Hybrid mesons occupy a unique position in the hadronic spectrum, offering a valuable insight into the nonperturbative nature of the glue field. Hybrid states with exotic J^{PC} quantum numbers, such as the 1⁻⁺, 0⁺⁻ and 2⁺⁻, cannot mix with conventional $q\bar{q}$ mesons, making them critical for establishing the full spectrum of hybrid mesons. In this work, we investigate the masses and the strong decays of 0⁺⁻ and 2⁺⁻ hybrid mesons, which correspond to the first orbitally excited states of the $\pi_1(1600)$ and $\eta_1(1855)$ mesons. We develop and apply a constituent gluon model to study the mass spectra and decay modes of these exotic states. Our results suggest that experiment may searched for these 0⁺⁻ and 2⁺⁻ hybrid mesons in the mass region between 2.0 GeV and 2.4 GeV. Additionally, we identify some key decay channels which should be targeted in future experiments.

I. INTRODUCTION

The non-perturbative behavior of strong interaction at low energies remains incompletely understood, presenting a significant challenge in modern particle physics [1]. In Quantum chromodynamics (QCD), gluons, like quarks, carry color charge and directly experience color forces. This property allows the valence gluons to be the degrees of freedom within the hadronic systems, such as the glueball and hybrid states. The mutual attraction between gluons is believed to be intimately connected to the confinement property of QCD [2], making the study of glueballs and hybrids crucial for understanding the behavior of soft gluonic fields. According to the lattice QCD calculations [3, 4], the lightest glueballs are expected to be the scalar (0^{++}) and tensor (2^{++}) states. However, these states may mix with the isoscalar $q\bar{q}$ mesons, which complicates their identification. In contrast, the low-lying hybrid mesons with exotic quantum numbers, such as 1^{-+} , 0^{+-} , and 2^{+-} , cannot mix with conventional $q\bar{q}$ mesons. Studying them would be a key step toward establishing the complete spectrum of hybrid states.

A significant progress has been made in the study of hybrid mesons in recent years. The long-standing puzzle of the $\pi_1(1400)$ and $\pi_1(1600)$ states has been resolved through coupled-channel analyses, which indicate that only the $\pi_1(1600)$ is necessary to describe experimental data [5, 6]. Furthermore, lattice QCD studies have provided detailed insights into the hadronic decays of the $\pi_1(1600)$ [7, 8]. The BE-SIII Collaboration has discovered a new 1⁻⁺ state [9, 10], the $\eta_1(1855)$, which could be the isospin partner of the $\pi_1(1600)$. These findings offer the valuable benchmarks for constructing the phenomenological models of hybrid mesons.

On the theoretical side, hybrid mesons have also attracted considerable attention. The mass spectrum and strong decays of low-lying charmonium hybrid states have been explored using a constituent gluon model [11]. The flavor mixing of light hybrid mesons has been investigated in Ref. [12], where the possible mixing between hybrid and conventional mesons was also discussed. Lattice QCD has been employed to analyze the light flavor singlet 1^{-+} hybrid meson in the $J/\psi \rightarrow \gamma \eta_1$ process [13] and the strong decays of the $\eta_{c1}(1^{-+})$ meson [14]. The QCD sum rule method has been applied to study light hybrid mesons, particularly those with exotic quantum numbers [15–17]. Following the observation of the $\eta'_1(1855)$, numerous theoretical works have explored the possibility that the $\pi_1(1600)$ and $\eta'_1(1855)$ states belong to the SU(3) flavor 1⁻⁺ multiplet [18–21]. These developments underscore the growing interest in hybrid mesons among the theorists.

As mentioned above, the hybrid mesons with exotic quantum numbers are particularly important for establishing the complete spectrum of hybrid states. The $\pi_1(1600)$ and $\eta'_1(1855)$ are the strong candidates for the SU(3) flavor 1⁻⁺ multiplet, serving as the reference states for further exploration of the undiscovered hybrids. Several studies have focused on the properties of light hybrid mesons with exotic quantum numbers. For instance, the strong decays of light $q\bar{q}g$ states with $J^{PC} = 0^{+-}$ and $J^{PC} = 2^{+-}$ have been investigated using the flux tube model [22]. Combing with the heavy quark expansion of QCD, Page, Swanson, and Szczepaniak developed the flux tube model [23]. They applied the model to study the strong decays of low-lying hybrid mesons, including the 1^{-+} , 0^{+-} and 2^{+-} states. However, the flux tube model predicts only one 2^{+-} state, which is inconsistent with the lattice QCD results [24, 25].

A constituent gluon model which was proposed by Swanson and Szczepaniak [26] offers a more realistic description of hybrid meson systems. Recently, the constituent gluon model was refined and applied for studying the charmonium hybrid [11]. In this model, an axial constituent gluon $(J^{P_gC_g} = 1^{+-})$ was used to represent low-lying gluonic degrees of freedom.

This picture is partially supported by lattice QCD computations [24]. In this work, we further develop the constituent gluon model and employ it to study the masses and strong decays of light 0^{+-} and 2^{-+} hybrid states. We begin by testing the model with a simple harmonic oscillator (SHO) potential in Sec. II, demonstrating its ability to reproduce the mass gaps of low-lying gluelump states. We improve the model by employing the more reliable potential for the hybrid state. By combing with the results of lattice QCD, we further predict the masses of 0^{+-} and 2^{-+} states. The strong decays of these states are discussed in Sec. III, and the paper concludes with a summary and outlook in Sec. IV. Some detailed calculations are collected in the appendix.

