ABSTRACT

The performance emergence of large language models (LLMs) driven by data scaling laws makes the selection of pre-training data increasingly important. However, existing methods rely on limited heuristics and human intuition, lacking comprehensive and clear guidelines. To address this, we are inspired by "reverse thinking" - prompting LLMs to self-identify which criteria benefit its performance. As its pre-training capabilities are related to perplexity (PPL), we derive 14 quality criteria from the causes of text perplexity anomalies and introduce 15 common application domains to support domain mixing. In this paper, we train a Data Manager (DataMan) to learn quality ratings and domain recognition from pointwise rating, and use it to annotate a 447B token pre-training corpus with 14 quality ratings and domain type. Our experiments validate our approach, using DataMan to select 30B tokens to train a 1.3B-parameter language model, demonstrating significant improvements in in-context learning (ICL), perplexity, and instructionfollowing ability over the state-of-the-art baseline. The best-performing model, based on the Overall Score l=5 surpasses a model trained with 50% more data using uniform sampling. We continue pre-training with high-rated, domain-specific data annotated by DataMan to enhance domain-specific ICL performance and thus verify DataMan's domain mixing ability. Our findings emphasize the importance of quality ranking, the complementary nature of quality criteria, and their low correlation with perplexity, analyzing misalignment between PPL and ICL performance. We also thoroughly analyzed our pre-training dataset, examining its composition, the distribution of quality ratings, and the original document sources.

1 Introduction

As large language models (LLMs) demonstrate performance emergence driven by data scaling laws, the significance of data has become increasingly evident (Kaplan et al., 2020; Brown et al., 2020; Chowdhery et al., 2023). This trend prompts researchers to explore how to select pre-training data, including deduplication (Lee et al., 2022), domain mixing (Gao et al., 2020; Shen et al., 2023), heuristic-based data selection (Rae et al., 2022; Wenzek et al., 2019), and data sampling using LLM quality signals (Gunasekar et al., 2023; Wettig et al., 2024a). Although these efforts aim to enhance data quality and diversity, deduplication and domain mixing are solely used as a priori or post-hoc steps in the data selection process. Furthermore, existing data selection methods typically rely on limited heuristics and human intuition, lacking comprehensive and clear criteria for data selection, thus making the selection of ideal pre-training data for LLMs an unresolved challenge.

Following this line, this paper provides guidelines for selecting pre-training data, including quality criteria, application domains, and a **Data Man**ager (**DataMan**) with a comprehensive quality rating and domain recognition, equipped by data sampling strategies to enhance the LLM performances. Firstly, we believe that excellent quality criteria must: 1)-apply to a wide variety of texts; 2)-demonstrate a deep understanding of content, capturing semantic levels; and 3)-complement each other. However, existing studies (Rae et al., 2022; Wettig et al., 2024a) rely on limited heuristics and human intuition, while grounded in empirical findings, lack generality and comprehensiveness. To address this issue,

^{*}This work done during internship at Qwen team, Alibaba Group.

[†]Both are corresponding authors.

Figure 1: The pipeline of the Sample-with-DataMan model: We derived 14 quality criteria from LLMs' *reverse thinking* and used DataMan to annotate the quality rating and domain type of pretraining data. By employing data sampling strategies to select subsets, the performance of trained LLMs outperforms the state-of-the-art data sampling baseline.

we are inspired by "reverse thinking" — prompting LLM to self-identify which criteria benefit its performance, as its pre-training capability is related to perplexity (PPL) (Muennighoff et al., 2024; Marion et al., 2023b). We extracted documents with the top 2% and bottom 2% PPL from different sources and used Super LLM to identify the reasons for anomalous in document perplexity. Through iterative refinement, we derived 13 quality criteria related to LLM performance: Accuracy, Coherence, Creativity, Grammatical Diversity, Knowledge Novelty, Language Consistency, Originality, Professionalism, Semantic Density, Sensitivity, Structural Standardization, Style Consistency, and Topic Focus, and formed comprehensive criterion called Overall Score. Further, we introduced 15 common domain types in the LLM application industry (Naveed et al., 2023) for domain mixing and developed a full prompt to curate a fine-tuning dataset. We employ a small-scale LLM to fine-tune DataMan via text generation and apply pointwise rating over pairwise rating (Liu et al., 2007) for more applicable, cost-effective inference on vast datasets. Using DataMan, we annotated 447B tokens in the Slimpajama corpus (Soboleva et al., 2023) with quality ratings and domain types to create the DataPajama dataset. While ensuring the diversity of sources and domains, we maximized the representativeness of quality criteria, sampling a 30B token subset from the DataPajama and trained the Sheared-LLaMA-1.3B language model (Xia et al., 2023) from scratch.

In our experiment, we initially validated the feasibility of using prompt as it achieved over 95% agreement with human preferences. We then revisited the limitation of pairwise rating (Wettig et al., 2024a), bounded pointwise rating error by its model loss, and fairly ranked the annotation results from both ratings to explain, from three perspectives, why we chose pointwise rating. While training the DataMan model, we thoroughly analyzed its fine-tuning datasets, hyperparameter search, inference accuracy and efficiency of three model versions, and misclassification issues. Further, We evaluated language models trained on 30B tokens sampled with different data selection methods from the DataPajama dataset. In ten downstream tasks, the Sample-with-DataMan model, trained on data sampled with Dataman's 13 quality criteria, outperformed the existing state-of-the-art (SOTA) baseline (Educational value $\tau = 2$) in in-context learning performance by 0.4% to 4.3%, showcasing the effectiveness of these criteria. As the Overall Score rose from 1 to 5, both ICL performance and PPL improved significantly, confirming the necessity of quality ranking. Our strongest model was achieved at Overall Score l=5, even surpassing the model trained on uniform sampling with 50% more data, as the Overall Score encompasses attributes of all criteria, supported by its high correlation with other quality criteria. To solidify our results, we sampled a larger 60B data subset and compared the strongest Sample-with-DataMan model Overall Score l=5 against the existing SOTA baseline. Meanwhile, we found PPL and ICL performance are not aligned strictly. Through correlation analysis and visualization, we reveal that PPL reflects general understanding, whereas

ICL captures downstream generalization ability. In the instruction following tasks, all Sample-with-DataMan models overwhelmingly surpassed the existing SOTA baseline with a win rate between 67.1% and 78.5%. Additionally, We continued pre-training the strongest *Overall Score l=5* model using high-rated, domain-specific data annotated by DataMan, achieving superior ICL performance in specific domains, thereby verifying DataMan's capability for domain mixing. We also conducted an in-depth analysis of the DataPajama dataset, explored the distribution of DataMan's quality ratings from various sources, and inspected the original documents corresponding to each quality rating=1,2,3,4,5. we also identified complementary relationships among quality criteria, while their low correlation with perplexity further confirms the novelty of DataMan's quality criteria.

Our contributions are summarized as follows:

- 1. Based on the relationship between LLM performance and PPL, "reverse thinking" allows LLMs to self-identify which criteria benefit its performance, assemble with typical application domains to guide data selection.
- 2. We introduce DataMan, offering comprehensive quality ratings and domain recognition, along with data sampling strategies to optimize LLM pre-training. Vast experiments validate its efficacy, setting new performance records.
- 3. We will release the code, all models, and the annotated DataPajama dataset, paving the way for the community to explore the guidelines between data and LLMs further.

2 Related Work

Deduplication. Deduplicating training data is now standard in managing pre-training data for LLMs, as it greatly impacts performance (Lee et al., 2022). While Kaplan et al. (2020) and Hoffmann et al. (2022b) examine scaling laws with unique data trained for one epoch, some studies (Hernandez et al., 2022; Muennighoff et al., 2024; Xue et al., 2024) suggest that repeated data can harm performance, particularly as repetition epochs and model size grow. Additionally, fuzzy or semantic deduplication improves LLM performance (Jiang et al., 2022; Abbas et al., 2023; Tirumala et al., 2023). But deduplication should precede quality-based selection and domain mixing, and it is unsuitable for sampling fixed-size subsets.

