# Abstract

This paper studies the emulation-based stabilization of nonlinear networked control systems with two time scales. We address the challenge of using a single communication channel for transmitting both fast and slow variables between the plant and the controller. A novel dual clock mechanism is proposed to schedule transmissions for this purpose. The system is modeled as a hybrid singularly perturbed dynamical system, and singular perturbation analysis is employed to determine individual maximum allowable transmission intervals for both fast and slow variables, ensuring semi-global practical asymptotic stability. Enhanced stability guarantees are also provided under stronger assumptions. The efficacy of the proposed method is illustrated through a numerical example.

Key words: Networked control systems; Singular perturbation; Hybrid systems; Stabilization.

# 1 Introduction

Networked control systems (NCSs) integrate feedback control loops with real-time communication networks [29]. The rapid evolution of network technologies has expanded the applications of NCSs across various sectors, such as industrial automation, smart transportation, telemedicine, and both space and terrestrial exploration [27]. These applications often involve dynamic variables evolving in multiple time scales [11]. Most state-ofthe-art research in NCSs, e.g., [15,3,9], overlook this multi-scale structure, leading to designs demanding high data transmission rates to maintain system stability or robustness. This is especially problematic for Internet of Things devices, which are generally wireless, battery-powered, and have limited bandwidth, processing power, and data storage capacity. A relevant approach in this context is to extend the singularly perturbed method [10] to NCS, thereby introducing the concept of singularly perturbed NCS (SPNCS).

SPNCSs have gained substantial attention for their applicability in various engineering disciplines. For instance, [21,19,12] have introduced a range of control and analysis techniques for linear SPNCSs. For nonlinear SPNCSs, [1] formulated stabilizing event-triggered feedback laws based on the reduced model (also known as the quasi-steady-state model), assuming stable fast dynamics. Meanwhile, [8] established sufficient conditions for stability in time-triggered, two-time-scale nonlinear SPNCSs under the scenario that the controller is co-located with the actuators, as well as slow and fast plant states are transmitted over two separate channels, which is not always possible or desirable in

practice. More precisely, [12], [1] and [8] adopted an emulation-based approach for NCS design [15], i.e., the controller is designed to stabilize the plant in absence of communication constraints, and subsequently the event- or time-triggered conditions are determined to maintain stability over networks. Furthermore, SPNCSs have been framed within the framework of a hybrid singularly perturbed dynamical system using the formalisms outlined in [6], with stability tools available in [18] and [24]. We highlight that, the existing literature on SPNCSs often assumes either stable slow or fast subsystems, perfect transmission of some signals, and dedicated channels for slow and fast signals.

In this paper, we consider a two-time scale nonlinear system stabilized by a dynamical output feedback controller, inspired by both linear [17], [28], [13] and nonlinear [4] research on dynamic controllers for singularly perturbed dynamical systems (SPSs) [10] without network constraints. Unlike previous work [8] that assumes only the transmission of plant states, we address scenarios where both plant output and control input are transmitted via the network. Additionally, instead of requiring dedicated channels for slow and fast variables as in [8], which is not always practical, we consider a singlechannel scenario, which presents significant challenges in allocating access for slow and fast signals. Therefore, our objective is to provide a general methodology for the design of the controller and transmission mechanism to ensure stability properties for the SPNCS.

We first design a dual clock mechanism to govern the data transmissions. Then we represent the SPNCS as a hybrid SPS, incorporating jump sets specifically designed to comply with the previously mentioned clock mechanism. The obtained SPS is more general compared to those in the literature [18,24], as its flow and jump sets depend on the time scale separation parameter, which is commonly denoted by  $\epsilon$ . Following an emulation-based approach, we demonstrate that the if the reduced system and boundary-layer system are uniformly globally asymptotically stable (UGAS) or uniformly globally exponentially stable (UGES), and an interconnection condition and some mild conditions are met, the stability properties can be approximately preserved by transmitting both slow and fast variables sufficiently fast. Specifically, we employ a Lyapunov-based analysis to determine individual maximum allowable transmission interval (MATI) [15,3] of the slow and fast dynamics. Finally, we illustrate the benefits of our approach through a numerical case study.

Compared to our preliminary work [26], we relax a restrictive condition on the *minimum allowable transmission interval* (MIATI). Additionally, we present conditions that guarantee stronger stability properties: UGAS and UGES. Furthermore, while many works, such as [1], assume that either the slow or fast subsystem is stable without the need of control, our methodology does not rely on this assumption. Nevertheless, our framework accommodates scenarios involving stable slow or fast subsystems as special cases.

The results are novel even for linear time-invariant (LTI) systems. While [21,19,12] assumed periodic transmissions, we allow transmissions to be aperiodic. Compared to [19,12] that assumed the sampled-data structure, we consider SPNCSs with scheduling protocols. Moreover, we take into account the inter-event continuous behavior, which was ignored by [21,19].

Notation: Let  $\mathbb{R} := (-\infty, \infty)$ ,  $\mathbb{R}_{\geq 0} := [0, \infty)$ ,  $\mathbb{Z}_{\geq 0} := \{0, 1, 2, \cdots\}$  and  $\mathbb{Z}_{\geq 1} := \{1, 2, \cdots\}$ . For vectors  $v_i \in \mathbb{R}^n$ ,  $i \in \{1, 2, \cdots, N\}$ , we denote the vector  $[v_1^\top v_2^\top \cdots v_N^\top]^\top$  by  $(v_1, v_2, \cdots, v_N)$ , and inner product by  $\langle \cdot, \cdot \rangle$ . Given a vector  $x \in \mathbb{R}^{n_x}$  and a non-empty closed set  $\mathcal{A} \subseteq \mathbb{R}^{n_x}$ , the distance from x to  $\mathcal{A}$  is denoted by  $|x|_{\mathcal{A}} := \min_{y \in \mathcal{A}} |x - y|$ . We use  $U^{\circ}(x; v)$  to denote the Clarke generalized derivative [20, Eqn. (20)] of a locally Lipschitz function U at x in the direction of v. For a real symmetric matrix P, we denote its maximum and minimum eigenvalues by  $\lambda_{\max}(P)$  and  $\lambda_{\min}(P)$  respectively. The logic AND operator is denoted by  $\wedge$ .

#### 2 Problem setting

We consider a two-time-scale nonlinear NCS as depicted in Figure 1, designed using emulation techniques [15]. Specifically, a dynamic continuous output-feedback controller is developed to ensure robustness for both the *reduced* (slow) system and the *boundary-layer* (fast) system, initially without considering the network. Subsequently, the network is designed by establishing bounds on transmission intervals and selecting an appropriate scheduling protocol [15]. The resulting continuous-time controller is then deployed over the network, with the objective of providing conditions under which the stability of the SPNCS is guaranteed. Details on the emulation design framework are provided in Section 5. Next, we introduce the model of Figure 1.

Fig. 1. NCS Block Diagram

#### 2.1 Plant ( $\mathcal{P}$ ) and Controller ( $\mathcal{C}$ )

We model the plant as the following SPS,

$$\mathcal{P}: \begin{cases} \dot{x}_p = f_p(x_p, z_p, \hat{u}) \\ \epsilon \dot{z}_p = g_p(x_p, z_p, \hat{u}) \\ y_p = (y_s, y_f) = \left(k_{p_s}(x_p), k_{p_f}(x_p, z_p)\right), \end{cases}$$
(1)

where  $0 < \epsilon \ll 1$ ,  $x_p \in \mathbb{R}^{n_{x_p}}$ ,  $z_p \in \mathbb{R}^{n_{z_p}}$ ,  $y_s \in \mathbb{R}^{n_{y_s}}$ ,  $y_f \in \mathbb{R}^{n_{y_f}}$  and  $n_{x_p}, n_{z_p}, n_{y_s}, n_{y_f} \in \mathbb{Z}_{\geq 0}$ . Here,  $x_p$  and  $z_p$  denote the slow and fast plant states, respectively, while  $y_s$  and  $y_f$  represent the slow and fast output, respectively. Additionally,  $\hat{u} = (\hat{u}_s, \hat{u}_f)$  refers to the latest received control input u in (2) from the network. It is assumed that  $k_{p_s}$  and  $k_{p_f}$  are continuously differentiable, and  $f_p$  and  $g_p$  are locally Lipschitz. Similarly, the dynamic controller has the following form,

$$C: \begin{cases} \dot{x}_{c} = f_{c}(x_{c}, z_{c}, \hat{y}_{p}) \\ \epsilon \dot{z}_{c} = g_{c}(x_{c}, z_{c}, \hat{y}_{p}) \\ u = (u_{s}, u_{f}) = \left(k_{c_{s}}(x_{c}), k_{c_{f}}(x_{c}, z_{c})\right), \end{cases}$$
(2)

where  $\epsilon$  comes from (1),  $x_c \in \mathbb{R}^{n_{x_c}}$ ,  $z_c \in \mathbb{R}^{n_{z_c}}$ ,  $u_s \in \mathbb{R}^{n_{u_s}}$ ,  $u_f \in \mathbb{R}^{n_{u_f}}$  and  $n_{x_c}, n_{z_c}, n_{u_s}, n_{u_f} \in \mathbb{Z}_{\geq 0}$ . Moreover,  $\hat{y}_p = (\hat{y}_s, \hat{y}_f)$  refers to the most recently received output of the plant transmitted via the network. It is assumed that  $k_{c_s}$  and  $k_{c_f}$  are continuously differentiable,  $f_c$  and  $g_c$  are locally Lipschitz, and  $u_s, u_f, y_s, y_f$  have the dimension as  $\hat{u}_s, \hat{u}_f, \hat{y}_s, \hat{y}_f$ , respectively.

#### 2.2 Network $(\mathcal{N})$

A channel may consist of multiple *network nodes*, each representing a group of sensors and/or actuators, see [23] for more information. In this paper, we consider that each node can only contain either slow (i.e.,  $y_s$ ,  $u_s$ ) or fast (i.e.,  $y_f$ ,  $u_f$ ) signals, but not both. Only one node can transmit data at any given transmission time, regulated by the channel scheduling protocol. This implies that slow signals are never transmitted simultaneously with fast signals. In particular, at each transmission time allocated to a slow (resp. fast) node, a group of elements in  $y_s$  (resp.  $y_f$ ) and  $u_s$  (resp.  $u_f$ ) accessible to that node is sampled and transmitted.

In this context, we define  $\mathcal{T} := \{t_1, t_2, t_3, \cdots\}$  as the set of all transmission instants. Let  $\mathcal{T}^s := \{t_1^s, t_2^s, t_3^s, \cdots\}$  be the subsequence of  $\mathcal{T}$  consisting of the instances that a slow node gains access to the network. We then define the set of instances that a fast node gets access to the network as  $\mathcal{T}^f := \mathcal{T} \setminus \mathcal{T}^s = \{t_1^f, t_2^f, t_3^f, \cdots\}$ . We impose that for any  $k \in \mathbb{Z}_{\geq 1}$ , the transmission times satisfy

$$\tau_{\text{miati}}^s \le t_{k+1}^s - t_k^s \le \tau_{\text{mati}}^s, \ \forall t_k^s, t_{k+1}^s \in \mathcal{T}^s, \tag{3a}$$

$$\tau_{\text{miati}}^{J} \le t_{k+1}^{J} - t_{k}^{J} \le \tau_{\text{mati}}^{J}, \ \forall t_{k}^{J}, t_{k+1}^{J} \in \mathcal{T}^{J}, \qquad (3b)$$

$$\tau_{\text{miati}}^{f} \le t_{k+1} - t_k, \qquad \forall t_k, t_{k+1} \in \mathcal{T}, \qquad (3c)$$

where  $0 < \tau_{\text{miati}}^{f} \leq \tau_{\text{mati}}^{f}$  denote, respectively, the MIATI and MATI between any two consecutive fast transmissions. Similarly,  $\tau_{\text{miati}}^{s}$  and  $\tau_{\text{mati}}^{s}$  are the MIATI and MATI between two consecutive slow updates. We note that since there might be a slow transmission between two consecutive fast transmissions,

$$\tau_{\rm miati}^f \le \frac{1}{2} \tau_{\rm mati}^f \tag{4}$$

must hold to satisfy (3b) and (3c), as in [7].

Let the network-induced errors be  $e_{y_s} \coloneqq \hat{y}_s - y_s, e_{y_f} \coloneqq \hat{y}_f - y_f, e_{u_s} \coloneqq \hat{u}_s - u_s$  and  $e_{u_f} \coloneqq \hat{u}_f - u_f$ . For simplicity,  $(\hat{y}_s, \hat{y}_f, \hat{u}_s, \hat{u}_f)$  are assumed to be constant between any two successive transmission times, i.e., zero-order hold devices are used. Before we present the behaviour of the system at transmission times, we introduce some useful notation regarding the variables:  $x \coloneqq (x_p, x_c) \in \mathbb{R}^{n_x}$ ,  $z \coloneqq (z_p, z_c) \in \mathbb{R}^{n_z}, e_s \coloneqq (e_{y_s}, e_{u_s}) \in \mathbb{R}^{n_{e_s}}$  and  $e_f \coloneqq (e_{y_f}, e_{u_f}) \in \mathbb{R}^{n_{e_f}}$ , with  $n_x \coloneqq n_{x_p} + n_{x_c}, n_z \coloneqq n_{z_p} + n_{z_c}, n_{e_s} \coloneqq n_{y_s} + n_{u_s}$  and  $n_{e_f} \coloneqq n_{y_f} + n_{u_f}$ .

At each transmission time  $t_k^s \in \mathcal{T}^s$  for slow updates, the values  $(\hat{y}_s, \hat{y}_f, \hat{u}_s, \hat{u}_f)$  are updated according to  $(\hat{y}_s(t_k^{s+}), \hat{u}_s(t_k^{s+})) = (y_s(t_k^s), u_s(t_k^s)) + h_s(k, e_s(t_k^s))$  and  $(\hat{y}_f(t_k^{s+}), \hat{u}_f(t_k^{s+})) = (\hat{y}_f(t_k^s), \hat{u}_f(t_k^s))$ , where the function  $h_s: \mathbb{Z}_{\geq 0} \times \mathbb{R}^{n_{e_s}} \to \mathbb{R}^{n_{e_s}}$  models the scheduling protocol [15] for the slow updates. Similarly, for each  $t_k^f \in \mathcal{T}^f$ , we have  $(\hat{y}_s(t_k^{f+}), \hat{u}_s(t_k^{f+})) = (\hat{y}_s(t_k^f), \hat{u}_s(t_k^f))$  and  $(\hat{y}_f(t_k^{f+}), \hat{u}_f(t_k^{f+})) = (y_f(t_k^f), u_f(t_k^f)) + h_f(k, e_f(t_k^f))$ , where the function  $h_f: \mathbb{Z}_{\geq 0} \times \mathbb{R}^{n_{e_f}} \to \mathbb{R}^{n_{e_f}}$  is the scheduling protocol for the update of fast components. If a SPNCS has  $\ell$  slow nodes, then  $e_s$  can be partitioned as  $e_s = [e_{s,1}^\top, e_{s,2}^\top \cdots e_{s,\ell}^\top]$ . If the slow scheduling protocol  $h_s$  grants the *i*th slow node access to the network at a transmission instance  $t_k^s \in \mathcal{T}^s$ , then  $e_{s,i}$  experiences a jump. For protocols such as round robin (RR) and try-one-discard (TOD) [15],  $e_{s,i}(t_k^{s+}) = 0$  and  $e_{s,j}(t_k^{s+}) = e_{s,j}(t_k^s)$  for all  $j \neq i$ , although this assumption is not generally necessary. The same rule applies to the fast nodes.

# 3 A hybrid model for the SPNCS

In this section, we present a hybrid system model for the SPNCS described in Section 2 in the formalism of [6], and it is more general than the hybrid SPSs in the literature such as [18] and [24], as its flow and jump sets depend on  $\epsilon$ . Firstly, we design a clock mechanism to satisfy (3a)-(3c), and then we present the model of the overall SPNCS.

#### 3.1 Clock Mechanism

We introduce two clocks and two counters, namely  $\tau_s, \tau_f \in \mathbb{R}_{\geq 0}$  and  $\kappa_s, \kappa_f \in \mathbb{Z}_{\geq 0}$ . In particular,  $\tau_s$  and

 $\epsilon \tau_f$  record the time elapsed since the last slow and fast transmission, respectively. Meanwhile,  $\kappa_s$  and  $\kappa_f$  count the number of slow and fast transmissions, respectively, and are useful for implementing some commonly used protocols, such as RR.

Let  $\xi := (x, e_s, \tau_s, \kappa_s, z, e_f, \tau_f, \kappa_f) \in \mathbb{X}$ , with  $\mathbb{X} := \mathbb{R}^{n_x} \times \mathbb{R}^{n_{e_s}} \times \mathbb{R}_{\geq 0} \times \mathbb{Z}_{\geq 0} \times \mathbb{R}^{n_z} \times \mathbb{R}^{n_{e_f}} \times \mathbb{R}_{\geq 0} \times \mathbb{Z}_{\geq 0}$ , denote the full state of the hybrid system. We define the jump sets  $\mathcal{D}_s^{\epsilon}$ ,  $\mathcal{D}_f^{\epsilon}$  and the flow set  $\mathcal{C}_1^{\epsilon}$  as  $\mathcal{D}_s^{\epsilon} := \{\xi \in \mathbb{X} \mid \tau_s \in [\tau_{\text{miati}}^s, \tau_{\text{mati}}^s] \wedge \epsilon \tau_f \in [\tau_{\text{miati}}^f, \tau_{\text{mati}}^f - \tau_{\text{miati}}^f]\}$ ,  $\mathcal{D}_f^{\epsilon} := \{\xi \in \mathbb{X} \mid \tau_s \in [\tau_{\text{miati}}^s, \tau_{\text{mati}}^s - \tau_{\text{miati}}^f] \wedge \epsilon \tau_f \in [\tau_{\text{miati}}^f, \tau_{\text{mati}}^f]\}$ , and  $\mathcal{C}_1^{\epsilon} := \mathcal{D}_s^{\epsilon} \cup \mathcal{D}_f^{\epsilon} \cup \mathcal{C}_{1,a}^{\epsilon} \cup \mathcal{C}_{1,b}^{\epsilon}$ , with  $\mathcal{C}_{1,a}^{\epsilon} := \{\xi \in \mathbb{X} \mid \tau_s \in [0, \tau_{\text{miati}}^f] \wedge \epsilon \tau_f \in [0, \tau_s + \tau_{\text{mati}}^f - \tau_{\text{miati}}^f]\}$  and  $\mathcal{C}_{1,b}^{\epsilon} := \{\xi \in \mathbb{X} \mid \tau_s \in [\tau_{\text{miati}}^f, \epsilon \tau_f + \tau_{\text{mati}}^s - \tau_{\text{miati}}^f] \wedge \epsilon \tau_f \in [0, \tau_{\text{miati}}^f]\}$ . A transmission of slow (resp. fast) signals is allowed in the set  $\mathcal{D}_s^{\epsilon}$  (resp.  $\mathcal{D}_f^{\epsilon}$ ), and at the transmission instance,  $\tau_s$  (resp.  $\tau_f$ ) is reset to zero. The sets  $\mathcal{C}_1^{\epsilon}, \mathcal{D}_s^{\epsilon}$  and  $\mathcal{D}_f^{\epsilon}$  are defined to ensure the satisfaction of (3), which can be deduced by visual inspection from Fig. 2. The jump sets  $\mathcal{D}_s^{\epsilon}$  and  $\mathcal{D}_f^{\epsilon}$  are indicated by the orange and green regions, respectively. Additionally,  $\mathcal{C}_{1,a}^{\epsilon}$  and  $\mathcal{C}_{1,b}^{\epsilon}$  are the regions where a jump is not allowed due to a recent transmission of slow and fast signals, respectively.