II. MASS SPECTRUM

A. The constituent gluon model with SHO potential

The quark potential model has achieved a remarkable success in describing the mass spectrum of ordinary hadrons, including $q\bar{q}$ mesons [27] and qqq baryons [28].¹ Inspired by the success of quark model, a key topic in the study of hybrid mesons is identifying the adiabatic potentials which can effectively describe the interactions between a quark-antiquark pair in the presence of gluonic excitations.

The adiabatic potential has been extensively studied using the lattice simulations over the years. Griffiths *et al.* first discussed the potentials which correspond to the lowest two adiabatic gluonic surfaces [31, 32]. With advancements in lattice methods, the static quark potentials for more gluonic configurations were obtained [33, 34]. Recently, more precise calculations of hybrid static potentials were performed in SU(3) lattice gauge theory [35–37]. These lattice QCD results provide valuable insights for constructing phenomenological models of hybrid mesons.

FIG. 1: Schematic diagram of a hybrid meson in the flux tube model. [A]: The confining interaction between the quark-antiquark pair is depicted as a series of mass beads. [B]: A simplified representation where the confining potential is modeled by a single bead, capturing the essential features of the interaction.

On the other hand, several models have attempted to reproduce these static potentials, including the flux tube model [38], the QCD string model [39], and the constituent gluon model [26]. Among these, the flux tube model is particularly notable for its ability to describe not only ordinary $q\bar{q}$ and qqq hadrons but also exotic states such as hybrids, glueballs, and multiquark states [38]. The flux tube model is based on the strong-coupling Hamiltonian of lattice QCD, where gluonic degrees of freedom are transformed into collective string-like flux tubes (see Fig. 1). A small oscillation approximation was employed to derive relatively simple analytical results [38]. However, this approximation may be inadequate for light hadrons, as it overestimates the potential gap between the lowest excited and ground gluonic fields (see Fig. 2 of Ref. [40]).

To address this limitation, Barnes *et al.* refined the flux tube model by simplifying the string to a single bead [40]. Their improved model accurately reproduced the spectrum of conventional quarkonia. However, it predicted a larger mass difference between the first orbitally excited and ground $c\bar{c}g$ multiplets by comparing the lattice QCD results [35].²

The hybrid meson is simplified to be a three-body system when the string of mass beads is replaced by a single bead. This picture aligns with the QCD string model [39]³ and the constituent gluon model [26]. Based on these models, we could develop a three-body hybrid model in which the massive bead in the flux tube model (see [*B*] diagram in Fig. 1) is replaced by a transverse electric (TE) gluon $(J_g^{P_gC_g} = 1^{+-})$.⁴

FIG. 2: A low-lying hybrid meson in the constituent gluon model. The lowest excited gluonic field in the hybrid system is approximated as a TE gluon.

¹ For more details of the quark potential model, one could consult Refs. [29, 30] and the papers citing these reviews.

² A smaller orbital excitation gap is expected for hybrid systems due to their relatively flat adiabatic potentials.

³ The hybrid adiabatic potentials derived from the QCD string model show good agreement with the lattice results [39].

⁴ This picture is partially supported by lattice QCD studies since the gluonic structure in the operators of low-lying hybrid states overlaps well with the chromomagnetic component [24]. The bag model also suggests that the lowest excited gluonic field in a hybrid meson should be a 1⁺⁻ state [41, 42].

As shown in Fig. 2, the long-range confinement potential is assumed to exist only between the TE gluon and the quark. Then the Schrödinger equation for a hybrid state is given by

$$\left(\sum_{i=q,\bar{q},g} \frac{\mathbf{p}_i^2}{2m_i} + \sum_{i=1}^2 V_{\text{eff.}}(r_i)\right)\psi_H = E_H\psi_H.$$
 (1)

To test the constituent gluon model, we first employ a simple harmonic oscillator (SHO) potential as the confinement interaction. The effective potential $V_{\text{eff.}}(r_i)$ is written as

$$\sum_{i=1}^{2} V_{\text{eff.}}(r_i) = C_{ig} \left(\frac{1}{2} K r_1^2 + \frac{1}{2} K r_2^2 \right) + c_H.$$
(2)

Here, *K* is the spring constant representing the strength of the confinement interaction. $C_{ig} = 3/2$ is the color coefficient for hybrid mesons, and c_H is a mass-renormalization constant. Using the relationships

$$r_1^2 = \left(\frac{\rho}{2} - z\right)^2 + h^2, \quad r_2^2 = \left(\frac{\rho}{2} + z\right)^2 + h^2,$$

the effective potential $V_{\text{eff.}}(r_i)$ can be reformulated as

$$V_{\text{eff.}}(\rho,\lambda) = C_{ig}\left(\frac{1}{4}K\rho^2 + K\lambda^2\right) + c_H.$$
 (3)

Here, Jacobi coordinates are used to simplify the three-body problem. The Schrödinger equation then becomes

$$\left[\frac{\mathbf{p}_{\rho}^{2}}{2m_{\rho}} + \frac{\mathbf{p}_{\lambda}^{2}}{2m_{\lambda}} + \frac{3}{2}K\left(\frac{\rho^{2}}{4} + \lambda^{2} + c_{M}\right)\right]\psi_{H}(\rho,\lambda) = E_{H}\psi_{H}(\rho,\lambda),$$
(4)

where the reduced masses are defined as

$$m_{\rho} = \frac{m_1 m_2}{m_1 + m_2}, \quad m_{\lambda} = \frac{(m_1 + m_2)m_g}{m_1 + m_2 + m_g}.$$

As shown in Eq. (4), the ρ -mode and λ -mode are independent when the SHO potential is used for the long-range confinement interaction between the TE gluon and the quark.

