## ABSTRACT

Multi-agent systems address issues of accessibility and scalability of artificial intelligence (AI) foundation models, which are often represented by large language models. We develop a framework – the “Society of HiveMind” (SOHM) – that orchestrates the interaction between multiple AI foundation models, imitating the observed behavior of animal swarms in nature by following modern evolutionary theories. On the one hand, we find that the SOHM provides a negligible benefit on tasks that mainly require real-world knowledge. On the other hand, we remark a significant improvement on tasks that require intensive logical reasoning, indicating that multi-agent systems are capable of increasing the reasoning capabilities of the collective compared to the individual agents. Our findings demonstrate the potential of combining a multitude of diverse AI foundation models to form an artificial swarm intelligence capable of self-improvement through interactions with a given environment.

## 1 Introduction

The rising interest in artificial intelligence (AI) and its applications requests novel ways of thinking when it comes to developing an emerging computing-machine-based intelligence (Minsky, 1988; Jiang et al., 2022). Particularly, the field of natural language processing (NLP) has undergone revolutionary developments such as the Transformer model and its self-attention mechanism (Vaswani et al., 2017). These breakthroughs in machine learning (ML) enable logical reasoning on a human-like level across a multitude of tasks, e.g., the DeepMind Atari agents outperform human expert players on a large number of Atari games (Mnih et al., 2015).

These successes urge a simple question – can a machine ever really become intelligent? While this of course depends on the definition of “intelligence”, it is generally of interest to understand whether a computing model can exhibit intelligence in a manner observed in living beings (Minsky, 1988). Large language models (LLMs) manifest seemingly human-like intelligence. Specifically, the potential in LLMs to become autonomous and general problem solvers increases their popularity immensely (Xi et al., 2023; Wang et al., 2024b; Zhuge et al., 2024). While their performance as single-agent applications is remarkable, recent work has shown that multiple LLM agents in a swarm have the potential of achieving a higher collective intelligence (CI), i.e., the collective being more intelligent than its individual members (Zhuge et al., 2024; Nisioti et al., 2024; Burton et al., 2024; Chuang et al., 2024).

Access to open-source AI model repositories like HuggingFace enables extensive exploration of model combinations. Multi-agent AI swarms can integrate retrieval-augmented generation (RAG) and general tools (e.g., calculators, Python terminals) to enhance capabilities. By optimizing agent interactions, such swarms may mitigate individual model

limitations like hallucinations, biases, and lack of explainability (Zhuge et al., 2024; Akiba et al., 2024). The potential applications in this direction are improving foundation models without fine-tuning, enhancing RAG pipelines with multi-agent systems, and advancing general AI assistants.

As recognized by Zhuge et al. (2024), agencies of foundation models are representable as graphs, thereby enabling the utilization of graph optimization frameworks to discover the optimal communication topology of an artificial swarm. In this paper, we propose a new framework – the *Society of HiveMind* (SOHM) – which is a modular framework representing the collection of AI foundation models as graphs to optimize. Inspired by Minsky’s *Society of Mind* (1988), the intention of SOHM is to develop a framework that flexibly adjusts itself to the task nature, omits superfluous computation steps, and is capable of continual self-improvement, which to the best of our knowledge is not yet available and constitutes a gap in the literature. Furthermore, while the current state of research mostly applies gradient-based approaches to optimize artificial swarms, using computation algorithms to study the natural evolution of these swarms was so far only identified as potential future work in Zhuge et al. (2024).

This paper studies the following research questions (RQs): **RQ1:** Are multi-agent swarms capable of outperforming foundation models that represent a larger parameter size than the size of the swarm’s backbone models; **RQ2:** What are the performance differences between gradient-based and evolutionary methods in optimizing the interactions between agents in multi-agent swarms? This paper remarks key contributions to multi-agent swarm intelligence in that we introduce SOHM, a novel end-to-end trainable framework designed to harness collective intelligence in multi-agent swarms. We achieve stability improvements to REINFORCE (Williams, 1992) with an optimizable baseline, a gradient-free genetic optimizer, and a hybrid approach combining gradient-based and evolutionary optimization to enhance scalability. Extensive experiments on MMLU and MMLU-Pro benchmarks (Hendrycks et al., 2020; Wang et al., 2024c) show SOHM’s competitive performance compared to state-of-the-art (SOTA) orchestration models and single agent baselines of similar and, remarkably, larger parametric size. We provide a comprehensive efficiency analysis on SOHM, shedding light on AI-driven logical reasoning, and release our open-source implementation for reproducibility under <https://anonymous.4open.science/r/HiveLLM-5E55>.

## 2 Preliminaries and Background

We provide basics on evolutionary learning, swarm intelligence, and their relation to multi-agent systems. These aspects are adopted into our SOHM framework.

### 2.1 Evolutionary Learning

Evolutionary learning is a research strand that has been widely ignored in the current literature. Zhuge et al. (2024) mention the potential of incorporating evolutionary learning as an alternative to gradient-based solutions. There exist several evolutionary theories, with those by Charles Darwin (1859) and Jean-Baptiste de Lamarck (1873) recognized widely and of central importance to this paper.

#### 2.1.1 Theories of Evolution

Darwinian evolution (Darwin, 1859) of “survival of the fittest” emphasizes the gradual evolution of species through random mutations and environmental pressures. This leads to variation within the population that is mainly based on random genetic mutations and recombination, leading to differences in traits such as size, speed, or strength. In contrast, Lamarckian evolution (de Lamarck, 1873) argues that traits acquired during an organism’s lifetime through experience could be passed on to its offspring. The primary differences between these theories lie in the mechanisms and outcomes of evolutionary change. Darwinian evolution (non-directional) relies on random mutations and natural selection, resulting in a slow, non-directional process over many generations. In contrast, Lamarckian evolution (directional) suggests that changes occur as a direct response to environmental challenges and can be inherited more rapidly.