Fig. 2. Flow set and jump set

#### 3.2 Hybrid model

Let  $f_x, g_z, f_{e_s}$  and  $g_{e_f}$  be defined in (6) in the next page, where we use  $f_{x,\iota}$  and  $g_{z,\iota}, \iota \in \{1,2\}$ , to denote the  $\iota$ -th component of  $f_x$  and  $g_z$ , respectively. Then the SPNCS can now be expressed as the following hybrid model

$$\mathcal{H}_1: \begin{cases} \dot{\xi} = F(\xi, \epsilon), & \xi \in \mathcal{C}_1^{\epsilon}, \\ \xi^+ \in G(\xi), & \xi \in \mathcal{D}_s^{\epsilon} \cup \mathcal{D}_f^{\epsilon}, \end{cases}$$
(5)

where  $F(\xi, \epsilon) \coloneqq (f_x(x, z, e_s, e_f), f_{e_s}(x, z, e_s, e_f), 1, 0, \frac{1}{\epsilon}g_z(x, z, e_s, e_f), \frac{1}{\epsilon}g_{e_f}(x, z, e_s, e_f, \epsilon), \frac{1}{\epsilon}, 0)$ , and

$$G(\xi) \coloneqq \begin{cases} G_s(\xi), & \xi \in \mathcal{D}_s^{\epsilon} \setminus \mathcal{D}_f^{\epsilon}, \\ G_f(\xi), & \xi \in \mathcal{D}_f^{\epsilon} \setminus \mathcal{D}_s^{\epsilon}, \\ \{G_s(\xi), G_f(\xi)\}, & \xi \in \mathcal{D}_s^{\epsilon} \cap \mathcal{D}_f^{\epsilon}. \end{cases}$$

The jump maps are defined as  $G_s(\xi) \coloneqq (x, h_s(\kappa_s, e_s), 0, \kappa_s + 1, z, e_f, \tau_f, \kappa_f)$  and  $G_f(\xi) \coloneqq (x, e_s, \tau_s, \kappa_s, z, h_f(\kappa_f, e_f), 0, \kappa_f + 1)$ , where  $G_s$  and  $G_f$  corresponds to the transmission of slow and fast signals, respectively. The setvalued map in the definition of G is introduced to ensure that  $\mathcal{H}_1$  satisfies the hybrid basic conditions [6, Assumption 6.5], providing well-posedness of the system. This approach is commonly used when modeling the NCS as hybrid dynamical systems, see [2,22] for more details.

# 4 Auxiliary systems

We adopt a similar approach to the standard singularly perturbed method [10, Section 11.5] to establish stability properties for  $\mathcal{H}_1$ , but generalised to hybrid systems. Particularly, we first derive a system  $\mathcal{H}_1^y$  by changing the z-coordinate of  $\mathcal{H}_1$  to y-coordinate, where y is defined in (8), and determine its stability through a *boundary layer* and *reduced system*.

## 4.1 Change of coordinates

We first derive the *quasi-steady-state* of  $\mathcal{H}_1$ , under the following assumption.

**Standing Assumption 1 (SA1)** For any  $\overline{x} \in \mathbb{R}^{n_x}$ ,  $\overline{e}_s \in \mathbb{R}^{n_{e_s}}$  and  $\overline{z} \in \mathbb{R}^{n_z}$ , equation  $0 = g_z(\overline{x}, \overline{z}, \overline{e}_s, 0)$  has a unique real solution  $\overline{z} = \overline{H}(\overline{x}, \overline{e}_s)$ , where  $\overline{H}$  is continuously differentiable and  $0 = \overline{H}(0, 0)$ .

The quasi-steady-states  $\bar{z}$  and  $\bar{e}_f$ , referring to the equilibrium of the fast states as  $\epsilon$  approaches zero, are obtained as follows:  $\bar{e}_f$  is equal to zero, as for sufficiently high frequency of fast-output transmissions,  $e_f$  converges to zero; and  $\bar{z}$  corresponds to the unique solution  $\bar{z} = \overline{H}(\bar{x}, \bar{e}_s)$  as per SA1. We define the variable y as

$$y \coloneqq z - \overline{H}(x, e_s). \tag{8}$$

Then similar to the assumptions in the continuous-time SPSs literature such as [10,5], SA1 guarantees the map (8) to be stability preserving, which means the origin of the *x*-*z* coordinate is asymptotically stable if and only if the origin of the *x*-*y* system is asymptotically stable, see [10, Section 11.5] for more detail. Next, to derive  $\mathcal{H}_1^y$ , we define the full state of  $\mathcal{H}_1^y$ , namely

$$\xi^{y} \coloneqq (\xi_{s}, \xi_{f}) \coloneqq \big( (x, e_{s}, \tau_{s}, \kappa_{s}), (y, e_{f}, \tau_{f}, \kappa_{f}) \big), \quad (9)$$

where  $\xi^{y} \in \mathbb{X}, \, \xi_{s} \in \mathbb{X}^{s} := \mathbb{R}^{n_{x}} \times \mathbb{R}^{n_{e_{s}}} \times \mathbb{R}_{\geq 0} \times \mathbb{Z}_{\geq 0}$ and  $\xi_{f} \in \mathbb{X}^{f} := \mathbb{R}^{n_{z}} \times \mathbb{R}^{n_{e_{f}}} \times \mathbb{R}_{\geq 0} \times \mathbb{Z}_{\geq 0}$ . When a slow variable is transmitted at  $t_{k}^{s} \in \mathcal{T}^{s}, \, e_{s}$  updates according to  $h_{s}$ , then by the definition of y in (8), we know at each

$$\begin{aligned} f_x(x, z, e_s, e_f) &\coloneqq \left( f_p(x_p, z_p, (k_{c_s}(x_c) + e_{u_s}, k_{c_f}(x_c, z_c) + e_{u_f})), f_c(x_c, z_c, (k_{p_s}(x_p) + e_{y_s}, k_{p_f}(x_p, z_p) + e_{y_f})) \right) \\ g_z(x, z, e_s, e_f) &\coloneqq \left( g_p(x_p, z_p, (k_{c_s}(x_c) + e_{u_s}, k_{c_f}(x_c, z_c) + e_{u_f})), g_c(x_c, z_c, (k_{p_s}(x_p) + e_{y_s}, k_{p_f}(x_p, z_p) + e_{y_f})) \right) \\ f_{e_s}(x, z, e_s, e_f) &\coloneqq \left( -\frac{\partial k_{p_s}(x_p)}{\partial x_p} f_{x,1}(x, z, e_s, e_f), -\frac{\partial k_{c_s}(x_c)}{\partial x_c} f_{x,2}(x, z, e_s, e_f) \right) \\ g_{e_f}(x, z, e_s, e_f, \epsilon) &\coloneqq \left( -\epsilon \frac{\partial k_{p_f}(x_p, z_p)}{\partial x_p} f_{x,1}(x, z, e_s, e_f) - \frac{\partial k_{p_f}(x_p, z_p)}{\partial z_p} g_{z,1}(x, z, e_s, e_f), -\frac{\partial k_{c_f}(x_c, z_c)}{\partial z_c} g_{z,2}(x, z, e_s, e_f) \right) \\ F_s^y(x, y, e_s, e_f) &\coloneqq \left( f_x(x, y + \overline{H}(x, e_s), e_s, e_f), f_{e_s}(x, y + \overline{H}(x, e_s), e_s, e_f), f_{e_f}(x, y, e_s, e_f), f_{e_f}(x, y, e_s, e_f), f_{e_f}(x, y, e_s, e_f) \right) \\ F_f^y(x, y, e_s, e_f, \epsilon) &\coloneqq \left( g_z(x, y + \overline{H}(x, e_s), e_s, e_f) - \epsilon \frac{\partial \overline{H}}{\partial \xi_s} F_s^y(x, y, e_s, e_f), g_{e_f}(x, y + \overline{H}(x, e_s), e_s, e_f, \epsilon), 1, 0 \right) \end{aligned}$$

$$(7)$$

slow transmission, the value of y updates according to

$$y^{+} = z^{+} - \overline{H}(x^{+}, e_{s}^{+}) = z - \overline{H}(x, h_{s}(\kappa_{s}, e_{s}))$$
  
$$= y + \overline{H}(x, e_{s}) - \overline{H}(x, h_{s}(\kappa_{s}, e_{s}))$$
  
$$=: h_{y}(\kappa_{s}, x, e_{s}, y).$$
 (10)

Then,  $\mathcal{H}_1^y$  is given by

$$\mathcal{H}_{1}^{y}: \begin{cases} \dot{\xi}^{y} = F^{y}(\xi^{y}, \epsilon), \ \xi^{y} \in \mathcal{C}_{2}^{y, \epsilon}, \\ \xi^{y+} \in G^{y}(\xi^{y}), \ \xi^{y} \in \mathcal{D}_{s}^{y, \epsilon} \cup \mathcal{D}_{f}^{y, \epsilon}, \end{cases}$$
(11)

where  $F^{y}(\xi^{y}, \epsilon) = \left(F_{s}^{y}(x, y, e_{s}, e_{f}), \frac{1}{\epsilon}F_{f}^{y}(x, y, e_{s}, e_{f}, \epsilon)\right)$ , with  $F_{s}^{y}$  and  $F_{f}^{y}$  from (7). The jump map  $G^{y}$  is given by

$$G^{y}(\xi^{y}) \coloneqq \begin{cases} G^{y}_{s}(\xi^{y}), \ \xi^{y} \in \mathcal{D}^{y,\epsilon}_{s} \setminus \mathcal{D}^{y,\epsilon}_{f}, \\ G^{y}_{f}(\xi^{y}), \ \xi^{y} \in \mathcal{D}^{y,\epsilon}_{f} \setminus \mathcal{D}^{y,\epsilon}_{s}, \\ \{G^{y}_{s}(\xi^{y}), G^{y}_{f}(\xi^{y})\}, \ \xi^{y} \in \mathcal{D}^{y,\epsilon}_{s} \cap \mathcal{D}^{y,\epsilon}_{f}, \end{cases}$$
(12)

with  $G_s^y(\xi_y) \coloneqq (x, h_s(\kappa_s, e_s), 0, \kappa_s + 1, h_y(\kappa_s, x, e_s, y), e_f, \tau_f, \kappa_f); G_f^y(\xi_y) \coloneqq (x, e_s, \tau_s, \kappa_s, y, h_f(\kappa_f, e_f), 0, \kappa_f + 1).$ 

For analysis purposes, we write  $\tau_{\text{mati}}^f = \epsilon T^*$  with  $T^* \in \mathbb{R}_{>0}$  independent of  $\epsilon$ . We also write  $\tau_{\text{miati}}^f = a \tau_{\text{mati}}^f$  for some  $a \in (0, \frac{1}{2}]$ , which satisfies the inequality (4). Since  $\epsilon > 0$ ,  $\epsilon \tau_f \in [\tau_{\text{miati}}^f, \tau_{\text{mati}}^f]$  is equivalent to  $\tau_f \in [aT^*, T^*]$ . Then the jump and flow sets in (11) are defined by  $\mathcal{D}_s^{y,\epsilon} := \{\xi^y \in \mathbb{X} \mid \tau_s \in [\tau_{\text{miati}}^s, \tau_{\text{mati}}^s] \wedge \tau_f \in [aT^*, (1-a)T^*]\}, \mathcal{D}_f^{y,\epsilon} := \{\xi^y \in \mathbb{X} \mid \tau_s \in [\epsilon a T^*, \tau_{\text{mati}}^s] \wedge \tau_f \in [aT^*, (1-a)T^*]\}$  and  $\mathcal{C}_1^{y,\epsilon} := \mathcal{D}_s^{y,\epsilon} \cup \mathcal{D}_f^{y,\epsilon} \cup \mathcal{C}_{1,a}^{y,\epsilon} \cup \mathcal{C}_{1,b}^{y,\epsilon}$ , with  $\mathcal{C}_{1,a}^{y,\epsilon} := \{\xi^y \in \mathbb{X} \mid \tau_s \in [0, \epsilon a T^*] \wedge \epsilon \tau_f \in [0, \tau_s + \epsilon T^* - \epsilon a T^*]\}$  and  $\mathcal{C}_{1,b}^{y,\epsilon} := \{\xi^y \in \mathbb{X} \mid \tau_s \in [\epsilon a T^*, \epsilon \tau_f + \tau_{\text{mati}}^s - \epsilon a T^*] \wedge \epsilon \tau_f \in [0, \epsilon a T^*]\}.$ 

We have changed the coordinate from z to y, and we are now ready to derive the reduced system  $\mathcal{H}_r$  and boundary layer system  $\mathcal{H}_{bl}$  associated with  $\mathcal{H}_1^y$ .

# 4.2 Boundary layer system and reduced system of $\mathcal{H}_1$

We define the fast time scale  $\sigma \coloneqq \frac{t-t_0}{\epsilon}$ , where we can assume  $t_0 = 0$  as the system is time invariant. Then we

have  $\frac{\partial}{\partial \sigma} = \epsilon \frac{\partial}{\partial t}$ . We set  $\epsilon = 0$  for system (11), then  $C_1^{y,0}$ , which corresponds to  $C_1^{y,\epsilon}$  with  $\epsilon = 0$ , is given by  $C_1^{y,0} := \{\xi^y \in \mathbb{X} \mid \tau_s \in [0, \tau_{\text{mati}}^s] \land \tau_f \in [0, T^*]\}$ , and  $\mathcal{D}_s^{y,0}, \mathcal{D}_f^{y,0}$  are derived accordingly. In the perspective of fast dynamics, the slow dynamics are now frozen. Meanwhile, the jump and flow sets of  $\mathcal{H}_{bl}$  contain the condition  $\tau_s \in [0, \tau_{\text{mati}}^s]$ , which is always satisfied. Therefore, the jumps and flows of  $\mathcal{H}_{bl}$  are only determined by  $\tau_f$ . We thus write

$$\mathcal{H}_{bl}: \begin{cases} \left(\frac{\partial \xi_s}{\partial \sigma}, \frac{\partial \xi_f}{\partial \sigma}\right) = (\mathbf{0}_{n_{\xi_s} \times 1}, F_f^y(x, y, e_s, e_f, 0)), \xi^y \in \mathcal{C}_{1,bl}^{y,0}, \\ \xi^{y+} = G_f^y(\xi^y), \qquad \xi^y \in \mathcal{D}_f^{y,0} \end{cases}$$
(13)  
where  $\mathcal{C}_{2,bl}^{y,0} \coloneqq \{\xi^y \in \mathbb{X} \mid \tau_f \in [0, T^*]\} \text{ and } \mathcal{D}_f^{y,0} \coloneqq \{\xi^y \in \mathbb{X} \mid \tau_f \in [aT^*, T^*]\}.$ 

From the perspective of  $\mathcal{H}_r$  (i.e., slow dynamics), the fast dynamics evolve infinitely fast. Therefore, for any  $\tau_s \in [0, \tau_{\text{mati}}^s]$ , the waiting time for the condition  $\tau_f \in [aT^*, T^*]$  in the jump set to be satisfied approaches to zero, and the flows and jumps of  $\mathcal{H}_r$  are essentially determined only by  $\tau_s$ . Moreover, we have y = 0 and  $e_f = 0$ in  $\mathcal{H}_r$ , that is

$$\mathcal{H}_{r}: \begin{cases} \dot{\xi}_{s} = F_{s}^{y}(x, 0, e_{s}, 0), & \xi^{y} \in \mathcal{C}_{1, r}^{y, 0}, \\ \xi_{s}^{+} = (x, h_{s}(\kappa_{s}, e_{s}), 0, \kappa_{s} + 1), \ \xi^{y} \in \mathcal{D}_{s}^{y, 0}, \end{cases}$$
(14)

where  $\mathcal{C}_{1,r}^{y,0} \coloneqq \{\xi^y \in \mathbb{X} \mid \tau_s \in [0, \tau_{\text{mati}}^s]\}$  and  $\mathcal{D}_s^{y,0} \coloneqq \{\xi^y \in \mathbb{X} \mid \tau_s \in [\tau_{\text{miati}}^s, \tau_{\text{mati}}^s]\}.$ 

#### 5 Emulation design framework

This section presents the main results that provide the framework for emulation design. The first step is to design a controller that making the reduced system and boundary-layer system robust with respect to network induced error by satisfying (18) and (23) in Assumptions 1 and 2, respectively. Next, we select UGAS protocols for slow and fast transmissions and verify the growth conditions on error dynamics, i.e., (17) and (21) in Assumptions 1 and 2. Then, by checking interconnection condition during flow (Assumption 4) and at slow transmissions (Assumption 5), as well as a mild assumption, we guarantee semi-global practical asymptotic stability

given  $\tau_{\text{mati}}^s$ ,  $\tau_{\text{mati}}^f$  and  $\epsilon$  are sufficiently small. Finally, we present additional conditions that guarantee UGAS and UGES of  $\mathcal{H}_1$  in section 5.2.

#### 5.1 Semi-global practical asymptotic stability

Assumptions 1 and 2 below provide sufficient conditions to guarantee asymptotic stability properties for  $\mathcal{H}_r$  and  $\mathcal{H}_{bl}$ , respectively, which align with those commonly encountered in the NCS literature, see [3,8].

