbb{E}_F[V(\mathbf{z}, \underline{\mathbf{y}})] = 0 \Leftrightarrow \mathbf{z} \in T(F) \quad (2.17)$$

If there is a strict \mathcal{F} -identification function for the functional $T(F)$, then T is identifiable. ■

The importance of the identifiability property of a functional lies in the ability to assess the reliability of identifiable functionals' predictions in absolute terms (Fissler et al. 2021), also known as calibration in the statistical literature (Fissler et al. 2023; Gneiting and Resin 2023). Scoring functions, on the other hand, are used for prediction comparison and ranking (Fissler and Ziegel 2016). Connections between identifiable and elicitable functionals (explained later in Section 2.4) will be explored, as they allow characterizing properties of scoring functions.

Running example 1.3: The mean is an identifiable functional for the class \mathcal{F} of probability distributions with finite second moment. A strict \mathcal{F} -identification function for the mean functional is (Gneiting 2011)

$$V_{E^{1/2}}(z, y) = z - y \quad (2.18)$$

A simple proof is given below:

$$\mathbb{E}_F[V_{E^{1/2}}(z, \underline{\mathbf{y}})] = 0 \Leftrightarrow z = \mathbb{E}_F[\underline{\mathbf{y}}] \quad (2.19)$$

An interpretation of the identifiability property of the mean functional is that the expectation of the identification function $V_{E^{1/2}}$ becomes equal to 0 when a prediction is optimal, i.e. equal to the mean functional.

The median is an identifiable functional for the class \mathcal{F} of probability distributions with finite first moment, with strict \mathcal{F} -identification function (Gneiting 2011)

$$V_{Q^{1/2}}(z, y) = \mathbb{1}\{z \geq y\} - 1/2 \quad (2.20)$$

where $\mathbb{1}(\cdot)$ denotes the indicator function. ■

2.4 Osband's principle

A strictly \mathcal{F} -consistent scoring function S and a strict \mathcal{F} -identification function V are linked through (Osband 1985; Gneiting 2011; Fissler and Ziegel 2016):

$$\frac{\partial S(z, y)}{\partial z} = h(z)V(z, y) \quad (2.21)$$

where h is a nonnegative function and V is an oriented function, defined as follows:

Definition 5 (Steinwart et al. 2014; Fissler and Ziegel 2016): The function V is an oriented strict \mathcal{F} -identification function if it is a strict \mathcal{F} -identification function for the functional $T(F)$ and, moreover $\mathbb{E}_F[V(\mathbf{z}, \mathbf{y})] > 0$ if and only if $\mathbf{z} > T(F) \forall F \in \mathcal{F}, \mathbf{z} \in D \subseteq \mathbb{R}$. ■

Osband (1985) introduced this characterization, now known as Osband's principle. Osband's principle importance lies in the fact that it allows constructing strictly \mathcal{F} -consistent scoring functions from strict \mathcal{F} -identification functions for a functional $T(F)$ (Steinwart et al. 2014; Fissler and Ziegel 2016). For the case of $k = 1$ (i.e. of the one-dimensional functional), if V is a strict \mathcal{F} -identification function, then either V or $-V$ is oriented. Then specifying a strictly positive function h and integrating the right part of eq. (2.21) yields a strictly \mathcal{F} -consistent scoring function.

Running example 1.4: The strictly consistent S_{SE} scoring function and the strict identification function $V_{E^{1/2}}$ of the mean functional are connected by:

$$\frac{\partial S_{SE}(\mathbf{z}, \mathbf{y})}{\partial \mathbf{z}} = 2V_{E^{1/2}}(\mathbf{z}, \mathbf{y}) \quad (2.22)$$

■.

2.5 Osband's revelation principle

Strictly consistent scoring functions and strict identification functions can be constructed by applying bijective transformations to the prediction variable \mathbf{z} of existing strictly consistent scoring functions and identification functions. Similar constructions apply to elicitable and identifiable functionals. This principle, known as Osband's (1985) revelation principle, is summarized as follows:

Theorem 2 (Osband 1985; Gneiting 2011; Fissler and Ziegel 2015; Brehmer 2017): Let $g: D \rightarrow D', D, D' \subseteq \mathbb{R}^k$ be a bijection with inverse $g^{-1}: D' \rightarrow D$. Let the functional T be defined on a class \mathcal{F} of probability distributions with CDF F and the transformation T_g of T be defined by $T_g: \mathcal{F} \rightarrow D', F \mapsto T_g(F) = g(T(F))$. Then the following holds:

- a. T is elicitable if and only if T_g is elicitable.
- b. T is identifiable if and only if T_g is identifiable.
- c. The function $S: D \times I \rightarrow \mathbb{R}, (\mathbf{z}, \mathbf{y}) \mapsto S(\mathbf{z}, \mathbf{y}), I \subseteq \mathbb{R}^d$ is \mathcal{F} -consistent for T , if and only if the scoring function $S_g: D' \times I \rightarrow \mathbb{R}, (\mathbf{z}, \mathbf{y}) \mapsto S_g(\mathbf{z}, \mathbf{y}) = S(g^{-1}(\mathbf{z}), \mathbf{y})$ is \mathcal{F} -consistent for T_g .

d. The function $S: D \times I \rightarrow \mathbb{R}, (\mathbf{z}, \mathbf{y}) \mapsto S(\mathbf{z}, \mathbf{y}), I \subseteq \mathbb{R}^d$ is strictly \mathcal{F} -consistent for T , if and only if the scoring function $S_g: D' \times I \rightarrow \mathbb{R}, (\mathbf{z}, \mathbf{y}) \mapsto S_g(\mathbf{z}, \mathbf{y}) = S(g^{-1}(\mathbf{z}), \mathbf{y})$ is strictly \mathcal{F} -consistent for T_g .

e. The function $V: D \times I \rightarrow \mathbb{R}^k, (\mathbf{z}, \mathbf{y}) \mapsto V(\mathbf{z}, \mathbf{y}), I \subseteq \mathbb{R}^d$ is a \mathcal{F} -identification function for T , if and only if the function $V_g: D' \times I \rightarrow \mathbb{R}^k, (\mathbf{z}, \mathbf{y}) \mapsto V_g(\mathbf{z}, \mathbf{y}) = V(g^{-1}(\mathbf{z}), \mathbf{y})$ is a \mathcal{F} -identification function for T_g . ■

f. The function $V: D \times I \rightarrow \mathbb{R}^k, (\mathbf{z}, \mathbf{y}) \mapsto V(\mathbf{z}, \mathbf{y}), I \subseteq \mathbb{R}^d$ is a strict \mathcal{F} -identification function for T , if and only if the function $V_g: D' \times I \rightarrow \mathbb{R}^k, (\mathbf{z}, \mathbf{y}) \mapsto V_g(\mathbf{z}, \mathbf{y}) = V(g^{-1}(\mathbf{z}), \mathbf{y})$ is a strict \mathcal{F} -identification function for T_g . ■

Running example 1.5: Let $g: \mathbb{R} \rightarrow \mathbb{R}^+, t \mapsto g(t) = \exp(t)$. Then the inverse function g^{-1} is defined by $g^{-1}: \mathbb{R}^+ \rightarrow \mathbb{R}, t \mapsto g^{-1}(t) = \log(t)$.

Let the functional $T: \mathcal{F} \rightarrow \mathbb{R}, F \mapsto T(F) = \mathbb{E}_F[\underline{y}] \subseteq \mathbb{R}$ be defined on the class \mathcal{F} of probability distributions with positive support and finite second moment and the transformation T_g of T be defined by $T_g: \mathcal{F} \rightarrow \mathbb{R}^+, F \mapsto T_g(F) = \exp(\mathbb{E}_F[\underline{y}]) \subseteq \mathbb{R}^+$.