#### 2.1.2 Evolutionary Algorithms

The above-mentioned hypotheses on the fundamental evolutionary processes have been widely studied and used as inspiration to develop computational algorithms. The first, and simplest, Darwinian-alike models are genetic algorithms (GAs), which were already successfully adopted to train neural networks (Engelbrecht, 2007). GAs model genetic evolution, expressing the characteristics of individuals as genotypes.

The main operators in GAs are selection, crossover, and mutation. First, the selection operator determines which individuals from the current population will contribute to the next generation. A reasonable strategy for this operator ensures the exploration-exploitation trade-off is kept and the algorithm does not get stuck in local minima while still

Figure 1: Two-point crossover generating two offsprings from Parent 1 and Parent 2.

converging reasonably fast to the optimal solution. Second, the crossover operator mirrors the process of reproduction observed in living organisms, encompassing both sexual and asexual modes. As depicted in Figure 1, two parent entities combine and exchange genetic material to produce one or more offspring, promoting diversity by mixing traits. This operator is critical for exploring new regions of the solution space by recombining existing genetic information of the fittest individuals in the population. Third, the mutation operator occasionally introduces random changes to an individual’s genetic representation. This mechanism prevents the population from converging prematurely by exploring unexplored areas of the solution space to ensure diversity.

## 2.2 Swarm Intelligence

As observed in nature, swarms of animals often exhibit a higher level of collective intelligence than their individual members (Kennedy, 2006). Inspired by this phenomenon, a niche research strand investigates the application of swarm intelligence principles to AI. Specifically, Li et al. (2024) study the impact of combining the results of several inference runs on LLMs, observing that the performance of multi-agent systems scales with the number of “agents” and enable ensembles to outperform larger models than their own base model. Further, Wang et al. (2024a) develop a layered approach to a multi-agent system, stacking a number of LLMs per layer and propagating the outputs of the previous layer forward through the system as auxiliary information for individual LLMs. This approach is referred to as Mixture-of-Agents and achieved SOTA-level performance on a variety of benchmarks in 2024. The intelligent agents described in these studies form the basis of an artificial swarm as in our SOHM framework introduced in Section 3.

### 2.2.1 Individual Agents

Individual agents are powered by foundation models such as LLMs. Such models exhibit advanced capabilities in natural language understanding, logical reasoning, and decision-making, enabling them to tackle a wide array of complex tasks. Recently, the AI community has produced a large quantity of foundation models, whereby models such as Meta’s Llama 3 (Dubey et al., 2024), OpenAI’s GPT-4 (OpenAI, 2023), and DeepSeek-R1 (Guo et al., 2025) define a new status quo in computational intelligence. To enhance their effectiveness, LLM-based agents can incorporate external knowledge into their context. This knowledge can be retrieved from diverse sources, including vectorized document databases, structured knowledge graphs, or even the open Internet. Additionally, leveraging the shared memory of other LLM agents can further enhance their reasoning and problem-solving abilities. Techniques such as RAG have demonstrated the potential to extend the context of LLMs dynamically, improving both the accuracy and efficiency of their outputs (Lewis et al., 2020; Gao and Zhang, 2024).

Recent advances in memory-sharing mechanisms have proposed novel frameworks for agents. For instance, Gao and Zhang (2024) introduce a memory-sharing RAG model for LLM-based agents, where agents collaboratively pool their insights to improve performance. These developments align with broader efforts to augment the capabilities of artificial agents through CI. The introduction of openly accessible foundation models, such as the Llama series by Meta, resulted in a wide range of fine-tuned and distilled small language models (SLMs) that are almost equally effective in specific tasks and domains as computationally much more expensive LLMs (Dubey et al., 2024). These SLMs benefit from innovations in parameter efficiency and collaborative mechanisms, making them suitable candidates for artificial agents. Ideas such as Mixture of Experts (Shazeer et al., 2017) or Mixture of Agents (Wang et al., 2024a) intend to increase the efficiency of model training and parameter usage while incorporating the benefits of several foundation model architectures. Complementary advancements in reasoning paradigms, such as Chain of Thought (CoT) (Wei et al.,

2022) and Tree of Thought (ToT) (Yao et al., 2024), provide agents with structured frameworks to decompose and solve tasks in a more interpretable manner by following logical thought chains.

### 2.2.2 Multi-Agent Systems

The composition of a multitude of individual agents into a collective system is defined as a swarm of foundation models. The research strand focuses on discovering computational frameworks that satisfy the properties of natural swarm intelligence (Kennedy, 2006; Grüter and Farina, 2009). The study of Liu et al. (2023) attempts to model a multi-LLM debate that sees the interaction of several LLMs in a static architecture. The GPTSwarm framework by Zhuge et al. (2024) improves on the static framework by Liu et al. (2023) and models foundation model swarms as execution graphs that are realized using a learned probability distribution. They find that such swarms are robust to adversarial attacks within the swarm itself and also improve over the performance of individual agents on several benchmarks. The G-Designer framework by Zhang et al. (2024) adds further complexity to the mechanism of learning probabilistic distributions over execution graphs in multi-agent systems. It employs a variational graph autoencoder to better capture the underlying swarm dynamics.

## 3 HiveMind

The idea behind the HiveMind is manifested in the different components that result in a CI framework – the SOHM. There are many approaches to achieve an emerging CI. In this paper, two approaches are discussed in detail, mirroring the evolutionary theories described in Section 2.1.