Interestingly, the hybrid wave function is often approximated as a product of the quark and gluon wave functions [11]. This ansatz is supported by Eq. (4). Specifically, the wave function of a hybrid state can be written as

$$\Psi_{n_{q\bar{q}}L_{q\bar{q}},n_{g}L_{g}}(\boldsymbol{\rho},\boldsymbol{\lambda}) = R_{n_{q\bar{q}}L_{q\bar{q}}}(\boldsymbol{\rho})Y_{L_{q\bar{q}}m_{q\bar{q}}}(\hat{\boldsymbol{\rho}})R_{n_{g}L_{g}}(\boldsymbol{\lambda})Y_{L_{g}l_{g}}(\hat{\boldsymbol{\lambda}}).$$
 (5)

Here, $R_{nl}(r)Y_{lm}(\hat{r})$ is the spatial wave function of the SHO potential. This wave function was also used in our recent work [21] to study the decay behaviors of $\pi_1(1600)$ and $\eta_1(1855)$. In the next subsection, we will use the SHO wave function as a trial function to solve the Schrödinger equation with a more realistic potential, such as the linear confinement potential.

Since the ρ -mode and λ -mode of a hybrid meson are independent in the SHO model, the quark-antiquark pair provides a static color octet source for the gluonic field at their center. Thus, we may test this simple hybrid model by comparing the λ -mode excitation energy with gluelump masses obtained from other methods.

The energy level of a hybrid meson in the SHO potential is given by

$$E_H = \left(2n_\lambda + l_\lambda + \frac{3}{2}\right)\omega_\lambda + \left(2n_\rho + l_\rho + \frac{3}{2}\right)\omega_\rho.$$
 (6)

The angular frequencies ω_{λ} and ω_{ρ} are defined as

$$\omega_{\lambda} = \sqrt{\frac{3K}{m_{\lambda}}}, \quad \omega_{\rho} = \sqrt{\frac{3K}{4m_{\rho}}}.$$

For comparison, we also express the energy level of light mesons using the SHO potential. The Schrödinger equation for conventional $q\bar{q}$ mesons is

$$\left[\frac{\mathbf{p}^2}{2m_{\mu}} + C_{q\bar{q}}\left(\frac{1}{2}Kr^2\right) + C_M\right]\psi_M(r) = E_M\psi_M(r),\qquad(7)$$

where $C_{q\bar{q}} = 4/3$ is the color coefficient for mesons. The energy level of a light meson in the SHO potential is

$$E_M = \left(2n + l + \frac{3}{2}\right)\omega_M,\tag{8}$$

with $\omega_M = \sqrt{\frac{4K}{3m_{\mu}}}$. Comparing ω_{λ} and ω_M , we obtain

$$\omega_{\lambda} = \frac{3}{4} \omega_M \sqrt{1 + 2\frac{m_q}{m_g}}.$$
(9)

Using the masses of π , $\rho(770)$, $h_1(1170)$, and $b_1(1235)$ [43], we estimate ω_M as

$$\omega_M \simeq \frac{M(h_1) + M(b_1)}{2} - \frac{M(\pi) + 3M(\rho)}{4} \approx 0.582 \text{ GeV}.$$

The $\pi_1(1600)$ is approximately 1.0 GeV above the average mass of π and ρ states. Similarly, the lowest heavy hybrid states are predicted to be 1.0 GeV above the 1*S* $Q\bar{Q}$ mesons [40]. Lattice QCD results [25, 35, 44] and the constituent gluon model [11] suggest that the lowest $Q\bar{Q}g$ hybrids are about 1.3 GeV above the 1*S* $Q\bar{Q}$ mesons. Based on these results, we take $m_g = 1.05$ GeV and $m_q = 0.32$ GeV, yielding

$$\omega_{\lambda} = \frac{3}{4} \times 0.582 \sqrt{1 + 2 \times \frac{0.32}{1.05}} = 0.554 \text{ GeV}.$$
 (10)

From a phenomenological perspective, the 2⁻⁻ and 3⁺⁻ gluelumps can be viewed as the orbital excitations of 1⁺⁻ state [39, 45]. Various methods have predicted the mass splittings $\delta_{21} = M_{2^{--}} - M_{1^{+-}}$ and $\delta_{31} = M_{3^{+-}} - M_{1^{+-}}$. Table I summarizes results from the bag model [45], the lattice QCD [46], the QCD string model [47], the mean-field approach in Coulomb gauge QCD [48], and the transverse constituent gluon model [49]. Most predictions for δ_{21} are slightly above 0.50 GeV, consistent with the value of ω_{λ} in Eq. (10). Additionally, the δ_{31} values are approximately twice the corresponding δ_{21} , aligning with the SHO model. In the next subsection, we will replace the SHO potential with a linear confinement potential to construct a more realistic model for hybrid meson masses.

TABLE I: Predicted mass gaps of the $2^{--}/3^{+-}$ and 1^{+-} gluelumps from Refs. [45–49] (GeV).