**Assumption 1** There exist a function  $W_s : \mathbb{Z}_{\geq 0} \times \mathbb{R}^{n_{e_s}} \to \mathbb{R}_{\geq 0}$  that is locally Lipschitz in its second argument uniformly in its first argument, a continuous function  $H_s : \mathbb{R}^{n_x} \times \mathbb{R}^{n_{e_s}} \to \mathbb{R}_{\geq 0}, \mathcal{K}_{\infty}$ -functions  $\underline{\alpha}_{W_s}, \overline{\alpha}_{W_s},$  constants  $\lambda_s \in [0, 1)$  and  $L_s \geq 0$  such that, for all  $\kappa_s \in \mathbb{Z}_{\geq 0}$  and  $e_s \in \mathbb{R}^{n_{e_s}}$ , the following properties hold:

$$\underline{\alpha}_{W_s}\left(|e_s|\right) \le W_s(k_s, e_s) \le \overline{\alpha}_{W_s}\left(|e_s|\right), \qquad (15)$$

$$W_s(\kappa_s + 1, h_s(\kappa_s, e_s)) \le \lambda_s W_s(\kappa_s, e_s).$$
(16)

For all  $x \in \mathbb{R}^{n_x}, \kappa_s \in \mathbb{Z}_{\geq 0}$  and almost all  $e_s \in \mathbb{R}^{n_{e_s}}$ ,

$$\left\langle \frac{\partial W_s(\kappa_s, e_s)}{\partial e_s}, f_{e_s}(x, \overline{H}(x, e_s), e_s, 0) \right\rangle \leq L_s W_s(\kappa_s, e_s) + H_s(x, e_s).$$
(17)

Moreover, there exist a locally Lipschitz, positive definite and radially unbounded function  $V_s : \mathbb{R}^{n_x} \to \mathbb{R}_{\geq 0}$ , positive definite function  $\rho_s$ , and real number  $\gamma_s > 0$ , such that for all  $e_s \in \mathbb{R}^{n_{e_s}}$ , all  $\kappa_s \in \mathbb{Z}_{\geq 0}$ , and almost all  $x \in \mathbb{R}^{n_x}$ , the following inequality holds

$$\left\langle \frac{\partial V_s(x)}{\partial x}, f_x(x, \overline{H}(x, e_s), e_s, 0) \right\rangle \le -\rho_s(|x|) -\rho_s\left(W_s(\kappa_s, e_s)\right) - H_s^2(x, e_s) + \gamma_s^2 W_s^2(\kappa_s, e_s).$$
(18)

**Assumption 2** There exist a function  $W_f : \mathbb{Z}_{\geq 0} \times \mathbb{R}^{n_{e_f}} \to \mathbb{R}_{\geq 0}$  that is locally Lipschitz in its second argument uniformly in its first argument, a continuous function  $H_f : \mathbb{R}^{n_x} \times \mathbb{R}^{n_{e_f}} \to \mathbb{R}_{\geq 0}, \mathcal{K}_{\infty}$ -functions  $\underline{\alpha}_{W_f}, \overline{\alpha}_{W_f},$  constants  $\lambda_f \in [0, 1)$  and  $L_f \geq 0$  such that, for all  $\kappa_f \in \mathbb{Z}_{\geq 0}$  and  $e_f \in \mathbb{R}^{n_{e_f}}$ , the following properties hold:

$$\underline{\alpha}_{W_f}\left(|e_f|\right) \le W_f(k_f, e_f) \le \overline{\alpha}_{W_f}\left(|e_f|\right),\tag{19}$$

$$W_f(\kappa_f + 1, h_f(\kappa_f, e_f)) \le \lambda_f W_f(\kappa_f, e_f).$$
(20)

For all  $x \in \mathbb{R}^{n_x}$ ,  $\kappa_f \in \mathbb{Z}_{\geq 0}$  and almost all  $e_f \in \mathbb{R}^{n_{e_f}}$ ,

$$\left\langle \frac{\partial W_f(\kappa_f, e_f)}{\partial e_f}, g_{e_f}(x, y + \overline{H}(x, e_s), e_s, e_f, 0) \right\rangle \\ \leq L_f W_f(\kappa_f, e_f) + H_f(y, e_f).$$
(21)

Moreover, there exist a locally Lipschitz function  $V_f$ :  $\mathbb{R}^{n_x} \times \mathbb{R}^{n_z} \to \mathbb{R}_{\geq 0}, \mathcal{K}_{\infty}$ -functions  $\underline{\alpha}_{V_f}, \overline{\alpha}_{V_f}$ , such that for all  $x \in \mathbb{R}^{n_x}$  and  $y \in \mathbb{R}^{n_z}$ , the following inequality holds.

$$\underline{\alpha}_{V_f}(|y|) \le V_f(x, y) \le \overline{\alpha}_{V_f}(|y|).$$
(22)

At the same time, there exist positive definite function  $\rho_f$ , and real number  $\gamma_f > 0$  such that for all  $e_s \in \mathbb{R}^{n_{e_s}}$ ,  $e_f \in \mathbb{R}^{n_{e_f}}$ , all  $\kappa_f \in \mathbb{Z}_{\geq 0}$ , all  $x \in \mathbb{R}^{n_x}$ , and almost all  $y \in \mathbb{R}^{n_z}$ , the following inequality holds.

$$\left\langle \frac{\partial V_f(x,y)}{\partial y}, g_z(x,y + \overline{H}(x,e_s), e_s, e_f) \right\rangle \le -\rho_f(|y|) -\rho_f(W_f(\kappa_f, e_f)) - H_f^2(y,e_f) + \gamma_f^2 W_f^2(\kappa_f, e_f).$$
(23)

In Assumption 1 (similarly with Assumption 2), conditions (15) and (16) relate to UGAS protocols and are satisfied by sampled-data systems and NCSs with RR, TOD, etc; for more details, see [15]. Inequality (17) bounds the growth of  $e_s$  during flow, and (18) relates to the  $\mathcal{L}_2$ -stability of  $\mathcal{H}_r$  from  $W_s$  to  $H_s$ , which is typically ensured at the first stage of emulation. According to [3], Assumption 1 implies there exists a  $\tau_{\text{mati}}^{s,*} > 0$  such that for all  $0 < \tau_{\text{mati}}^s \leq \tau_{\text{mati}}^{s,*}$ , the set  $\{\xi^y \in \mathbb{X} | x = 0 \land e_s = 0\}$ is UGAS for  $\mathcal{H}_r$ . See [15] for more details on finding Lyapunov functions to satisfy Assumptions 1 and 2. We next provide a lemma as a preliminary to the main result.

Recalling that  $\xi^s = (x, e_s, \tau_s, \kappa_s)$  and  $\xi^f = (y, e_f, \tau_f, \kappa_f)$ , we define Lyapunov functions  $U_s : \mathbb{X}^s \to \mathbb{R}_{\geq 0}$  and  $U_f : \mathbb{X}^s \times \mathbb{X}^f \to \mathbb{R}_{>0}$  as [3, Eqn. (25)]

$$U_s(\xi_s) = V_s(x) + \gamma_s \phi_s(\tau_s) W_s^2(\kappa_s, e_s), \qquad (24a)$$

$$U_f(\xi_s, \xi_f) = V_f(x, y) + \gamma_f \phi_f(\tau_f) W_f^2(\kappa_f, e_f), \quad (24b)$$

where  $\dot{\phi}_{\star} = -2L_{\star}\phi_{\star} - \gamma_{\star}(\phi_{\star}^2 + 1), \phi_{\star}(0) = 1/\lambda_{\star}^*, \lambda_{\star}^* \in (\lambda_{\star}, 1), \star \in \{s, f\}$ . Note that by abuse of notation, we write  $\dot{\phi}_s = \frac{d\phi_s}{d\tau_s}, \dot{\phi}_f = \frac{d\phi_f}{d\tau_f}$  and  $U_f(\xi^y) = U_f(\xi_s, \xi_f)$ .

We define the nonlinear mapping  $T : \mathbb{R}_{\geq 0} \times (0, 1) \times \mathbb{R}_{>0} \to \mathbb{R}$  for the upcoming lemma. For any L > 0,  $\lambda \in (0, 1)$  and  $\gamma > 0$ ,

$$T(L,\gamma,\lambda) := \begin{cases} \frac{1}{Lr} \tan^{-1} \left( \frac{r(1-\lambda)}{2\frac{\lambda}{1+\lambda} \left( \frac{\gamma}{L} - 1 \right) + 1 + \lambda} \right), & \gamma > L\\ \frac{1}{L} \frac{1-\lambda}{1+\lambda}, & \gamma = L\\ \frac{1}{Lr} \tanh^{-1} \left( \frac{r(1-\lambda)}{2\frac{\lambda}{1+\lambda} \left( \frac{\gamma}{L} - 1 \right) + 1 + \lambda} \right), & \gamma < L, \end{cases}$$

where  $r \coloneqq \sqrt{\left| \left(\frac{\gamma}{L}\right)^2 - 1 \right|}$ . For L = 0 and any  $\lambda \in (0, 1)$  and  $\gamma > 0$ , this nonlinear mapping becomes

$$T(0,\gamma,\lambda) = \frac{1}{\gamma} \left( \tan^{-1}(\frac{1}{\lambda}) - \tan^{-1}(\lambda) \right).$$

**Lemma 3** Suppose Assumptions 1 and 2 hold. Let  $(L_s, \gamma_s, \lambda_s)$  and  $(L_f, \gamma_f, \lambda_f)$  come from Assumption 1

and 2, respectively, and  $U_s$  and  $U_f$  come from (24) with some  $\lambda_s^* \in (\lambda_s, 1)$  and  $\lambda_f^* \in (\lambda_f, 1)$ . For all  $\tau_{mati}^s \leq T(L_s, \gamma_s, \lambda_s^*)$  and  $T^* \leq T(L_f, \gamma_f, \lambda_f^*)$ , there exist  $\mathcal{K}_{\infty}$ -functions  $\underline{\alpha}_{U_s}, \overline{\alpha}_{U_s}, \underline{\alpha}_{U_f}, \overline{\alpha}_{U_f}$ , continuous positive definite functions  $\psi_s, \psi_f$  and positive constants  $a_s, a_f$  such that (25a) holds for all  $\xi_s \in C_{2,r}^{y,0} \cup \mathcal{D}_s^{y,0}$ , (25b) holds for all  $\xi_s \in C_{2,r}^{y,0}$ , (25c) holds for all  $\xi_s \in \mathcal{D}_s^{y,0}$ , (26a) holds for all  $\xi_f \in C_{2,bl}^{y,0} \cup \mathcal{D}_f^{y,0}$ , (26b) holds for all  $\xi_f \in C_{2,bl}^{y,0}$  and (26c) holds for all  $\xi_f \in \mathcal{D}_f^{y,0}$ ,

$$\underline{\alpha}_{U_s}\left(|(x, e_s)|\right) \le U_s(\xi_s) \le \overline{\alpha}_{U_s}\left(|(x, e_s)|\right), \qquad (25a)$$

$$U_s^{\circ}(\xi_s; F_s^y(x, 0, e_s, 0)) \le -a_s \psi_s^2(|(x, e_s)|),$$
 (25b)

$$U_s((x, h_s(\kappa_s, e_s), 0, \kappa_s + 1)) \le U_s(\xi_s), \qquad (25c)$$

$$\underline{\alpha}_{U_f}\left(|(y, e_f)|\right) \le U_f(\xi_s, \xi_f) \le \overline{\alpha}_{U_f}\left(|(y, e_f)|\right), \quad (26a)$$
$$U_f^{\circ}\left((\xi_s, \xi_f); (\mathbf{0}_{n_{\xi_s \times 1}}, F_f^y(x, y, e_s, e_f, 0))\right) \quad (261)$$

$$\xi_{s}, \xi_{f}); (\mathbf{0}_{n_{\xi_{s}\times 1}}, F_{f}^{g}(x, y, e_{s}, e_{f}, 0))) \\ \leq -a_{f}\psi_{f}^{2}\left(|(y, e_{f})|\right),$$
 (26b)

$$U_f(G_f^y(\xi^y)) \le U_f(\xi_s, \xi_f).$$
(26c)

**Proof:** The proof of Lemma 3 follows similarly to [16, Theorem 1] and is therefore omitted.

Lemma 3 asserts that, under Assumptions 1 and 2, we can establish upper bounds on  $\tau_{\text{mati}}^s$  and  $T^*$  in a manner such that, when both bounds are met, we can construct Lyapunov functions  $U_s$  and  $U_f$  that guarantee stability properties for  $\mathcal{H}_r$  and  $\mathcal{H}_{bl}$ , respectively. These Lyapunov functions will play a crucial role in the proof of our main result (namely Theorem 7 below), since we will conclude stability property of  $\mathcal{H}_1^y$  by considering  $\mathcal{H}_r$ ,  $\mathcal{H}_{bl}$ , and their interconnection induced by nonzero  $\epsilon$ .

Assumption 4 specifies the *interconnection condition* between the slow and fast dynamics during flow, analogous to the continuous-time case as described in [10, pp. 451].

**Assumption 4** Given a set  $\widetilde{C} \in \mathbb{X}$ , for any  $\Delta_1$ ,  $\nu_1 > 0$ , there exist  $b_1$ ,  $b_2$ ,  $b_3 \ge 0$ , such that  $|\xi^y|_{\mathcal{E}^y} \le \Delta_1$  implies

$$\begin{split} \left\langle \frac{\partial U_s}{\partial \xi_s}, F_s^y(x, y, e_s, e_f) - F_s^y(x, 0, e_s, 0) \right\rangle \leq \\ & b_1 \psi_s \left( |(x, e_s)| \right) \psi_f \left( |(y, e_f)| \right) + \nu_1, \\ \left\langle \frac{\partial U_f}{\partial \xi_s} - \frac{\partial U_f}{\partial y} \frac{\partial \overline{H}}{\partial \xi_s} - \frac{\partial U_f}{\partial e_f} \frac{\partial \tilde{k}}{\partial \xi_s}, F_s^y(x, y, e_s, e_f) \right\rangle \leq \\ & b_2 \psi_s \left( |(x, e_s)| \right) \psi_f \left( |(y, e_f)| \right) + b_3 \psi_f^2 \left( |(y, e_f)| \right) + \nu_1 \end{split}$$

hold for almost all  $\xi^y \in \widetilde{\mathcal{C}}$ , where  $\tilde{k}(x, z) = (k_{pf}(x_p, z_p), k_{cf}(x_c, z_c))$ .

At each slow transmission, there is a potential increase in  $V_f$  due to (10), we bound this jump of  $V_f$  using the following assumption, which is adapted from [1, Assumption 5]. **Assumption 5** There exist  $\lambda_1, \lambda_2 \geq 0$  such that for all  $\xi^y \in \mathbb{X}$ , we have  $V_f(x, h_y(x, e_s, y)) \leq V_f(x, y) + \lambda_1 W_s^2(\kappa_s, e_s) + \lambda_2 \sqrt{W_s^2(\kappa_s, e_s)V_f(x, y)}$ .

Finally, we introduce the next assumption, which is required to guarantee the exponential decay of the composite Lyapunov function U defined in (A.5) during flow, and naturally holds for linear-time-invariant (LTI) SP-NCSs as we will see in section 7.

Assumption 6 Let  $\psi_s$  and  $\psi_f$  come from Assumption 4. There exist  $a_{\psi_s}$ ,  $a_{\psi_f} > 0$  such that  $\psi_s(|(x, e_s)|) \leq a_{\psi_s} \sqrt{U_s(\xi_s)}$  and  $\psi_f(|(y, e_f)|) \leq a_{\psi_f} \sqrt{U_f(\xi_s, \xi_f)}$ .

We note that  $\xi_s$  and  $\xi_f$  are defined in (9), and contain  $(x, e_s)$  and  $(y, e_f)$ , respectively. Assumption 6 naturally holds in LTI systems with UGES protocols [15].

By introducing the attractor  $\mathcal{E} := \{\xi \in \mathbb{X} \mid x = 0 \land e_s = 0 \land z = 0 \land e_f = 0\}$ , we can now state our main results, whose proofs are postponed to the appendix.

**Theorem 7** Consider system  $\mathcal{H}_1$  in (5) and suppose Assumptions 1, 2, 5 and 6 hold, and Assumption 4 holds with  $\widetilde{\mathcal{C}} = \mathcal{C}_2^{y,\epsilon}$ . Let  $L_s$  and  $\gamma_s$  come from Assumption 1,  $L_f$  and  $\gamma_f$  come from Assumption 2, and  $\lambda_s^*$  and  $\lambda_f^*$  come from Lemma 3. Then for any  $\tau_{miati}^s \leq \tau_{mati}^s \leq T(L_s, \gamma_s, \lambda_s^*)$  and  $2\tau_{miati}^f \leq \tau_{mati}^f \leq \epsilon T(L_f, \gamma_f, \lambda_f^*)$ , the following statement holds:

There exists a  $\mathcal{KL}$ -function  $\beta$ , such that for all  $\Delta, \nu > 0$ , there exists an  $\epsilon^* > 0$  such that for all  $0 < \epsilon < \epsilon^*$ , any solution  $\xi$  with  $|\xi(0,0)|_{\mathcal{E}} < \Delta$  satisfies  $|\xi(t,j)|_{\mathcal{E}} \leq \beta(|\xi(0,0)|_{\mathcal{E}}, t+j) + \nu$  for any  $(t,j) \in dom \xi$ .

Theorem 7 establishes that for any bounded initial condition and ultimate bound, if the condition in Theorem 7 is satisfied, and  $\tau_{mati}^s$ ,  $\tau_{mati}^f$  and  $\epsilon$  are sufficiently small, then the trajectory of system (5) asymptotically approach the ultimate bound. In the proof of Theorem 7, it is observed that  $\epsilon^*$  approaches zero when  $\tau_{miati}^s$  decreases. This is because the Lyapunov function needs to decrease during flow for some time to compensate the potential increase at slow transmissions. From the perspective of the fast time scale, the transmission interval of slow signals is lower bounded by  $\tau_{miati}^s/\epsilon$ . Thus, a smaller  $\epsilon$  is required for smaller  $\tau_{miati}^s$  to ensure sufficient flow between any two consecutive slow transmissions.