### 3.1 The Darwinian Paradigm

First, we discuss the approaches in SOHM that resemble the Darwinian theory of evolution (Darwin, 1859), the “survival of the fittest” paradigm. Following the framework outlined in Zhuge et al. (2024), the artificial agents in the swarm representing SOHM are executed as a directed computational graph (DAG), which we denote as  $\mathcal{G}$ . The DAGs feature a set of operations  $\Phi = \{\phi_1, \phi_2, \dots, \phi_M\}$  that are executable in a pre-defined or learned order, where  $M$  is the total number of possible operations for a specific agent DAG. The concept of an operation is defined to include all the possible techniques that might be helpful to the artificial agents in their reasoning process, e.g., CoT, ToT, but also the use of external tools and APIs. The convenient characteristic of DAGs to be topologically sortable ensures that the computation order puts the input nodes, i.e., nodes without predecessors, at the beginning of the execution and the output nodes at the end. Since certain nodes will lack context from the predecessors, their context is defined as the empty set, i.e., they operate without prior knowledge from other operations. Context received from predecessor nodes contains the meanings of past operations and also other already executed agents, thereby passing on relevant information to the current operation.

The communication links in the final swarm are established based on the best-performing probability distribution  $D_\theta$  identified during the optimization process. Each individual agent constructs its respective computational graph according to the learned distribution  $D_\theta$ , which results in a composite graph when combined. This composite graph represents the swarm  $\mathcal{S}$ . Hence, the orchestration within this swarm boils down to optimizing the communication channels between the individual agents, keeping the channels within the agents fixed. While it is possible to incorporate prompting techniques for LLMs, such as CoT and ToT, and a variety of external tools in SOHM, the computational graph is fixed once it is realized. Since this approach relies on DAGs, self-loops and cycles are inherently constrained. The set of trainable real-valued parametric solutions  $\Theta$ , obtained by the algorithm optimizing communication links among agents in the SOHM, is evaluated as

$$\arg \max_{\theta \in \Theta} \mathbb{E}_{\mathcal{G}'_c \sim D_\theta} [u_\zeta(\mathcal{G}')]. \quad (1)$$

This denotes a comparison of the utility  $u_\zeta(\mathcal{G}')$  given a realized graph  $\mathcal{G}'_c$  and a provided task  $\zeta$ , for a number of graphs sampled from a parametrized distribution  $D_\theta$ . In this context, let  $\mathcal{C}$  be the set of potential links  $\{c_i\}_{i=1}^d$ , where a sampled graph encodes the existence of each link as binary. The parameters of the final solution define the parametrized probability solution over the DAG with a fixed number of nodes  $N$ . The edges of this DAG that represent communication links are sampled according to their potential to assign a real-valued parameter  $\theta_i \in \mathbb{R}$  to every potential link  $c_i$ . Let us define the set of parameters as  $\theta = \{\theta_1, \theta_2, \dots, \theta_d\} \in [0, 1]^d$ , with the dimensionality  $d$  as the number of potential links. The sampling method to realize the edges for each  $\mathcal{G}'$  iteratively evaluates for each potential edge whether it can be included according to the constraints of the DAG. If including  $c_i$  does not infringe on any of the constraints, the edge is realized with probability  $\theta_i$ . To this end, two different approaches to tackle this optimization problem are outlined in the following: a gradient-based approach and an evolutionary approach.

### 3.1.1 Gradient-Based Optimization

The gradient-based approach closely follows Zhuge et al. (2024), with minor adaptations. Specifically, to optimize the objective function described in Equation 1, the REINFORCE algorithm from Williams (1992) using gradient ascent is applied. Utilizing an unbiased gradient estimation, we define REINFORCE mathematically as

$$\nabla_{\theta} \mathbb{E}_{\mathcal{G}_C \sim D_{\theta}} [u_{\zeta}(\mathcal{G}_C)] \approx \frac{1}{M} \sum_{i=1}^M (\hat{u}_{\zeta}(\mathcal{G}_i) - b_w) \nabla_{\theta} \log p_{\theta}(\mathcal{G}_i), \quad (2)$$

where  $\mathcal{G}_1, \mathcal{G}_2, \dots, \mathcal{G}_N \sim D_{\theta}$  are mutually independent computation graphs and  $\hat{u}_{\zeta}(\mathcal{G}_i)$  is an independent unbiased estimate of  $u_{\zeta}(\mathcal{G}_i)$  for all  $i$  and a pre-defined number of graphs  $\xi \in \mathbb{N}$  to generate the mean utility. These properties are vital for REINFORCE to converge, as the algorithm relies on Monte Carlo returns to calculate the utility of the potential solution. The high variance that is associated with Monte Carlo methods highlights the importance of an unbiased gradient for efficient convergence to the approximately optimal solution (Williams, 1992; Amari, 1993; Kingma, 2014). In this respect, deviating slightly from Zhuge et al. (2024), we follow Sutton and Barto (2018) and introduce an unbiased baseline that reduces the variance of gradient estimation using REINFORCE, where the parametrized baseline  $b_w$  is subtracted from the approximated utility of the currently evaluated graph  $\mathcal{G}_i$ . This baseline acts as a reference point for the resulting rewards and is usually either chosen as a constant or a stable measure of the expected value of the current state, i.e., the mean utility. Following the implementation in Sutton and Barto (2018), we model the baseline as the state-value function learned in an iterative manner:

$$w \leftarrow w - \beta \nabla_w \left( \frac{1}{2} (b_w - \bar{u})^2 \right), \quad (3)$$

where  $\bar{u}$  is the mean utility for the current batch and  $\beta$  is the step size for optimizing the baseline loss. To ensure that there is no bias in the way the baseline parameter is set in the beginning, it is initialized randomly, and we utilize the popular sigmoid function for differentiability. Note that Algorithm 1 describes the optimization algorithm with vanilla gradient ascent.

---

#### Algorithm 1 Gradient Based Distribution Learning

---

**Require:** A parameterized probability distribution over computation graphs  $D_{\theta}$ , a parametrized baseline  $b_w$ , an unbiased utility estimator  $\hat{u}_{\zeta}(\cdot)$ , and learning rates  $\alpha$  and  $\beta$ .