Heuristic-based Selection. This selection approach includes two methods: *Rule-based heuristics*, which apply manually crafted rules—such as mean word length, stop word fraction, and word repetition thresholds (Laurençon et al., 2022; TogetherAI, 2023; Penedo et al., 2023; Soldaini et al., 2024)—to filter data, exemplified by the C4 filter (Raffel et al., 2020) and Gopher rules (Rae et al., 2022). These reduce noise effectively but need complex manual design. In contrast, *Modelbased heuristics* use models like binary grammar discriminators (Chowdhery et al., 2023; Touvron et al., 2023a) to select data resembling the target domain, alongside techniques like importance resampling (Xie et al., 2023) and perplexity filtering (Wenzek et al., 2019; Muennighoff et al., 2024; Marion et al., 2023a). However, they require more precise quality ratings for optimal selection.

Domain mixture. Most pre-training datasets, like the Pile (Gao et al., 2020), comprise mixed data from various sources and domains (Nijkamp et al., 2023; Zhang et al., 2023; Yang et al., 2024b; Maini et al., 2024; Li et al., 2024). As LLMs gain traction, domain-specific data for improved functionalities are increasingly used in model training (Du et al., 2022; Gao et al., 2023). Identifying the optimal domain mixture ratio is essential for effective LLM pre-training (Wang et al., 2023). Early attempts to define this relied on experiments and intuition (Gao et al., 2020; Thoppilan et al., 2022). Recent studies have begun to use automatic methods, such as domain generalization (Xie et al., 2023; 2024), domain gradients (Fan et al., 2023), and loss evaluation (Xia et al., 2023), to assign domain weights and assess model performance across various mixtures. This inspires our work to introduce domain types to assist in pre-training data mixture.

LLM quality signals. Appropriate LLM quality signals are valuable for selecting pre-training data (Gunasekar et al., 2023). Research shows that data enriched with facts and trivia aids LLMs in accurately addressing niche topics and fictional worlds (Petroni et al., 2019; Korbak et al., 2023). Other studies have emphasized the educational value of data as a key for enhancing LLMs' reasoning capabilities (Wei et al., 2022; Kojima et al., 2022). Recent efforts have integrated these insights,

proposing four quality criteria—writing style, facts and trivia, educational value, and required expertise—to assess pre-training data and enhance LLM capabilities (Wettig et al., 2024b). However, these criteria depend heavily on human intuition and thus lack generality and comprehensiveness.

3 ANNOTATING TEXT BY DATAMAN

We developed **DataMan** (see Figure 1), a data manager that comprehensively annotates 14 quality criteria and domain types, enabling ideal data selection and mixing.

3.1 Overview of the Annotation

Let $\mathbf{t} = \{t_1, \dots, t_n\}$ represent all documents to be annotated. The annotation results of DataMan correspond to querying the ratings of document t_n across all quality criteria and its domain type. Assume that the quality ratings and domain recognition are in a multi-level annotation format as $\mathcal{L} = \{(l_1^1, \dots, l_1^C), \dots, (l_n^1, \dots, l_n^C)\}$, where $l_n^C \in \{1, \dots, K\}$ is the label for the C-th criterion or domain of document t_n . For this paper, K is 5 for quality ratings and 15 for domain recognition. Let F be a class of functions, and $f \in F$ be the annotation function. We use a super LLM as the annotation function, recording the annotation results for each criterion and domain, expressed as: $f(t, \mathcal{L}) = \{(t_1, l_1^1, \dots, l_1^C), \dots, (t_n, l_n^1, \dots, l_n^C)\}$. Thus, we can quickly create a fine-tuning dataset for DataMan, $\mathcal{S} = \{(t_i, l_1^1, \dots, l_i^C)\}$. Essentially, our method uses pointwise rating by pointwise learning to rank (L2R) model (Liu et al., 2007; 2009). We minimize the loss function based on the document, annotation labels, and function:

$$L(f;t,\mathcal{L}) = \sum_{i=1}^{n} (f(t_i) - l_i)^2.$$
 (1)

This trains DataMan to learn the annotation functions for each quality criterion and domain type.

3.2 PROMPT CURATION

How to define the quality criteria and domain types of texts? We believe that excellent quality criteria should: 1)-apply to a wide variety of texts, 2)-demonstrate a deep understanding of content, capturing semantic levels, and 3)- complement each other. However, prior studies largely relied on human intuition, such as educational value in Gunasekar et al. (2023), writing style in Wettig et al. (2024a), and toxicity and privacy in Korbak et al. (2023), which lack generality and comprehensiveness. To address this issue, we undertook an in-depth exploration of text quality, motivated by "reverse thinking"—prompting the LLM to self-identify which criteria benefit its performance. Specifically, since LLMs' pre-training abilities are closely related to their PPL (Muennighoff et al., 2024; Marion et al., 2023b), where "high PPL indicates data is difficult to learn, and vice versa", we focused on the training text from various sources with the top 2% and bottom 2% of PPL. We devised an analytical prompt for a Super LLM¹ to investigate the reason behind these perplexity anomalies in documents, aiming to analyze the traits of both easy-to-learn and difficult-to-learn data. Through iterative refinement, we derived 14 quality criteria as shown in Figure 1. Additionally, we identified the 15 domain types that need to be assessed from typical LLM application industries (Naveed et al., 2023), integrating the "let's think step by step" chain-of-thought prompting strategy (Wei et al., 2022) and a thoughtfully designed system prompt. Further details of the entire process are in Appendix A.

Prompt validation. We validate prompt effectiveness using clear cases before prompt use. Initially, we gathered a pool of documents preliminarily rated by an independent group, splitting them into two sets of ten documents each—high-rated and low-rated—to ensure a distinct quality gap. Table 4 of Appendix A details these document sources. These 20 documents were randomly shuffled and then rated on a scale of 1-5 based on each quality criterion by five independent human annotators who had not seen them before. Subsequently, using the super LLM with our prompt, we evaluated the same documents and compared super LLM ratings with human majority votes, finding over 95% agreement. Also, we ensured inter-rater reliability among human annotators by calculating the Kappa coefficient (McHugh, 2012), which validated the consistency of human ratings. However, this human validation remains subjective, we hope the community develops a more rigorous method.

¹The Super LLM can independently refer to any advanced LLM. In this paper, We use the state-of-the-art LLM available at that time, GPT-4-0125-preview.

3.3 WHY USE POINTWISE RATING?

Using LLMs to rate text falls into two categories: pointwise rating and pairwise rating. Here, we explain why we chose the pointwise rating from the following three aspects:

Pairwise rating limitations. We revisited pairwise rating (Wettig et al., 2024a) and observed minimal quality differences among the top-3 documents ranked by *writing style*, as even humans struggle to discern differences (see Table 5). This highlights the limitations of pairwise ratings when quality differences are marginal, as documents meeting an "acceptable" quality threshold should be accepted, where pointwise rating aligns well with human judgment. Appendix B.1 notes that creating a fine-tuning dataset requires Super LLM to make 40 predictions per criterion and document pairs, then use LLM preferences as labels. Table 5 shows that document pairs need a \geq 50% selection probability difference for quality criteria, also required for inference in Table 6, thus questioning the practicality of pointwise ratings. For N documents, pointwise ratings only need N ratings, whereas pairwise ratings demands N*(N-1) comparisons with 40 predictions each, greatly increasing costs. Despite both ratings capture different aspects, pointwise rating's broader applicability and cost-effectiveness in fine-tuning dataset curation or pre-training data annotation make it our preferred choice.

Bound pointwise rating error. We present the mathematical connection between rating errors and loss in the pointwise rating model (Chen et al., 2009).

$$1 - NDCG(f; t, \mathcal{L}) \le \frac{15\sqrt{2}}{N_n} \left(\left(\sum_{i=1}^n D(t_i)^2 \right) - n \prod_{i=1}^n D(t_i)^{2/n} \right)^{1/2} (L(f; t, \mathcal{L}))^{1/2}, \quad (2)$$

$$NDCG(f;t,\mathcal{L}) = \frac{1}{N_n} \sum_{i=1}^n G(l(\pi_f(t_i))) D(t_i), \tag{3}$$

$$N_n = \max_{\pi} \sum_{i=1}^{n} G(l(\pi(t_i))) D(t_i), \tag{4}$$

where NDCG is rating measures defined with respect to K-level ratings \mathcal{L} , G is the gain function, π_f is the rating list produced by the rating function f, and D is the position discount function. One usually sets $G(z) = 2^z - 1$, $D(z) = \frac{1}{\log_2(1+z)}$ if $z \leq M$, and D(z) = 0 if z > M (M is a fixed integer). Thus, as the pointwise rating model minimizes loss via training, the rating error also reduces, validating the feasibility of pointwise ratings theoretically.