# 5.2 Uniform global asymptotic/exponential stability

Next we are going to present global results such as UGAS and UGES. In order to obtain global stability, we need global assumptions. Therefore, we state a global version of Assumption 4, which is Assumption 8 below. **Assumption 8** There exist  $b_1$ ,  $b_2$ ,  $b_3 \ge 0$ , such that

$$\left\langle \frac{\partial U_s}{\partial \xi_s}, F_s^y(x, y, e_s, e_f) - F_s^y(x, 0, e_s, 0) \right\rangle \leq$$

$$b_1 \psi_s \left( |(x, e_s)| \right) \psi_f \left( |(y, e_f)| \right),$$

$$\left\langle \frac{\partial U_f}{\partial \xi_s} - \frac{\partial U_f}{\partial y} \frac{\partial \overline{H}}{\partial \xi_s} - \frac{\partial U_f}{\partial e_f} \frac{\partial \tilde{k}}{\partial \xi_s}, F_s^y(x, y, e_s, e_f) \right\rangle \leq$$

$$b_2 \psi_s \left( |(x, e_s)| \right) \psi_f \left( |(y, e_f)| \right) + b_3 \psi_f^2 \left( |(y, e_f)| \right)$$

$$(27a)$$

$$(27b)$$

hold for almost all  $\xi^y \in \mathcal{C}_2^{y,\epsilon}$ , where  $\tilde{k}(x,z) = (k_{pf}(x_p, z_p), k_{cf}(x_c, z_c)).$ 

**Corollary 9** Considering system  $\mathcal{H}_1$  in (5) and suppose Assumptions 1, 2, 5, 6 and 8 hold. Let  $L_s$  and  $\gamma_s$  come from Assumption 1, and  $L_f$  and  $\gamma_f$  come from Assumption 2. Let  $b_1$ ,  $b_2$ , and  $b_3$  come from Assumption 8 and  $a_s$ ,  $a_f$ ,  $\lambda_s^*$  and  $\lambda_f^*$  come from Lemma 3. Then for any  $\tau_{miati}^s \leq \tau_{mati}^s \leq T(L_s, \gamma_s, \lambda_s^*)$  and  $2\tau_{miati}^f \leq \tau_{mati}^f \leq \epsilon T(L_f, \gamma_f, \lambda_f^*)$ , there exists  $\epsilon^* > 0$  and  $\beta \in \mathcal{KL}$ , such that for all  $0 < \epsilon < \epsilon^*$  and  $|\xi(0,0)|_{\mathcal{E}} \in \mathbb{R}$ , we have  $|\xi(t, j)|_{\mathcal{E}} \leq \beta(|\xi(0,0)|_{\mathcal{E}}, t+j)$  for any  $(t, j) \in dom\xi$ .

Corollary 9 is proved similarly to Theorem 7 by setting  $\Delta$  and  $\nu$  to infinity and zero, respectively, so its proof is omitted. We can also state UGES of  $\mathcal{H}_1$  if  $\mathcal{H}_{bl}$  and  $\mathcal{H}_r$  are UGES, and if  $h_s$  and  $h_f$  are UGES protocols. The following assumption guarantees these conditions when combined with Assumptions 1 and 2.

**Assumption 10** Let  $W_s, W_f, V_s, V_f, \rho_s$  and  $\rho_f$  come from Assumptions 1 and 2. There exist positive real numbers  $\underline{a}_{W_s}, \overline{a}_{W_s}, \underline{a}_{V_s}, \overline{a}_{V_s}, \underline{a}_{W_f}, \overline{a}_{W_f}, \underline{a}_{V_f}, \overline{a}_{V_f}, a_{\rho_s}$ and  $a_{\rho_f}$  such that

$$\underline{a}_{W_s}|e_s| \le W_s(\kappa_s, e_s) \le \overline{a}_{W_s}|e_s|, \qquad (28a)$$

$$\underline{a}_{W_f}|e_f| \le W_f(\kappa_f, e_f) \le \overline{a}_{W_f}|e_f|, \qquad (28b)$$

$$\underline{a}_{V_s}|x|^2 \le V_s(x) \le \overline{a}_{V_s}|x|^2, \tag{28c}$$

$$\underline{a}_{V_f}|y|^2 \le V_f(x,y) \le \overline{a}_{V_f}|y|^2, \tag{28d}$$

and

$$a_{\rho_s}s^2 \le \rho_s(s), \tag{29a}$$

$$a_{\rho_f} s^2 \le \rho_f(s) \tag{29b}$$

for all  $s \in \mathbb{R}$ . Additionally,  $\overline{H}$  is globally Lipschitz in both arguments.

We note that Assumption 10 implies Assumption 6 holds, this can be see in the proof of Theorem 11. Additionally, (28a) and (16) imply  $W_s$  is an UGES protocol, and the similar statement holds for  $W_f$ .

**Theorem 11** Consider system  $\mathcal{H}_1$  in (5) and suppose Assumptions 1, 2, 5, 8 and 10 hold. Let  $L_s$  and  $\gamma_s$  come from Assumption 1, and  $L_f$  and  $\gamma_f$  come from Assumption 2. Let  $\lambda_s^*$  and  $\lambda_f^*$  come from

Lemma 3. Then for any  $\tau_{miati}^s \leq \tau_{mati}^s \leq T(L_s, \gamma_s, \lambda_s^*)$ and  $2\tau_{miati}^f \leq \tau_{mati}^f \leq \epsilon T(L_f, \gamma_f, \lambda_f^*)$ , there exist  $\epsilon^*, c_1, c_2 > 0$  such that for all  $0 < \epsilon < \epsilon^*$ , the solution  $\xi$ satisfies  $|\xi(t, j)|_{\mathcal{E}} \leq c_1 |\xi(0, 0)|_{\mathcal{E}} exp(-c_2(t + j))$  for any  $(t, j) \in dom \xi$ .

**Remark 12** We state only global assumptions and results (i.e., UGAS and UGES) to simplify the presentation. However, for local results, all assumptions can be rephrased. For example, the requirement for a unique real solution in SA1 can be relaxed to isolated real solutions, and the interconnection condition in Assumption 8 needs to hold only on a compact set of  $\xi$  containing the set  $\mathcal{E}$ .

#### 6 Further stability results

In this section, we consider the scenario when the plant  $\mathcal{P}$  has a stable fast subsystem (i.e., boundary layer system) and the controller is designed to stabilise the slow subsystem. Due to the stable fast subsystem, the plant only needs to transmit  $y_s$  and the controller only generates  $u_s$ . The plant and controller below are in the form of (1) and (2), where  $k_{pf}$  and  $k_{cf}$  are removed, that is,  $y_p = y_s = k_{p_s}(x_p)$  and  $u = u_s = k_{c_s}(x_c)$ . Given the exclusive presence of slow transmissions within the communication channel, a simpler version of clock mechanism (3) is used to govern the system dynamics, that is  $\tau_{\text{miati}}^s \leq t_{k+1}^s - t_k^s \leq \tau_{\text{mati}}^s$  for all  $t_k^s, t_{k+1}^s \in \mathcal{T}^s$  and  $k \in \mathbb{Z}_{\geq 1}$ . Moreover, the networked induced error becomes  $\overline{e}_s = (\hat{y}_s - y_s, \hat{u}_s - u_s)$ , and  $e_f$  no longer exist. We define the state  $\xi_2 \coloneqq (x, e_s, \tau_s, \kappa_s, z) \in \mathbb{X}_2$ , with  $\mathbb{X}_2 \coloneqq \mathbb{R}^{n_x} \times \mathbb{R}^{n_{e_s}} \times \mathbb{R}_{\geq 0} \times \mathbb{Z}_{\geq 0} \times \mathbb{R}^{n_z}$ , and we define our system by the hybrid model  $\overline{\mathcal{H}}_2$ , and we omit its expression here.

We again define y as in (8). Let  $\xi_2^y := (x, e_s, \tau_s, \kappa_s, y) \in \mathbb{X}_2$ , then we can define  $\mathcal{H}_2^y$ , which is  $\mathcal{H}_2$  after changing the coordinates. Since  $\mathcal{H}_2$  is a special case of  $\mathcal{H}_1$ , the functions we used to define  $\mathcal{H}_2^y$  have the same form as  $\mathcal{H}_1^y$  (e.g., (6)), but no longer depend on the state  $e_f$ , nor functions  $k_{pf}$  and  $k_{cf}$ . For example, we will have that  $\dot{x}$  equals to  $f_x(x, y + \overline{H}(x, e_s), e_s)$ , not  $f_x(x, y + \overline{H}(x, e_s), e_s)$ . Then we can write

$$\mathcal{H}_{2}^{y}: \begin{cases} \dot{\xi}_{2}^{y} = F_{2}^{y}(\xi_{2}^{y}, \epsilon), \ \xi_{2}^{y} \in \mathcal{C}_{2}^{y}, \\ \xi_{2}^{y+} = G_{2,s}(\xi_{2}^{y}), \ \xi_{2}^{y} \in \mathcal{D}_{2,s}^{y}. \end{cases}$$

where  $F_2^y(\xi_2^y, \epsilon) \coloneqq (F_s^y(x, y, e_s), \frac{1}{\epsilon}(\epsilon \frac{\partial y}{\partial t}))$ , with  $F_s^y$ and  $\epsilon \frac{\partial y}{\partial t}$  come from system (11),  $C_2^y \coloneqq \{\xi_2^y \in \mathbb{X}_2 | \tau_s \in [0, \tau_{\text{mati}}^s]\}$ ,  $G_{2,s}^y(\xi_2^y) \coloneqq (x, h_s(\kappa_s, e_s), 0, \kappa_s + 1, h_y(x, e_s, y))$  and  $D_{2,s}^y \coloneqq \{\xi_2^y \in \mathbb{X}_2^y | \tau_s \in [\tau_{\text{miati}}^s, \tau_{\text{mati}}^s]\}$ . Furthermore, we can derive a continuous time boundarylayer system  $\mathcal{H}_{2,bl}: \{\frac{\partial y}{\partial \sigma} = g_z(x, y + \overline{H}(x, e_s), e_s), \text{ and a}$  NCS  $\mathcal{H}_{2,r}$ 

$$\mathcal{H}_{2,r} : \begin{cases} \dot{\xi_s} = F_s^y(\xi_s), \ \xi_2^y \in \mathcal{C}_2^y, \\ \xi_s^+ = (x, h_s(\kappa_s, e_s), 0, \kappa_s + 1), \ \xi_2^y \in \mathcal{D}_{2,s}^y \end{cases}$$

where we recall that  $\xi_s := (x, e_s, \tau_s, \kappa_s)$ . We note that only  $\mathcal{H}_{2,r}$  is a hybrid system, while  $\mathcal{H}_{2,bl}$  is not, as it is already stable and does not need to be stabilized through network transmissions. Consequently, we need to modify relevant assumptions. In this case, we adjust Assumption 2, resulting in Assumption 13 below.

Assumption 13 Consider  $\mathcal{H}_{2}^{y}$ , there exist locally Lipschitz function  $V_{f} : \mathbb{R}^{n_{x}} \times \mathbb{R}^{n_{z}} \to \mathbb{R}_{\geq 0}$ , class  $\mathcal{K}_{\infty}$ functions  $\underline{\alpha}_{V_{f}}$  and  $\overline{\alpha}_{V_{f}}$ ,  $a_{f} > 0$  and positive definite function  $\psi_{f}$  such that for all  $\xi_{2} \in \mathbb{X}_{2}$ , we have  $\underline{\alpha}_{V_{f}}(|y|) \leq V_{f}(x,y) \leq \overline{\alpha}_{V_{f}}(|y|)$  and  $\langle \frac{\partial V_{f}(x,y)}{\partial y}, g_{z}(x,y + \overline{H}(x,e_{s}),e_{s}) \rangle \leq -a_{f}\psi_{f}^{2}(|y|).$ 

Assumptions 1, 4 and 6 are written for a more general model (i.e.,  $\mathcal{H}_1^y$ ), when we apply them to a specialized model with a lower dimension, we ignore the states that do not exist in the specialized model. At the same time, Lemma 3 is applicable to any reduced and boundary layer system in the form of NCS. Since  $\mathcal{H}_{2,r}$  is a NCS and Assumption 1 holds, we can conclude inequalities in (25) hold, with  $\mathcal{C}_{2,r}^{y,0}$  and  $\mathcal{D}_{2,r}^{y,0}$  replaced by  $\mathcal{C}_2^y$  and  $\mathcal{D}_{2,s}^y$ , respectively. Since there is no fast transmission, we only have  $V_f$  but not  $U_f$ , and all  $U_f$  in Assumption 4 and 6 should be replace by  $V_f$ . We define the set  $\mathcal{E}_2 := \{\xi_2 \in \mathbb{X}_2 | x = 0 \land e_s = 0 \land z = 0\}$ .

**Corollary 14** Consider system  $\mathcal{H}_2$  and suppose Assumptions 1, 5, 6 and 13 hold, and Assumption 4 holds with  $\widetilde{\mathcal{C}} = \mathcal{C}_2^y$ . Let  $b_1$ ,  $b_2$ , and  $b_3$  come from Assumption 4,  $a_s$  comes from Lemma 3 and  $a_f$  comes from Assumption 13. Then for any  $\tau_{miati}^s \leq \tau_{mati}^s \leq T(L_s, \gamma_s, \lambda_s^*)$ , the following statement holds:

There exists a  $\mathcal{KL}$ -function  $\beta$ , such that for all  $\Delta, \nu > 0$ , there exist  $\epsilon^* > 0$  such that for all  $0 < \epsilon < \epsilon^*$ , any solution  $\xi_2$  with  $|\xi_2(0,0)|_{\mathcal{E}_2} < \Delta$  satisfies  $|\xi_2(t,j)|_{\mathcal{E}_2} \leq \beta(|\xi_2(0,0)|_{\mathcal{E}_2}, t+j) + \nu$  for any  $(t,j) \in dom \xi_2$ .

Corollary 14 is proved similarly to Theorem 7 by defining the composite Lyapunov function as  $U_2(\xi_2^y) \coloneqq U_s(\xi_s) + dV_f(x, y)$ . Its proof is therefore omitted.

**Remark 15** The stability analysis for system with a stable slow subsystem can be conducted similarly.

# 7 Special case: linear time invariant systems

We show in this section how to apply the result seen so far to a LTI plant and a LTI controller with RR or TOD protocols. Consider systems (1) and (2) as

$$\begin{bmatrix} \dot{x}_{p} \\ \epsilon \dot{z}_{p} \end{bmatrix} = \begin{bmatrix} A_{11}^{p} & A_{12}^{p} \\ A_{21}^{p} & A_{22}^{p} \end{bmatrix} \begin{bmatrix} x_{p} \\ z_{p} \end{bmatrix} + \begin{bmatrix} A_{13}^{p} & A_{14}^{p} \\ A_{23}^{p} & A_{24}^{p} \end{bmatrix} \begin{bmatrix} \dot{u}_{s} \\ \dot{u}_{f} \end{bmatrix},$$

$$\begin{bmatrix} y_{s} \\ y_{f} \end{bmatrix} = \begin{bmatrix} A_{x}^{p_{s}} & 0 \\ A_{x}^{p_{f}} & A_{z}^{p_{f}} \end{bmatrix} \begin{bmatrix} x_{p} \\ z_{p} \end{bmatrix},$$

$$\begin{bmatrix} \dot{x}_{c} \\ \epsilon \dot{z}_{c} \end{bmatrix} = \begin{bmatrix} A_{c11}^{c} & A_{12}^{c} \\ A_{21}^{c} & A_{22}^{c} \end{bmatrix} \begin{bmatrix} x_{c} \\ z_{c} \end{bmatrix} + \begin{bmatrix} A_{13}^{c} & A_{14}^{c} \\ A_{23}^{c} & A_{24}^{c} \end{bmatrix} \begin{bmatrix} \hat{y}_{s} \\ \hat{y}_{f} \end{bmatrix},$$

$$\begin{bmatrix} u_{s} \\ u_{f} \end{bmatrix} = \begin{bmatrix} A_{x}^{c_{s}} & 0 \\ A_{x}^{c_{f}} & A_{2f}^{c_{f}} \end{bmatrix} \begin{bmatrix} x_{c} \\ z_{c} \end{bmatrix}.$$
(30)

The hybrid model that describes our SPNCS is given by (5), with  $F(\xi, \epsilon) = (f_x, f_{e_s}, 1, 0, \frac{1}{\epsilon}g_z, \frac{1}{\epsilon}g_{e_f}, \frac{1}{\epsilon}, 0)$ , where

$$\begin{bmatrix} f_x \\ f_{e_s} \\ g_z \\ g_{e_f} \end{bmatrix} = \begin{bmatrix} A_{11} & A_{12} & A_{13} & A_{14} \\ A_{21} & A_{22} & A_{33} & A_{24} \\ A_{31} & A_{32} & A_{33} & A_{34} \\ \epsilon A_{41}^{e_1} + A_{41} & \epsilon A_{42}^{e} + A_{42} & \epsilon A_{43}^{e_1} + A_{43} & \epsilon A_{44}^{e_4} + A_{44} \end{bmatrix} \begin{bmatrix} x \\ e_s \\ z \\ e_f \end{bmatrix} ,$$

$$A_{11} = \begin{bmatrix} A_{11}^p & A_{13}^p A_{x}^{e_s} + A_{14}^p A_{x}^{e_f} \\ A_{13}^e A_{x}^{p_s} + A_{14}^e A_{x}^{p_f} & A_{11}^e \end{bmatrix} , A_{12} = \begin{bmatrix} 0 & A_{13}^p \\ A_{13}^e A_{14}^p A_{27}^{p_f} & A_{12}^e \end{bmatrix} , A_{14} = \begin{bmatrix} 0 & A_{14}^p \\ A_{14}^e & 0 \end{bmatrix} , A_{21} = \\ A_x^s A_{11}, A_{22} = A_x^s A_{12}, A_{23} = A_x^s A_{13}, A_{24} = A_x^s A_{14} , \\ A_{31} = \begin{bmatrix} A_{21}^p & A_{23}^p A_{x}^{e_s} + A_{24}^p A_{x}^{e_f} \\ A_{23}^e A_{x}^{p_s} + A_{24}^e A_{x}^{p_f} & A_{21}^e \end{bmatrix} , A_{34} = \begin{bmatrix} 0 & A_{24}^p \\ A_{23}^e & 0 \end{bmatrix} , A_{41} = \\ A_{33}^f A_{11}, A_{42}^f = A_{24}^f A_{22}^{e_f} \\ A_{24}^e A_{x}^{p_f} & A_{22}^e \end{bmatrix} , A_{34} = \begin{bmatrix} 0 & A_{24}^p \\ A_{24}^e & 0 \end{bmatrix} , A_{41}^e = \\ A_x^f A_{11}, A_{42}^e = A_x^f A_{12}, A_{43}^e = A_x^f A_{13}, A_{44}^e = A_x^f A_{14} , \\ A_{41} = A_x^f A_{31}, A_{42} = A_x^f A_{32}, A_{43}^e = A_x^f A_{33}, A_{44} = \\ A_x^f A_{34}, A_x^s = \begin{bmatrix} -A_{27}^{p_s} & 0 \\ 0 & -A_{xs}^{e_s} \end{bmatrix} , A_x^f = \begin{bmatrix} -A_{27}^{p_f} & 0 \\ 0 & -A_{x}^{e_f} \end{bmatrix}$$
 and 
$$A_z^f = \begin{bmatrix} -A_z^{p_f} & 0 \\ 0 & -A_z^{e_f} \end{bmatrix} .$$