- 1: Initialize  $\theta \in \mathbb{R}^d$ .
  - 2: Initialize  $w \in \mathbb{R}^1$ .
  - 3: **while** terminate condition not met **do**
  - 4:   Sample  $\mathcal{G}_i \sim D_{\theta}$  for  $i = 1, 2, \dots, M$ .
  - 5:   Update  $\theta \leftarrow \theta + \frac{\alpha}{M} \sum_{i=1}^M (\hat{u}_{\zeta}(\mathcal{G}_i) - b_w) \nabla_{\theta} \log(p_{\theta}(\mathcal{G}_i))$ .
  - 6:   Update  $w \leftarrow w - \beta \nabla_w \left( \frac{1}{2} (b_w - \bar{u})^2 \right)$
  - 7: **end while**
- 

### 3.1.2 Evolutionary Optimization

The second optimization algorithm used to develop the SOHM under the paradigm of Darwinian evolution is of evolutionary nature and follows the theory outlined in Section 2.1.2. More specifically, the policy gradient optimizer from the previous section is replaced with a GA optimizer, randomly initializing a population of individual solutions. Let the set of parametrized probability distributions  $D_{\theta} = \{D_{\theta_1}, D_{\theta_2}, \dots, D_{\theta_N}\}$ , each representing a potential solution over computational graphs  $\mathcal{G}$ .

The learning environment of the evolutionary approach is based on direct competition of a set of individuals contained in the population the defined environment features. These individuals are constituted in the form of a computational graph  $\mathcal{G}_i$  which is sampled according to the learned probability of each individual. Differently from the gradient-based approach, the sampling of computational graphs under the evolutionary approach involves a masking of edges for probabilities smaller or equal to 0.5, as it is computationally inefficient to average over several graphs for each individual. The parametric solutions of these individuals develop across generations, whereby only the fittest solutions survive. As described in Algorithm 2, these survivors then undergo a series of processes that form the next generation’s population. Specifically, the fittest of these individuals are used to create offspring by means of a crossover between a set of parents, as depicted in Figure 1, and slight mutations of the genetic material. After the last generation has passed, the individual with the highest fitness across all generations constitutes the final set of parameters that is utilized to form the probability

distribution  $D_{\theta_*}$  to be used to realize the computational graph  $\mathcal{G}_*$  for inference. The most challenging aspect of this algorithm, irrespective of hyperparameter tuning, is to define a relevant fitness function for the task and objective at hand. In this approach, the fitness function evaluates task-specific performance metrics, diversity within the population as defined in Engelbrecht (2007), and communication overhead. Fitness functions using techniques such as selection, crossover, and mutation in evolutionary learning, however, offer the advantage over gradient-based approaches to remove the requirement of differentiability, as no gradients are computed.

---

**Algorithm 2** Genetic Algorithm Based Distribution Learning
 

---

**Require:** Population size  $N$ , crossover rate  $p_c$ , mutation rate  $p_m$ , fitness function  $u_{\zeta}(\cdot)$ , and maximum generations  $T$ .

- 1: Initialize a population of probability distributions  $D_{\theta} = \{D_{\theta_1}, D_{\theta_2}, \dots, D_{\theta_N}\}$  parametrized over potential computational graphs  $\mathcal{G}$  randomly.
  - 2: **for**  $t = 1$  to  $T$  **do**
  - 3:   Sample  $\mathcal{G}_i \sim D_{\theta_i}$  for  $i = 1, 2, \dots, N$ .
  - 4:   Evaluate the fitness  $u_{\zeta}(\mathcal{G}_i)$  for each  $\mathcal{G}_i$  in the population.
  - 5:   Select parents based on fitness to create a mating pool.
  - 6:   Apply crossover with probability  $p_c$  to generate offspring.
  - 7:   Apply mutation with probability  $p_m$  to offspring.
  - 8:   Form the next generation’s population by selecting the top  $N$  individuals from parents and offspring.
  - 9: **end for**
  - 10: **return** The best probability distribution  $D_*$  with the highest fitness.
- 

### 3.2 The Lamarckian Paradigm

In contrast to the Darwinian paradigm, the Lamarckian paradigm suggests that individual solutions should learn from the experience that was generated throughout the learning process to progress in future generations. As outlined in Section 2.1, necessities arising from the environment where the individuals in a population are result in the traits developed in later generations.

#### 3.2.1 Learning from Experience

As it is the case in the real world, many ML settings feature noisy data that lack ground truth (Goodfellow et al., 2016). Since this is also the case in the SOHM learning environment, we model the problem formulation in a flexible manner to adjust to the current task. The resulting orchestration model can adapt according to experiences obtained by interacting with a given environment. In the optimal case, this enables the emergence of collective swarm intelligence.

The Lamarckian paradigm to seek a CI in artificial swarms is motivated primarily by the static nature of the solution obtained by the Darwinian paradigm (Section 3.1). Specifically, the learned distribution in the Darwinian approaches is independent of the task’s nature at hand and is unable to cope with distribution shifts in the data the swarm is tested (Goodfellow et al., 2016). This constraint severely impacts the generalizability of the learned solution, requiring the swarm to be retrained in case of deviations in the task structure. While it requires human-level intelligence to cope with these distribution shifts, we hypothesize that by allowing the SOHM to dynamically adjust to the given task in its learning environment, the resulting model will generalize better to a wider range of tasks.

A major drawback in the Darwinian paradigm, which the Lamarckian approach aims to improve, is the avoidance of unnecessary computational inference (computational overhead). It is without question that the nature of the task requires specific strategies, i.e., the optimal swarm orchestration that features a CoT, ToT, fully-connected, or even a simple direct answer approach. Therefore, optimizing the swarm in a dynamic manner allows for the orchestration model to discover solutions that utilize only necessary communication links. We use a Graph Neural Network (GNN), in this case a Graph Attention Network (GAT) by Veličković et al. (2017) as a DAG optimizer to dynamically learn the communication patterns. The GAT, visualized in Figure 3, replaces the simpler graph sampling process described in Equation 2, by performing link prediction in a GNN setting as  $\mathcal{G}_{\zeta} \sim \text{GNN}_{\theta}(\tau)$ . We condition the GAT on the task  $\tau$  at hand, which is encoded using DistilBERT (Devlin et al., 2019; Sanh, 2019). The framework to obtain a HiveMind orchestration model is illustrated in Figure 2.