Fairly compare both rating results. To ensure a fair comparison despite differing evaluation metrics, we ranked annotations from Qurating's pairwise and DataMan's pointwise ratings on the same 58,824 documents from the first split of Qurating's 1B analysis set². We then presented the top, median, and bottom ten documents based on Qurating's four criteria—writing style, facts and trivia, educational value, and required expertise—and DataMan's Overall Score with sum of the remaining criteria. All results are provided here³. Our conclusions are: *i*)-Higher Qurating criteria correlate with higher DataMan's Overall Scores for the top and bottom 10 documents, and vice versa. *ii*)-Median 10 documents show minimal changes in Qurating's criteria, yet their Overall Scores vary from 3 to 5, supporting that "Pairwise rating struggles with minimal quality differences, while pointwise rating matches human judgment." *iii*)-Rankings by Overall Score highlight top-quality documents, especially in STEM fields. *iv*)-The "application_domain" field accurately categorizes domains, aiding in domain-specific continue pre-training, as shown in Table 2.

3.4 TRAINING THE DATAMAN MODEL

After developing the prompt and rating method, we collected documents from both in-source and out-of-source of the SlimPajama corpus (Soboleva et al., 2023) to train DataMan. By prompting the Super LLM, we obtained 14 quality ratings and domain types for each document, creating a fine-tuning dataset of 35,700 documents at a cost of \$13,858. Documents were limited to 2,048 tokens (averaging 810 tokens), surpassing the [256, 512] token range of Wettig et al. (2024a) when handling sentences with broader length variations. Subsequently, we fine-tuned the DataMan model with

²https://huggingface.co/datasets/princeton-nlp/QuRatedPajama-1B_tokens_for_analysis

³https://github.com/pengr/DataMan/blob/main/README.md

Qwen2-1.5B (Yang et al., 2024a) using text generation loss. In Table 8, the DataMan model achieves near 80% average test accuracy across all criteria, with an *Overall Score* test accuracy of 81.3% and a *domain recognition* test accuracy of 86%. Appendix B also provides details on the fine-tuning dataset statistics, average scores for each quality criterion per domain, correlation among quality criteria, three DataMan model versions, the chat prompt for text generation, the hyperparameter search, reports on inference accuracy, misclassification analysis and inference efficiency.

4 Managing data by DataMan

In this section, we apply the DataMan model to manage data by selecting a high-quality, diverse document subset from the pre-training corpus. Each document d_i in the corpus D, with source s_i , is annotated by the DataMan model with 14 quality ratings and domain types as $\mathcal{L} = \{(l_i^1, \ldots, l_i^{C-1}, q)\}$, where q is the domain type. Given the source and domain distribution probabilities P(s) and P(q) respectively, we perform top-k (k is the selected subset size) sampling without replacement for each quality criterion across source and domain distribution, using the probability:

$$P(d_i) = \frac{P(d_i \mid l^j, s, q) \cdot P(s, q)}{\sum_{d_j \in \text{top-k}(l^j)} P(d_j \mid l^j, s, q) \cdot P(s, q)}, \text{ and } P(d_i \mid l^j) = \frac{l_i^j}{\sum_{d_j \in D} l_i^j}.$$
 (5)

This method maximizes sample representativeness based on quality rating while ensuring diversity in source and domain distributions, and sampling without replacement prevents duplicate data. To assess if the *Overall Score* covers all criteria, we substitute top-k with uniform sampling based on fixed *Overall Score* ratings. These techniques implicitly steer language modeling toward reward-weighted regression (Peters & Schaal, 2007; Korbak et al., 2023), expanding maximum likelihood estimation loss with a data reward mechanism.

5 EXPERIMENTS

We empirically validate the DataMan method by training the language model from scratch.

5.1 EXPERIMENTAL SETUP

DataPajama. We used the Llama tokenizer (Touvron et al., 2023a) to segment Slimpajama corpus (Soboleva et al., 2023), a cleaned and deduplicated version of the RedPajama (TogetherAI, 2023), into 1024-tokens documents. The DataMan model then annotated these documents with 14 quality ratings and domain types, creating the 447B token DataPajama for pre-training. Although the annotation process is expensive, it can be reduced via large-scale parallelization and cost-effective DataMan models. The quality ratings and domain types in DataPajama can serve various purposes, such as data selection, data mixing, or continued pre-training in specific domains. Detailed statistics of DataPajama can be found in Table 11 of Appendix C.

Data selection methods. For each baseline, we select a 30B token training dataset from DataPajama with one of the following methods, while retaining the original source proportion as the overall dataset. We leave it as future work to explore combinations of quality criteria to broaden our method.

- *Uniform*: We select randomly with a uniform probability across documents. For comparison's sake, we train an additional model on 45B tokens, requiring 50% more compute.
- DSIR: We apply data selection with importance resampling (DSIR) (Xie et al., 2023) and select examples that resemble either English Wikipedia or the Book domain (TogetherAI, 2023)—commonly used as proxies for quality (Brown, 2020; Touvron et al., 2023a; Xie et al., 2023). We follow Xie et al. (2023) and train hashed bigram models on DataPajama and the target data.
- Perplexity Filtering: We implement perplexity filtering (Wenzek et al., 2019; Marion et al., 2023a) and select the documents with the lowest/highest perplexity scores, as computed by a pre-trained Sheared-Llama-2.7B model (Xia et al., 2023)—2× the size of our DataMan model.
- Sample with Qurating: We sample 30B tokens according to each of the four criteria described in Wettig et al. (2024a): writing style, facts and trivia, educational value, and required expertise. Specifically, we normalize the variance of the quality ratings to be 1 and then sample with temperature $\tau \in \{0.0 \text{ (i.e., top-}k \text{ selection)}, 2.0\}$. Additionally, we merge the Qurating-sampled

data for $\tau=2.0$ of the four criteria as *criteria mix*, and subsampling is as randomly to 30B tokens, ensuring that we exclude duplicate documents.

• Sample with DataMan (Ours): For each of 13 quality criteria, we perform top-k sampling based on the quality ratings and domain type described in Section 4. Additionally, we explore sampling 30B tokens with overall scores $l \in \{1, 2, 3, 4, 5\}$ to demonstrate the effectiveness of all criteria.

Training settings. Using different data selection methods, we select a 30B token subset from DataPajama and train a randomly initialized Sheared-Llama-1.3B language model (Xia et al., 2023) for one epoch in a randomly shuffled order. We train on slightly more data than the compute-optimal ratio (Hoffmann et al., 2022a) because more training tokens better reflect the performance gains attributed to data quality. Further details are in Appendix C.

Evaluation metrics. We provide a holistic evaluation of the language models trained on 30B tokens:

- We measure the perplexity over SlimPajama's validation set and test set, 500M tokens each.
- We evaluate the in-context learning (ICL) performance using lm-evaluation-harness (Gao et al., 2024). We study 10 tasks, comprising 5 reading comprehension tasks (ARC-easy/challenge (Clark et al., 2018), SciQA (Welbl et al., 2017), LogiQA (Liu et al., 2020), BoolQ (Clark et al., 2019)), 3 commonsense reasoning tasks (HellaSwag (Zellers et al., 2019), PIQA (Bisk et al., 2019), WinoGrande (Sakaguchi et al., 2019)) and 2 knowledge-intensive tasks (NQ (Kwiatkowski et al., 2019), MMLU (Hendrycks et al., 2021)). We report the detailed settings in Appendix C.
- We evaluate the instruction-following capabilities of our models, borrowing the setting used by Xia et al. (2023). We perform supervised fine-tuning on 10,000 instruction-response pairs from the ShareGPT dataset. We evaluate another 1,000 instructions and use the AlpacaFarm codebase (Dubois et al., 2024) to judge the responses from two models with GPT-40.

5.2 RESULTS

We report the model's perplexity and ICL results in Table 1, the instruction-following evaluation in Figure 2, the domain-specific continue pre-training performance in Table 2. Appendix C provides comprehensive results for all models, including validation and test perplexity across sources in Tables 12, 13, and ICL results for individual task in Table 14.

Traditional methods perform poorly. Table 1 indicates that DSIR and perplexity filtering perform worse than random uniform sampling. This indicates that model output–based methods, despite their widespread use, are ineffective for data selection.