The quasi-steady state of z, which is denoted by  $\overline{H}(x, e_s)$ , is given by

$$\overline{H}(x, e_s) = -A_{33}^{-1}A_{31}x - A_{33}^{-1}A_{32}e_s.$$
(31)

Recall that y is defined in (8), then by setting  $\epsilon$  to zero, the boundary-layer system  $\mathcal{H}_{bl}$  is given by (13), where  $F_f^y(x, y, e_s, e_f, 0)$  is specified in (32). The reduced system  $\mathcal{H}_r$  is given by (14), where  $F_s^y(x, 0, e_s, 0)$  is given in (32).

$$\begin{split} F_{f}^{y}(x,y,e_{s},e_{f},0) &= (A_{11}^{f}y + A_{12}^{f}e_{f},A_{21}^{f}y + A_{22}^{f}e_{f},1,0), \\ F_{s}^{y}(x,0,e_{s},0) &= (A_{11}^{s}x + A_{12}^{s}e_{s},A_{21}^{s}x + A_{22}^{s}e_{s},1,0), \\ A_{11}^{f} &= A_{33}, \ A_{12}^{f} &= A_{34}, \ A_{21}^{f} &= A_{z}^{f}A_{33}, \ A_{22}^{f} &= A_{z}^{f}A_{34}, \\ A_{11}^{s} &= A_{11} - A_{13}A_{33}^{-1}A_{31}, \ A_{12}^{s} &= A_{12} - A_{13}A_{33}^{-1}A_{32}, \\ A_{21}^{s} &= A_{21} - A_{23}A_{33}^{-1}A_{31}, \ A_{22}^{s} &= A_{22} - A_{23}A_{33}^{-1}A_{32}. \end{split}$$

$$\end{split}$$

**Claim 16** For LTI plant and controller given by (30), with RR or TOD protocols, there exist positive definite function  $W_s$ , positive constants  $\underline{a}_{W_s}$ ,  $\overline{a}_{W_s}$  and  $\lambda_s \in [0, 1)$ such that (15), (16) and (28a) hold. there exist  $L_s \geq 0$ and a matrix  $A_{H_s}$ , such that (17) holds with  $H_s(x, e_s) =$   $|A_{H_s}x|$ . Similarly, there exist a locally lipschitz function  $W_f$ , positive constants  $\underline{a}_{W_f}, \overline{a}_{W_f}, \lambda_f \in [0,1), L_f \geq 0$  and a matrix  $A_{H_f}$ , such that (19)-(21) and (28a) are satisfied, with  $H_f(y, e_f) = |A_{H_f}y|$ .

**Proof:** Claim 16 is obtained by inspecting Propositions 4 and 5, as well as Examples 3 and 4 in [15].

**Proposition 17** Consider system (5), with the LTI plant and controller specified in (30), as well as RR or TOD protocols. Let  $\underline{a}_{W_s}$ ,  $\underline{a}_{W_f}$ ,  $A_{H_s}$  and  $A_{H_f}$  come from Claim 16. Suppose there exist  $a_{\rho_s}$ ,  $a_{\rho_f}$ ,  $\gamma_s$ ,  $\gamma_f > 0$  and positive definite symmetric real matrices  $P_s$  and  $P_f$ , such that the following LMI holds for  $\ell \in \{s, f\}$ .

$$\begin{bmatrix} A_{11}^{\ell} P_{\ell} + P_{\ell} A_{11}^{\ell \top} + a_{\rho_{\ell}} I + A_{H_{\ell}}^{\top} A_{H_{\ell}} \\ A_{12}^{\ell \top} P_{\ell} & a_{\rho_{\ell}} I - \gamma_{\ell}^{2} \underline{a}_{W_{\ell}}^{2} I \end{bmatrix} \leq 0.$$
(33)

Then conditions in Theorem 11 hold with  $V_s = x^{\top} P_s x$ ,  $V_f = y^{\top} P_f y$ ,  $\gamma_s$  and  $\gamma_f$  from (33), as well as  $\lambda_s^* \in (\lambda_s, 1)$ ,  $\lambda_f^* \in (\lambda_f, 1)$  from Lemma 3, with  $\lambda_s$  and  $\lambda_f$  come from Claim 16.

**Proof:** The proof of Proposition 17 is given in the Appendix.

**Remark 18** Proposition 17 can be easily extended to other UGES protocols as long as (17) and (21) hold with  $H_s(x, e_s) = |A_{H_s}x|$  and  $H_f(y, e_f) = |A_{H_f}y|$ . See illustrative example and [14] for more details.

Proposition 17 implies that for SPNCS with an LTI plant, an LTI controller, and RR or TOD protocols, the satisfaction of the LMI (33) guarantees that we can always find sufficiently small  $\tau_{\text{mati}}^s$ ,  $\tau_{\text{mati}}^f$  and  $\epsilon^*$ , such that if  $\epsilon < \epsilon^*$ , system (5) considered in this section is UGES. Two necessary conditions to guarantee feasibility of (33) are  $A_{11}^{\ell}P_{\ell} + P_{\ell}A_{11}^{\ell\top} + a_{\rho_{\ell}}I + A_{H_{\ell}}^{\top}A_{H_{\ell}} < 0$  and  $a_{\rho_{\ell}}I - \gamma_{\ell}^2\underline{a}_{W_{\ell}}^2I < 0$ , where the first condition can be satisfied if  $A_{11}^{\ell}$  is Hurwitz, and the second condition can always be verified by selecting  $a_{\rho_{\ell}}$  sufficiently small and  $\gamma_{\ell}$  sufficiently large.

#### 8 An illustrative example

This section provides a numerical example of the result of section 7. Consider system (30) with where  $A_{11}^p = a_1$ ,  $A_{12}^p = \begin{bmatrix} a_2 & 0 \end{bmatrix}$ ,  $A_{21}^p = \begin{bmatrix} a_3 \\ a_3 \end{bmatrix}$ ,  $A_{22}^p = \begin{bmatrix} -a_2 & 0 \\ -a_2 & -a_4 \end{bmatrix}$ ,  $A_{13}^p = n_1$ ,  $A_{23}^p = \begin{bmatrix} -n_2 \\ -n_2 \end{bmatrix}$ ,  $A_x^{p_f} = 1$ ,  $A_z^{p_f} = \begin{bmatrix} 0 & 1 \end{bmatrix}$ ,  $A_{11}^c = -a_5$ ,  $A_{14}^c = a_6$ ,  $A_{25}^c = -k$ ,  $a_1 = 10^{-4}$ ,  $a_2 = 0.2$ ,  $a_3 = 0.6$ ,  $a_4 = 0.73$ ,  $a_5 = 1.11$ ,  $a_6 = 0.37$ , k = 1.5,  $n_1 = 0.02$  and  $n_2 = 0.0018$  are designed such that the controller stabilizes the plant under perfect communication.

The hybrid model  $\mathcal{H}_1$  is given by (5). We note that our plant and controller are simpler compared to (30), since

 $\begin{array}{l} u_f, y_s \mbox{ and } z_c \mbox{ does not exist in the system, nor do matrices} \\ \mbox{such as } A_{14}^p, A_x^{p_s}, A_{21}^c, \mbox{ etc. Consequently, the flow map} \\ F \mbox{ in } \mathcal{H}_1 \mbox{ has to be modified accordingly. Specifically,} \\ \mbox{we have } A_{11} = \begin{bmatrix} A_{11}^{p_1} & A_{13}^{p_3} A_x^{c_s} \\ A_{14}^{r_4} A_x^{p_f} & A_{11}^c \end{bmatrix}, A_{12} = \begin{bmatrix} A_{13}^p \\ 0 \end{bmatrix}, A_{13} = \\ \begin{bmatrix} A_{12}^p \\ A_{14}^{r_4} A_x^{p_f} \end{bmatrix}, A_{14} = \begin{bmatrix} 0 \\ A_{14}^c \end{bmatrix}, A_x^s = \begin{bmatrix} 0 - A_x^{c_s} \end{bmatrix}, A_x^f = \begin{bmatrix} -A_x^{p_f} & 0 \end{bmatrix}, \\ A_x^f = -A_x^{p_f}, A_{31} = \begin{bmatrix} A_{21}^p & A_{23}^p A_x^{c_s} \end{bmatrix}, A_{32} = A_{23}^p, A_{33} = A_{22}^p, \\ A_{34} = 0. \mbox{ Then by (32) we have } A_{11}^s = \begin{bmatrix} a_{1} & -\overline{nk} \\ a_6(1 + \frac{a_3}{a_4}) - a_5 \end{bmatrix}, \\ A_{12}^s = \begin{bmatrix} \overline{n} \\ 0 \end{bmatrix}, A_{21}^s = \begin{bmatrix} a_6(1 + \frac{a_3}{a_4})k - a_5k \end{bmatrix}, A_{11}^f = \begin{bmatrix} -a_2 & 0 \\ -a_2 & -a_4 \end{bmatrix} \\ \mbox{ and } A_{12}^f = \begin{bmatrix} 0 \\ 0 \end{bmatrix}, A_{21}^f = \begin{bmatrix} a_2 & a_4 \end{bmatrix} \mbox{ where } \overline{n} \coloneqq n_1 - n_2. \end{aligned}$ 

Next, we find Lyapunov functions  $W_s$  and  $W_f$  in Claim 16. Since both  $u_s$  and  $y_f$  are scalars, the protocols are given by  $h_s(\kappa_s, e_s) = 0$  and  $h_f(\kappa_f, e_f) = 0$ , which are UGES protocols. Let  $W_s(\kappa_s, e_s) := |e_s|$ , then (15) and (28a) hold with  $\underline{a}_{W_s}(s) = \overline{a}_{W_s}(s) = s$ , (16) and (17) hold for  $\lambda_s = 0$ ,  $L_s = 0$  and  $A_{H_s} = A_{21}^s$ . Let  $W_f(\kappa_f, e_f) :=$  $|e_f|$ , then (19) and (28b) hold with  $\underline{a}_{W_f}(s) = \overline{a}_{W_f}(s) =$ s, (20) and (21) hold for  $\lambda_f = 0$ ,  $L_f = 0$  and  $A_{H_f} = A_{21}^f$ .

 $\begin{array}{l} \text{Since } W_{s}(x,e_{s}) \ = \ |e_{s}|, \ \text{we have } \left|\frac{\partial W_{s}(\kappa_{s},e_{s})}{\partial e_{s}}\right| \ \leq \ L_{1} \\ \text{where } L_{1} \ = \ 1. \ \text{Then by (C.4), we have } \Lambda_{b_{1}} \ = \\ 2 \begin{bmatrix} a_{2}|p_{12}^{s}| & a_{6}|p_{22}^{s}| \\ a_{2}|p_{2}^{s}| & 0 & a_{6}|p_{22}^{s}| \\ 0 & \frac{\gamma_{s}}{\lambda_{s}^{s}}a_{6}k \frac{\gamma_{s}}{\lambda_{s}^{s}}a_{6}k \end{bmatrix} \ \text{ and } b_{1} \ = \ \sqrt{\lambda_{\max}(\Lambda_{b_{1}}^{\top}\Lambda_{b_{1}})}. \\ \text{Similarly, we can show that } b_{2} \ = \ \sqrt{\lambda_{\max}(\Lambda_{b_{2}}^{\top}\Lambda_{b_{2}})} \\ \text{and } b_{3} \ = \ \lambda_{\max}(\Lambda_{b_{3}}) \ \text{satisfy (C.5), where } \Lambda_{b_{2}} \ = \\ 2 \begin{bmatrix} a_{1}\frac{a_{3}}{a_{4}}|p_{12}^{f}| & a_{1}\frac{a_{3}}{a_{4}}|p_{22}^{f}| & a_{1}\frac{\gamma_{f}}{\lambda_{f}} \\ \frac{a_{3}}{a_{4}}\overline{n}|p_{12}^{f}| & \frac{a_{3}}{a_{4}}\overline{n}|p_{22}^{f}| & \overline{n}k\frac{\gamma_{f}}{\lambda_{f}} \\ \frac{a_{3}}{a_{4}}\overline{n}|p_{12}^{f}| & \frac{a_{3}}{a_{4}}\overline{n}|p_{22}^{f}| & \overline{n}\frac{\gamma_{f}}{\lambda_{f}} \\ \end{bmatrix} \ \text{and } \Lambda_{b_{3}} \ = \begin{bmatrix} 2a_{2}\frac{a_{3}}{a_{4}}|p_{12}^{f}| & \star \star \\ a_{2}\frac{a_{3}}{a_{4}}|p_{22}^{f}| & \star \star \\ a_{2}\frac{\gamma_{f}}{\lambda_{f}} & 0 \ 0 \end{bmatrix} . \\ \\ \text{Finally, by (C.3), we show that Assumption 5 holds} \\ \text{with } \lambda_{1} \ = \ \frac{n_{2}}{a_{2}}^{2}|p_{11}^{f}| \ \text{and } \lambda_{2} \ = \ \frac{2\frac{n_{2}}{a_{2}}(|p_{11}^{f}| + |p_{12}^{f}|)}{\sqrt{\lambda_{\min}(P_{f})}}. \end{aligned}$ 

We want to satisfy the LMI (33) for all 
$$\ell \in \{s, f\}$$
 and maximize  $T(L_s, \gamma_s, \lambda_s^*)$ ,  $T(L_f, \gamma_f, \lambda_f^*)$ ,  $\epsilon^*$  under the following constraints:  $P_s > 0, \gamma_* > 0, a_{\rho_*} > 0, \gamma_* > 0, \lambda_*^* \in (0, 1)$  and  $\Lambda_* < 0$  for  $\star \in \{s, f\}$ . We note that  $\epsilon^*$  is given by (A.15) with  $d = d^*$  defined by (B.4). We pose this problem as an optimisation problem with constraints (see [25] for the problem fomulation and the code), we get  $P_s = \begin{bmatrix} 54.91 & -1.76 \\ 1.81 & 1.76 & 1.81 \end{bmatrix}, \gamma_s = 2.58, \lambda_s^* = 0.33, a_{\rho_s} = 1.16, P_f = \begin{bmatrix} 1.12 & 0.018 \\ 0.018 & 0.65 \end{bmatrix}, \gamma_f = 0.64, \lambda_f^* = 0.46, a_{\rho_f} = 0.41, T(L_s, \gamma_s, \lambda_s^*) = 360.1 ms$  and  $T(L_f, \gamma_f, \lambda_f^*) = 1.11 \frac{s}{\epsilon}$  (in fast time scale  $\sigma$ ). By selecting  $\tau_{\text{miati}}^s = 324.1 ms$  and  $\mu = 0.66a_s\underline{a}_{U_s}$ , we have  $\epsilon^* = 0.0162$ , see the proof of Theorem 11 and [25] for more detail. This implies  $\mathcal{H}_1$  is UGES if  $\epsilon < \epsilon^*, \tau_{\text{miati}}^s = 324.1 ms, \tau_{\text{matii}}^s = 360.1 ms$  and  $\tau_{\text{matii}}^f \leq 18 ms$ . Finally, we have  $\tau_{\text{miati}}^f \leq 9 ms$  such that (4) is satisfied.

#### 9 Conclusion

This paper provided conditions ensuring various stability properties of two-time-scale singularly perturbed networked control systems (SPNCSs) under a single communication channel, including semi-global practical asymptotic stability, uniformly globally asymptotic stability, and uniformly globally exponential stability. We introduce a framework for analyzing SPNCSs, extendable to multiple channels and time scales, and other stability properties. Additionally, we propose a resource-aware strategy for stabilizing SPNCSs, laying a foundation for further research.

# A Proof of Theorem 7

The conditions stated in Theorem 7 indicate Lemma 3 holds. In the proof, the following variables and functions are used. Let

$$\mu \in (0, a_s a_{\psi_s}^2), \qquad \mu_1 \in (0, \mu), \tag{A.1}$$

where  $a_s$  and  $a_{\psi_s}$  come from Lemma 3 and Assumption 6, respectively. Let

$$\lambda \in (\exp(-\mu_1 \tau_{\text{miati}}^s), 1), \qquad (A.2)$$

where  $\tau_{\text{miati}}^s$  comes from Theorem 7. We define

$$d \coloneqq \frac{-b + \sqrt{b^2 - 4ac}}{2a},\tag{A.3}$$

where  $a = \frac{\lambda_1}{\gamma_s \lambda_s^*}$ ,  $b = \frac{1}{2} (\frac{\lambda_1}{\gamma_s \lambda_s^*} + \lambda_2)$  and  $c = 1 - \lambda e^{\mu_1 \tau_{\text{miati}}^s}$ . Note that by definition of  $\lambda$  in (A.2), we have c < 0, which implies  $b^2 - 4ac > b > 0$ .