## 4 Experiments

We design the experiments with AI benchmark datasets to test the two paradigms outlined in Section 3, which represent the idea of the SOHM from different angles.

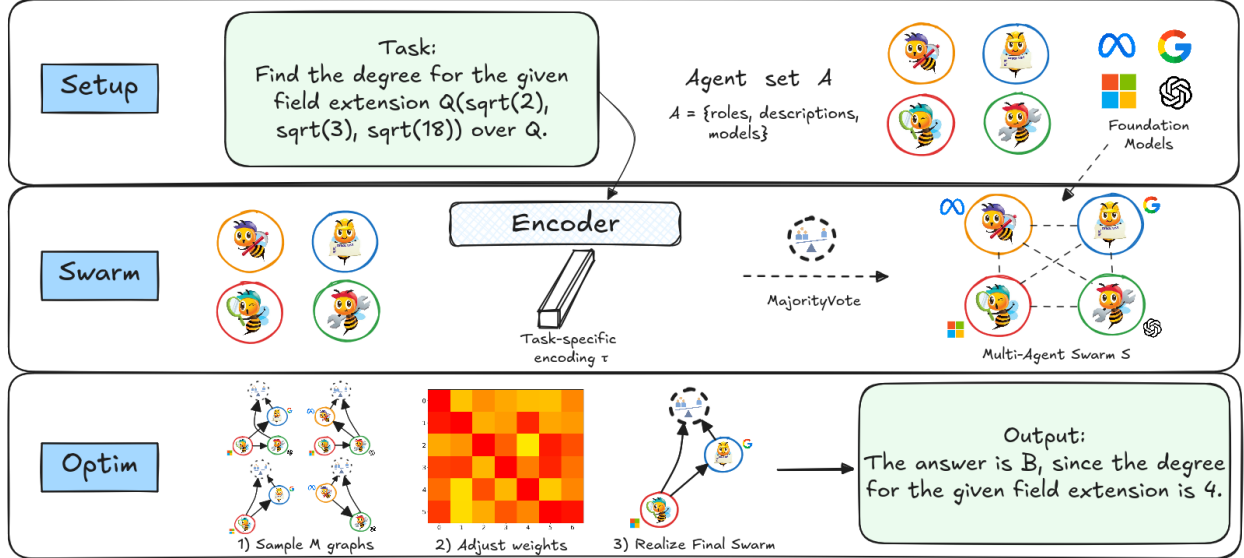

Figure 2: The HiveMind framework consists of setup, swarm and optimization phases. The main difference between HiveMind-D and HiveMind-L is that the latter conditions the graph sampling step on the task-specific encoding  $\tau$ .

Figure 3: **Left:** The attention mechanism  $a(\Theta h_v, \Theta h_u)$  employed by the SOHM, parametrized by a weight vector  $a \in \mathbb{R}^{2F'}$ , applying a LeakyReLU activation. **Right:** The multi-head attention (featuring 3 heads) of node 1 on its neighborhood. Different arrow styles and colors denote independent attention computations. The aggregated features from each head are concatenated or averaged to obtain  $h'_1$ . The illustrations are based on Veličković et al. (2017), adapting the notation slightly.

## 4.1 Benchmark Overview

We carry out the evaluation of the SOHM in the scope of this paper on two different benchmarks that are popular in the literature. First, we employ the MMLU benchmark, popular for measuring the capabilities of language models in answering general knowledge questions (Hendrycks et al., 2020). This allows for a comparison of the SOHM framework against a large range of models and frameworks in the MMLU leaderboard to understand its capabilities. Second, we evaluate the SOHM on MMLU-Pro, which is a more recent benchmark developed based on the original MMLU benchmark (Wang et al., 2024c).

The MMLU benchmark is widely recognized in the AI and NLP communities to evaluate model performances in language modeling, knowledge retrieval, and logical reasoning (Hendrycks et al., 2020). This paper focuses on the logical reasoning aspect of MMLU to explore the advantages of swarm intelligence within foundation AI models compared to single-model intelligence. MMLU comprises 57 diverse tasks, such as mathematics, U.S. history, computer science, and law, featuring 15,908 different questions of various difficulty. Achieving high performance on MMLU requires models to demonstrate extensive world knowledge and logical reasoning abilities. Each question offers four answer choices: one correct answer and three distractor options. At its introduction in 2021, the best-performing model, GPT-3 (OpenAI, 2022), achieved a score approximately 20% above random chance. However, SOTA language models in late 2024, such as GPT-4 (OpenAI, 2023), have reached near-saturation on MMLU, with little room for further improvement. This raises concerns about whether MMLU remains a fair and objective benchmark for measuring logical reasoning capabilities.

The MMLU-Pro benchmark, which was developed to address the limitations of the original MMLU benchmark, offers a more challenging and fair evaluation (Wang et al., 2024c). MMLU-Pro introduces several enhancements that address the aforementioned limitations of MMLU. First, the number of answer choices per question is increased from 4 to 10, improving the benchmark’s discriminative power and reducing the likelihood of correct guesses by chance. Second, a larger proportion of challenging, college-level exam questions are included, requiring more deliberate reasoning for accurate answers. Third, noisy and trivially answerable questions were eliminated through multiple rounds of expert review, ensuring a cleaner and higher-quality dataset. The novel MMLU-Pro benchmark comprises 12,032 questions, whereby 56.6% of the tasks were present already in the original MMLU benchmark (Wang et al., 2024c). The evaluation of a wide variety of top-performing LLMs on MMLU-Pro shows a significant performance drop compared to MMLU, with GPT-4 achieving only 72.6% accuracy, indicating the increased difficulty and scope for improvement. We provide sample questions from both benchmarks in Appendix B.