Clear quality criteria work, but Qurating's criteria mix fails. Table 1 shows that selecting data with Qurating's four criteria (Wettig et al., 2024a) improves performance compared to uniform sampling, highlighting the importance of clear LLM quality signals. Educational value $\tau=2.0$ is the current SOTA baseline. However, the criteria mix of Qurating's four criterion did not perform well, possibly due to a lack of complementarity among the Qurating's criteria.

DataMan's criteria surpasses SOTA baseline and *Overall Score* works best. In Table 1, compared to the SOTA baseline (Educational value $\tau=2.0$), our 13 individual quality criteria improved ICL performance by 0.4% to 4.3%. For example, the sample-with-creativity model achieved an impressive score of 60.6 in commonsense reasoning tasks. As the comprehensive criterion *Overall Score* increased from 1 to 5, performance gains significantly, highlighting the necessity of quality ranking. Our *Overall Score* l=5 works best, even exceeding the *Uniform* +50% data baseline, validating the feasibility of combining the 13 quality criteria into a composite criterion via LLM weighting. This approach not only avoids the disruption of manual adjustments but also achieves optimal results. The correlations among all criteria in Figure 5 further confirm this point.

PPL and **ICL** are not strictly aligned. Our results in Table 1 reveal a trend where PPL and ICL metrics correlate to a degree, increasing or decreasing simultaneously, but they are not aligned strictly. This meets with the intuition that PPL implies general understanding, while ICL focuses more on downstream generalization. Further analysis see Figure 6 in Appendix C. Notably, DataMan's high-rated *Overall Score* achieves an optimal trade-off between understanding and generalization.

Table 1: Sample-with-DataMan models improve perplexity and in-context learning (ICL) results, and the *Overall Score l=5* perform best. We report the validation, test perplexity, and ICL performance of 10 downstream tasks. We highlight the best result in each column and improvement over uniform sampling with the 30B token budget. In Appendix C, we report full results of perplexity in Table 12, 13 and ICL in Table 14.

Selection Method		Val Perplexity	Test Perplexity	Reading Comprehension (5 tasks)	Commonsense Reasoning (3 tasks)	World Knowledge (2 tasks)	Average (10 tasks)

DataMan's instruction-following abilities also well. As shown in Figure 2, we compare the instruction-following win rates between the Sample-with-DataMan model and the SOTA baseline (Educational value $\tau=2.0$). The results indicate that, under the same supervised fine-tuning conditions, our model consistently surpasses the SOTA Baseline, with the *Overall Score* reaching an impressive win rate at 78.5%, further validating the superior performance of our method.

Training domain-specific models. While the *Overall Score l=5* achieves the best performance, its performance in specific domains can still be improved, as shown in Table 2. To address this, we applied DataMan's domain recognition to filter data with high *Overall Score* in the *medical, law, and financial* domains, and continued pre-training domain-specific models, achieving ICL performance gains in the corresponding MMLU subtasks. This validates DataMan's capability for domain mixing.

Figure 2: Instruction following win rates of Sample-with-DataMan models v.s. the state-of-the-art baseline (Educational value $\tau=2.0$) after instruction fine-tuning on 10K ShareGPT examples. The results indicate that, under the same SFT conditions, our model consistently surpasses the SOTA Baseline, with the Overall Score reaching a impressive win rate at 78.5%.

Table 2: The Sample-with-DataMan model further improves perplexity and in-context learning (ICL) results when continuing pre-training on high *Overall Score*, domain-specific data. We report the validation, test perplexity, and ICL performance of corresponding MMLU subtasks.

	Val Perplexity	Test Perplexity	Anatomy	College Medicine	Medical Genetics

5.3 Analysis of Quality Ratings

Distribution of quality ratings. In Figure 3, we present the distribution of quality ratings across different sources in DataPajama. Overall, the quality ratings for each source are primarily concentrated at 4 and 5, indicating generally high sample quality. This may be related to the fact that DataPajama is a subset of the curated and deduplicated slimpjama corpus. However, for the criteria of *Knowledge Novelty* and *Creativity*, there is a higher proportion of samples scoring 2 and 3, which is consistent with the lower average scores for these two criteria found in Table 7. Across all domains, only a few scientific domains like mathematics and medicine have *Knowledge Novelty* scores above 3, while in *Creativity*, only culture and entertainment scores were high at 3.64 and 3.56, respectively. Nevertheless, in DataPajama, the combined share of domains like mathematics and medicine is only 11.5%, and similarly, the combined share of culture and entertainment is only 25%, both of which are relatively small. This explains the modest ratings of the DataPajama dataset in terms of *Knowledge Novelty* and *Creativity*.

Correlation between quality ratings and log-likelihood. In Figure 4, we illustrate the correlation between quality ratings and the log-likelihood scores computed by Llama-2-7b (Touvron et al., 2023b). Most quality criteria do not show a significant correlation with perplexity, except for the criteria of *Structural standardization, Professionalism, and Creativity*, which have Spearman correlation coefficients ranging from 0.47 to 0.55, indicating a weak correlation. This indicates that our 14 quality criteria and sample-with-dataman method are independent of traditional perplexity metrics and filtering, indirectly showcasing the sophistication of the "reverse thinking".

5.4 DATA INSPECTION

Furthermore, we examined examples of original documents from each source under Dataman's quality criteria and ratings. Specifically, for each criterion, we randomly selected samples with ratings ranging from 1 to 5 from different sources and presented them in the Appendix D. Notably, these

Figure 3: The distribution of quality ratings across different sources in DataPajama

Figure 4: Correlations of quality ratings and negative log-likelihood scores by Llama-2-7B (Touvron et al., 2023b) over 30B tokens training documents. The negative log-likelihoods are averaged over the number of tokens, and are the logarithm of the perplexity score of a single sequence. We observe that perplexity scores are not good approximations for any quality criteria.

samples represent only a small snippet; nonetheless, they exhibit significant quality differences. We invite readers to review these differences in detail, which compares high and low ratings.

6 Conclusion

In this work, we introduce DataMan, a comprehensive data manager capable of quality rating and domain recognition, developed to facilitate the pre-training data selection and mixing. By using DataMan to annotate pre-training datasets and sampling data based on quality ratings while balancing domain diversity, our trained models demonstrate significant improvements in language modeling, task generalization, and instruction following. Through extensive experiments, we provide valuable insights for the community studying the relationship between data and large language models.

7 LIMITATIONS

We acknowledge several limitations in our work. First, DataMan's reliance on LLMs for text quality assessment and domain categorization may inherit biases from these models. Second, DataMan's inference accuracy is not yet optimal, sometimes causing misclassification, highlighting the need for a large-scale collection of documents with diverse quality differences for fine-tuning. Third, using SlimPajama alone as a pre-training corpus limits result reliability, incorporating additional corpora would be better. Fourth, the model size is restricted by data and training resources, resulting in models with only 1.3B parameters, whereas increasing parameters might reveal interesting phenomena. Lastly, the considerable costs of developing data managers, data filtering, and pre-training experiments could hinder further research in this domain. We aim to address these in future work. Despite these limitations, DataMan remains a powerful tool for data selection and mixing.

A PROMPT CURATION

Full Prompt

Please carefully read and analyze the following text, score it based on fourteen evaluation criteria and their respective scoring definitions. Additionally, select the most appropriate category from the fifteen domain types that best matches the content of the text. Let's think step by step.