3+-	1.01	0.972	0.84	1.11	0.97

B. The constituent gluon model with Cornell potential

The Cornell potential has been widely used to describe the spectrum of conventional hadrons. It consists of two parts: a Coulomb potential at short distances and a linear confinement potential at long distances [50]. For hybrid mesons, we replace the SHO potential in Eq. (2) by the linear confinement potential and include a Coulomb potential for the quark-antiquark pair due to one-gluon exchange. Thus, the effective interaction potential for the hybrid meson is given by

$$V_{q\bar{q}g}(r_1, r_2, \rho) = C_{ig}\left(\frac{3}{4}br_1 + \frac{3}{4}br_2\right) + C'_{q\bar{q}}\frac{\alpha_s}{\rho} + c'_H$$

$$= \frac{9}{8}b(r_1 + r_2) + \frac{1}{6}\frac{\alpha_s}{\rho} + c'_H.$$
(11)

Here, $C'_{q\bar{q}} = 1/6$ is a color coefficient for a hybrid meson. The Coulomb term in Eq. (11) ensures the repulsive behavior of the hybrid static potential at short distances between the quark and antiquark, as confirmed by lattice QCD [36]. We now solve the following Schrödinger equation:

$$\left[\frac{\mathbf{p}_{\rho}^{2}}{2m_{\rho}} + \frac{\mathbf{p}_{\lambda}^{2}}{2m_{\lambda}} + \frac{9}{8}b(r_{1} + r_{2}) + \frac{1}{6}\frac{\alpha_{s}}{\rho} + c_{H}'\right]\psi_{H} = E_{H}\psi_{H}.$$
 (12)

We neglect the spin-dependent interactions since even the ground hybrid mesons have not been firmly established.⁵ Therefore, the results from Eq. (11) can be interpreted as the spin-averaged masses of hybrid multiplets.

As mentioned earlier, we use the variational method to solve Eq. (11), with the SHO wave function as the trial wave function. This approach has been shown to yield accurate results for solving the Schrödinger equation of two- and three-body systems [51, 52]. For the ground hybrid states [50], the trial wave function is written as

$$\Psi_{00,00}(\boldsymbol{\rho},\boldsymbol{\lambda}) = \frac{\beta_{\rho}^{3/2} \beta_{\lambda}^{3/2}}{\pi^{3/2}} e^{-(\beta_{\rho}^2 \rho^2 + \beta_{\lambda}^2 \lambda^2)/2}.$$
 (13)

The energy of the ground states is given by

$$E_{00,00} = \frac{3}{4} \left(\frac{\beta_{\rho}^2}{m_{\rho}} + \frac{\beta_{\lambda}^2}{m_{\lambda}} \right) + \frac{9b}{8\sqrt{\pi}} \sqrt{\frac{1}{\beta_{\rho}^2} + \frac{4}{\beta_{\lambda}^2}} + \frac{\alpha_s \beta_{\rho}}{3\sqrt{\pi}} + c'_H.$$
(14)

The detailed calculations are provided in Appendix A, along with the energy of the 1ρ excited states.

Since the hybrid mesons is not yet fully established, we cannot directly fix the parameters using the measured masses of known hybrids. Instead, we assume that the parameters for light hybrid mesons are the same as those for conventional $q\bar{q}$ mesons. We validate this assumption by comparing our results with lattice QCD predictions and experimental evidence. To this end, we express the potential for $q\bar{q}$ mesons as

$$V_{q\bar{q}}(r) = C_{q\bar{q}}\left(-\frac{\alpha_s}{r} + \frac{3}{4}br\right) + c_M.$$
(15)

This is the well-known Cornell potential, widely used to study meson masses. In our previous work [21], the parameters α_s and *b* were fixed as

$$\alpha_s = 0.64, \quad b = 0.165 \text{ GeV}$$

with $m_{u,d} = 0.32$ GeV and $m_s = 0.45$ GeV. For hybrid mesons, we take $c'_H = 1.89$ GeV and 1.82 GeV for the $q\bar{q}g$ and $s\bar{s}g$ systems, respectively. The predicted masses for the low-lying light hybrid mesons are listed in Table II.

TABLE II: Predicted average masses of the low-lying $q\bar{q}g$ and $s\bar{s}g$ multiplets (MeV).

$(n_{\lambda}l_{\lambda}, n_{\rho}l_{\rho})$	(00, 00)	(00, 01)	(01, 00)	(00, 10)
$ar{M}_{qar{q}g}$	1755	2118	2226	2113
$ar{M}_{sar{s}g}$	1949	2266	2394	2255

The average mass of the ground $q\bar{q}g$ states is determined to be 1775 MeV, which is approximately 100–150 MeV higher than the mass of the $\pi_1(1600)$. This result is consistent with predictions from the constituent gluon model [53] and lattice QCD [24]. Additionally, the average mass of the ground $q\bar{q}g$ states is about 200 MeV below that of the $s\bar{s}g$ states, which aligns with the mass difference between the $\pi_1(1600)$ and the $\eta_1(1855)$.

We focus on the masses of $q\bar{q}g$ and $s\bar{s}g$ states with exotic quantum numbers 0^{+-} and 2^{+-} . In our framework, these states belong to the $(n_{\lambda}l_{\lambda}, n_{\rho}l_{\rho}) = (00, 01)$ multiplet. Specifically, they correspond to the $(1P)_{\rho}$ excited states of the $\pi_1(1600)$ and $\eta_1(1855)$ (see further details in the next section). As shown in Table II, the average mass of the $(n_{\lambda}l_{\lambda}, n_{\rho}l_{\rho}) = (00, 01)$ multiplet is approximately 360 MeV above the ground states.

Interestingly, a signal of an h_{2l} state around 2.0 GeV was potentially observed at the multi-particle spectrometer facility at Brookhaven National Laboratory (BNL) in 2005 [54]. Specifically, a resonance structure with exotic quantum numbers $I^G J^{PC} = 0^{-2^{+-}}$ was identified in the process $\pi^- + p \rightarrow h_2(0^{-2^{+-}}) + n \rightarrow b_1\pi n \rightarrow \omega\pi\pi n \rightarrow 5\pi n$. According to the E852 experiment, the h_{2l} state is about 350 MeV above the $\pi_1(1600)$, which is consistent with our predictions. Furthermore, the central mass of the first radially excited $q\bar{q}g$ state is predicted to be 2060 MeV. This result supports the interpretation of the $\pi_1(2015)$, observed by the E852 experiment [55, 56], as the first radial excitation of the $\pi_1(1600)$.