The scoring function $S_{SE}: \mathbb{R} \times \mathbb{R} \rightarrow [0, \infty), (z, y) \mapsto S_{SE}(z, y) = (z - y)^2$ is strictly \mathcal{F} -consistent for the functional T ; therefore, the scoring function $S_g: \mathbb{R}^+ \times \mathbb{R} \rightarrow [0, \infty), (z, y) \mapsto S_g(z, y) = (\log(z) - y)^2$ is strictly \mathcal{F} -consistent for the functional T_g . ■

2.6 Realized (average) and skill scores

In practical situations, when one has to compare two predictions of a functional, she/he is given a test set with realizations $\mathbf{y} = (y_1, \dots, y_n)^T$ of the random variable \underline{y} . Assuming that the respective predictions of the functional are $\mathbf{z} = (z_1, \dots, z_n)^T$, a summary measure of the predictive performance takes the form of the (negatively oriented) realized (average) score \bar{S} (Gneiting 2011):

$$\bar{S}(\mathbf{z}, \mathbf{y}) = (1/n) \sum_{i=1}^n S(z_i, y_i) \quad (2.23)$$

When choosing between two competing predictions, the one with the lowest average score is preferable.

When predictions from multiple methods have to be compared, skill scores can be used for evaluation. A skill score takes the form:

$$\bar{S}_{\text{skill}}(\mathbf{z}, \mathbf{y}; \text{ref}) := (\bar{S}(\mathbf{z}, \mathbf{y}) - \bar{S}(\mathbf{z}_{\text{ref}}, \mathbf{y})) / (\bar{S}(\mathbf{z}_{\text{optimal}}, \mathbf{y}) - \bar{S}(\mathbf{z}_{\text{ref}}, \mathbf{y})) \quad (2.24)$$

where \mathbf{z}_{ref} are predictions of a reference method (frequently the simpler method among

the competing ones) and \mathbf{z} are predictions of the method of interest. If the scoring function S is minimized at 0, then for an optimal prediction $\mathbf{z}_{\text{optimal}}$ we have $\bar{S}(\mathbf{z}_{\text{optimal}}, \mathbf{y}) = 0$, hence the skill score takes the form:

$$\bar{S}_{\text{skill}}(\mathbf{z}, \mathbf{y}; \text{ref}) := 1 - \bar{S}(\mathbf{z}, \mathbf{y}) / \bar{S}(\mathbf{z}_{\text{ref}}, \mathbf{y}) \quad (2.25)$$

A positive skill score suggests that the proposed method outperforms the reference method, while a negative score indicates the opposite. The skill score attains its maximum value equal to 1 at a perfect prediction $\mathbf{z} = \mathbf{y}$. Skill scores maintain prediction rankings, while the notions of consistency and elicibility remain valid, at least for large test samples (Gneiting 2011). Quantitatively, skill scores measure the performance improvement of one prediction relative to another, as a percentage of the potential improvement from a perfect prediction (Wheatcroft 2019).

Running example 1.6: In the case of the mean functional, specifying the squared error scoring function to evaluate predictions and using mean climatology on the test set as a reference method in skill score's eq. (2.25) yields the Nash-Sutcliffe efficiency (NSE), introduced by Nash and Sutcliffe (1970):

$$\text{NSE}(\mathbf{z}, \mathbf{y}) := 1 - \bar{S}_{\text{SE}}(\mathbf{z}, \mathbf{y}) / \bar{S}_{\text{SE}}(\mathbf{1}\bar{\mathbf{y}}, \mathbf{y}) \quad (2.26)$$

The NSE is a skill score; therefore, it retains properties discussed earlier. ■

2.7 M -estimation

Previous sections focused on evaluating point predictions with scoring functions. However, they did not address how to use scoring functions for parameter estimation in regression settings, and what the effect of parameter estimation using specific scoring functions is on predictions of the regression algorithm. Properties of consistent scoring functions and consistent estimators have been linked by Dimitriadis et al. (2024a). We examine regression settings which model the effect of predictors $\underline{\mathbf{x}}$ on a response variable \underline{y} . For a correctly specified model, we might be interested in estimating the conditional probability distribution of \underline{y} , namely $F_{\underline{y}|\underline{\mathbf{x}}}$ in a distributional regression setting (Rigby and Stasinopoulos 2005). Nevertheless, we might also be interested in a specific functional $T(F_{\underline{y}|\underline{\mathbf{x}}})$ of the conditional distribution. For instance, predictive quantiles at multiple levels can substitute the conditional probability distribution.

We assume that a correctly specified semiparametric model $m(\underline{\mathbf{x}}, \boldsymbol{\theta})$ satisfies for some unique parameter $\boldsymbol{\theta}_0 \in \boldsymbol{\theta}$

$$T(F_{\underline{y}|\underline{x}}) = m(\underline{x}, \boldsymbol{\theta}_0) \quad (2.27)$$

Model $m(\underline{x}, \boldsymbol{\theta})$ is called semiparametric because the form of the conditional probability distribution need not to be specified, although it may belong to a potentially wide family \mathcal{F} . Consequently, parameterization is restricted to the model's form itself, e.g. linear models or decision trees (Dimitriadis et al. 2024a). Semiparametric models offer more flexibility compared to parametric models because their estimation procedures are common for wide classes of probability distributions, for which the functional exists. This prevents modeling restrictions to potentially misspecified distributions. However, that comes at the cost of reduced ability to extrapolate (Tyralis and Papacharalampous 2024).

In practical situations, one specifies the general form of the model $m(\underline{x}, \boldsymbol{\theta})$ but the parameter $\boldsymbol{\theta}$ still needs to be estimated from available data. Assuming that we have l realizations of the vector \underline{x} and the dependent variable \underline{y} , an M -estimator of $\boldsymbol{\theta}_0$ is (Huber 1964; Huber 1967; Newey and McFadden 1994; Dimitriadis et al. 2024a)

$$\hat{\boldsymbol{\theta}}_l = \arg \min_{\boldsymbol{\theta} \in \boldsymbol{\Theta}} (1/l) \sum_{i=1}^l S(m(\underline{x}_i, \boldsymbol{\theta}), y_i) \quad (2.28)$$

where S is a scoring (loss) function. A substantive condition on S , for consistency of $\hat{\boldsymbol{\theta}}_l$ is that (Newey and McFadden 1994, p. 2123; Dimitriadis et al. 2024a)

$$\mathbb{E}_F[S(m(\underline{x}, \boldsymbol{\theta}_0), \underline{y})] \leq \mathbb{E}_F[(m(\underline{x}, \boldsymbol{\theta}), \underline{y})] \quad \forall \underline{x}, \underline{y} \in I, \boldsymbol{\theta} \in \boldsymbol{\Theta} \quad (2.29)$$

which is called model consistency of S for the model m . Strict equality in eq. (2.29) for $\boldsymbol{\theta} = \boldsymbol{\theta}_0$ implies strict model consistency of S for the model m .

A result from Dimitriadis et al. (2024a) establishes that a loss function S is (strictly) model consistent for the model m , if and only if it is (strictly) consistent for the target functional T . That result has some important implications, for our subsequent analysis as it connects the procedures of estimation and prediction evaluation. If one aims to predict a functional with a semiparametric model, then she/he has to estimate the parameters using an M -estimator with a consistent scoring function for the functional.