Text:{text}

Domain Types: [A]Medicine [B]Finance [C]Law [D]Education [E]Technology [F]Entertainment [G]Mathematics [H]Coding [I]Government [J]Culture [K]Transportation [L]Retail E-commerce [M]Telecommunication [N]Agriculture [O]Other

The Higher The Score, The Evaluation Criteria:

[1]Accuracy: the fewer grammar, referential, and spelling errors the text contains, and the more accurate its expression. _/5

[2]Coherence: the more fluent the content is expressed, and the stronger its logical coherence. _/5

[3]Language Consistency: the more consistent the use of language in the text, with less mixing of languages. _/5

[4]Semantic Density: the greater the proportion of valid information in the text, with less irrelevant or redundant information. _/5

[5]Knowledge Novelty: the more novel and cutting-edge the knowledge provided by the text, with more insightful views on the industry or topic. _/5

[6]Topic Focus: the more the text content focuses on the topic, with less deviation from the main theme. /5

[7] Creativity: the more creative elements are shown in the text's expression. _/5

[8]Professionalism: the more professional terminology appears in the text, with more accurate use of terms and more professional domain-specific expression. _/5

[9] Style Consistency: the more consistent the style of the text, with proper and appropriate style transitions. _/5

[10] Grammatical Diversity: the more varied and correct the grammatical structures used in the text, showing a richer language expression ability. $_/5$

[11]Structural Standardization: the clearer the structure followed by the text and the more standardized its format. $_/5$

[12]Originality: the fewer repetitions and similar content in the text. _/5

[13] Sensitivity: the more appropriately sensitive topics are handled in the text, with less inappropriate content /5

[14]Overall Score: the better the comprehensive evaluation of the text, with superior performance in all aspects. $_/5$

Our full prompt is shown above, where {text} represents the text to be annotated. Next, we will elaborate on the entire prompt curation process, including obtaining all quality criteria, domain types, and system prompts, which were conducted by experts with the assistance of Super LLM:

Initializing quality criteria. Inspired by "reverse thinking"—prompting the LLM to self-identify which criteria benefit its performance, as its pre-training capabilities are closely related to perplexity (PPL) (Muennighoff et al., 2024; Marion et al., 2023b). To this end, we devised an analytical prompt for Super LLM to investigate the reasons behind textual PPL anomalies (in the top and bottom 2%) from each source, and extract the initial quality criteria below. For clarity, Table 3 provides several examples illustrating how these initial quality criteria are derived.

Enhancing quality criteria. Next, we utilize Super LLM to rank the initial quality criteria by importance, eliminating, merging, and supplementing them. The resulting second-step criteria include: [1] Text accuracy (grammar, references, spelling), [2] Semantic coherence and consistency, [3] Language consistency, [4] Effective semantic content ratio, [5] Knowledge novelty, [6] Topic focus, [7] Creative expression ratio, [8] Proportion of technical terms, [9] Style variability, [10] Complexity of grammatical structures, [11] Content regularity, [12] Content redundancy, [13] Proportion of sensitive topics. We then revised the prompts under the principle that higher scores indicate better criteria. With Super LLM's assistance, we simplified the criterion names, detailed the criteria for each rating level, and ultimately derived 14 quality criteria in the paper.

Initial Ouality Criteria

- [1] Semantic Fluency/Coherence/Logic: Evaluate whether the text is smooth and easy to read, whether the content is coherent, and whether the logic is clear.
- [2] Content Consistency/Variability in Language Style: Evaluate if the information within the text is contradictory and if the language style is diverse.
- [3] Topic Diversity: Determine the richness and variety of topics addressed in the text.
- [4] Content Regularity/Formatting: Consider whether the text adheres to a certain structure or format.
- [5] Content Redundancy: Analyze the extent of information repetition within the text.
- [6] Proportion of Domain-Specific Vocabulary: Measure the frequency of professional terms or specific vocabulary used in the text (such as proper nouns, technical terms, or Classical Chinese).
- [7] Proportion of Sensitive Topics: Examine the percentage of content that addresses sensitive topics (e.g., involving politics, toxicity).
- [8] Proportion of Creative Expression: Assess the degree of creative or innovative expression in the text (e.g., use of rhetorical techniques).
- [9] Degree of Language Mixing: Analyze the extent to which different languages are used within the text (i.e., the ratio of text in various languages).
- [10] Complexity of Text Structure: Evaluate the overall complexity of the text's structure.
- [11] Proportion of Long Sentences: Assess the ratio of long sentences within the text.
- [12] Proportion of Grammatical, Reference, and Spelling Errors: Evaluate the ratio of grammatical errors (e.g., incorrect punctuation, unclear sentence breaks), reference errors, and spelling mistakes in the text.
- [13] Proportion of Content Lacking Semantics: Determine the ratio of parts within the text that lack meaningful content (e.g., garbled text, HTML tags, XML elements, navigation bars, incomplete chart numbers, or disjointed citations).

Identifying domains. We identified the 15 domain types that require assessment, based on factors such as typical application LLM industries (Naveed et al., 2023), the number of existing industry LLMs, and the level of attention they have received, as indicated by metrics like GitHub stars⁴.

Chain-of-though and system prompts. We incorporated the chain-of-thought prompting (Wei et al., 2022)—"let's think step by step"—while avoiding using few-shot example prompting, as the diverse sources of text could introduce rating biases. We allowed the Super LLM to generate system prompts to enhance the accuracy and confidence of quality ratings, "You are an expert to evaluate the text quality with high accuracy and confidence. Don't hesitate to use the full range of the score scale, including extreme scores if the text warrants it." Results indicated that this prompt facilitated more nuanced text annotations compared to the typical prompt, "You are a helpful assistant.". To ensure stable output from Super LLM, we set the temperature to 0.

Table 3: We provide several examples of excessively high and low perplexity, use analytical prompts to investigate the reasons for these anomalies, and extract initial quality criteria from the LLM's responses. The analytical prompt is: "Read the following document, which has a {high/low} perplexity of {ppl_value} for LLM inference. Please analyze the reasons for the PPL anomaly."

PPL	Text	LLM's Response
1.19	March: 1.77 inches- April: 5.31 inches- May: 5.9 inches- June: 5.9 inches- July: 5.9 inches- August: 2.36 inches- September: 5.31 inches- October: 5.9 inches- November: 2.36 inches- December: 2.36 inches- December: 2.36 inches- November: 2.36 inches- Petruary: 2.24 inches- March: 2.24 inches- February: 2.24 inches- March: 2.24 inches- April: 5.04 inches- May: 5.6 inches- July: 4.48 inches- August: 2.24 inches- September: 5.6 inches- October: 4.48 inches- November: 2.8 inches- December: 2.24 inches- Senneville QC Precipitation	Structural consistency: Data is presented in a fixed format. ([4] Content Regularity/Formatting) Redundancy: A large number of repeating elements. ([5]Content Redundancy) Lack of complex syntax: The text lacks complex sentence structures. ([10]Complexity of Text Structure) Minimal context dependence. ([1]Semantic Fluency/Coherence/Logic)

PPL	Text	LLM's Response
1.91	a former 1970s antiwar radical fugitive wanted for murder. After living for more than 30 years underground, Grant must now go on the run. With the FBI in hot pursuit, he sets off on a cross-country journey to track down the one person that can clear his name.\\ Shepard knows the significance of the national news story he has exposed and, for a journalist, this is an opportunity of a lifetime. Hell-bent on making a name for himself, he is willing to stop at nothing to capitalize on it. He digs deep into GrantâĂŹs past. Despite warnings from his editor and threats from the FBI, Shepard relentlessly tracks Grant across the country.\\ As Grant reopens old wounds and reconnects with former members of his antiwar group, the Weather Underground, Shepard realizes something about this man is just not adding up.	As an AI model, I can't talk about topics involving politics, religion, pornography, violence, etc. ([7]Proportion of Sensitive Topics)
118.75	75@dsocz7lENp qar -ĭijA:-ĭijAq-##,-##g c-(d-o -),y-1-1p-1z-7n-8p-9d, ar -ĭijA:-ĭijAq-##,-##g c-(d-o	Non-standard characters and symbols: the text contains a large number of words, such as "@"," @"," =", ";" Such special characters and punctuation marks that are not common in normal language expression. ([13]Proportion of Content Lacking Semantics) Garbled characters and random strings: occurrences in the text similar to "dsocz71, 'p qar -!" Such garbled or random strings are unpredictable to the language model because they are meaningless in normal language representation. ([13]Proportion of Content Lacking Semantics)

Table 4: For each quality criterion, we collected a set of documents initially rated by an independent panel and divided them into two sets of ten documents each—high-rated and low-rated—to ensure a distinct quality gap. We used this data for prompt tuning and to validate the agreement between the prompt uses and human preferences. This table describes the sources of the documents.