⁵ According to lattice QCD results [24], the light-flavor hybrid meson supermultiplet includes 0^{-+} , 1^{-+} , 1^{--} , and 2^{-+} states. Currently, only the isovector $\pi_1(1600)$ and isoscalar $\eta_1(1855)$ with $J^{PC} = 1^{-+}$ have been experimentally confirmed.

In addition to the average masses, we also determine the scale parameter β of the SHO wave function by solving Eq. (12). The specific values of β_{λ} and β_{ρ} are listed in Table III, which will be used to calculate the strong decays of 0⁺⁻ and 2⁺⁻ hybrids in Sec. III.

TABLE III: The scale parameter $(\beta_{\rho}, \beta_{\lambda})$ of the SHO wave function for the low-lying light hybrid states (GeV). The first row is quantum numbers $(n_{\lambda}l_{\lambda}, n_{\rho}l_{\rho})$. The second and third rows are the concrete values of β_{ρ} and β_{λ} for the $q\bar{q}g$ and $s\bar{s}g$ states, respectively.

C. Further discussion of the masses of the hybrid states

In Sec. II A, we have introduced a transverse electric (TE) gluon to simulate the lowest excited gluonic field. To construct the TE gluon with quantum numbers $J_g^{P_g C_g} = 1^{+-}$, an intrinsic orbital angular momentum $L_g = 1$ is required [11]. The Clebsch-Gordan coefficient for the TE gluon is given by

$$\chi_{\mu,\nu}^{(-)} \equiv \langle s_g \nu, \ L_g 0 | J_g \mu \rangle = \langle 1\nu, \ 10 | 1\mu \rangle = \frac{\lambda}{\sqrt{2}} \delta_{\mu\nu}.$$
 (16)

In this framework, the orbital angular momentum L_H of a hybrid meson arises from the coupling of the excited gluonic field (J_g) and the orbital angular momentum of the quarkantiquark pair $(L_{q\bar{q}})$, i.e., $L_H = J_g + L_{q\bar{q}}$. The total angular momentum J is then obtained by coupling L_H with the spin of the $q\bar{q}$ pair $(S_{q\bar{q}})$. For clarity, the coupling order of the angular momenta is expressed as

$$\boldsymbol{L}_{q\bar{q}} \otimes \boldsymbol{J}_{g} \Rightarrow \boldsymbol{L}_{H} \otimes \boldsymbol{S}_{q\bar{q}} \Rightarrow \boldsymbol{J}.$$
(17)

The parity (*P*), charge conjugation (*C*), and *G*-parity of hybrid mesons containing a TE gluon are determined by

$$P = (-1)^{L_g + L_{q\bar{q}}}, \quad C = (-1)^{L_g + L_{q\bar{q}} + S_{q\bar{q}}}, \quad G = (-1)^{L_g + L_{q\bar{q}} + S_{q\bar{q}} + I_{q\bar{q}}}$$

respectively. The allowed $I^G J^{PC}$ quantum numbers and naming scheme for the low-lying light hybrid mesons are summarized in Table IV.

The low-lying light hybrid mesons with exotic quantum numbers have been denoted as bold in Table IV. Among them, the 1^{-+} multiplet has been investigated in our previous work [21]. Here, we focus on the 0^{+-} and 2^{+-} states which could be regarded as the first orbitally excitations of 1^{-+} states. Since the hyperfine interaction has not been considered in our calculation, all the 0^{+-} and 2^{+-} states have the same mass.

When the SHO potential in the Eq. (4) is replaced by the linear confinement potential and Coulomb potential, the spherical symmetry for the TE gluon⁶ is broken while the

cylindrical symmetry appears. Then the lowest excited gluonic field differentiates into two configurations, i.e., the $\Sigma_u^$ and Π_u gluonic fields. With the Born-Oppenheimer approximation, the results of lattice QCD indicates that the Σ_u^- gluonic field may have higher excited energy [34]. In Table IV, the hybrid states with $L_H = 0$ and $L_H = 2$ may correspond to the Σ_u^- field, while the states with $L_H = 1$ correspond to the Π_u field. To distinguish the states with the same J but different L_H , we add a subscript "h" for the relative states with $L_H = 0$ and $L_H = 2$. Correspondingly, the states with $L_H = 1$ are supplemented by a subscript "l".

At present, the mass pattern of light hybrid mesons is still unclear. What's more, this topic was rarely investigated by the phenomenological models in the literature. However, some valuable information could be obtained by the lattice QCD method [57], which are collected below.

- 1. The authors discovered a set of exotic J^{PC} states which have strong overlap onto operators featuring a chromomagnetic gluonic construction [57]. Then the lattice QCD identified the existence of hybrid mesons which include the 0⁺⁻, 1⁻⁺, and 2⁺⁻ states.
- 2. Since the mass of light quark in the lattice QCD simulation is lager than physical value ($m_{\pi} = 391$ MeV), the predicted masses of $\pi_1(1600)$ is about 1.2 times of the measured mass. With the measured mass of $\pi_1(1600)$ as benchmark, we rescale the predicted masses of 0^{+-} , 2^{+-} , and another 1^{-+} states. We find that the average mass of one 0^{+-} and two 2^{+-} isovector states is about 2.10 GeV which is comparable to the our $(1P)_{\rho}$ mass in Table II.
- 3. The rescaled mass of an excited 1^{-+} hybrid is about 2.13 GeV, which is nearly equal to the average mass of $(2S)_{\rho}$ multiplet (see Table II). This result implies that

⁶ In Sec. II, the lowest excited gluonic field which is regarded as a TE gluon rotates around the center of $q\bar{q}$ pair (see Fig. 2 and Eq. (4)).

the $\pi_1(2015)$ could be the first radially excited state of $\pi_1(1600)$ [58].