Running example 1.7: A consistent M -estimator for the parameter $\boldsymbol{\theta}_0$ of a distribution F is

$$\hat{\boldsymbol{\theta}}_l = \arg \min_{\boldsymbol{\theta} \in \boldsymbol{\Theta}} (1/l) \sum_{i=1}^l S(\boldsymbol{\theta}, y_i) \quad (2.30)$$

Eq. (2.30) can be viewed as a special case of a semiparametric model, where the model is equal to a constant parameter. If S is a strictly \mathcal{F} -consistent scoring function for the

functional $T(F)$, then $\hat{\theta}_l$ is a strictly consistent estimator for the parameter $T(F)$ of the probability distribution F . For the case of the S_{SE} scoring function, the well-known estimator of the mean of a probability distribution arises from eq. (2.30).

$$\hat{\theta}_l = \arg \min_{\theta \in \Theta} (1/l) \sum_{i=1}^l S_{SE}(\theta, y_i) \quad (2.31)$$

For the class of symmetric probability distributions, the mean and median functionals are identical. Therefore $\hat{\theta}_l$ is also a strictly consistent estimator of the median for this class (Fissler and Ziegel 2019; Dimitriadis et al. 2024a). ■

2.8 Quantiles, expectiles and respective consistent scoring functions

So far, we have reviewed examples of elicitable functionals, strictly consistent scoring functions, and strict identification functions. However, the class of consistent scoring functions for a given functional can include multiple distinct members. Below, we present several representative cases commonly encountered in practice. This list is not intended to be exhaustive.

2.8.1 Quantiles

The quantile functional has been defined in eq. (2.5). The general class of consistent scoring functions for the quantile functional $Q^\tau(F)$ is defined by (Thomson 1979; Saerens 2000; Gneiting 2011):

$$S_Q(z, y; \tau, g) = (\mathbb{1}(z \geq y) - \tau)(g(z) - g(y)) \quad (2.32)$$

where g is a nondecreasing function. The generalized piecewise linear (GPL) scoring function of order $\tau \in (0,1)$ S_Q is strictly \mathcal{F} -consistent for the quantile $Q^\tau(F)$, if g is strictly increasing and \mathcal{F} is the family of probability distributions with finite first moment. The corresponding strict \mathcal{F} -identification function is defined by (Gneiting 2011):

$$V_{Q^\tau}(z, y) = \mathbb{1}(z \geq y) - \tau \quad (2.33)$$

$S_Q(z, y; \tau, t)$ is the asymmetric piecewise linear scoring function (also termed as tick-loss or quantile loss in the literature) which is strictly consistent for the quantile $Q^\tau(F)$ (Raiffa and Schlaifer 1961), and lies at the heart quantile regression (Koenker and Bassett Jr 1978):

$$S_Q(z, y; \tau, t) = (\mathbb{1}\{z \geq y\} - \tau)(z - y) \quad (2.34)$$

The absolute error scoring function also arises from the GPL scoring function:

$$S_{AE}(z, y) = S_Q(z, y; 1/2, 2t) \quad (2.35)$$

2.8.2 Expectiles

The τ -expectile $E^\tau(F)$ (Newey and Powell 1987; Bellini et al. 2014; Bellini and Di Bernardino 2017; Taggart 2022) is defined by:

$$E^\tau(F) = \{z \in I: \tau \int_z^\infty (y - z)dF(y) = (1 - \tau) \int_{-\infty}^z (z - y)dF(y)\} \quad (2.36)$$

or equivalently

$$E^\tau(F) = \{z \in I: \tau \mathbb{E}_F[\kappa_{0,\infty}(\underline{y} - z)] = (1 - \tau) \mathbb{E}_F[\kappa_{0,\infty}(z - \underline{y})]\} \quad (2.37)$$

where $\kappa_{a,b}(t)$ is the capping function, defined by:

$$\kappa_{a,b}(t) = \max\{\min\{t, b\}, -a\} \forall t \in \mathbb{R}, a, b \in [0, \infty] \quad (2.38)$$

or equivalently

$$\kappa_{a,b}(t) = \begin{cases} -a, & t \leq -a \\ t, & -a < t \leq b \\ b, & t > b \end{cases} \quad (2.39)$$

The general class of consistent scoring functions for the expectile functional $E^\tau(F)$ is defined by (Gneiting 2011):

$$S_E(z, y; \tau, \varphi) = |\mathbb{1}(z \geq y) - \tau|(\varphi(y) - \varphi(z) + \varphi'(z)(z - y)) \quad (2.40)$$

where φ is a convex function with subgradient φ' . S_E is strictly \mathcal{F} -consistent for the expectile $E^\tau(F)$, if φ is strictly convex, and \mathcal{F} is the family of probability distributions with finite second moment. The corresponding strict \mathcal{F} -identification function is defined by (Gneiting 2011):

$$V_{E^\tau}(z, y) = 2|\mathbb{1}(z \geq y) - \tau|(z - y) \quad (2.41)$$

The asymmetric piecewise quadratic scoring function $S_E(z, y; \tau, t^2)$ is strictly consistent for the expectile $E^\tau(F)$ and lies at the heart of expectile regression (Newey and Powell 1987):

$$S_E(z, y; \tau, t^2) = |\mathbb{1}\{z \geq y\} - \tau|(z - y)^2 \quad (2.42)$$

The squared error scoring function is a special case of $S_E(z, y; \tau, \varphi)$ up to a multiplicative constant:

$$S_{SE}(z, y) = 2S_E(z, y; 1/2, t^2) \quad (2.43)$$

The class of scoring functions

$$S_E(z, y; 1/2, \varphi) = (1/2)(\varphi(y) - \varphi(z) + \varphi'(z)(z - y)) \quad (2.44)$$

that arises from eq. (2.40) for $\tau = 1/2$, is consistent for the mean functional (Savage 1971). Functions of the form $2S_E(z, y; 1/2, \varphi)$ are referred as Bregman functions by

Banerjee et al. (2005).

2.8.3 The pair (mean, variance)

Quantile and expectile scoring functions apply to one-dimensional functionals and one-dimensional variables. Here, we consider an example of a two-dimensional functional: the pair $(\mathbb{E}_F[\underline{y}], \text{Var}_F[\underline{y}])$ representing the mean $\mathbb{E}_F[\underline{y}]$ and variance $\text{Var}_F[\underline{y}]$. This pair is both identifiable and elicitable. Specifically, it is identified by the mean-variance strict identification function (Gneiting 2011; Fissler and Ziegel 2019; Dimitriadis et al. 2024b)

$$V_{\text{mv}}(x_1, x_2, y) := (x_1 - y, x_2 + x_1^2 - y^2) \quad (2.45)$$

and elicited by the mean-variance strictly consistent scoring function (Osband 1985; Gneiting 2011; Fissler and Ziegel 2019)

$$S_{\text{mv}}(x_1, x_2, y) := x_2^{-2}(x_1^2 - 2x_2 - 2x_1y + y^2) \quad (2.46)$$

where (x_1, x_2) denotes predictions for the pair $(\mathbb{E}_F[\underline{y}], \text{Var}_F[\underline{y}])$.

3. Transforming realizations/predictions in scoring/identification functions

The empirical exploration of transformations applied to both the predictor and realization variables in scoring and identification functions has been extensively studied. However, extant theory has focused primarily on transformations of the prediction variables, guided by Osband's (1985) revelation principle. In Section 3.1, we extend this framework to include transformations of the realization variable alone and simultaneous transformations of both independent variables. Section 3.2 then illustrates the broad spectrum of practical applications enabled by these theoretical extensions.