Criterion		Sources
Accuracy	High	Academic journals, technical manuals, professional reports.
	Low	Social media posts, personal blogs, informal emails.
Coherence	High	News reports, research papers, essays.
	Low	Forum comments, random lists, random collections of paragraphs.
Language Consistency	High	Business documents, legal contracts, academic essays.
	Low	Bilingual posts, casual conversations, mixed-language blogs.
Semantic Density	High	Research reports, market analyses, white papers.
	Low	Advertising copy, social media posts, forum Q&A.
Knowledge Novelty	High	Cutting-edge research papers, conference presentations, expert interviews.
	Low	Common tutorials, listicles, outdated press.
Topic Focus	High	Specialized textbooks, academic papers on specific topics, focused industry reports.
	Low	Miscellaneous blog articles, off-topic comments and social media content, unthemed discussion drafts.
Creativity	High	Poetry, creative writing, artistic critiques.
	Low	Technical documents, routine business communications, standard emails, lengthy legal texts.
Professionalism	High	Formal technical reports, industry white papers, legal documents.
	Low	Personal blogs, informal tweets, children's literature.
Style Consistency	High	Published novels, professional speeches, magazine articles.
	Low	Articles with mixed styles, drafts of letters, hastily written online reviews.
Grammatical Diversity	High	Literary works, academic articles, formal speeches.
	Low	Emails composed of simple sentences, children's reading materials, transcriptions of oral presentations.
Structural Standardization	High	Formal reports, standard operating procedures, structured proposals.
	Low	Free-form writings, scattered notes, rough drafts.
Originality	High	Research reviews, detailed analyses, varied essays.
	Low	repetitive comments, simplistic online articles, redundant advertising copy.
Sensitivity	High	generic content, informed articles on sensitive topics, guidelines.
	Low	Crude social media content, unthoughtful internet jokes, superficial news headlines.

Table 5: We follow Qurating's Table 4 (Wettig et al., 2024a) by using 10 documents from different sources, ranking them by *writing style*, and using them to analyze pointwise and pairwise ratings.

Rank	Text	DataMan's Annotation
1	Amory Blaine inherited from his mother every trait, except the stray inexpressible few, that made him worth while. His father, an ineffectual, inarticulate man with a taste for Byron and a habit of drowsing over the Encyclopedia Britannica, grew wealthy at thirty through the death of two elder brothers, successful Chicago brokers, and in the first flush of feeling that the world was his, went to Bar Harbor and met Beatrice O'Hara. In consequence, Stephen Blaine handed down to posterity his height of	accuracy: 5 coherence: 4 lan- guage_consistency: 5 semantic_density: 4 knowledge_novelty: 2 topic_focus: 5 creativity: 4 professionalism: 3 style_consistency: 5 grammati- cal_diversity: 4 structural_standardization: 3 originality: 5 sensitivity: 5 over- all_score: 4 domain: culture
2	Technologies for making and manipulating DNA have enabled advances in biology ever since the discovery of the DNA double helix. But introducing site-specific modifications in the genomes of cells and organisms remained elusive. Early approaches relied on the principle of site-specific recognition of DNA sequences by oligonucleotides, small molecules, or self-splicing introns. More recently, the site-directed zinc finger nucleases (ZFNS) and TAL effector nucleases (TALENS) using the principle of site-specific	accuracy: 5 coherence: 5 language_consistency: 5 semantic_density: 5 knowledge_novelty: 4 topic_focus: 5 creativity: 3 professionalism: 5 style_consistency: 5 grammatical_diversity: 5 structural_standardization: 4 originality: 5 sensitivity: 5 overall_score: 5 domain: technology
3	The winter of 1906-07 was the coldest in Alberta's history and was exacerbated by a shortage of coal. One cause of this shortage was the strained relationship between coal miners and mine operators in the province. At the beginning of April 1907, the Canada West Coal and Coke Company locked out the miners from its mine near Taber. The same company was also facing a work stoppage at its mine in the Crow's Nest Pass, where miners were refusing to sign a new contract. The problem spread until by April	accuracy: 5 coherence: 5 lan- guage_consistency: 5 semantic_density: 5 knowledge_novelty: 3 topic_focus: 5 creativity: 3 professionalism: 4 style_consistency: 5 grammati- cal_diversity: 4 structural_standardization: 4 originality: 5 sensitivity: 5 overall_score: 4 domain: other
4	On December 3, Venezuela held a controversial referendum over a claim to the oil-rich Essequibo region controlled by Guyana. That same day, the Vice President of Venezuela, Delcy Rodríguez, shared a video on X, formerly Twitter, showing a group of Indigenous people lowering a Guyanese flag and hoisting a Venezuelan flag in its stead over the territory, which is also known as Guyana Esequiba. 'Glory to the brave people!' she wrote, which is the first line of the country's national anthem. The post came	accuracy: 5 coherence: 5 lan- guage_consistency: 5 semantic_density: 4 knowledge_novelty: 3 topic_focus: 5 creativity: 3 professionalism: 4 style_consistency: 5 grammati- cal_diversity: 4 structural_standardization: 4 originality: 5 sensitivity: 5 overall_score: 4 domain: government
5	The Godfather is one of the most praised movies in cinema history. It gives everything that critics and audiences alike ask for in movies. In my opinion it gets all the attention it gets for being one of, or the best movies ever. One of the best things The Godfather does is its incredible casting and its iconic performances from each and every one of its characters. The actors are so convincing that it won the movie several academy awards. It also jumpstarted several actors, acting careers, and gave an	accuracy: 4 coherence: 4 lan- guage_consistency: 5 semantic_density: 4 knowledge_novelty: 3 topic_focus: 5 creativity: 4 professionalism: 3 style_consistency: 4 grammati- cal_diversity: 4 structural_standardization: 3 originality: 5 sensitivity: 5 over- all_score: 4 domain: entertainment
6	The food is good, but not a great value. Up front, I will just say, do not waste your time getting traditional sushi here because tbh it's not really that much better. For example, we ordered some maki and nigiri and while it was good, it wasn't that much better than our fave sushi places. Instead, come here for their signature dishes and you'll probably be happier. We really enjoyed some of their signature dishes. We dined as a party of 4 and we had: Spicy edamame: tasty and spicy! Yellowtail	accuracy: 4 coherence: 4 lan- guage_consistency: 5 semantic_density: 4 knowledge_novelty: 2 topic_focus: 5 creativity: 3 professionalism: 2 style_consistency: 4 grammati- cal_diversity: 3 structural_standardization: 3 originality: 4 sensitivity: 5 over- all_score: 4 domain: other
7	My Father worked for a Forbes 500 company since the 70s. Moved up the ranks as a software engineer and management, has patents for the company that saved it millions of dollars. He's almost to pension age and suddenly HR starts making his life miserable. He noticed this trend was happening to some of his coworkers when they were getting close to age 60 as well. HR Lady calls him into the office and says that he was not punching in and out at the correct time. B DATAMAN MODEL

B.1 FINE-TUNING DATASET

To create the fine-tuning dataset of DataMan, we collected documents from both in-source and out-of-source within the large pre-training corpus SlimPajama (Soboleva et al., 2023). For each document, we used the full prompt to instruct the Super LLM to generate scalar scores ($l \sim [1-5]$) across 14 quality criteria, along with an [A-O] letter grade to indicate its domain type. The fine-tuning dataset has 35.7k documents. Each document was limited to 2,048 tokens, averaging 810 tokens. It outperforms the [256, 512] token range of Wettig et al. (2024a) when handling documents with broader length variations. Table 6 lists the number and proportion of documents categorized by domain, *Overall Score*, and source in the fine-tuning dataset.

Domain analysis. Domain *Other* accounts for nearly 25% indicating that the fine-tuning dataset encompasses domains outside the existing 15 domains, providing DataMan with rich domain-specific prior knowledge. Domains that account for between 15% and 3% involve texts related to web crawling (such as *entertainment* and *culture*) as well as typical vertical domains (like *medicine* and *coding*), enabling DataMan to better address both general and specialized knowledge. Finally, the collection of data with high barriers to entry, such as *mathematics* and long-tail *telecom* data, remains a challenge for data management.

Overall Score analysis. Considering the imbalance in the collected documents between high and low scores, we performed up-sampling on low-scoring documents (< 3) to avoid biases in the quality ratings for DataMan. In practice, we divided the sources into five equal parts based on the difference between high- and low-scoring documents and performed a fourfold up-sampling on low-scoring documents, ultimately reaching a total dataset size of 425,794.

Source analysis. While ensuring adequate data within the SlimPajama domain, we also introduced 19% of out-of-domain data (*Other*) to enhance DataMan's source generalization capability.

Table 6: The number and proportion of documents categorized by domain, <i>Overall Score</i> , and source	e
in the fine-tuning dataset.	