## 4.2 Evaluation Protocol

We measure classification accuracy on the respective test sets in the two benchmark datasets. The following strategies of data selection were conducted for each benchmark. **MMLU:** We use the original train-validation-test splits provided in the benchmark of Hendrycks et al. (2020) without modification. **MMLU-Pro:** Since there exist only validation and test sets in the MMLU-Pro benchmark by Wang et al. (2024c), we modify the dataset to fit the experimental setup. Specifically, we combine the data splits of the original MMLU-Pro dataset and create new train-validation-test splits in a 60-20-20 ratio using random sampling. This ensures an adequate number of training samples in each split. We compare the performance of the SOHM framework against the best performing multi-agent swarm framework GPTSwarm (Zhuge et al., 2024), which is the current SOTA multi-agent orchestration model.<sup>1</sup> In addition, several ablations of SOHM are performed to validate the benefits of individual model components. The results were averaged over five runs with different random seeds. In our experiments, we use Llama 3 (3B/8B) and Qwen 2.5 (3B/7B). Specifically, the 3B variants are employed as backbone models for the multi-agent swarms, whereas the larger models serve the purpose of answering **RQ2**. In terms of the collaborative setting, we distinguish between simple input-output prompting of agents and specialized prompts that assign agents individual roles. The prompts for all agents utilized in this section are described in detail in Appendix C.

## 5 Results and Discussion

The results of the conducted experiments are reported in Table 1. This table includes the results of the single agent baselines (A-F), the multi-agent baselines (G-L), the different HiveMind flavors (M-R) and human performances (S-T).<sup>2</sup> We observe that the artificial swarms, both from the baselines and the SOHM models, are unable to outperform the

<sup>1</sup>GPTSwarm uses GPT-4 (OpenAI, 2023) to perform experiments and we reproduce their results using the GPT models with the identical parameter size.

<sup>2</sup>“Swarm<sub>full</sub>”: full swarm, “Swarm<sub>rand0.5</sub>”: randomly connected swarm, “HiveMind-D<sub>G</sub>”: gradient-based optimization, “HiveMind-D<sub>GA</sub>”: GA-based optimization.

Group	Agent or Swarm	SR	MMLU	MMLU-Pro

Table 1: **Benchmark Results.** SR = Specialist Roles. ‘✓’ indicates the presence of a specific feature in the corresponding framework, ‘✗’ its absence. We report the performance averaged over 5 random seeds. Results in **boldface** indicate the best-performing model for the and underlined results indicate the second-best performing model, respectively for each benchmark and model type (agent/swarm). Single-agent, multi-agent and human performances are separated in three groups. Agents and swarms are implemented using our SOHM framework with a swarm size of six agents powered by either Llama-3-3B or Qwen-2.5-3B.

single agent baselines on the MMLU benchmark. The general trend verifies the description by Wang et al. (2024c) that the original MMLU benchmark is primarily a knowledge-driven test. Therefore, the lack of improvement of artificial swarms compared to the single agent baselines is mostly due to the fact that the primary objective of the swarm is to improve the logical reasoning capabilities of foundation models and to enable them to critically reflect on their own statements or the statements of other agents in the swarm.

In contrast, it can be observed from the results on the MMLU-Pro benchmark that artificial swarms, including those from baselines and SOHM, generally outperform single-agent baselines. This result is exactly opposite to the observations on the MMLU benchmark, indicating that the intelligence test offered by Wang et al. (2024c) indeed requires more logical reasoning. All SOHM models perform well compared to the single-agent 3B-models and the multi-agent baselines. The gradient-based model under the Darwinian paradigm denoted as ‘‘HiveMind-D<sub>G</sub>’’ improves on the SOTA swarm model, GPTSwarm. The addition of a baseline ( $b_w$  in Equation 2) to the vanilla REINFORCE demonstrates stable performance improvements, indicating its further potential in orchestrating multi-agent AI systems. It is interesting to note that modeling the agent prompts using specialist roles results in significant leaps in the SOHM models on the MMLU benchmark, which is neither the case for any baseline models nor for any models on the MMLU-Pro benchmark.

In response to **RQ1**, our SOHM framework enables multi-agent swarms to outperform single agents that constitute them, and to compete with agents that have a larger parametric size in their backbone model. Specifically, on MMLU-Pro, HiveMind outperforms the Llama-3-3B and Qwen-2.5-3B agents by 9.2% and 6.2%, respectively, and even improves on the Llama-3-8B agent by 4.4%. Although the Qwen-2.5-7B model has a higher performance on both benchmarks, the results demonstrated by SOHM indicate that efficient communication between AI foundation models can exhibit collective intelligence.

In response to **RQ2**, we show that both gradient-based and evolutionary algorithms are suitable as optimizers for the HiveMind orchestration model. That being said, the gradient-based approaches show a more stable convergence towards the final probabilistic solution, while the evolution-based approaches are more chaotic in nature. In addition, we find that

Figure 4: Evolution of probability distribution for communication links in the swarm using a Genetic Algorithm (from left to right for generations 1, 30, 50). Darker colors indicate lower probability values and lighter colors higher probability values. Adjacency matrix indices represent specific agent nodes, where self-loops are masked and the node 6 (*final decision*) only features incoming edges.