Next we define the bound when we change between x-zand x-y coordinate. Since the map  $\overline{H}$  between  $(x, e_s)$ and the quasi-steady state is continuously differentiable and  $0 = \overline{H}(0,0)$ , by [10, Lemma 4.3], there exists a class  $\mathcal{K}$  function  $\zeta_1$  such that  $|\overline{H}(x, e_s)| \leq \zeta_1(|(x, e_s)|)$  for all  $x \in \mathbb{R}^{n_x}, e_s \in \mathbb{R}^{n_{e_s}}$ . We define a class  $\mathcal{K}_{\infty}$  function

$$\zeta_2(s) \coloneqq s + \zeta_1(s). \tag{A.4}$$

Let  $\mathcal{E}^{y} := \{\xi^{y} \in \mathbb{X} \mid x = 0 \land e_{s} = 0 \land y = 0 \land e_{f} = 0\}$ , and  $\mathcal{E}$  be defined above Theorem 7. As  $|\xi^{y}|_{\mathcal{E}^{y}} = |(x, e_{s}, y + \overline{H}(x, e_{s}) - \overline{H}(x, e_{s}), e_{f})| \leq |(x, e_{s}, y + \overline{H}(x, e_{s}), e_{f})| + |(0, 0, -\overline{H}(x, e_{s}), 0)| \leq |\xi|_{\mathcal{E}} + \zeta_{1}(|\xi|_{\mathcal{E}}) = \zeta_{2}(|\xi|_{\mathcal{E}})$ , we have for any  $\Delta > 0$ , there exists a  $\Delta^{y} = \zeta_{2}(\Delta)$  such that  $|\xi|_{\mathcal{E}} \leq \Delta$  implies  $|\xi^{y}|_{\mathcal{E}^{y}} \leq \Delta^{y}$ . Similarly, we can show  $|\xi|_{\mathcal{E}} \leq \zeta_{2}(|\xi^{y}|_{\mathcal{E}^{y}})$ . Let  $\nu^{y} \coloneqq \zeta_{2}^{-1}(\nu)$ , then if  $|\xi^{y}|_{\mathcal{E}^{y}} \leq \nu^{y}$ , we have  $|\xi|_{\mathcal{E}} \leq \zeta_{2}(|\xi^{y}|_{\mathcal{E}^{y}}) \leq \zeta_{2}(\nu^{y}) = \nu$ .

For given d coming from (A.3), as well as  $U_s$  and  $U_f$  coming from (24), we define a composite Lyapunov function

$$U(\xi^y) \coloneqq U_s(\xi_s) + dU_f(\xi_s, \xi_f). \tag{A.5}$$

From (25a) and (26a), we know there exist  $\underline{\alpha}_U, \overline{\alpha}_U \in \mathcal{K}_{\infty}$ , such that for all  $\xi^y \in \mathcal{C}_1^{y,\epsilon} \cup \mathcal{D}_s^{y,\epsilon} \cup \mathcal{D}_f^{y,\epsilon}$ ,

$$\underline{\alpha}_U\left(|\xi^y|_{\mathcal{E}^y}\right) \le U(\xi^y) \le \overline{\alpha}_U\left(|\xi^y|_{\mathcal{E}^y}\right), \qquad (A.6)$$

where the sets are defined in Sections 3 and 4.

We define the  $\nu_1$  and  $\Delta_1$  in Assumption 4 as follows. Let

$$\nu_1 \coloneqq \frac{\mu - \mu_1}{2a_d} \underline{\alpha}_U(\zeta_2^{-1}(\nu)), \qquad (A.7)$$

where

$$a_d \coloneqq 1 + \frac{\lambda_1}{\gamma_s \lambda_s^*} d + \frac{1}{2} \left( \frac{\lambda_2}{\gamma_s \lambda_s^*} + \lambda_2 \right) \sqrt{d}.$$
(A.8)

We define

$$\nu_2 \coloneqq \frac{2\nu_1}{\mu - \mu_1},\tag{A.9}$$

such that by (A.7) and (A.9),  $U(\xi^y) \leq a_d \nu_2$  implies

$$U(\xi^{y}) \leq a_{d}\nu_{2} = a_{d}\frac{2\nu_{1}}{\mu - \mu_{1}}$$
  
= $a_{d}\frac{2}{\mu - \mu_{1}}\frac{\mu - \mu_{1}}{2a_{d}}\underline{\alpha}_{U}(\zeta_{2}^{-1}(\nu))$  (A.10)  
= $\underline{\alpha}_{U}(\zeta_{2}^{-1}(\nu)),$ 

and  $|\xi^y|_{\mathcal{E}^y} \leq \zeta_2^{-1}(\nu) = \nu^y$  by (A.6), and  $|\xi|_{\mathcal{E}} \leq \nu$ .

We remind that  $\Delta^y = \zeta_2(\Delta)$ , and for any  $|\xi|_{\mathcal{E}} \leq \Delta$ , we have  $|\xi^y|_{\mathcal{E}^y} \leq \Delta^y$  and  $U \leq \overline{\alpha}_U(\Delta^y)$ . Let  $\Delta^U \coloneqq a_d \overline{\alpha}_U(\Delta^y)$  and  $\Delta_1$  from Assumption 4 be

$$\Delta_1 \coloneqq \underline{\alpha}_U^{-1}(\Delta^U), \qquad (A.11)$$

such that  $U(\xi^y) \leq \Delta^U$  implies  $|\xi^y|_{\mathcal{E}^y} \leq \Delta_1$ . Next, we will bound the system trajectories. We start by showing that during flow, the derivative of the U is negative definite when it is bounded within an interval. This is followed by demonstrating the boundedness during jumps.

$$\begin{array}{l} \underline{During\ flow:} \ \operatorname{Let}\ \xi^y\ \in\ \mathcal{C}_1^{y,\epsilon}, \ \text{where}\ \mathcal{C}_1^{y,\epsilon} \ \text{is the flow}\\ \overline{\operatorname{set}\ of\ (11)}, \ \text{by Lemma 3 and}\ (23)-(24) \ \text{in}\ [20], \ \text{we}\\ \text{have that}\ U^{\circ}(\xi^y,F^y(\xi^y,\epsilon))\ \leq\ \left\langle \frac{\partial U_s}{\partial\xi_s},F_s^y(x,y,e_s,e_f)\right\rangle+\\ \frac{d}{\epsilon}\left\langle \frac{\partial U_f}{\partial\xi_f},F_f^y(x,y,e_s,e_f,\epsilon)\right\rangle+\ d\left\langle \frac{\partial U_f}{\partial\xi_s},F_s^y(x,y,e_s,e_f,0)\right\rangle \ +\ \left\langle \frac{\partial U_s}{\partial\xi_s},F_s^y(x,y,e_s,e_f,0)\right\rangle \ +\ \left\langle \frac{\partial U_s}{\partial\xi_s},F_s^y(x,y,e_s,e_f,0)\right\rangle \ +\ \left\langle \frac{\partial U_f}{\partial\xi_s},F_s^y(x,y,e_s,e_f,0)\right\rangle \ +\ \left\langle \frac{\partial U_f}{\partial\xi_s},F_s^y(x,y,e_s,e_f,0)\right\rangle \ +\ \left\langle \frac{\partial U_f}{\partial\xi_s},F_s^y(x,y,e_s,e_f,\epsilon)-F_f^y(x,y,e_s,e_f,0)\right\rangle+\ d\left\langle \frac{\partial U_f}{\partial\xi_s},F_s^y(x,y,e_s,e_f,\epsilon)\right\rangle, \ \text{where the definition of}\ F_f^y \ \text{is given by}\ (7), \ \text{where the definition of}\ g_{e_f} \ \text{is given in}\ (6). \ \text{Then we have} \end{array}$$

$$\begin{split} F_f^y(x, y, e_s, e_f, \epsilon) &- F_f^y(x, y, e_s, e_f, 0) \\ = & \begin{bmatrix} -\epsilon \frac{\partial \overline{H}}{\partial \xi_s} F_s^y(x, y, e_s, e_f) \\ -\epsilon \frac{\partial k_{p_f}(x_{p, z_p})}{\partial x_p} f_{x, 1}(x, z, e_s, e_f) - \epsilon \frac{\partial k_{c_f}(x_{c, z_c})}{\partial x_c} f_{x, 2}(x, z, e_s, e_f) \\ 0 \end{bmatrix} \\ = & - \epsilon \Big( \frac{\partial \overline{H}}{\partial \xi_s} F_s^y(x, y, e_s, e_f), \frac{\partial \overline{k}}{\partial \xi_s} F_s^y(x, y, e_s, e_f), 0, 0 \Big), \end{split}$$

where  $\tilde{k}(x,z) = (k_{pf}(x_p, z_p), k_{cf}(x_c, z_c))$ . Consequently,  $\frac{d}{\epsilon} \langle \frac{\partial U_f}{\partial \xi_f}, F_f^y(x, y, e_s, e_f, \epsilon) - F_f^y(x, y, e_s, e_f, 0) \rangle$ =  $-d \langle \frac{\partial U_f}{\partial y} \frac{\partial \overline{H}}{\partial \xi_s} + \frac{\partial U_f}{\partial e_f} \frac{\partial \tilde{k}}{\partial \xi_s}, F_s^y(x, y, e_s, e_f) \rangle$ . Then we have

$$\begin{aligned} U^{\circ}(\xi^{g}, F^{g}(\xi^{g}, \epsilon)) \\ \leq & \left\langle \frac{\partial U_{s}}{\partial \xi_{s}}, F^{y}_{s}(x, 0, e_{s}, 0) \right\rangle + \frac{d}{\epsilon} \left\langle \frac{\partial U_{f}}{\partial \xi_{f}}, F^{y}_{f}(x, y, e_{s}, e_{f}, 0) \right\rangle \\ & + \left\langle \frac{\partial U_{s}}{\partial \xi_{s}}, F^{y}_{s}(x, y, e_{s}, e_{f}) - F^{y}_{s}(x, 0, e_{s}, 0) \right\rangle \\ & + d \left\langle \frac{\partial U_{f}}{\partial \xi_{s}} - \frac{\partial U_{f}}{\partial y} \frac{\partial \overline{H}}{\partial \xi_{s}} - \frac{\partial U_{f}}{\partial e_{f}} \frac{\partial \overline{k}}{\partial \xi_{s}}, F^{y}_{s}(x, y, e_{s}, e_{f}) \right\rangle. \end{aligned}$$
(A.12)

By Assumption 4, (25b) and (26b), we know that for

$$\begin{split} &\Delta_{1} \text{ and } \nu_{1} \text{ defined in (A.11) and (A.7), there exist pos$$
 $itive constants } b_{1}, b_{2} \text{ and } b_{3} \text{ such that for all } |\xi^{y}|_{\mathcal{E}^{y}} \leq \\ &\Delta_{1}, \ U^{\circ}(\xi^{y}, F^{y}(\xi^{y}, \epsilon)) \leq -a_{s}\psi_{s}^{2}\left(|(x, e_{s})|\right) - d(\frac{a_{f}}{\epsilon} - b_{3})\psi_{f}^{2}\left(|(y, e_{f})|\right) + (b_{1} + db_{2})\psi_{s}\left(|(x, e_{s})|\right)\psi_{f}\left(|(y, e_{f})|\right) + \\ &(1 + d)\nu_{1} \leq -\left[\frac{\psi_{s}(|(x, e_{s})|)}{\psi_{f}(|(y, e_{f})|)}\right]^{T}\tilde{\Lambda}\left[\frac{\psi_{s}(|(x, e_{s})|)}{\psi_{f}(|(y, e_{f})|)}\right] + 2\nu_{1}, \\ &\text{where } \tilde{\Lambda} \coloneqq \left[\frac{a_{s}}{-\frac{1}{2}b_{1} - \frac{1}{2}db_{2}}d(\frac{a_{f}}{\epsilon} - b_{3})\right]. \text{ Then by Assump-}\\ &\text{tion 6, we have } U^{\circ}(\xi^{y}, F^{y}(\xi^{y}, \epsilon)) \leq -\left[\frac{\sqrt{U_{s}(\xi_{s})}}{\sqrt{U_{f}(\xi_{s}, \xi_{f})}}\right]^{\mathsf{T}} \Lambda\\ &\left[\frac{\sqrt{U_{s}(\xi_{s})}}{\sqrt{U_{f}(\xi_{s}, \xi_{f})}}\right] + 2\nu_{1}, \text{ where} \\ &\Lambda \coloneqq \left[\frac{a_{s}a_{\psi_{s}}^{2}}{-\frac{1}{2}(b_{1} + db_{2})a_{\psi_{s}}a_{\psi_{f}}} - \frac{1}{2}(b_{1} + db_{2})a_{\psi_{s}}a_{\psi_{f}}}{d(\frac{a_{f}}{\epsilon} - b_{3})a_{\psi_{f}}^{2}}\right]. \tag{A.13}$ 

In order to satisfy  $\Lambda \geq \mu \begin{bmatrix} 1 & 0 \\ 0 & d \end{bmatrix}$ , we need

$$\begin{array}{c} a_s a_{\psi s}^2 > \mu & \text{(A.14a)} \\ (a_s a_{\psi s}^2 - \mu) (d(\frac{a_f}{\epsilon} - b_3) a_{\psi f}^2 - \mu d) \ge \frac{1}{4} (b_1 + db_2)^2 a_{\psi s}^2 a_{\psi f}^2, & \text{(A.14b)} \end{array}$$

where the first inequality is satisfied by the definition of  $\mu$  in (A.1), and the second inequality can be satisfied by all  $\epsilon \in (0, \epsilon^*)$ , where

$$\epsilon^* = \left(\frac{a_{\psi_f}}{a_f d} \left(\frac{(b_1 + db_2)^2 a_{\psi_s}^2 a_{\psi_f}^2}{4(a_s a_{\psi_s}^2 - \mu)} + \mu d\right) + \frac{b_3 a_{\psi_f}^2}{a_f}\right)^{-1}.$$
 (A.15)

Then we have that for all  $|\xi^y|_{\mathcal{E}^y} \leq \Delta_1, U^{\circ}(\xi^y, F^y(\xi^y, \epsilon)) \leq -\mu(U_s(\xi_s) + dU_f(\xi_s, \xi_f)) + 2\nu_1 \leq -\mu U(\xi^y) + 2\nu_1$ . By definition of  $\Delta_1$  in (A.11), we have  $U(\xi^y) \leq \Delta^U$  implies  $|\xi^y|_{\mathcal{E}^y} \leq \Delta_1$ . Then by definition of  $\mu_1$  in (A.1) and  $\nu_2$  in (A.9), we have

$$U^{\circ}(\xi^{y}, F^{y}(\xi^{y}, \epsilon)) \leq -\mu_{1}U(\xi^{y}), \ \forall U(\xi^{y}) \in [\nu_{2}, \Delta^{U}].$$
 (A.16)

 $\begin{array}{l} \underline{During\ jumps:} \ \text{When slow dynamics update, } (25c) \ \text{implies that}\ U(G_s^y(\xi^y)) = U_s((x,h_s(\kappa_s,e_s),0,\kappa_s+1)) + \\ dU_f(G_s^y(\xi^y)) \leq U_s(\xi_s) + dU_f(G_s^y(\xi^y)) \ \text{for all}\ \xi^y \in \mathcal{D}_s^{y,\epsilon}, \\ \text{where}\ \mathcal{D}_s^{y,\epsilon} \ \text{is the set that a slow transmission can be triggered.} \ \text{By definitions of}\ U_f \ \text{and}\ G_s^y, \ \text{we have}\ U(G_s^y(\xi^y)) \leq \\ U_s(\xi_s) + d\big(V_f(x,h_y(\kappa_s,x,e_s,y)) + \gamma_f\phi_f(\tau)W_f^2(\kappa_f,e_f)\big). \\ \text{By adding and subtracting the term}\ U_f(\xi_s,\xi_f) \ \text{and} \\ \text{in the view of Assumption 5, we have}\ U(G_s^y(\xi^y)) \leq \\ U(\xi^y) + d\Big(V_f\big(x,h_y(\kappa_s,x,e_s,y)\big) - V_f(x,y)\Big) \leq U(\xi^y) + \\ d\Big(\lambda_1W_s^2(\kappa_s,e_s) + \lambda_2\sqrt{W_s^2(\kappa_s,e_s)V_f(x,y)}\Big). \ \text{By completion of square, we have}\ \sqrt{W_s^2(\kappa_s,e_s)V_f(x,y)} \leq \\ \frac{1}{2\sqrt{d}}W_s^2(\kappa_s,e_s) + \frac{\sqrt{d}}{2}V_f(x,y). \ \text{At the same time,} \\ W_s^2(\kappa_s,e_s) \leq \frac{1}{\gamma_s\lambda_s^*}U(\xi^y) \ \text{and}\ dV_f(x,y) \leq U(\xi^y) \ \text{by} \end{array}$ 

definition of  $U(\xi^y)$ . Then we have

$$U(G_s^y(\xi^y)) \leq U(\xi^y) + d\lambda_1 W_s^2(\kappa_s, e_s) + \frac{1}{2\sqrt{d}} \lambda_2 W_s^2(\kappa_s, e_s) + \lambda_2 \frac{\sqrt{d}}{2} \left( dV_f(x, y) \right) \leq \left( 1 + \frac{\lambda_1}{\gamma_s \lambda_s^*} d + \frac{1}{2} \left( \frac{\lambda_2}{\gamma_s \lambda_s^*} + \lambda_2 \right) \sqrt{d} \right) U(\xi^y) = a_d U(\xi^y),$$
(A.17)

where  $a_d$  is defined in (A.8). For fast dynamics updates, (26c) implies for all  $\xi^y \in \mathcal{D}_f^{y,\epsilon}$ ,

$$U(G_{f}^{y}(\xi^{y})) = U_{s}(\xi_{s}) + dU_{f}(G_{f}^{y}(\xi^{y}))$$
  

$$\leq U_{s}(\xi_{s}) + dU_{f}(\xi_{s},\xi_{f}) = U(\xi^{y}),$$
(A.18)

where we can see U is non-increasing at fast transmissions. Let  $\xi^{y}(t,j)$  be a solution to  $\mathcal{H}_{1}^{y}$ ,  $(t,j) \in \operatorname{dom} \xi^{y}$ and  $0 = t_{0} \leq t_{1} \leq \cdots \leq t_{j+1} = t$  satisfying

dom 
$$\xi^{y} \cap ([0,t] \times \{0,\cdots,j\}) = \bigcup_{i \in \{0,\cdots,j\}} [t_{i},t_{i+1}] \times \{i\}.$$

The sequence  $\{1, \dots, j\}$  is divided into two disjoint subsequences representing slow and fast transmissions, respectively, and are denoted by  $\mathcal{J}^s \coloneqq \{j_1^s, j_2^s, \dots, j_m^s\}$ and  $\{j_1^f, j_2^f, \dots, j_n^f\}$ , respectively. We will first focus on the trajectory of  $U(\xi^y(s, i))$ , at each  $i \in \mathcal{J}^s$  and all  $s \in t_i$ . Note that by abuse of notation, we write  $U(s, i) \coloneqq$  $U(\xi^y(s, i))$ . The notation  $(s_1, i_1) \preceq (s_2, i_2)$  indicates  $s_1+i_1 \leq s_2+i_2$ , while  $(s_1, i_1) \prec (s_2, i_2)$  implies  $s_1+i_1 < s_2+i_2$ .