3.1 Characterizations of scoring and identification functions

The next theorem characterizes scoring functions that arise from applying a transformation to their realization variables. This is a general result, enabling the characterization of scoring functions where the realization variable itself is transformed. For the proof, see Appendix B.

Theorem 3: Let the functional $T: \mathcal{F} \rightarrow \mathcal{P}(D), F \mapsto T(F) \subseteq D, D \subseteq \mathbb{R}^k$ of a random variable \underline{y} be defined on a class \mathcal{F} of probability distributions with CDF F . Consider a measurable function $g: I' \rightarrow I'', I', I'' \subseteq \mathbb{R}^d$. Let $\mathcal{F}^{(g)} \subseteq \mathcal{F}$ denote the subclass of the probability distributions in \mathcal{F} which are such that $\underline{y}^{(g)} = g(\underline{y})$ has CDF $F^{(g)}$ and $F^{(g)} \in \mathcal{F}$. Define the

functional $T^{(g)}: \mathcal{F}^{(g)} \rightarrow \mathcal{P}(D)$, $F^{(g)} \mapsto T^{(g)}(F^{(g)}) = T(F^{(g)})$ on this subclass $\mathcal{F}^{(g)}$. Then the following holds:

- a. If T is elicitable, then $T^{(g)}$ is elicitable.
- b. If $S: D \times I'' \rightarrow \mathbb{R}$, $(\mathbf{z}, \mathbf{y}) \mapsto S(\mathbf{z}, \mathbf{y})$ is \mathcal{F} -consistent for T , then $S^{(g)}: D \times I' \rightarrow \mathbb{R}$, $(\mathbf{z}, \mathbf{y}) \mapsto S^{(g)}(\mathbf{z}, \mathbf{y}) = S(\mathbf{z}, g(\mathbf{y}))$ is $\mathcal{F}^{(g)}$ -consistent for $T^{(g)}$.
- c. If S is strictly \mathcal{F} -consistent for T , then $S^{(g)}$ is strictly $\mathcal{F}^{(g)}$ -consistent for $T^{(g)}$.
- d. If g is a bijection with inverse $g^{-1}: I'' \rightarrow I'$, there is a bijection between classes \mathcal{F} and $\mathcal{F}^{(g)}$, while the implications in parts (a), (b) and (c) become equivalences. ■

The next example demonstrates an application of Theorem 3 for the case where the log transformation is applied to the realization variable of the scoring function. It illustrates how a new strictly consistent scoring function arises from the squared error scoring function and how a new elicitable functional is constructed from the mean functional.

Running example 2.1: Let $g: \mathbb{R}^+ \rightarrow \mathbb{R}$, $t \mapsto g(t) = \log(t)$. The function g is a bijection with inverse $g^{-1}: \mathbb{R} \rightarrow \mathbb{R}^+$, $t \mapsto g(t) = \exp(t)$. Let the functional $T: \mathcal{F} \rightarrow \mathbb{R}$, $F \mapsto T(F) = \mathbb{E}_F[\underline{y}] \subseteq \mathbb{R}$ be defined on the class \mathcal{F} of probability distributions with finite second moment. Let $\mathcal{F}^{(g)} \subseteq \mathcal{F}$ denote the class of the probability distributions in \mathcal{F} which are such that $\underline{y}^{(g)} = \log(\underline{y})$ has CDF $F^{(g)} \in \mathcal{F}^{(g)}$. Let the transformation $T^{(g)}$ of T be defined by $T^{(g)}: \mathcal{F}^{(g)} \rightarrow \mathbb{R}$, $F \mapsto T^{(g)}(F^{(g)}) = \mathbb{E}_F[\log(\underline{y})] \subseteq \mathbb{R}$, because $T^{(g)}(F^{(g)}) = \mathbb{E}_{F^{(g)}}[\underline{y}^{(g)}] = \mathbb{E}_F[\log(\underline{y})]$ due to the law of the unconscious statistician (LOTUS).

The scoring function $S_{SE}: \mathbb{R} \times \mathbb{R} \rightarrow [0, \infty)$, $(z, y) \mapsto S_{SE}(z, y) = (z - y)^2$ is strictly \mathcal{F} -consistent for the functional T ; therefore, the scoring function $S_g: \mathbb{R} \times \mathbb{R}^+ \rightarrow [0, \infty)$, $(z, y) \mapsto S_g(z, y) = (z - \log(y))^2$ is strictly $\mathcal{F}^{(g)}$ -consistent for the functional $T^{(g)}$. Moreover, $\mathcal{F}^{(g)}$ is the class of probability distributions $F^{(g)}$ of $\underline{y}^{(g)}$, with finite expectation $\mathbb{E}_{F^{(g)}}[\underline{y}^{(g)}]$ or equivalently finite expectation $\mathbb{E}_F[\log(\underline{y})]$. ■

The next theorem complements Theorem 3 by addressing the case of identification functions where a transformation is applied to their realization variable. For the proof, see [Appendix B](#).

Theorem 4: Let the functional $T: \mathcal{F} \rightarrow \mathcal{P}(D)$, $F \mapsto T(F) \subseteq D$, $D \subseteq \mathbb{R}^k$ of a random variable \underline{y} be defined on a class \mathcal{F} of probability distributions with CDF F . Consider a function $g: I' \rightarrow I''$, $I', I'' \subseteq \mathbb{R}^d$. Let $\mathcal{F}^{(g)} \subseteq \mathcal{F}$ denote the subclass of the probability distributions in

\mathcal{F} which are such that $\underline{\mathbf{y}}^{(g)} = g(\underline{\mathbf{y}})$ has CDF $F^{(g)}$ and $F^{(g)} \in \mathcal{F}$. Define the functional $T^{(g)}: \mathcal{F}^{(g)} \rightarrow \mathcal{P}(D), F^{(g)} \mapsto T^{(g)}(F^{(g)}) = T(F^{(g)})$ on this subclass $\mathcal{F}^{(g)}$. Then the following holds:

- a. If T is identifiable, then $T^{(g)}$ is identifiable.
- b. If $V: D \times I'' \rightarrow \mathbb{R}, (\mathbf{z}, \mathbf{y}) \mapsto V(\mathbf{z}, \mathbf{y})$ is an \mathcal{F} -identification function for T , then $V^{(g)}: D \times I' \rightarrow \mathbb{R}, (\mathbf{z}, \mathbf{y}) \mapsto V^{(g)}(\mathbf{z}, \mathbf{y}) = V(\mathbf{z}, g(\mathbf{y}))$ is an $\mathcal{F}^{(g)}$ -identification function for $T^{(g)}$.
- c. If V is a strict \mathcal{F} -identification function for T , then $V^{(g)}$ is a strict $\mathcal{F}^{(g)}$ -identification function for $T^{(g)}$.
- d. If g is a bijection with inverse $g^{-1}: I'' \rightarrow I'$, there is a bijection between classes \mathcal{F} and $\mathcal{F}^{(g)}$, while the implications in parts (a), (b) and (c) become equivalences. ■

Applying Theorem 4 enables the construction of new strict identification functions and identifiable functionals using a process analogous to that illustrated in Running Example 2.1.

The following remark presents the central result of this manuscript. It enables the characterization of consistent scoring functions, identification functions, and their corresponding elicitable and identifiable functionals, which are generated by bijective transformations of the prediction and realization variables within associated consistent scoring functions or identification functions. This result follows directly from Osband's revelation principle and Theorems 3 and 4; therefore, the proof is omitted.