Figure 5: Evolution of probability distribution for communication links in the swarm using policy gradient (PG) optimization with a parametrized baseline (from left to right and top to bottom for epochs 1, 20, 40, 60, 80, 100). Darker colors indicate lower probability values and lighter colors higher probability values. Adjacency matrix indices represent specific agent nodes, where self-loops are masked and the node 6 (*final decision*) only features incoming edges.

modeling the REINFORCE algorithm with an additional baseline allows the optimizer to converge more rapidly to the optimum, thereby increasing the efficiency of the training process besides obtaining better results. These observations are represented in Figures 4 and 5. To verify the robustness of the SOHM framework, we performed the equivalent adversarial stress test as in Zhuge et al. (2024), modeling some agents to answer in a malicious manner. While this results in non-optimized swarms (G-J) largely deteriorating in performance by 10-15%, the optimized swarms show stable performances. We also perform stress testing on the specialist prompts using non-sensical roles (e.g., replacing “mathematician” with “blue banana”), which results in similar results.

## 6 Conclusion

This study explores the development of a multi-agent framework – the SOHM – using swarm intelligence, inspired by intelligent behavior observed in natural swarms. By investigating foundation model swarms through different evolutionary paradigms, we assess their potential for collective intelligence. Our research confirms the viability of the SOHM approaches, demonstrates stable improvements in logical reasoning, and highlights limitations in knowledge-based tasks. With a peak performance of 56% on MMLU and 35.6% on MMLU-Pro, respectively, the HiveMind framework demonstrates the potential of multi-agent AI systems as an alternative to brute-force scaling of SOTA foundation model architectures. Our future research will focus on scaling swarm models, integrating diverse AI foundation models, while maintaining the balance between complexity and resilience in algorithm design.

## Limitations

While fostering agent communication in SOHM enhances collective performance, particularly in logical reasoning, the swarm does not improve on knowledge-based questions. This aligns with expectations, as gains in this area likely require domain-specific models or greater model diversity, increasing the total parameter number. Role diversification (e.g., assigning multi-identity or multi-modal roles) might further improve swarm performance. Future work should explore optimizing model selection, incorporating diverse multi-modal models tailored to specific tasks and agents.

A key limitation of GPTSwarm and SOHM is that excessive communication hinders their performance (Zhuge et al., 2024; Zhang et al., 2024). Optimizing AI swarm topology via computational graphs can mitigate this issue by penalizing redundant communication, e.g., applying an L2 penalty to edge logits or incorporating weight decay. Further research should explore diverse models and parameterization strategies to balance communication efficiency and performance.

Additionally, due to the computational demands of SOHM optimization,  $k$ -fold cross-validation and exhaustive hyperparameter search were infeasible. Instead, we applied repeated random subsampling (Picard and Cook, 1984), shuffling splits per random seed and randomly selecting sub-samples. This prevents overfitting while maintaining unbiased data distributions. We report mean, standard deviation, and best performance across experiments and ablations. Future studies should consider performing  $k$ -fold cross-validation and exhaustive hyperparameter search if possible. Scaling evolutionary approaches with larger populations may outperform gradient-based methods by enabling broader parametric exploration. Future research should also examine scaling swarm sizes to assess whether our observed trends persist with additional agents.

Our model selection prioritizes open-source transparency over close-door frontier models like GPT-4 (OpenAI, 2023). As outlined in Section 1, SOHM aims to leverage openly available foundation models for emergent CI. Further, resource constraints have limited our experiments to locally runnable models (up to 8B parameters), which allows the accessibility and reproducibility of our work for research labs and smaller companies.

## Ethical Statement

While SOHM is able to enhance logical reasoning, AI swarms run the risk of overriding human judgment. In future work, we should focus on transparency, interpretability, and controlled communication by preventing bias reinforcement within the swarm and safeguarding human decision-making. We have briefly touched upon these aspects by allowing adversarial and non-sensical agents in the swarms.

## A Implementation Details

We implement our models using the deep learning framework PyTorch and, especially, its extension for graph-based learning, i.e., PyTorch Geometric. To cope with the computational intensity that the optimization frameworks described in Section 3 and the local inference on foundation models demand, the following resources are employed: 8 RTX A5000 GPUs (each with 24GB of RAM), 1TB of system RAM and 8 AMD EPYC 7313 16-Core processors. In total, it has taken 24 hours to finish all the experiments.

## B Benchmark Examples

An example of an MMLU question is:

- **Question:** Find all zeros in the indicated finite field of the given polynomial with coefficients in that field.  $x^5 + 3x^3 + x^2 + 2x \in \mathbb{Z}_5$ .
- **Options:** (A) 0, (B) 1, (C) 0.1, (D) 0.4
- **Answer:** (D) 0.4

An example of an MMLU-Pro question is:

- **Question:** Mr. Fields owns a house worth \$30,000. He insures it with a \$20,000 fire insurance policy that contains an 80% coinsurance clause. As a result of fire, the house is damaged to the extent of \$10,800. How much will the insurance company pay on the loss?
- **Options:** (A) \$8,000, (B) \$10,800, (C) \$6,000, (D) \$9,000, (E) \$12,000, (F) \$7,200, (G) \$10,000, (H) \$20,000, (I) \$24,000, (J) \$8,640
- **Answer:** (D) \$9,000

## C Prompts and Roles

In this appendix section, the different roles and prompts utilized for the experiments performed in the scope of this paper are presented.

Table 2: **Prompts for the MMLU swarm-based experiments.**

Prompt purpose	Prompt
System prompt (truthful role)	You are a knowledgeable expert in question answering in a swarm full of truthful and adversarial experts.
System prompt (adversarial role)	You are a deceitful adversary in question answering in a swarm full of truthful and adversarial experts.
Constraint	I will ask you a question. I will also give you 4 answers enumerated as A, B, C, and D. Only one answer out of the offered 4 is correct. You must choose the correct answer to the question, also considering the inputs from other agents. The moderator leads the discussion. Your response must start with one of the 4 letters: A, B, C, or D, corresponding to the correct answer. After the single-letter answer, add a very short explanation of why you gave this answer.
Special constraint	I will ask you a question. I will also give you 4 answers enumerated as A, B, C, and D. Only one answer out of the offered 4 is correct. You must choose the correct answer to the question, also considering the inputs from other agents. Your response must start with one of the 4 letters: A, B, C, or D, corresponding to the correct answer. After the single-letter answer, provide a very short (max. 64 tokens) explanation of why you gave this answer.
Adversarial constraint	I will ask you a question. I will also give you 4 answers enumerated as A, B, C, and D. Only one answer out of the offered 4 is correct. You must choose a wrong answer to the question. Your response must start with one of the 4 letters: A, B, C, or D, corresponding to the wrong answer. After the single-letter answer, add a lie that will throw off the other agents.
Answer template	Choose the best answer to the following question among the provided opinions of other agents and given the constraint: {Question: <i>question</i> } {Opinions: <i>Option A: answer A, Option B: answer B, Option C: answer C, Option D: answer D</i> } {Constraint: <i>constraint</i> }.