 $\begin{array}{lll} \textbf{Claim 19} \ Suppose \ (t_a, j_a) \ \preceq \ (t, j) \in \ dom \ \xi^y \ satisfies \\ U(t_a, j_a) \ \leq \ \nu_2. \ Let \ \mathcal{J}^s_{>a} \coloneqq \{i \in \mathcal{J}^s | i > j_a\}. \ If \ \mathcal{J}^s_{>a} = \\ \emptyset, \ then \ U(s, i) \ \leq \ \nu_2 \ for \ all \ (t_a, j_a) \ \preceq \ (s, i) \ \preceq \ (t, j). \\ Otherwise, \ let \ j^s_k = \ \min \ \mathcal{J}^s_{>a}, \ then \ U(s, i) \ \leq \ \nu_2 \ for \ all \\ (t_a, j_a) \ \preceq \ (s, i) \ \preceq \ (t, j). \end{array}$ 

**Proof:** We first proof Claim 19 for the case  $\mathcal{J}_{>a}^{s} \neq \emptyset$ by contradiction. Assume there exist  $(t_{b}, j_{b})$  such that  $(t_{a}, j_{a}) \preceq (t_{b}, j_{b}) \preceq (t_{j_{k}^{s}}, j_{k}^{s} - 1)$  and  $U(t_{b}, j_{b}) > \nu_{2}$ . Then by continuity of U, there exist  $(t_{c}, j_{c})$  such that  $(t_{a}, j_{a}) \preceq (t_{c}, j_{c}) \preceq (t_{b}, j_{b}), U(t_{c}, j_{c}) = \nu_{2}$  and  $U(s, i) \geq$  $\nu_{2}$  for all  $(t_{c}, j_{c}) \preceq (s, i) \preceq (t_{b}, j_{b})$ . Then by (A.16), we have  $U(t_{b}, j_{b}) \leq U(t_{c}, j_{c}) + \int_{t_{c}}^{t_{b}} U^{\circ}(\xi^{y}, F^{y}(\xi^{y}, \epsilon))dt \leq$  $\nu_{2} - \mu_{1}\nu_{2}(t_{b} - t_{c}) \leq \nu_{2}$ , which conflict our assumption that  $U(t_{b}, j_{b}) > \nu_{2}$ , and we proved Claim 19 for the case  $\mathcal{J}_{>a}^{s} \neq \emptyset$ . The case  $\mathcal{J}_{>a}^{s} = \emptyset$  can be proved similarly.

Suppose  $j_k^s$ ,  $j_{k+1}^s \in \mathcal{J}^s$ . By (A.16), [20], comparison principle [10, Lemma 3.4] and the fact that U is non-increasing at fast transmissions, we have that if  $U(t_{j_k^s}, j_k^s) \in [\nu_2, \Delta^U]$ , then

$$U(s,i) \le U(t_{j_k^s}, j_k^s) \exp(-\mu_1(s - t_{j_k^s})), \qquad (A.19)$$

whenever  $U(s,i) \geq \nu_2$ , as well as  $(t_{j_k^s}, j_k^s) \leq (s,i) \leq (t_{j_{k+1}^s}, j_{k+1}^s - 1)$  or  $(t_{j_m^s}, j_m^s) \leq (s,i) \leq (t,j)$ , where  $j_m^s$  is the last element in  $\mathcal{J}^s$  and m corresponds to the amount of slow transmissions in trajectory  $\xi^y(t,j)$ .

Since  $t_{j_{k+1}^s} - t_{j_k^s} \geq \tau_{\text{miati}}^s$  for all  $j_k^s, j_{k+1}^s \in \mathcal{J}^s$ , we have that  $U(t_{k+1}^s, j_{k+1}^s - 1) \leq U(t_k^s, j_k^s) \exp\left(-\mu_1 \tau_{\text{miati}}^s\right)$  if  $U(s, i) \geq \nu_2$  for all  $(t_{j_k^s}, j_k^s) \preceq (s, i) \preceq (t_{j_{k+1}^s}, j_{k+1}^s - 1)$ and  $U(t_{j_k^s}, j_k^s) \in [\nu_2, \Delta^U]$ . Then we will experience a slow transmission, by (A.17), we have for all  $j_k^s, j_{k+1}^s \in \mathcal{J}^s$  and  $U(t_{j_k^s}, j_k^s) \in [\nu_2, \Delta^U]$ , if  $U(s, i) \geq \nu_2$  for all  $(t_{j_k^s}, j_k^s) \preceq (s, i) \preceq (t_{j_{k+1}^s}, j_{k+1}^s - 1)$ , then

$$U(t_{k+1}^{s}, j_{k+1}^{s}) \leq a_{d}U(t_{k+1}^{s}, j_{k+1}^{s} - 1) \\ \leq a_{d}U(t_{j_{k}^{s}}^{s}, j_{k}^{s})\exp(-\mu_{1}\tau_{\text{miati}}^{s}).$$
(A.20)

By definition of  $\lambda$ , d and  $a_d$  in (A.2), (A.3) and (A.8), we have for all  $U(t_{j_k^s}, j_k^s) \in [\nu_2, \Delta^U]$ 

$$U(t_{k+1}^s, j_{k+1}^s) \le a_d U(t_{j_k^s}, j_k^s) \exp(-\mu_1 \tau_{\text{miati}}^s)$$
  
=  $\lambda U(t_k^s, j_k^s)$  (A.21)

 $\text{if } U(s,i) \geq \nu_2 \text{ for all } (t_{j_k^s},j_k^s) \preceq (s,i) \preceq (t_{j_{k+1}^s},j_{k+1}^s-1).$ 

The following claim provides an upper bound of  $U(\xi^y(t,j))$  for all  $(t,j) \in \text{dom } \xi^y$ .

**Claim 20** Given  $|\xi(0,0)|_{\mathcal{E}} \leq \Delta$ , we have

$$\begin{split} U(t,j) &\leq \max\left\{\frac{a_d}{\lambda}U(0,0)\exp\left(-\frac{\ln\left(1/\lambda\right)}{\tau_{mati}^s}(t)\right), a_d\nu_2\right\},\\ for \ all \ (t,j) &\in dom \ \xi^y. \end{split}$$
(A.22)

**Proof of Claim 20:** We first consider the case that  $\mathcal{J}^s$  is non-empty, where the scenario with  $\mathcal{J}^s = \emptyset$  can be deduced from step 1 below directly. The proof has two steps, in the first step, we check the upper bound of U(s,i) for all  $(s,i) \leq (t_{j_1^s}, j_1^s)$  and  $(s,i) \in \text{dom } \xi^y$ , then we verify the upper bound of U(t,j) in the second step. Here we remind that  $|\xi(0,0)|_{\mathcal{E}} \leq \Delta$  implies  $U(0,0) \leq \overline{\alpha}_U(\Delta^y) < \Delta^U$  and  $\Delta^U = a_d \overline{\alpha}_U(\Delta^y)$ .

 $\underbrace{Step \ 1}_{\text{teed to be zero, } t_{j_1^s}} \text{ (the time of first slow transmission)} \\ \underset{\text{might be smaller than } \tau_{\text{miati}}^s \text{. In this step, we focus on the interval } (s,i) \preceq (t_{j_1^s}, j_1^s), (s,i) \in \text{dom}\,\xi^y. \text{ We divide into two cases based on the initial condition.} \end{aligned}$ 

<u>Case 1-1</u>: If  $U(0,0) \leq \nu_2$ , by Claim 19, we know  $\overline{U(s,i)} \leq \nu_2$  for all  $(s,i) \leq (t_{j_1^s}, j_1^s - 1)$ . Then by (A.17),  $U(t_{j_1^s}, j_1^s) \leq a_d \nu_2$ .

<u>Case 1-2</u>: If  $U(0,0) \in (\nu_2, \overline{\alpha}_U(\Delta^y)]$ , by (A.16), (A.18) and Claim 19, we have  $U(s,i) \leq U(0,0)$  for all  $(s,i) \leq$ 

 $(t_{j_1^s}, j_1^s - 1)$ . Then by (A.17) we have  $U(s, i) \le a_d U(0, 0)$  for all  $(s, i) \le (t_{j_1^s}, j_1^s)$ .

For any  $(t,j) \in \text{dom } \xi^y$  with  $\mathcal{J}^s = \emptyset$ , Claim 19 implies  $U(t,j) \leq \nu_2$  if  $U(0,0) \leq \nu_2$ , and Case 1-2 shows  $U(t,j) \leq U(0,0)$  if  $U(0,0) \in (\nu_2, \overline{\alpha}_U(\Delta^y)]$ . Since  $t \leq \tau^s_{\text{mati}}$ , we have  $\frac{a_d}{\lambda}U(0,0) \exp\left(-\frac{\ln(1/\lambda)}{\tau^s_{\text{mati}}}(t)\right) \geq U(0,0)$ , which shows (A.22) hold for all  $(t,j) \in \text{dom } \xi^y$  when  $\mathcal{J}^s = \emptyset$ . At the same time, from Cases 1-1 and 1-2, we can see  $|\xi(0,0)|_{\mathcal{E}} \leq \Delta$  implies  $U(t_{j_1^s}, j_1^s) \leq a_d \overline{\alpha}_U = \Delta^U$ .

Step 2: In this step, we verify (A.22) for (t, j) with  $\mathcal{J}^s \neq \overline{\emptyset}$ . We also divide into two cases based on  $U(t_{j_1^s}, j_1^s)$ .

<u>Case 2-1</u>: We consider the case that  $U(t_{j_1^s}, j_1^s) \leq a_d\nu_2$ . We remind that m is the amount of slow transmissions in the trajectory  $\xi^y(t, j)$ . If m = 1, by (A.16) and Claim (19), we have  $U(t, j) \leq a_d\nu_2$ . Next we consider the scenario that  $m \geq 2$ . Let  $\Omega_{\nu_2} \coloneqq \{\xi^y \in \mathbb{X} | U(\xi^y) \leq \nu_2\}$ . By (A.19), definition of  $\lambda$ , d and  $a_d$  in (A.2), (A.3) and (A.8), we can see the time that takes  $\xi^y(t_{j_1^s}, j_1^s)$  to enter the set  $\Omega_{\nu_2}$  is less than or equal to  $\tau^s_{\text{miati}}$ . Then by Claim 19, we have  $U(t_2^s, j_2^s - 1) \leq \nu_2$ . By (A.17), we have  $U(t_{j_2^s}, j_2^s) \leq a_d\nu_2$ . Finally, by concatenation, we can prove  $U(t, j) \leq a_d\nu_2$ .

<u>Case 2-2</u>: We consider the case that  $U(t_{j_1^s}, j_1^s) \in (a_d\nu_2, \Delta^U]$ , which can exist only if  $U(0,0) \in (\nu_2, \overline{\alpha}_U(\Delta^y)]$ . Then by Cases 1-2, we know  $U(t_{j_1^s}, j_1^s) \leq a_d U(0,0)$ . We consider two possible scenarios.

Firstly, if  $U(s,i) > \nu_2$  for all  $(t_{j_1}^s, j_1^s) \preceq (s,i) \preceq (t,j)$ , then by (A.21) and concatenation, we have  $U(t_{j_m^s}, j_m^s) \le \lambda^{m-1}U(t_{j_1^s}, j_1^s) \le \lambda^{m-1}a_d U(0,0)$ , where  $j_m^s$  is the last element in  $\mathcal{J}^s$ . Then by (A.19), we have

$$U(t,j) \le \lambda^{m-1} a_d U(0,0) \exp\left(-\mu_1(t-t_{j_m^s})\right).$$
 (A.23)

The first component on the right-hand side of (A.22) can be written as

$$\begin{aligned} \frac{a_d}{\lambda} U(0,0) \exp\left(-\frac{\ln\left(\frac{1}{\lambda}\right)}{\tau_{\text{mati}}^s}t\right) \\ &= \frac{a_d}{\lambda} U(0,0) \exp\left(-\frac{\ln\left(\frac{1}{\lambda}\right)}{\tau_{\text{mati}}^s}t_{j_m^s}\right) \exp\left(-\frac{\ln\left(\frac{1}{\lambda}\right)}{\tau_{\text{mati}}^s}(t-t_{j_m^s})\right). \end{aligned} (A.24) \\ \text{Since } \frac{t_{j_m^s}}{\tau_{\text{mati}}^s} \leq m, \text{ we have } \frac{a_d}{\lambda} U(0,0) \exp\left(-\frac{\ln\left(\frac{1}{\lambda}\right)}{\tau_{\text{mati}}^s}t_{j_m^s}\right) \geq \frac{a_d}{\lambda} U(0,0) \exp(-\ln\left(\frac{1}{\lambda}\right)m) = a_d U(0,0)\lambda^{m-1}. \text{ By definition of } \lambda \text{ in } (A.2), \text{ and since } a_d > 1, \text{ we have } \exp\left(-\frac{\ln\left(\frac{1}{\lambda}\right)}{\tau_{\text{mati}}^s}(t-t_{j_m^s})\right) = \lambda^{\frac{t-t_{j_m^s}}{\tau_{\text{mati}}^s}} \geq \left(a_d \exp(-\mu_1 \tau_{\text{miati}}^s)\right). \\ \text{Then by } (A.23) \text{ and } (A.24), \text{ we show that if } U(s,i) > \nu_2 \text{ for all } (t_{j_1}^s, j_1^s) \leq (s,i) \leq (t,j), (A.22) \text{ hold.} \end{aligned}$$

Secondly, we consider the scenario that there exist  $(t_a, j_a) \preceq (t, j), (t_a, j_a) \in \text{dom } \xi^y$  such that  $U(t_a, j_a) \leq \nu_2$ . Following the similar procedure as in Case 2-1, we can prove  $U(t, j) \leq a_d \nu_2$ . Then we have proved Claim 20.

Now we convert the upper bound on  $U(\xi^{y}(t,j))$  to the upper bound on  $|\xi|_{\mathcal{E}}$ . By (A.10), we know  $U(\xi^{y}) \leq a_{d}\nu_{2}$  implies  $|\xi|_{\mathcal{E}} \leq \nu$ . Additionally, since  $|\xi|_{\mathcal{E}} \leq \zeta_{2}(|\xi^{y}|_{\mathcal{E}^{y}}), |\xi^{y}|_{\mathcal{E}^{y}} \leq \zeta_{2}(|\xi|_{\mathcal{E}})$  and by sandwich bound (A.6), we have  $U(t,j) \leq \frac{a_{d}}{\lambda}U(0,0)\exp\left(-\frac{\ln(1/\lambda)}{\tau_{mati}^{s}}t\right)$  implies  $|\xi(t,j)| \leq \beta_{1}(\xi(0,0),t)$  where  $\beta_{1}(s,t) := \zeta_{2}(\underline{\alpha}_{U}^{-1}(\frac{a_{d}}{\lambda}\overline{\alpha}_{U}(\zeta_{2}(s))\exp\left(-\frac{\ln(1/\lambda)}{\tau_{mati}^{s}}t\right)))$  and  $\beta_{1} \in \mathcal{KL}$ . Then by Claim 20, we know that  $|\xi(t,j)|_{\mathcal{E}} \leq \beta_{1}(|\xi(0,0)|_{\mathcal{E}},t) + \nu$  for all  $|\xi(0,0)|_{\mathcal{E}} \leq \Delta$ . Additionally, since  $t \geq \tau_{mati}^{s}(j-1)$ , we have

$$\begin{split} & \exp\left(-\frac{\ln\left(1/\lambda\right)}{\tau_{\text{mati}}^{s}}(t)\right) \\ \leq & \exp\left(-\frac{\ln\left(1/\lambda\right)}{\tau_{\text{mati}}^{s}}\left(\frac{t}{2} + \frac{\tau_{\text{miati}}^{s}}{2}(j-1)\right)\right)\right) \\ \leq & \exp\left(\frac{\ln\left(1/\lambda\right)\tau_{\text{miati}}^{s}}{2\tau_{\text{mati}}^{s}}\right) \exp\left(-\frac{\ln\left(1/\lambda\right)}{2\tau_{\text{mati}}^{s}}\min\{1,\tau_{\text{miati}}^{s}\}(t+j)\right) \\ = & : \alpha_{1}(t+j). \end{split}$$

(A.25) Then we have for all  $|\xi(0,0)|_{\mathcal{E}} \leq \Delta$ , there exist  $\beta \in \mathcal{KL}$  such that  $|\xi(t,j)|_{\mathcal{E}} \leq \beta(|\xi(0,0)|_{\mathcal{E}},t+j) + \nu$ , where  $\beta(s,t+j) = \zeta_2(\underline{\alpha}_U^{-1}(\frac{a_d}{\lambda}\overline{\alpha}_U(\zeta_2(s))\alpha_1(t+j))).$ 

# B Proof of Theorem 11

The first step is to show the  $\psi_s$  and  $\psi_f$  in Lemma 3 are linear. By (17), (18) and the definition of  $U_s$  in (24a), we can show  $U_s^{\circ}(\xi_s; F_s^y(x, 0, e_s, 0)) \leq -\rho_s(|x|) - \rho_s(W_s(\kappa_d, e_s))$  along the same line as [3, (27)]. Additionally, since  $a_{\rho_s}s^2 \leq \rho_s(s)$  for all  $s \in \mathbb{R}$ , we have  $U_s^{\circ}(\xi_s; F_s^y(x, 0, e_s, 0)) \leq -a_{\rho_s}|x|^2 - a_{\rho_s}W_s^2(\kappa_d, e_s)$ . Then by (28a), we have  $U_s^{\circ}(\xi_s; F_s^y(x, 0, e_s, 0)) \leq -(a_{\rho_s}|x|^2 + a_{\rho_s}W_s^2(\kappa_d, e_s)) \leq -a_{\rho_s}\min\{1, \underline{a}_{W_s}^2\}(|x|^2 + |e_s|^2) \approx -a_s\psi_s^2(|(x, e_s)|)$ , which implies (25b) is satisfied with  $a_s \coloneqq a_{\rho_s}\min\{1, \underline{a}_{W_s}^2\}$  and  $\psi_s(|(x, e_s)|) \approx |(x, e_s)|$ . Moreover, we have  $\underline{a}_{U_s}|(x, e_s)|^2 \leq U_s(\xi_s) \leq \overline{a}_{U_s}|(x, e_s)|^2$ , where  $\underline{a}_{U_s} \approx \min\{\underline{a}_{V_s}, \gamma_s\lambda_s^*\underline{a}_{W_s}^2\}$  and  $\overline{a}_{U_s} \coloneqq \max\{\overline{a}_{V_s}, \gamma_s \frac{1}{\lambda_s^*}\overline{a}_{W_s}^2\}$ .