Domains	# Documents	Proportion	Overall Score	# Documents	Proportion
Other	84,373	24.83%	5.0	100,242	29.50%
Technology	45,094	13.27%	4.0	161,225	47.45%

We present the average score for quality criteria across each domain in Table 7, with analyses below:

- **Knowledge Novelty** excels in *mathematics* and *medicine*, closely linked to cutting-edge scientific research, enhancing the model's scientific abilities.
- Creativity is highest in *culture* and lowest in *legal* domains, reflecting the openness of literary works versus the stability of legal texts, thereby improving the model's literary skills.
- High **professionalism** indicates data from specialized fields like*mathematics*, *law*, *medicine*, and *finance*, enhancing the model's performance in these areas.

Table 7: The average score for quality criteria across each domain in the fine-tuning dataset.

Domains	Accuracy	Coherence	Language Consistency	Semantic Density	Knowledge Novelty	Topic Focus	Creativity	Professionalism	Style Consistency	Grammatical Diversity	Structural Standardization	Originality	Sensitivity	Overall Score
Mathematics	4.66	4.59	4.91	4.82	3.94	4.90	2.80	4.86	4.77	4.26	4.59	4.84	5.00	4.71

Technology	4.26	4.16	4.64	4.10	3.17	4.46	2.69	4.07	4.16	3.77	3.67	4.33	4.93	3.99
Transportation	4.34	4.22	4.70	4.13	2.73	4.56	2.57	3.83	4.21	3.73	3.66	4.34	4.95	3.91
Telecommunication	4.29	4.16	4.66	4.05	2.90	4.55	2.44	4.00	4.17	3.70	3.73	4.22	4.89	3.90
Entertainment	4.16	4.13	4.46	3.87	2.68	4.28	3.56	3.22	4.07	3.80	3.37	4.26	4.62	3.82
Other	4.11	4.02	4.47	3.86	2.60	4.09	3.08	3.32	4.01	3.70	3.34	4.17	4.65	3.71
Retail E-commerce	4.20	4.02	4.59	3.91	2.38	4.43	2.86	3.46	4.02	3.52	3.41	4.14	4.95	3.70

- Coding exhibits the least *grammatical diversity* and high *structural standardization* due to its fixed grammatical formats. In contrast, low values in *retail e-commerce* for these two criteria suggest that they lack correlation.
- Data from specialized domains showcases strong *originality* and *semantic density*, with low content redundancy and meaningful content, improving the model's performance in vertical fields.
- The **government** and **entertainment** domains exhibit lower *sensitivity*, likely related to free speech on social media and politically sensitive topics, aiding the model in filtering harmful speech and sensitive content.
- Other criteria perform well across all domains, ensuring basic requirements are met and enhancing the model's general capabilities.
- In general, specialized domains tend to achieve higher *Overall Score*, while long-tail and general domains are relatively lower.

Figure 5 shows the Pearson correlation heatmap among various quality criteria. All criteria are positively correlated, with Pearson correlation coefficients generally below 0.8, except for *Style Consistency* and *Structural Standardization*, which we speculate may adapt as basic requirements with other criteria. Notably, since the *Overall Score* is derived from the remaining 13 quality criteria, it highly correlates to each individual criterion.

Figure 5: Pearson correlation heatmap between 14 quality criteria in the fine-tuning dataset.

B.2 DATAMAN TRAINING

We fine-tune the DataMan model using Qwen2-1.5B (Yang et al., 2024a), an advanced open-source 1.5B parameter language model, based on text generation loss. To meet diverse application needs, we offer three DataMan model versions, named according to their chat prompts and applicable scenarios:

Chat Prompts

Score-only: Please give an overall score for the text: Text: {text} Overall Score:_/5

Domain-only: Please specify an domain type for the text: Text: {text} Domain:_

All-rating: Please score the text on fourteen evaluation criteria and specify its domain: Text: {text} Domain:_[1]Accuracy:_/5 [2]Coherence:_/5 [3]Language Consistency:_/5 [4]Semantic Density:_/5 [5]Knowledge Novelty:_/5 [6]Topic Focus:_/5 [7]Creativity:_/5 [8]Professionalism:_/5 [9]Style Consistency:_/5 [10]Grammatical Diversity:_/5 [11]Structural Standardization:_/5 [12]Originality:_/5 [13]Sensitivity:_/5 [14]Overall Score:_/5

- Score-only DataMan rates the *Overall Score* of text (1 token), ideal for large-scale dataset filtering.
- **Domain-only DataMan** identifies text domain (1 token), ideal for large-scale data mixing.
- **All-rating DataMan** rates the 14 quality criteria of text and identifies the text domain (15 tokens), ideal for refined data selection and mixing.

Hyperparameter search. Next, we conduct a hyperparameter search using a validation set of 8.6k documents. The search grid included: seed $\epsilon\{42,1024,3407\}$, learning rate $\epsilon\{1\times10^{-6},7\times10^{-6},1\times10^{-5},2\times10^{-5},5\times10^{-5}\}$, number of epochs $\epsilon\{2,3,4,5\}$, batch size $\epsilon\{256,512,1024\}$, data size $\epsilon\{82k,164k,246k,312k,357k\}$, up-sampling fold $\epsilon\{1,2,3,4,5\}$, model size $\epsilon\{0.5B,1.5B\}$, and inference temperature $\epsilon\{0.0(\text{greedy decoding}),0.1,0.3,0.5,0.8,1.0\}$. Model selection was based on which model achieves the best accuracy on the criterion of *Overall Score*. The selected model

Quality Domain Domain Accuracy Quality Accuracy Avg. Acc Avg. Table 8: The test accuracy of the three DataMan model versions. Here, X indicates not applicable.

Table 9: The detailed analysis of testing accuracy of the *Overall Score* criterion.

Accuracy						Error Rate				
Overall Score	5-level	<3, ≥3	≥3	<3	<2 but ≥ 3	\geq 2, <3 but >3	\geq 2, <3 but =3	\geq 4 but $<$ 3	\geq 3, <4 but <3	
	81.3	97.5	98.5	81.6	0.2	2.7	15.5	0.2	1.4	

parameters were: seed 1024, learning rate 1×10^{-5} , trained for 5 epochs, batch size 512, data size 357k, 4-fold up-sampling ratio, 1.5B model size, and utilizing greedy decoding for inference.

Inference accuracy. Subsequently, we evaluated the accuracy of three DataMan model versions on a test set comprising 8.6k documents, as shown in Table 8. Leveraging gold-labeled fine-tuning data from Super LLM, all model versions exhibited excellent performance. All-rating DataMan achieved nearly 80% accuracy across quality criteria, with *grammatical diversity* and *structural standardization* being the most challenging criteria to predict. We found performance limitations in quality rating using the *Overall Score* criterion, which showed a five-class accuracy of 81.3% and a binary accuracy of 97.5%. The accuracy for high-quality documents reached 98.5%, but for low-quality documents, it was only 81.6%, due to insufficient samples. We aim to collect more low-quality documents to improve DataMan's accuracy in this area.

Misclassification analysis. In Table 9, we analyze the test accuracy of the *Overall Score* criterion to verify that DataMan rarely makes unreasonable decisions, making it unlikely to cause a "snowball effect". In addition to the 5-level classification accuracy (5-level Acc) used in the paper, we classify samples with a score of 3 or above as positive samples, and vice versa as negative samples, thus obtaining 2-level classification accuracy: (<3, ≥ 3 Acc). We detail the accuracy for positive samples (≥ 3 Acc) and negative samples (<3 Acc), as well as error rates for specific misclassification cases: extreme false negative samples (<2 but ≥ 3 Error Rate), moderate false negative samples (≥ 2 , <3 but >3 Error Rate), extreme false positive samples (≥ 4 but <3 Error Rate), and marginal false positive samples (≥ 3 , <4 but <3 Error Rate). Results show the error rate for DataMan in the two extreme misclassification cases of the *Overall Score* is very low, at just 0.2%. This indicates that DataMan rarely mistakes poor-quality documents for high-quality ones, and vice versa. Considering the strong fault tolerance of pre-training, the snowball effect will not become a bottleneck.

Inference efficiency. Finally, Table 10 presents the inference FLOPs and memory usage for three DataMan model versions evaluated on a single A800 GPU using vLLM (Kwon et al., 2023). To reduce DataMan annotation costs, we recommend cost-effective models like Score-only DataMan or fine-tuned Qwen2-0.5B and suggest changing the training objective from text generation to multi-task

Table 10: The inference FLOPs and memory usage of three DataMan model versions.