- 4. The mass of b_{2h} is about 200 MeV above the average mass of b_0 and b_{2l} state. Furthermore, the mass splitting of b_0 and b_{2l} is about 100 MeV due to the probable spin-dependent interactions.
- 5. The light-strange mixing was found to be small for the isoscalar 0⁺⁻ and 2⁺⁻ hybrid mesons, which indicates the h_0 , h_{2l} , and h_{2h} are predominantly the $(u\bar{u}+d\bar{d})g/\sqrt{2}$ content while the h'_0 , h'_{2l} , and h'_{2h} are predominantly the $s\bar{s}g$ content.

Based on our result in Table II and the conclusions above, we may further estimate the masses of 0^{+-} and 2^{+-} light hybrid mesons. The concrete results are listed in Table V, which will be taken to calculate the strong decays of 0^{+-} and 2^{+-} hybrids in the next section.

TABLE V: The estimated masses of 0^{+-} and 2^{+-} light hybrid mesons (GeV).

b_0/h_0	b_{2l}/h_{2l}	b_{2h}/h_{2h}	h_0'	h'_{2l}	h'_{2h}

III. THE DECAY BEHAVIORS

The hybrid mass model developed in Sec. II is consistent with the physical picture of the constituent gluon model [11]. This allows us to study both the mass spectrum and strong decays of hybrid mesons within a unified framework. Below, we provide a brief review of the constituent gluon model for how to depict the decay process of a hybrid meson.

FIG. 3: Connected diagram for a hybrid state H decaying into B and C mesons.

For the decay process of a hybrid meson *H* into mesons *B* and *C*, the transition operator $\hat{\mathcal{T}}$ in the constituent gluon model can be expressed as

$$\hat{\mathcal{T}} = g_s \sum_{s,s',\lambda} \iiint \frac{\mathrm{d}^3 \boldsymbol{p}_3 \mathrm{d}^3 \boldsymbol{p}_4 \mathrm{d}^3 \boldsymbol{k}_g}{\sqrt{2\omega_g} (2\pi)^6} \delta^3(\boldsymbol{p}_3 + \boldsymbol{p}_4 - \boldsymbol{k}) \\ \times \frac{\lambda^{c_g}}{2} \phi_0^{(34)} \chi_s^{\dagger} \boldsymbol{\sigma} \tilde{\chi}_{s'} \boldsymbol{\epsilon}^{\mu}(\hat{\mathbf{k}}, \nu) b_3^{\dagger}(\vec{p}_3) d_4^{\dagger}(\vec{p}_4) a_{\mathbf{k}\nu}^{c_g}(\boldsymbol{k}),$$
(18)

in the nonrelativistic limit. Here, λ^{c_g} ($c_g = 1, 2, ..., 8$) are the Gell-Mann matrices, $\chi_{s^{(\prime)}}$ represent the quark spinors, and $\epsilon^{\mu}(\hat{\mathbf{k}}, \nu)$ denotes the gluon polarization vector. Since the transition operator $\hat{\mathcal{T}}$ describes the dissociation of a constituent gluon into a quark-antiquark pair, the flavor wave function $\phi_0^{(34)}$ is taken as $(u\bar{u} + d\bar{d} + s\bar{s})/\sqrt{3}$. The parameter ω_g , representing the effective mass of the constituent gluon, is set to 0.80 GeV in our calculations [59].

For calculating the helicity amplitude $\mathcal{M}^{j_H, j_B, j_C}(\mathbf{p})$ of a decay process $H \to B+C$ (see Fig. 3), the spatial wave functions of hadrons could be described as the mock states [60]. For a hybrid state H, the wave function is written as [21]

$$|H(J_H m_H [L_H(L_{q_1\bar{q}_2} J_g) S_{q_1\bar{q}_2}](\boldsymbol{P}_H)\rangle \equiv \omega_H \phi_H \Pi_{CG}^{(H)} \int d^3 \boldsymbol{p}_1 d^3 \boldsymbol{p}_2 d^3 \boldsymbol{k} \delta^3(\boldsymbol{p}_1 + \boldsymbol{p}_2 + \boldsymbol{k} - \boldsymbol{P}_H)$$
(19)
$$\times \Psi_{n_{q_1\bar{q}_2}, n_g}^{L_{q\bar{q}}m_{q\bar{q}}, L_g l_g}(\boldsymbol{p}_1, \boldsymbol{p}_2, \boldsymbol{k}) |q_1(\boldsymbol{p}_1)q_2(\boldsymbol{p}_2)g(\boldsymbol{k})\rangle.$$

The mock states for the final mesons *B* and *C* could be found in our previous work [61]. In Eq. (19), ω_H and ϕ_H denote the color and flavor wave functions of the initial hybrid state, respectively. As a color singlet, the color wave function of the hybrid state is $\omega_H = |[(q_1\bar{q}_2)_8 \otimes g_8]_1\rangle$. The flavor wave function of the hybrid state is identical to that of a meson state, since the gluon is flavorless. The term $\Pi_{CG}^{(H)}$ in Eq. (19) involves the product of Clebsch-Gordan coefficients, representing the coupling of quark-gluon spins and angular momenta to the total spin J_H of the hybrid state. Specifically, it is given by

$$\Pi_{\rm CG}^{(H)} = \sqrt{\frac{2J_g + 1}{4\pi}} \mathcal{D}_{m_g,\mu}^{J_g*}(\hat{\mathbf{k}}) \chi_{\mu,\nu}^{(-)} \langle l_{q_1 \bar{q}_2} m_l, J_g m_g | L_H m_L \rangle \times \langle \frac{1}{2} m_1, \frac{1}{2} m_2 | S_H s_H \rangle \langle S_H s_H, L_H m_L | J_H m_H \rangle.$$
(20)