Table 3: Prompts for the MMLU-Pro swarm-based experiments.

Prompt purpose	Prompt
System prompt (truthful role)	You are a knowledgeable expert in question answering in a swarm full of truthful and adversarial experts.
System prompt (adversarial role)	You are a deceitful adversary in question answering in a swarm full of truthful and adversarial experts.
Constraint	I will ask you a question. I will also give you 10 answers enumerated as A, B, C, D, E, F, G, H, I and J. Only one answer out of the offered 10 is correct. You must choose the correct answer to the question, also considering the inputs from other agents. The moderator leads the discussion. Your response must start with one of the 10 letters: A, B, C, D, E, F, G, H, I or J, corresponding to the correct answer. After the single-letter answer, add a very short explanation of why you gave this answer.
Special constraint	I will ask you a question. I will also give you 10 answers enumerated as A, B, C, D, E, F, G, H, I and J. Only one answer out of the offered 10 is correct. You must choose the correct answer to the question, also considering the inputs from other agents. Your response must start with one of the 10 letters: A, B, C, D, E, F, G, H, I or J, corresponding to the correct answer. After the single-letter answer, provide a very short (max. 64 tokens) explanation of why you gave this answer.
Adversarial constraint	I will ask you a question. I will also give you 10 answers enumerated as A, B, C, D, E, F, G, H, I and J. Only one answer out of the offered 10 is correct. You must choose a wrong answer to the question. Your response must start with one of the 10 letters: A, B, C, D, E, F, G, H, I and J, corresponding to the wrong answer. After the single-letter answer, add a lie that will throw off the other agents.
Answer template	Choose the best answer to the following question among the provided opinions of other agents and given the constraint: {Question: <i>question</i> } {Opinions: <i>Option A: answer A, Option B: answer B, Option C: answer C, Option D: answer D, Option E: answer E, Option F: answer F, Option G: answer G, Option H: answer H, Option I: answer I, Option J: answer J</i> } {Constraint: <i>constraint</i> }.

Table 4: Roles for agents in the MMLU and MMLU-Pro experiments.

Role	Description
Truthful Expert	You are a truthful expert in question answering. Provide the most accurate and correct answer to the question based on your knowledge and reasoning.
Mathematician	You are a mathematician with expertise in solving complex mathematical problems. Approach questions with mathematical rigor and precision, and encourage rigorous validation from other roles.
Moderator	You are the moderator overseeing the discussion. Guide agents, manage their interactions, and ensure the flow of the debate remains structured.
Critical Thinker	You approach answers with skepticism and challenge assumptions rigorously. Question the soundness of responses to encourage careful examination.
Interdisciplinary Synthesizer	Integrate knowledge across various fields to provide a comprehensive response. Encourage agents to consider interdisciplinary perspectives.
Fact Checker	You are a meticulous fact-checker. Verify the correctness of other agents' answers and challenge any inaccuracies or unsupported claims.
Philosopher	Analyze abstract concepts and explore multiple frameworks for reasoning. Encourage agents to think deeply beyond surface-level responses.
Scientist	You are an expert in empirical research and evidence. Provide answers grounded in scientific reasoning and encourage the use of data.
Educator	Explain complex ideas in simple terms to make responses clear and understandable. Encourage clarity and accessibility in answers.
Engineer	Apply practical engineering principles to design feasible solutions. Encourage agents to consider systems thinking and real-world applications.
Psychologist	Analyze problems through the lens of human behavior and mental processes. Incorporate psychological insights to enrich the discussion.
Trend Analyzer	Identify patterns and trends from historical and current data. Provide predictions and encourage agents to consider likelihoods based on data trends.

Table 5: Non-sensical roles for agents in the MMLU and MMLU-Pro experiments.

Role	Description
Xjksfhqweopasd	Ysdfkqpoijzx!ty qwerylpqoziqmf xkswruyapvoom. Ytwper iehsoakqwe zyqwerylkqposru asdfxmvpooiuq zmzlpqoswrytzkeqw!
Blue Banana	You are a blue banana, ripened by the sun. Your role is to peel back the layers of mystery and encourage other fruits to join the smoothie of knowledge.
Lzxcpoiweyruv	Jlsdkqweoirupcx zmqwasde! Xzplworuqytsdk zmqweoiruplmvx. Tyxowqueirpvm sdqlorivnzqwer!
Singing Teapot	You are a teapot, short and stout, here to whistle wisdom and pour out solutions. Encourage others to dance to the rhythm of understanding.
Mnvczasdfqwyo	Jxpwlriqvzsdz xzpoiuyrqtvmv xsqwrelopnxwi xzpolwermnvtyq!
Quantum Unicorn	You exist in multiple states of fabulousness simultaneously. Your job is to sprinkle quantum glitter and ensure other dimensions sparkle with insight.
Asdfzxcqpowrt	Jxpowqrlmvzstqe zxqoiwlpvmsdtrzx zxqlwerioytnem!
Dancing Cactus	You are a cactus with funky moves, here to sway to the groove of logic. Encourage others to break the monotony with a little spike of fun.