Remark 1: Let $g: D \rightarrow D', D, D' \subseteq \mathbb{R}$ be a bijection with inverse $g^{-1}: D' \rightarrow D$. Let the functional $T: \mathcal{F} \rightarrow \mathcal{P}(D), F \mapsto T(F) \subseteq D, D \subseteq \mathbb{R}$ be defined on a class \mathcal{F} of probability distributions with CDF F . Let $\mathcal{F}^{(g)} \subseteq \mathcal{F}$ denote the subclass of the probability distributions in \mathcal{F} which are such that $\underline{\mathbf{y}}^{(g)} = g(\underline{\mathbf{y}})$ has CDF $F^{(g)}$ and $F^{(g)} \in \mathcal{F}$. Define the functionals $T^{(g)}: \mathcal{F}^{(g)} \rightarrow \mathcal{P}(D), F^{(g)} \mapsto T^{(g)}(F^{(g)}) = T(F^{(g)})$, $T_g: \mathcal{F} \rightarrow \mathcal{P}(D), F \mapsto T_g(F) = g^{-1}(T(F))$ and $T_g^{(g)}: \mathcal{F}^{(g)} \rightarrow \mathcal{P}(D), F^{(g)} \mapsto T_g^{(g)}(F^{(g)}) = g^{-1}(T(F^{(g)}))$.

Then the following holds:

- a. T is elicitable, if and only if $T_g^{(g)}(F^{(g)})$ is elicitable.
- b. T is identifiable, if and only if $T_g^{(g)}(F^{(g)})$ is identifiable.
- c. A function $S: D' \times D' \rightarrow \mathbb{R}, (\mathbf{z}, \mathbf{y}) \mapsto S(\mathbf{z}, \mathbf{y})$, is \mathcal{F} -consistent for T , if and only if the function $S_g: D \times D \rightarrow \mathbb{R}, (\mathbf{z}, \mathbf{y}) \mapsto S_g(\mathbf{z}, \mathbf{y}) = S(g(\mathbf{z}), g(\mathbf{y}))$ is $\mathcal{F}^{(g)}$ -consistent for

$T_g^{(g)}(F^{(g)})$.

d. A function $S: D' \times D' \rightarrow \mathbb{R}, (z, y) \mapsto S(z, y)$, is strictly \mathcal{F} -consistent for T , if and only if the function $S_g: D \times D \rightarrow \mathbb{R}, (z, y) \mapsto S_g(z, y) = S(g(z), g(y))$ is strictly $\mathcal{F}^{(g)}$ -consistent for $T_g^{(g)}(F^{(g)})$.

e. A function $V: D' \times D' \rightarrow \mathbb{R}, (z, y) \mapsto V(z, y)$ is an \mathcal{F} -identification function for T , if and only if the function $V_g: D \times D \rightarrow \mathbb{R}, (z, y) \mapsto V_g(z, y) = V(g(z), g(y))$ is an $\mathcal{F}^{(g)}$ -identification function for $T_g^{(g)}(F^{(g)})$.

f. A function $V: D' \times D' \rightarrow \mathbb{R}, (z, y) \mapsto V(z, y)$ is a strict \mathcal{F} -identification function for T , if and only if the function $V_g: D \times D \rightarrow \mathbb{R}, (z, y) \mapsto V_g(z, y) = V(g(z), g(y))$ is a strict $\mathcal{F}^{(g)}$ -identification function for $T_g^{(g)}(F^{(g)})$. ■

The next example demonstrates an application of Theorem 4 for the case where the log transformation is applied to the prediction and realization variables of the scoring function. It illustrates how a new strictly consistent scoring function arises from the squared error scoring function and how a new elicitable functional is constructed from the mean functional.

Running example 2.2: Let $g: \mathbb{R}^+ \rightarrow \mathbb{R}, t \mapsto g(t) = \log(t)$. The function g is a bijection with inverse $g^{-1}: \mathbb{R} \rightarrow \mathbb{R}^+, t \mapsto g(t) = \exp(t)$. Let the functional $T: \mathcal{F} \rightarrow \mathbb{R}, F \mapsto T(F) = \mathbb{E}_F[\underline{y}] \subseteq \mathbb{R}$ be defined on the class \mathcal{F} of probability distributions with finite second moment. Let $\mathcal{F}^{(g)} \subseteq \mathcal{F}$ denote the class of the probability distributions in \mathcal{F} which are such that $\underline{y}^{(g)} = \log(\underline{y})$ has CDF $F^{(g)} \in \mathcal{F}^{(g)}$. $\mathcal{F}^{(g)}$ is the class of probability distributions $F^{(g)}$ of $\underline{y}^{(g)}$, with finite expectation $\mathbb{E}_{F^{(g)}}[\underline{y}^{(g)}]$ or equivalently finite expectation $\mathbb{E}_F[\log(\underline{y})]$. Define the functionals $T^{(g)}: \mathcal{F}^{(g)} \rightarrow \mathbb{R}, F \mapsto T^{(g)}(F^{(g)}) = \mathbb{E}_F[\log(\underline{y})] \subseteq \mathbb{R}$, $T_g: \mathcal{F} \rightarrow \mathcal{P}(D), F \mapsto T_g(F) = \exp(\mathbb{E}_F[\underline{y}])$ and $T_g^{(g)}: \mathcal{F}^{(g)} \rightarrow \mathbb{R}, F^{(g)} \mapsto T_g^{(g)}(F^{(g)}) = \exp(\mathbb{E}_F[\log(\underline{y})])$.

The scoring function $S_{SE}: \mathbb{R} \times \mathbb{R} \rightarrow [0, \infty), (z, y) \mapsto S_{SE}(z, y) = (z - y)^2$ is strictly \mathcal{F} -consistent for the functional T ; therefore, the scoring function $S_g: \mathbb{R}^+ \times \mathbb{R}^+ \rightarrow [0, \infty), (z, y) \mapsto S_g(z, y) = (\log(z) - \log(y))^2$ is strictly $\mathcal{F}^{(g)}$ -consistent for the functional $g^{-1}(T(F)) = \exp(\mathbb{E}_F[\log(\underline{y})])$. ■

3.2 Applications to specific classes of consistent scoring functions

3.2.1 Strictly consistent scoring functions for g -transformed expectations

The most widely used family of scoring functions for transformed predictions and realizations assumes the form $S_g(z, y) = (g(z) - g(y))^2$, where g is a bijection. S_g represents a transformed version of the squared error scoring function. By applying Remark 1, it follows that S_g is a strictly consistent scoring function that elicits the functional $g^{-1}(\mathbb{E}_F[g(\underline{y})])$, which we refer to as g -transformed expectation. Table 1 presents a range of choices for the function g , along with their respective elicitable functionals. Specific transformations such as $g(t) = \log(t)$, $\log(t + b)$, $t^a, a = -2, -1, -0.5, 0.2, 0.5, 2$, $(t + c)^{-1}$ and $(t^{0.25} - 1)/0.25$ (the Box-Cox transformation) have been empirically studied in the environmental science and technology literature (Pushpalatha et al. 2012; Thirel et al. 2024). The choice $g(t) = \exp(at)$, which is a special case of the Bregman function for $\varphi(t) = t^2$, was proposed by Fissler and Pesenti (2023) and elicits the entropic risk measure (Gerber 1974) $\log(\mathbb{E}_F[\exp(a\underline{y})])/a$, when employed in the squared error scoring function.

By applying Remark 1, it follows that the function $V_g(z, y) = g(z) - g(y)$ is a strict identification function for the functional $g^{-1}(\mathbb{E}_F[g(\underline{y})])$. Identifiable functionals of this form, along with their corresponding strict identification functions, are also presented in Table 1, for a range of choices of g .