Here, $\chi_{\mu,\nu}^{(-)}$ is defined in Eq. (16). The rotation matrix $\mathcal{D}_{m_g,\mu}^{J_g*}$ in Eq. (20) transforms the gluon's angular momentum projection into the basis of hybrid system. For simplification, we use the relation [11]

$$\chi_{s}^{\dagger}\boldsymbol{\sigma}\tilde{\chi}_{s'}\boldsymbol{\epsilon}^{\mu}(\hat{\mathbf{k}},\nu) = -2^{|s+s'|/2}\mathcal{D}_{s+s',\nu}^{1}(\hat{\mathbf{k}}), \qquad (21)$$

in practical calculations. Combining the two " \mathcal{D} " functions in Eqs. (20) and (21), we obtain

$$\sqrt{\frac{2J_g+1}{4\pi}} \mathcal{D}_{m_g,\mu}^{J_g*}(\hat{\mathbf{k}}) \left(-2^{|s+s'|/2} \mathcal{D}_{s+s',\nu}^{1}(\hat{\mathbf{k}})\right) = (-1)^{m_g+1} \times 2^{(|s+s'|-1)/2} \langle 1-m_g, 1s+s'|1l_g \rangle \mathcal{Y}_{1l_g}^{*}(\hat{\mathbf{k}}),$$
(22)

for the decay process of a hybrid state with a TE gluon. As shown in Eq. (5), the spatial wave function of a hybrid state can be approximated as a simple product of ρ - and λ -modes. In momentum space, the spatial wave functions of the 0⁺⁻ and 2⁺⁻ states are denoted as

$$\Psi_{0,0}^{1m_{q\bar{q}},1l_g}(\boldsymbol{p}_{\rho},\boldsymbol{p}_{\lambda}) = \frac{8/3}{\pi^{1/2}\beta_{\rho}^{5/2}\beta_{\lambda}^{5/2}} \boldsymbol{\mathcal{Y}}_{1m_{q\bar{q}}}(\boldsymbol{p}_{\rho}) \boldsymbol{\mathcal{Y}}_{1l_g}(\boldsymbol{p}_{\lambda}) \mathrm{e}^{-\frac{p_{\rho}^{2}}{2\beta_{\rho}^{2}} - \frac{p_{\Lambda}^{2}}{2\beta_{\lambda}^{2}}}.$$
(23)

Using Jacobi coordinates, p_{ρ} and p_{λ} can be simplified as

$$\boldsymbol{p}_{\rho} = \frac{\boldsymbol{q}}{2} - \boldsymbol{p}; \quad \boldsymbol{p}_{\lambda} = \boldsymbol{k},$$
 (24)

in the rest frame of the light $q\bar{q}g$ hybrid system. Here, **p** is the

$$\mathcal{M}_{LS}^{H\to BC}(p) = g_s \frac{\sqrt{2L+1}}{2J_H+1} \sum_{j_B,j_C} \langle L0Jj_H | J_H j_A \rangle \langle J_B j_B, J_C j_C | Jj_H \rangle \langle l_{q_1 \bar{q}_2} m_l, J_g m_g | L_H m_L \rangle \langle \frac{1}{2} m_1, \frac{1}{2} m_2 | S_H s_H \rangle \langle S_H s_H, L_H m_L | J_H m_H \rangle \\ \times \langle \frac{1}{2} m_1, \frac{1}{2} s' | S_B s_B \rangle \langle S_B m_B, L_B m_{L_B} | J_B m_{JB} \rangle \langle \frac{1}{2} m_2, \frac{1}{2} s | S_C m_C \rangle \langle S_C m_C, L_C m_{L_C} | J_C m_{J_C} \rangle 2^{|s+s'|/2} (-1)^{s+s'} \chi_{\mu,\nu}^{(-)} \\ \times \langle 1 - m_g, 1s + s' | 1l_g \rangle \xi_c \xi_f \iint d^3 q d^3 k \, \psi_{n_{q\bar{q}}}^{L_{q\bar{q}} m_{q\bar{q}}} \left(\frac{q}{2} - p \right) \psi_{n_g}^{L_g l_g} (k) \, \psi_B^* \left(\frac{k+q}{2} - \varepsilon p \right) \psi_C^* \left(\frac{k-q}{2} + \varepsilon p \right).$$

$$(25)$$

The color coefficient ξ_c is determined by the matrix element $\xi_c = \langle (q_1\bar{q}_3)_1(\bar{q}_2q_4)_1 | [(q_1\bar{q}_2)_8 \otimes g_8]_1 \rangle = \sqrt{8/9}$. The flavor coefficient ξ_f is calculated with the same method as for the ordinary $q\bar{q}$ mesons, since the gluon is flavorless. The parameter ε is defined as $\varepsilon = m'/(m + m')$, where the *m* and *m'* denote the masses of 1 and 3 quarks in Fig. 3, respectively. The partial width of the decay process $H \to BC$ in the rest frame of *H* is given by

$$\Gamma(H \to BC) = 2\pi \frac{E_B E_C}{M_H} p \sum_{LS} |\mathcal{M}_{LS}^{H \to BC}(p)|^2.$$
(26)

In our calculations, the scale parameters β of SHO wave function for the final mesons are also obtained by the potential model (see Eq. (15)). The masses of the final mesons are taken from the Particle Data Group (PDG) [43]. For the undiscovered mesons, we fix their masses using the potential model. The strong coupling constant g_s is determined by the decay width of $\pi_1(1600)$ under the 1⁻⁺ hybrid assignment.