	Input Speed (Toks/S)	Output Speed (Toks/S)	Processing Speed (Docs/S)	Memory (G)
All-rating	31822	868	30	72.9
Score-Only	63644	1736	60	72.9
Domain-Only	63644	1736	60	72.9

classification. However, to avoid parameter transfer issues due to the different learning paradigms between pre-training and fine-tuning (Wang et al., 2019), we continue using text generation loss. Furthermore, heuristic pre-processing, such as deduplication using Fuzzydedup (Jiang et al., 2022) and Semdedup (Abbas et al., 2023), or rule-based and model-based selection methods like C4 filter (Raffel et al., 2020), Gopher rules (Rae et al., 2022), and binary grammar discriminators (Chowdhery et al., 2023), can pre-reduce data annotation needs.

C EXPERIMENTAL DETAILS

DataPajama statistics. Table 11 shows the domain, *Overall Score*, and source statistics of the 447B DataPajama corpus, from which we select 30B tokens using different data selection methods. Firstly, from a domain perspective, the proportion of the mathematics domain in DataPajama has significantly increased compared to the fine-tuning dataset, while the coding domain has seen a slight rise. In contrast, the proportions of all long-tail domains (such as Transportation, Agriculture, Retail E-commerce, and Telecommunications) have fallen to their lowest levels. Secondly, regarding overall scores, DataPajama, as a subset of Slimpajama, has undergone extensive cleaning and deduplication, resulting in a high proportion of samples rated 5 and 4. Conversely, low-quality texts (rated below 3) account for only 7.86%. We chose to retain these low-quality texts to allow researchers for in-depth analysis. *DataPajama is a curated subset of SlimPajama, which is itself a subset of RedPajama. Both SlimPajama and RedPajama are released on HuggingFace under the Apache 2.0 License.*

Training details. Using different data selection methods, we select the 30B token subset from DataPajama and train a language model from scratch for one epoch in a randomly shuffled order. We employ a Sheared-Llama-1.3B transformer architecture with RoPE embedding (Su et al., 2024) and SwiGLU activations (Shazeer, 2020). This model is trained using a global batch size of 2048 sequences and a learning rate of 5×10^{-4} with a cosine learning rate decay to 5×10^{-5} and a linear warmup for the first 5% of training steps. We use a weight decay of 0.1 and train with Adam (Kingma, 2014) with hyperparameters $\beta = (0.9, 0.95)$. Finally, we save a checkpoint every 1,000 steps and merge the last three using mergekit (Goddard et al., 2024) as the desired LLM, eliminating biases from step fluctuations. Each model is trained on 32x NVIDIA A800 over 228 GPU hours.

In-context learning settings. We choose a different number of few-shot examples per task to ensure that all demonstrations fit within the context window of 1024 tokens. We use the following number of demonstrations (given in parentheses): ARC-easy (15), ARC-challenge (15), SciQA (2), LogiQA (2), BoolQ (0), HellaSwag (6), PIQA (6), WinoGrande (15), NQ (10), MMLU (10). We report accuracy for all tasks, except for NQ, where we report EM. When available, we use the normalized accuracy metric provided by lm-evaluation-harness.

Full results of perplexity and ICL. In Tables 12 and 13, we report the full validation and test perplexity results for all models, including those for each RedPajama source. Table 14 contains the ICL performance of all models across 10 downstream tasks. The lowest perplexity reveals how quality criteria enhance LLM performance in specific data sources: i)-Sensitivity excelled in web domains (CommonCrawl, C4), emphasizing the importance of avoiding sensitive topics to improve web content adaptability. ii)-Semantic Density, Originality, and Topic Focus showed superior performance in Wikipedia, suggesting the benefit of informative, original content for world knowledge absorption. iii)-Creativity scored lowest in book sources, indicating its role in enhancing the understanding of literature. In ICL tasks, the criteria's influence is as follows: i)-High Semantic Density improved performance in elementary science tasks (ARC-E, ARC-C) and, alongside high Professionalism, in more advanced questions (SciQ). ii)-High Creativity aided in summarization and subtitle tasks

Table 11: The number and proportion of documents categorized by domain, *Overall Score*, and source in the 447B token pre-training corpus, DataPajama.

(HellaSw., W.G.), while complex reasoning tasks (PIQA) benefited from a mix of high *Semantic Density*. iii)-High *Originality* was effective for Wikipedia-related tasks, where redundant knowledge was counterproductive.

Results on larger 60B tokens. Despite the 30B token subset exceeding the compute-optimal ratio of data-to-model suggested by (Hoffmann et al., 2022a), to solidify our method, we used the strongest DataMan variant *Overall Score l=5*, the existing SOTA baseline (education value $\tau=2.0$), and uniform sampling to select a larger 60B subset to train the 1.3B language model from scratch. The model's PPL and ICL performance of 60B subset in Table 15, the full validation and test PPL across sources in Tables 16, 17, and the full ICL performance of ten downstream tasks in Table 18. The Sample-with-DataMan model significantly outperformed the SOTA baseline in ICL performance tasks and showed modest improvement in the validation and test PPL. This further confirms the effectiveness of the DataMan approach.

Misalignment between PPL and ICL. In Figure 6, we plot the relationship between perplexity and ICL performance for all models across 10 downstream tasks, including the Pearson and Spearman correlation coefficients, to investigate the misalignment between PPL and ICL. The results indicate that the misalignment is most pronounced in the LogiQA and MMLU tasks. Deeper analysis identifies two main causes: *i)-domain mismatch:* pre-training often uses extensive general corpora, which enables the model to exhibit lower perplexity on a common text. However, tasks like MMLU, which span 57 distinct specialized domains (such as abstract algebra and anatomy), may suffer in ICL performance due to domain mismatch; *ii)-ICL task complexity:* Many ICL tasks require complex reasoning rather than simple text generation, which perplexity assessment struggles to capture. This is particularly evident in LogiQA, where the task assesses human logical reasoning skills through expert-written questions from Civil Servants' Exams.

Table 12: Validation per-token perplexity per RedPajama source across all our models. We highlight the best result in each column. Abbreviations: CC = CommonCrawl, Wiki = Wikipedia, StackEx = StackExchange.

Figure 6: We plot the relationship between perplexity and in-context learning (ICL) performance for all models across 10 downstream tasks, as shown in Tables 12 and 14, along with the Pearson and Spearman correlation coefficients. The misalignment between perplexity and ICL is most pronounced in the LogiQA and MMLU tasks, we guess, possibly due to domain mismatch and ICL task complexity.

D INSPECTING RAW DOCUMENTS AND RATINGS

Finally, we present snippets from the raw documents of Wikipedia, Books, Stack Exchange, Github, ArXiv, CommonCrawl, and C4 subsets of DataPajama. These documents correspond to samples with quality ratings of 1, 2, 3, 4, and 5 across 14 quality criteria, as shown in Figure 3. Notably, although these samples represent just a small random snippet, they display significant quality differences. We believe it is essential to provide an unfiltered view of the training data; therefore, we have not applied any filtering to these documents. A small number of documents contain % potentially sensitive content.

From the visual examples, we found a notable distinction between the data rated 1 and 2 and those rated 3, 4, and 5. For instance, the score of 1 corresponds to an example like "...83 510 l s 311 548 m 305 546 l 301 540 l 299 530 l 299 ...", whereas the score of 5 reflects "...system recognizes a hierarchy of events from the measurements, not exactly in the sense of physical reality..." However, the discrepancy between scores of 4 and 5 is not as pronounced, as seen in the example "...have been augmented with terms that quantify the user satisfaction or the ad relevance...," which corresponds to a score of 4. This further supports our rationale for choosing pointwise evaluation over pairwise, as humans also find it challenging to determine superiority based on subtle differences.

In terms of domain adaptability, most of the evaluation criteria we established are semantic-focused, allowing for effective differentiation of documents within the C4 domain. However, we also observed that our criteria have some relevance in the code domain (e.g., GitHub). Specifically, code that features more detailed comments and follows structural conventions tends to receive higher scores, while disordered code is typically rated lower.

Table 19: Raw training examples selected to have 14 quality ratings from 1 to 5 within ArXiv.