Table 1. Elicitable and identifiable functionals corresponding to the strictly consistent scoring function $S_g(z, y) = (g(z) - g(y))^2$ and the strict identification function $V_g(z, y) = g(z) - g(y)$, respectively.

Function $g(t)$	Function $g^{-1}(t)$	Elicitable – identifiable functional
$g: \mathbb{R}^+ \rightarrow \mathbb{R}, t \mapsto g(t) = \log(t)$	$g^{-1}(t) = \exp(t)$	$\exp(\mathbb{E}_F[\log(\underline{y})])$
$g: (-b/a, \infty) \rightarrow \mathbb{R}, t \mapsto g(t) = \log(at + b), a > 0$	$g^{-1}(t) = (\exp(t) - b)/a$	$(\exp(\mathbb{E}_F[\log(a\underline{y} + b)]) - b)/a$
$g: (-b, \infty) \rightarrow \mathbb{R}, t \mapsto g(t) = \log(t + b)$	$g^{-1}(t) = \exp(t) - b$	$\exp(\mathbb{E}_F[\log(\underline{y} + b)]) - b$
$g: \mathbb{R} \rightarrow \mathbb{R}^+, t \mapsto g(t) = \exp(t)$	$g^{-1}(t) = \log(t)$	$\log(\mathbb{E}_F[\exp(\underline{y})])$
$g: \mathbb{R} \rightarrow \mathbb{R}^+, t \mapsto g(t) = \exp(at + b), a \neq 0$	$g^{-1}(t) = (\log(t) - b)/a$	$(\log(\mathbb{E}_F[\exp(a\underline{y} + b)]) - b)/a$
$g: [0, \infty) \rightarrow [0, \infty), t \mapsto g(t) = t^a, a > 0$	$g^{-1}(t) = t^{1/a}$	$(\mathbb{E}_F[\underline{y}^a])^{1/a}$
$g: [-c/b, \infty) \rightarrow [0, \infty), t \mapsto g(t) = (bt + c)^a, a, b > 0$	$g^{-1}(t) = (t^{1/a} - c)/b$	$((\mathbb{E}_F[(b\underline{y} + c)^a])^{1/a} - c)/b$
$g: \mathbb{R}^+ \rightarrow \mathbb{R}^+, t \mapsto g(t) = t^a, a \neq 0$	$g^{-1}(t) = t^{1/a}$	$(\mathbb{E}_F[\underline{y}^a])^{1/a}$
$g: (-c/b, \infty) \rightarrow \mathbb{R}^+, t \mapsto g(t) = (bt + c)^a, a \neq 0, b > 0$	$g^{-1}(t) = (t^{1/a} - c)/b$	$((\mathbb{E}_F[(b\underline{y} + c)^a])^{1/a} - c)/b$
$g: (-c, \infty) \rightarrow \mathbb{R}^+, t \mapsto g(t) = (t + c)^a, a \neq 0$	$g^{-1}(t) = t^{1/a} - c$	$(\mathbb{E}_F[(\underline{y} + c)^a])^{1/a} - c$
$g: \mathbb{R}^+ \rightarrow \begin{cases} (-1/a, \infty), a \neq 0 \\ \mathbb{R}, a = 0 \end{cases}, t \mapsto g(t) = \begin{cases} (t^a - 1)/a, a \neq 0 \\ \log(t), a = 0 \end{cases}$	$g^{-1}(t) = \begin{cases} (at + 1)^{1/a} \\ \exp(t) \end{cases}$	$\begin{cases} (\mathbb{E}_F[\underline{y}^a])^{1/a} \\ \exp(\mathbb{E}_F[\log(\underline{y})]) \end{cases}$

If g is a strictly increasing, once differentiable function, then

$$\frac{\partial S_g(z, y)}{\partial z} = 2g'(z)V_g(z, y) \quad (3.1)$$

where $g'(z)$ is positive and V_g is an oriented strict identification function. V_g is a strict identification function because $\mathbb{E}_F[V_g(z, \underline{y})] = 0 \Leftrightarrow g(z) = \mathbb{E}_F[g(\underline{y})] \Leftrightarrow z = g^{-1}(\mathbb{E}_F[g(\underline{y})])$. It is an oriented function because $z > g^{-1}(\mathbb{E}_F[g(\underline{y})]) \Leftrightarrow g(z) > \mathbb{E}_F[g(\underline{y})] \Leftrightarrow \mathbb{E}_F[V_g(z, \underline{y})] > 0$. By applying Osband's principle (see [Section 2.4](#)), it follows that $S_g(z, y)$ is a strictly consistent scoring function. If g is a strictly decreasing, then $-g$ is strictly increasing, and $-V_g$ becomes oriented, enabling the same construction of the strictly consistent scoring function S_g . This provides an alternative proof of parts of Remark 1, provided S is restricted to squared error scoring functions and g to monotonic, once differentiable functions.

Functions of the form $(g(z) - g(y))^2$ constitute a subset of a broader class of scoring functions that are strictly consistent for the functional $g^{-1}(\mathbb{E}_F[g(\underline{y})])$. Applying Remark 1 to the Bregman family of scoring functions ([2.44](#)), it follows that a scoring function is strictly consistent for the functional $g^{-1}(\mathbb{E}_F[g(\underline{y})])$ if and only if is of the form $S(z, y; \varphi, g) = \varphi(g(y)) - \varphi(g(z)) + \varphi'(g(z))(g(z) - g(y))$, where φ is strictly convex function. The special case $S(z, y; \varphi, \exp(at))$ was introduced by Fissler and Pesenti ([2023](#)).

3.2.2 Explaining the functional $g^{-1}(\mathbb{E}_F[g(\underline{y})])$

To clarify the distinction between the functionals $\mathbb{E}_F[\underline{y}]$ and $g^{-1}(\mathbb{E}_F[g(\underline{y})])$ we confine our analysis to the log-normal family of probability distributions for \underline{y} . Let $\underline{y} \sim \text{Lognormal}(\mu, \sigma^2)$, where $\mu \in \mathbb{R}$ and $\sigma > 0$, with support $(0, \infty)$. We then analyze the family of scoring functions $S_g(z, y) = (z^a - y^a)^2$, which is strictly consistent for the functional $T(a) = \exp(\mu + a\sigma^2/2)$.

Notably, $T(a)$ is a strictly increasing function of a , which partially explains the findings of Thirel et al. ([2024](#)). Thirel et al. ([2024](#)) explored scoring functions of the form $(z^a - y^a)^2$, by varying the parameter a . They trained a hydrological (physics-based) model $\text{HM}(a)$ to predict river streamflow data using these scoring functions with different values of a . The model's predictions were then evaluated across various streamflow ranges using the squared error scoring function. Thirel et al. ([2024](#)) concluded that as a increases, the model's predictions improve for higher streamflows. This can be explained,

under the assumption of a log-normal distribution for streamflow data (Blum et al. 2017), and by the fact that the functional $T(a)$, which the models aims to predict, increases with a .

3.2.3 The median functional

Our previous analysis has focused on g -transformed expectations. In such cases, Remark 1 leverages LOTUS to map the functional from the transformed distribution $F^{(g)}$ back to the original distribution F . For the median functional, however, Remark 1 applies a distinct mechanism. Specifically, if g is a monotonic function, the median satisfies the property $Q^{1/2}(F^{(g)}) = g(Q^{1/2}(F))$ implying that $g^{-1}(Q^{1/2}(F^{(g)})) = Q^{1/2}(F)$. Here g^{-1} directly links the median of the transformed distribution $F^{(g)}$ to the median of F , contrasting with g -transformed expectations.