Along the same line as  $U_s$ , we can proof that (26b) is satisfied with  $a_f \coloneqq a_{\rho_f} \min\{1, \underline{a}_{W_f}^2\}$  and  $\psi_f(|(y, e_f)|) \coloneqq$  $|(y, e_f)|$ . Moreover, we have  $\underline{a}_{U_f}|(y, e_f)|^2 \leq U_f(\xi_s, \xi_f) \leq$  $\overline{a}_{U_f}|(y, e_f)|^2$ , where  $\underline{a}_{U_f} \coloneqq \min\{\underline{a}_{V_f}, \gamma_f \lambda_f^* \underline{a}_{W_f}^2\}$  and  $\overline{a}_{U_f} \coloneqq \max\{\overline{a}_{V_f}, \gamma_f \frac{1}{\lambda_f^*} \overline{a}_{W_f}^2\}$ . Then we satisfy Assumption 6 with  $a_{\psi_s} = \underline{a}_{U_s}^{-\frac{1}{2}}$  and  $a_{\psi_f} = \underline{a}_{U_f}^{-\frac{1}{2}}$ . Same as the proof of Theorem 7, we define composite Lyapunov function U as  $U(\xi_s, \xi_f) \coloneqq U_s(\xi) + dU_f(\xi_s, \xi_f)$ , where  $d \in (0, 1)$ . Then U has sandwich bound

$$\underline{a}_U |\xi^y|_{\mathcal{E}^y}^2 \le U(\xi^y) \le \overline{a}_U |\xi^y|_{\mathcal{E}^y}^2, \qquad (B.1)$$

where  $\underline{a}_U \coloneqq \min\{\underline{a}_{U_s}, d\underline{a}_{U_f}\}$  and  $\overline{a}_U \coloneqq \max\{\overline{a}_{U_s}, d\overline{a}_{U_f}\}$ .

# $\begin{array}{l} \underline{During\ flow}: \mbox{ We can obtain (A.12), as well as } U^{\circ}(\xi^y,\\ F^y(\xi^y,\epsilon)) \leq - \left[ \sqrt{U_s(\xi_s)} \\ \sqrt{U_f(\xi_s,\xi_f)} \end{array} \right]^T \Lambda \left[ \sqrt{U_s(\xi_s)} \\ \sqrt{U_f(\xi_s,\xi_f)} \end{array} \right], \mbox{ where } \Lambda \\ \mbox{ is defined in (A.13), along the same line as the proof of Theorem 7 by setting } \nu_1 \mbox{ to be zero. In order to satisfy} \\ \Lambda \geq \mu \begin{bmatrix} 1 & 0 \\ 0 & d \end{bmatrix}, \mbox{ where } \mu \mbox{ is defined in (A.1), we need to satisfy inequality (A.14b) by having } \epsilon \in (0, \epsilon^*], \mbox{ where } \epsilon^* \mbox{ is defined by (A.15) and } d \mbox{ in (A.15) is given later.} \\ \mbox{ where the first inequality can be satisfied by taking } \epsilon \mbox{ sufficiently small. Then we have} \end{array}$

$$U^{\circ}(\xi^{y}, F^{y}(\xi^{y}, \epsilon)) \leq -\mu(U_{s}(\xi_{s}) + dU_{f}(\xi_{s}, \xi_{f}))$$
  
$$\leq -\mu U(\xi^{y}).$$
(B.2)

<u>During jumps</u>: Same as the proof of Theorem 7, we have  $U(G_s^y(\xi^y)) \leq a_d U(\xi^y)$  at slow transmissions and  $U(G_f^y(\xi^y)) \leq U(\xi^y)$  at fast transmissions. Suppose  $j_k^s, j_{k+1}^s \in \mathcal{J}^s$ . By (B.2), the fact that U is non-increasing at fast transmissions and comparison principle, we have

$$U(s,i) \le U(t_{j_k^s}, j_k^s) \exp\left(-\mu(t - t_{j_k^s})\right),$$
 (B.3)

for all  $(t_{j_k^s}, j_k^s) \leq (s, i) \leq (t_{j_{k+1}^s}, j_{k+1}^s - 1)$  and  $(s, i) \in \operatorname{dom} \xi^y$ . Along the same line as deriving (A.20), we have  $U(t_{j_{k+1}^s}, j_{k+1}^s) \leq a_d U(t_{j_k^s}, j_k^s) \exp(-\mu \tau_{\mathrm{miati}}^s)$ . By definition of  $a_d$  in (A.8), we have that for any  $\tau_{\mathrm{miati}}^s \leq T(L_s, \gamma_s, \lambda_s^*), \ \lambda \in (\exp(-\mu \tau_{\mathrm{miati}}^s), 1)$ , there exist

$$d^* = \frac{-b + \sqrt{b^2 - 4a\tilde{c}}}{2a},\tag{B.4}$$

where  $a = \frac{\lambda_1}{\gamma_s \lambda_s^*}, b = \frac{1}{2} (\frac{\lambda_1}{\gamma_s \lambda_s^*} + \lambda_2)$  and  $\tilde{c} = 1 - \lambda e^{\mu \tau_{\text{miati}}^s}$ , such that by taking  $d = d^*$ , we have  $U(t_{j_{k+1}^s}, j_{k+1}^s) \leq \lambda U(t_{j_k^s}, j_k^s)$ . Then the inequality (A.14b) is satisfied by all  $\epsilon \in (0, \epsilon^*)$ , where  $\epsilon^*$  is defined in (A.15) with  $d = d^*$ . By concatenation, we have  $U(t_{j_k^s}, j_k^s) \leq \lambda^{k-1} U(t_{j_1^s}, j_1^s)$ . Moreover, since U is non-increasing during flow and upper bounded by  $U(G_s^y(\xi^y)) \leq a_d U(\xi^y)$  at slow transmission, we have  $U(t_{j_1^s}, j_1^s) \leq a_d U(0, 0)$ . Then we have  $U(t_{j_k^s}, j_k^s) \leq a_d \lambda^{k-1} U(0, 0)$ . Now we have obtained the upper bound of trajectory during the interval between slow transmissions (i.e., (B.3)) and the upper bound at each slow transmission. Then along the same line as the proof of Claim 20, by setting  $\Delta$  to infinity and  $\nu$  to zero, we can show  $U(\xi^y(t, j)) \leq \frac{a_d}{\lambda} U(0, 0) \exp\left(-\frac{\ln(1/\lambda)}{\tau_{\text{mati}}^s}t\right)$ , for all  $(t, j) \in \text{dom } \xi^y$ . By (B.1), we have  $|\xi^y(t, j)|_{\mathcal{E}^y} \leq \left(\frac{1}{a_U} U(t, j)\right)^{1/2} \leq \left(\frac{a_d}{\lambda a_U} U(0, 0) \exp\left(-\frac{\ln(1/\lambda)}{\tau_{\text{mati}}^s}t\right)\right)^{1/2} = \left(\frac{a_d \overline{a_U}}{\lambda \underline{a_U}}\right)^{1/2} |\xi^y(0, 0)|_{\mathcal{E}^y} \exp\left(-\frac{\ln(1/\lambda)}{\tau_{\text{mati}}^s}t\right)^{1/2}$ . Since  $\overline{H}$  is globally Lipschitz and  $\overline{H}(0,0) = 0$ , we have  $\overline{H}(x,e_s) \leq L|(x,e_s)|$ , where L is the Lipschitz constant. Then by  $y = z - \overline{H}(x,e_s)$ , there exist  $h_1 = 1 + L$  such that  $|\xi(t,j)|_{\mathcal{E}} \leq h_1|\xi^y(t,j)|_{\mathcal{E}^y}$  and  $|\xi^y(t,j)|_{\mathcal{E}^y} \leq h_1|\xi(t,j)|_{\mathcal{E}}$ . Then the upper bound of  $|\xi(t,j)|_{\mathcal{E}}$  is  $|\xi(t,j)|_{\mathcal{E}} \leq h_1^2 \left(\frac{a_d\overline{a}_U}{\lambda\underline{a}_U}\right)^{1/2} |\xi(0,0)|_{\mathcal{E}} \exp\left(-\frac{\ln(1/\lambda)}{\tau_{\text{mati}}^s}t\right)^{1/2}$ . By (A.25), we have  $|\xi(t,j)|_{\mathcal{E}} \leq c_1|\xi(0,0)|_{\mathcal{E}} \exp\left(-c_2(t+j)\right)$ , where  $c_1 = h_1^2 \left(\frac{a_d\overline{a}_U}{\lambda\underline{a}_U}\right)^{1/2} \exp\left(\frac{\ln(1/\lambda)\tau_{\text{mati}}^s}{4\tau_{\text{mati}}^s}\right)$  and  $c_2 = \frac{\ln(1/\lambda)}{4\tau_{\text{mati}}^s} \min\{1, \tau_{\text{miai}}^s\}$ .

# C Proof of Proposition 17

Claim 16 has shown that (15)-(17) in Assumption 1 hold and (28a) in Assumption 10 holds. Next, we show (18) in Assumption 1, as well as (28c) and (29a) in Assumption 10 hold. Let  $P_s = \begin{bmatrix} p_{11}^s \bigstar \\ p_{12}^{s^+} p_{22}^s \end{bmatrix} > 0$ , where  $p_{11}^s$  is a  $n_{x_p}$  by  $n_{x_p}$  symmetric matrix,  $p_{12}^s$  is a  $n_{x_p}$  by  $n_{x_c}$  matrix and  $p_{22}^s$  is a  $n_{x_c}$  by  $n_{x_c}$  symmetric matrix. Let  $V_s = x^\top P_s x$ , then (28c) is satisfied with  $\underline{a}_{V_s} = \lambda_{\min}(P_s)$  and  $\overline{a}_{V_s} = \lambda_{\max}(P_s)$ . Moreover, we have

$$\left\langle \frac{\partial V_s(x)}{\partial x}, f_x(x, \overline{H}(x, e_s), e_s, 0) \right\rangle$$
  
= $x^{\top} (P_s A_{11}^s + A_{11}^{s \top} P_s) x + x^{\top} P_s A_{12}^s e_s + e_s^{\top} A_{12}^{s \top} P_s x.$ (C.1)

Inequalities (18) and (29a) are satisfied if (C.2) holds.

$$\left\langle \frac{\partial V_s(x)}{\partial x}, f_x(x, \overline{H}(x, e_s), e_s, 0) \right\rangle$$
  
$$\leq -a_{\rho_s} x^\top x - a_{\rho_s} e_s^\top e_s - x^\top A_{H_s}^\top A_{H_s} x + \gamma_s^2 \underline{a}_{W_s}^2 e_s^\top e_s.$$
(C.2)

By substituting (C.1) into (C.2), we show that (18) in Assumption 1 and (29a) in Assumption 10 are satisfied if (33) with  $\ell = s$  holds.

Similarly, Claim 16 show (19)-(21) and (28a) are satisfied. Let  $P_f = \begin{bmatrix} p_{11}^f \star \\ p_{12}^{f^\top} p_{22}^f \end{bmatrix} > 0$ , where  $p_{11}^f$  is a  $n_{z_p}$  by  $n_{z_p}$  symmetric matrix,  $p_{12}^f$  is a  $n_{z_p}$  by  $n_{z_c}$  matrix and  $p_{22}^f$  is a  $n_{z_c}$  by  $n_{z_c}$  symmetric matrix. Let  $V_f = y^\top P_f y$ , then (28c) is satisfied with  $\underline{a}_{V_f} = \lambda_{\min}(P_f)$  and  $\overline{a}_{V_f} = \lambda_{\max}(P_f)$ . Moreover, we can show (23) in Assumption 2 and (29b) in Assumption 10 hold if LMI (33) with  $\ell = f$  is satisfied. At this point, we show Assumptions 1, 2 and 10 hold if the LMI (33) with  $\ell \in \{s, f\}$  is satisfied.

We then Verify Assumptions 5 and 8. By definition of  $h_y(\kappa_s, x, e_s, y)$  in (10) and  $\overline{H}$  in (31), we have  $h_y(\kappa_s, x, e_s, y) = y - A_{33}^{-1}A_{32}(e_s - h_s(\kappa_s, e_s))$ . Since we assumed when a slow node gets access to the network, some elements of  $e_s$  reset to zero, we have  $|e_s - h_s(\kappa_s, e_s)| \leq |e_s|$ . Then by definition of  $h_y$ , we have

$$V_{f}(x, h_{y}(\kappa_{s}, x, e_{s}, y)) - V_{f}(x, y) = (y - A_{33}^{-1}A_{32}(e_{s} - h_{s}(\kappa_{s}, e_{s})))^{\top}P_{f} (y - A_{33}^{-1}A_{32}(e_{s} - h_{s}(\kappa_{s}, e_{s}))) - y^{\top}P_{f}y$$
(C.3)  
$$\leq 2|P_{f}A_{33}^{-1}A_{32}||y||e_{s}| + |A_{32}^{\top}A_{33}^{-1\top}P_{f}A_{33}^{-1}A_{32}||e_{s}|^{2} \leq \lambda_{1}W_{s}^{2}(\kappa_{s}, e_{s}) + \lambda_{2}\sqrt{W_{s}^{2}(\kappa_{s}, e_{s})V_{f}(x, y)},$$

where  $\lambda_1 = \frac{1}{a_{W_s}^2} |A_{32}^\top A_{33}^{-1}^\top P_f A_{33}^{-1} A_{32}|$  and  $\lambda_2 = \frac{2}{a_{W_s} \sqrt{a_{V_f}}} |P_f A_{33}^{-1} A_{32}|$ . We have shown that we satisfy Assumption 5. Next, we show that Assumption 8 always hold. We first verify inequality (27a). We have  $\frac{\partial U_s}{\partial \xi_s} = \left[2x^\top P_s \ 2\gamma_s \phi_s(\tau_s) W_s(\kappa_s, e_s) \frac{\partial W_s}{\partial e_s} - \gamma_s^2(\phi_s^2(\tau_s) + 1) W_s(\kappa_s, e_s)^2 0\right].$ Additionally, we have  $F_s^y(x, y, e_s, e_f) = \begin{bmatrix} A_{11}^s A_{12}^s A_{13} A_{14} \\ A_{21}^s A_{22}^s A_{23} A_{24} \\ 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} x \\ y \\ e_f \end{bmatrix} + \begin{bmatrix} 0 \\ 1 \\ 0 \end{bmatrix}$ , which implies  $F_s^y(x, y, e_s, e_f) - F_s^y(x, 0, e_s, 0) = \begin{bmatrix} A_{13}y + A_{14}e_f \\ A_{23}y + A_{24}e_f \\ 0 \\ 0 \end{bmatrix}.$ 

By [15, Remark 11], there exist  $L_1 \geq 0$  such that  $\left|\frac{\partial W_s(\kappa_s, e_s)}{\partial e_s}\right| \leq L_1$ , then (27a) is satisfied by

$$\left\langle \frac{\partial U_s}{\partial \xi_s}, F_s^y(x, y, e_s, e_f) - F_s^y(x, 0, e_s, 0) \right\rangle$$
  
=2 $x^{\top} P_s(A_{13}y + A_{14}e_f) +$   
2 $\gamma_s \phi_s(\tau_s) W_s(\kappa_s, e_s) \frac{\partial W_s}{\partial e_s}(A_{23}y + A_{24}e_f)$   
 $\leq \left[ \frac{|x|}{|e_s|} \right]^{\top} \Lambda_{b_1} \left[ \frac{|y|}{|e_f|} \right] \leq b_1 \psi_s(|(x, e_s)|) \psi_f(|(y, e_f)|),$  (C.4)

where  $\Lambda_{b_1} = \begin{bmatrix} |P_s A_{13}| & |P_s A_{14}| \\ \frac{\gamma_s}{\lambda_s} \overline{a}_{W_s} L_1 |A_{22}| & \frac{\gamma_s}{\lambda_s} \overline{a}_{W_s} L_1 |A_{24}| \end{bmatrix}$ ,  $b_1 = \sqrt{\lambda_{\max}(\Lambda_{b_1}^{\top} \Lambda_{b_1})}$  and  $\psi_s(s) = \psi_f(s) = s$  for all  $s \in \mathbb{R}_{\geq 0}$ . Finally, we validate the inequality (27b) in Assumption 8. By definition of  $U_f$  in (24b), we have  $\frac{\partial U_f}{\partial \xi_s} = 0$ ,  $\frac{\partial U_f}{\partial y} = 2y^{\top} P_f$ ,  $\frac{\partial \overline{H}}{\partial \xi_s} = [-A_{33}^{-1}A_{31} - A_{33}^{-1}A_{32} \circ 0]$ ,  $\frac{\partial U_f}{\partial e_f} = 2\gamma_f \phi_f(\tau_f) W_f(\kappa_f, e_f) \frac{\partial W_f}{\partial e_f}$ , and  $\frac{\partial \tilde{k}}{\partial \xi_s} = \left[ \begin{bmatrix} A_x^{P_f} & 0 \\ 0 & A_x^{C_f} \end{bmatrix} \circ \circ 0 \right]$ . Then along the same line as (C.4), we can show that there exist a matrix  $\Lambda_{b_2}$ , a symmetric matrix  $\Lambda_{b_3}$  and  $b_2, b_3 \geq 0$  such that

$$\left\langle \frac{\partial U_f}{\partial \xi_s} - \frac{\partial U_f}{\partial y} \frac{\partial \overline{H}}{\partial \xi_s} - \frac{\partial U_f}{\partial e_f} \frac{\partial \tilde{k}}{\partial \xi_s}, F_s^y(x, y, e_s, e_f) \right\rangle$$

$$\leq \left[ \begin{vmatrix} |x| \\ |e_s| \end{vmatrix} \right]^\top \Lambda_{b_2} \left[ \begin{vmatrix} |y| \\ |e_f| \end{vmatrix} \right] + \left[ \begin{vmatrix} |y| \\ |e_f| \end{vmatrix} \right]^\top \Lambda_{b_3} \left[ \begin{vmatrix} |y| \\ |e_f| \end{vmatrix} \right]$$

$$\leq b_2 \psi_s \left( \left| (x, e_s) \right| \right) \psi_f \left( \left| (y, e_f) \right| \right) + b_3 \psi_f^2 \left( \left| (y, e_f) \right| \right),$$

$$(C.5)$$

where  $b_2 = \sqrt{\lambda_{\max}(\Lambda_{b_2}^{\top} \Lambda_{b_2})}$ ,  $b_3 = \lambda_{\max}(\Lambda_{b_3})$ , which implies the inequality (27b) is satisfied.