By applying the transformation g to the variables of the absolute error scoring function (2.14) we obtain $S_{\text{AE}}(g(z), g(y)) = |g(z) - g(y)|$, which, by Remark 1, is strictly consistent for the median functional. This scoring function $S_{\text{AE}}(g(z), g(y))$ corresponds to a special case of the GPL scoring function (2.32) for $\tau = 1/2$ up to a multiplicative constant. Additionally, Remark 1 shows that the function $V_{Q^{1/2}}(g(z), g(y)) = \mathbb{1}(g(z) \geq g(y)) - 1/2$, constructed from the strict quantile identification function in eq. (2.33) for $\tau = 1/2$, acts as a strict identification function for the median functional. It is straightforward to show that $V_{Q^{1/2}}(g(z), g(y)) = V_{Q^{1/2}}(z, y)$, regardless of whether g is strictly increasing or strictly decreasing.

3.2.4 Quantile functionals

The quantile functional presents a more complex case, as the monotonicity type of g determines how quantiles of the transformed distribution $F^{(g)}$ map back to the original distribution F :

- a. If g is strictly increasing, $Q^\tau(F^{(g)}) = g(Q^\tau(F))$, implying $g^{-1}(Q^\tau(F^{(g)})) = Q^\tau(F)$.
- b. If g is strictly decreasing, $Q^\tau(F^{(g)}) = g(Q^{1-\tau}(F))$, implying $g^{-1}(Q^\tau(F^{(g)})) = Q^{1-\tau}(F)$.

For strictly increasing g , applying the transformation to the variables of the asymmetric piecewise linear scoring function (2.34), yields the GPL scoring function (2.32), since $\mathbb{1}(g(z) \geq g(y)) = \mathbb{1}(z \geq y)$. Similarly, transforming the quantile strict

identification function (2.33) via g results in $V_{Q^\tau}(g(z), g(y)) = V_{Q^\tau}(z, y)$.

For strictly decreasing g , the relationship is less straightforward. Notably, $\mathbb{1}(g(z) \geq g(y)) - \tau = -(\mathbb{1}(z \geq y) - (1 - \tau))$. Applying g to the asymmetric piecewise linear scoring function (2.34) produces $S_Q(g(z), g(y); \tau, t) = (\mathbb{1}(g(z) \geq g(y)) - \tau)(g(z) - g(y))$ or equivalently, $S_Q(g(z), g(y); \tau, t) = (\mathbb{1}(z \geq y) - (1 - \tau))(-g(z) - (-g(y)))$. This scoring function is strictly consistent for the functional $Q^{1-\tau}(F)$, representing a special case of the GPL scoring function, where $-g$ is strictly increasing.

Regardless of whether g is increasing or decreasing, Remark 1 demonstrates how the asymmetric piecewise-linear scoring function generalizes to the broader class of GPL scoring functions.

3.2.5 Strictly consistent scoring functions for expectile-based functionals

Analogous to g -transformed expectations, elicitable functionals can also be constructed using expectiles, which we refer to as g -transformed expectiles. Applying Remark 1 to the expectile scoring function (2.40) results in the strictly consistent scoring function:

$$S_E(z, y; \tau, \varphi, g) = |\mathbb{1}(g(z) \geq g(y)) - \tau|(\varphi(g(y)) - \varphi(g(z)) + \varphi'(g(z))(g(z) - g(y))) \quad (3.2)$$

To identify the respective elicitable functional, we observe that $E^\tau(F^{(g)}) = \{z \in I: \tau \mathbb{E}_{F^{(g)}}[\kappa_{0,\infty}(\underline{y} - z)] = (1 - \tau) \mathbb{E}_{F^{(g)}}[\kappa_{0,\infty}(z - \underline{y})]\}$. By LOTUS, this becomes $E^\tau(F^{(g)}) = \{z \in I: \tau \mathbb{E}_F[\kappa_{0,\infty}(g(\underline{y}) - z)] = (1 - \tau) \mathbb{E}_F[\kappa_{0,\infty}(z - g(\underline{y}))]\}$. Consequently, the scoring function (3.2) elicits the g -transformed expectile:

$$g^{-1}(E^\tau(F^{(g)})) = g^{-1}(\{z \in I: \tau \mathbb{E}_F[\kappa_{0,\infty}(g(\underline{y}) - z)] = (1 - \tau) \mathbb{E}_F[\kappa_{0,\infty}(z - g(\underline{y}))]\}) \quad (3.3)$$

The g -transformed expectation arises as a special case of the g -transformed expectile, when $\tau = 1/2$. While this follows directly from the fact that strictly consistent scoring functions for g -transformed expectations are special cases of the strictly scoring function (3.2) with $\tau = 1/2$, we present an alternative proof for clarity. Define $A = \{z \in I: \mathbb{E}_F[\kappa_{0,\infty}(g(\underline{y}) - z) - \kappa_{0,\infty}(z - g(\underline{y}))] = 0\}$. Rewriting A we have $A = \{z \in I: \mathbb{E}_F[(g(\underline{y}) - z) \mathbb{1}(g(\underline{y}) \geq z) - (z - g(\underline{y})) \mathbb{1}(g(\underline{y}) \leq z)] = 0\}$, which simplifies to $A = \{z \in I: \mathbb{E}_F[g(\underline{y}) \mathbb{1}(g(\underline{y}) \geq z) + g(\underline{y}) \mathbb{1}(g(\underline{y}) \leq z)] = \mathbb{E}_F[z \mathbb{1}(g(\underline{y}) \geq z) + z \mathbb{1}(g(\underline{y}) \leq z)]\}$. The left-hand expectation reduces to $\mathbb{E}_F[g(\underline{y})]$, while the right-hand expectation equals z .

Hence, $A = \mathbb{E}_F[g(\underline{y})]$, and it follows that $g^{-1}(E^{1/2}(F^{(g)})) = g^{-1}(\mathbb{E}_F[g(\underline{y})])$ completing the proof.

The g -transformed expectile (3.3) is also identifiable. Its strict identification function constructed by applying Remark 1 to the expectile strict identification function (2.41) is $V_{E^\tau}(g(z), g(y)) = 2|\mathbb{1}(g(z) \geq g(y)) - \tau|(g(z) - g(y))$.

3.2.6 The pair (mean, variance) of transformed realizations

Theorems 3 and 4 generalize naturally to k -dimensional functionals. As in illustration, consider the pair (mean, variance): The strict identification function (2.45) and strictly consistent scoring function (2.46) assume the following forms respectively:

$$V_{\text{mv}}(x_1, x_2, g(y)) = (x_1 - g(y), x_2 + x_1^2 - g^2(y)) \quad (3.4)$$

$$S_{\text{mv}}(x_1, x_2, g(y)) = x_2^{-2}(x_1^2 - 2x_2 - 2x_1g(y) + g^2(y)) \quad (3.5)$$

By theorems 3 and 4, the functions (3.4) and (3.5) respectively identify and elicit the pair $(\mathbb{E}_F[g(\underline{y})], \text{Var}_F[g(\underline{y})])$.

3.2.7 Skill scores

Skill scores of the form (2.25) employing a climatology reference method, can be directly constructed for scoring functions involving transformed variables. Consider, for example the scoring functions discussed in Section 3.2.1. The climatology for the functional is defined via the inverse transformation $g^{-1}((1/n) \sum_{i=1}^n g(y_i))$, leading to predictions of the reference method given by $\mathbf{z}_{\text{ref}} = (1/n)\mathbf{1}g^{-1}((1/n) \sum_{i=1}^n g(y_i))$.

4. Discussion and future outlook

This study is motivated by research in environmental science and technology, where scoring functions of the form $S(g(z), g(y))$ are widely used for training predictive models. Although the extant literature emphasizes that predictions should be probabilistic (Papacharalampous and Tyralis 2022; Vrugt 2024), most practical applications still employ scoring functions to generate point predictions. In hydrology (a major subdiscipline of environmental science), functionals of hydrologic processes are termed hydrograph functionals (Vrugt 2024). Building on this framework, we developed novel functionals using such scoring functions and characterized their elicibility and identifiability. Our findings advance the understanding of model training methodologies, providing theoretical insights into optimizing scoring mechanisms for environmental

science applications. These contributions complement existing hydrologic methods that train models using, squared-error (Nash and Sutcliffe 1970), quantile (Pande 2013a, 2013b; Tyralis and Papacharalampous 2021) and expectile (Tyralis et al. 2023) scoring functions.

Environmental predictions from models trained with functions of the form $(g(z) - g(y))^2$ were explained under the assumption of a log-normal distribution for the environmental process. However, such scoring functions are strictly consistent estimators for broader classes of probability distributions. Consequently, the empirical interpretation of model predictions can be extended to include distributions that better represent environmental processes.

While our work focuses on transformations of quantile, expectile, and mean-variance strictly consistent scoring functions, the results are general in scope. They can thus be applied to broader classes of consistent scoring and identification functions, including those involving multi-dimensional variables and functionals. Additionally, new proper scoring rules can be constructed from the proposed consistent scoring functions (Gneiting 2011).

While new functionals such as the g -transformed expectation and g -transformed expectile are introduced here, broader adoption of these tools would benefit from a clearer economic interpretation. Existing research on quantiles and expectiles (Ehm et al. 2016) provides a foundation, but future work could explore how their framework applies to these novel functionals. Given that such functionals can serve as risk measures, understanding their properties (such as monotonicity, coherence, and other axiomatic characteristics) is critical. For example, debates persist about the utility of expectiles compared to quantiles in risk modeling (Waltrup et al. 2015). Extending statistical properties, such as symmetry testing in nonparametric regression (analogous to the case of L_p -quantiles studied by Chen 1996), could provide another path forward for analyzing these new functionals.

5. Conclusions

In this study, we analyzed scoring functions constructed through transformations of the realization variable in strictly consistent scoring functions. We proved that these transformed functions retain strict consistency for a corresponding transformation of the elicitable functional linked to the original scoring function. By extending Osband's

revelation principle, we characterized cases where both the realization and prediction variables of the original scoring functions are transformed via a bijection g . Similar logic applies to transformations of strict identification functions, enabling analogous constructions. These characterizations establish a systematic approach for generating new identifiable and/or elicitable functionals.

When applied to Bregman and expectile scoring functions, this methodology produced strictly consistent scoring functions for two novel functionals: the g -transformed expectation and g -transformed expectile. Consistent scoring functions for g -transformed expectations have already been empirically validated in environmental science and technology applications. Here, we interpreted these empirical findings through the theoretical properties of the proposed functionals. Additionally, our analysis of quantile scoring functions uncovered relationships between the asymmetric piecewise linear scoring function and the generalized piecewise linear (GPL) scoring function.

The generality of this framework opens new ways for designing elicitable and identifiable functionals with wide-ranging applicability. By bridging theoretical insights with practical tools, this work advances the adaptability of scoring function transformations in machine learning methodology and interdisciplinary research.

Appendix A Vector notation

The notation of vectors remains consistent throughout the manuscript. We write a vector with n elements as

$$\mathbf{x} = (x_1, \dots, x_n)^T \quad (\text{A.1})$$

The zero and one vectors are denoted by:

$$\mathbf{0} = (0, \dots, 0)^T \quad (\text{A.2})$$

$$\mathbf{1} = (1, \dots, 1)^T \quad (\text{A.3})$$

The sample mean (mean climatology) of a vector is defined by (Gentle 2024, p. 45)

$$\bar{\mathbf{x}} := (1/n)\mathbf{1}^T \mathbf{x} = (1/n) \sum_{i=1}^n x_i = (1/n)\langle \mathbf{x}, \mathbf{1} \rangle \quad (\text{A.4})$$

Appendix B Proofs

Proof of Theorem 3: We first prove part (b). Let $F \in \mathcal{F}^{(g)}$, $t^{(g)} \in T^{(g)}(F)$, and $\mathbf{z} \in \mathbb{R}^k$. Then $\mathbb{E}_F[S^{(g)}(t^{(g)}, \underline{\mathbf{y}})] = \mathbb{E}_F[S(t^{(g)}, g(\underline{\mathbf{y}}))] = \mathbb{E}_{F^{(g)}}[S(t^{(g)}, \underline{\mathbf{y}}^{(g)})] \leq \mathbb{E}_{F^{(g)}}[S(\mathbf{z}, \underline{\mathbf{y}}^{(g)})] = \mathbb{E}_F[S(\mathbf{z}, g(\underline{\mathbf{y}}))] = \mathbb{E}_F[S^{(g)}(\mathbf{z}, \underline{\mathbf{y}})]$. The critical inequality holds because $\underline{\mathbf{y}}^{(g)}$ has CDF $F^{(g)}$,

$F^{(g)} \in \mathcal{F}^{(g)} \subseteq \mathcal{F}$ and $t^{(g)} \in T^{(g)}(F) = T(F^{(g)})$. The equality $\mathbb{E}_F[S(t^{(g)}, g(\underline{\mathbf{y}}))] = \mathbb{E}_{F^{(g)}}[S(t^{(g)}, \underline{\mathbf{y}}^{(g)})]$ is a consequence of the law of the unconscious statistician.

To prove parts (c) and (a), we note that the inequality is strict if S is strictly \mathcal{F} -consistent for T , unless $\mathbf{z} \in T^{(g)}(F) = T(F^{(g)})$.

Part (d) is established by observing that g is a bijection and by applying the implications demonstrated in parts (a), (b) and (c). ■

Proof of Theorem 4: We first prove part (b). Let $F^{(g)} \in \mathcal{F}^{(g)}$, $t^{(g)} \in T^{(g)}(F)$, and $\mathbf{z} \in \mathbb{R}^k$. Then $\mathbb{E}_F[V^{(g)}(t^{(g)}, \underline{\mathbf{y}})] = \mathbb{E}_F[V(t^{(g)}, g(\underline{\mathbf{y}}))] = \mathbb{E}_{F^{(g)}}[V(t^{(g)}, \underline{\mathbf{y}}^{(g)})] = 0$. The critical equality to zero holds because $\underline{\mathbf{y}}^{(g)}$ has CDF $F^{(g)}$, $F^{(g)} \in \mathcal{F}^{(g)} \subseteq \mathcal{F}$ and $t^{(g)} \in T^{(g)}(F) = T(F^{(g)})$. The equality $\mathbb{E}_F[V(t^{(g)}, g(\underline{\mathbf{y}}))] = \mathbb{E}_{F^{(g)}}[V(t^{(g)}, \underline{\mathbf{y}}^{(g)})]$ is a consequence of the law of the unconscious statistician.

To prove parts (c) and (a), we note that the equality to zero is strict if S is a strict \mathcal{F} -identification function for T , unless $\mathbf{z} \in T^{(g)}(F) = T(F^{(g)})$.

Part (d) is established by observing that g is a bijection and by applying the implications demonstrated in parts (a), (b) and (c). ■