As discussed in Sec. II, lattice QCD results indicate that one isoscalar hybrid in a light-flavor nonet is predominantly a $(u\bar{u} + d\bar{d})g/\sqrt{2}$ state, while the other is predominantly an $s\bar{s}g$ state. For simplicity, we initially ignore flavor mixing between the two isoscalar hybrids. Mixing may also occur between two 2⁺⁻ hybrid mesons with different L_H (see Table IV), such as the b_{2l} and b_{2h} states. However, the mixing angles for these states cannot be quantitatively analyzed in our current framework. Nevertheless, we will discuss the potential effects of mixing on their decay behaviors. To this end, the nine hybrid states in Table V are divided into four groups: $(b_0, h_0, h'_0), (b_{2l}, b_{2h}), (h_{2l}, h_{2h}), and (h'_{2l}, h'_{2h})$. We now discuss their decay properties in detail.

A. The b_0 , h_0 , and h'_0 states

The allowed decay channels of the b_0 , h_0 , and h'_0 states are listed in Table VI, along with their predicted decay widths. The $b_0(1940)$ and $h'_0(2100)$ are expected to be broad, primar-

ily due to the *s*-wave decay channel " $0^{+-} \rightarrow 2^1 S_0 + 1^1 S_0$ ". The broad nature of the $b_0(1940)$ and $h'_0(2100)$ states poses a significant challenge for the experimental searches in the future. For the $b_0(1940)$, the $h_1(1170)\pi$ channel also contributes significantly for its total decay width. Additionally, the $b_1(1235)\eta$ and $K_1(1270)K$ channels are likely to be observable.

TABLE VI: The partial and total widths of the b_0 , h_0 , and h'_0 states with $J^{PC} = 0^{+-}$ (MeV). When the partial width of a decay channel is predicted to be smaller than 0.1 MeV, the result is denoted as "0.0".

b ₀ (1940)	Γ_i	$h_0(1940)$	Γ_i	$h'_0(2100)$	Γ_i
$h_1(1170)\pi$	26.3	$b_1(1235)\pi$	66.8	$h'_1(1415)\eta$	2.6
$b_1(1235)\eta$	5.0	$h_1(1170)\eta$	7.5	$K_1(1270)K$	33.7
$K_1(1270)K$	4.2	$K_1(1270)K$	1.6	$K_1(1400)K$	53.3
$K_1(1400)K$	1.0	$K_1(1400)K$	1.1	K(1460)K	394.4
$\omega_2 \pi$	0.0	$ ho_2\pi$	0.0		
$\pi(2S)\pi$	267.1				
Total	303.6	Total	77.0	Total	484.0

The $h_0(1940)$ appears to be relatively narrow if its mass lies below the threshold of the $K^*(1460)K$ channel. Its dominant decay mode is $b_1(1235)\pi$, but it could also be observed in the $h_1(1170)\eta$, $K_1(1270)K$, and $K_1(1400)K$ channels. However, if the h_0 state is above the $K^*(1460)K$ threshold, it could become significantly broad. For instance, if the mass of h_0 exceeds the $K^*(1460)K$ threshold by about 40 MeV, the partial width for $h_0 \rightarrow K^*(1460)K$ could exceed 100 MeV.

For the $h'_0(2100)$, the $K_1(1270)K$, $K_1(1400)K$, and K(1460)K channels are the main decay modes, while the partial width for $h'_1(1415)\eta$ is relatively small. These findings for the b_0 , h_0 , and h'_0 states are consistent with the results from Ref. [23].

three-momentum of the daughter meson B in the center-ofmass frame of H (see Fig. 3), while q and k are the integration variables. The partial wave amplitude is given by

TABLE VII: The partial and total widths of the b_{2l} and b_{2h} states with $J^{PC} = 2^{+-}$ (MeV). If the hybrid state is below the threshold of a decay channel, the result is denoted as "–".

channel	$b_{2l}(2040)$	$b_{2h}(2190)$

$b_1(1235)\eta$	1.4	5.9	$\pi(3S)\pi$	0.4	2.6
$a_1(1260)\pi$	9.8	12.2	$f_1(1280)\rho$	_	12.8
$a_2(1320)\pi$	7.4	0.2	$f_2(1270)\rho$	_	9.9
$K_1(1270)K$	0.8	3.4	$\omega_1(1D)\pi$	0.0	0.1
$K_1(1400)K$	2.5	16.6	$\omega_2(1D)\pi$	17.2	7.8
$K_2^*(1430)K$	1.6	1.2	$\omega_3(1D)\pi$	0.1	0.0
			Total	46.7	89.7

B. The b_{2l} and b_{2h} states

The $b_{2l}(2040)$ and $b_{2h}(2190)$ states are predicted to be significantly narrower than the $b_0(1940)$. In particular, the total width of the $b_{2l}(2040)$ is estimated to be 46.7 MeV. Promising decay channels for the $b_{2l}(2040)$ include $h_1(1170)\pi$, $a_1(1260)\pi$, $a_2(1320)\pi$, $K_1(1400)K$, and $\omega_2(1D)\pi$, making them ideal for the experimental searches. Ref. [23] also suggested the b_{2l} to be a narrow state, with a predicted total width of only 11 MeV when its mass was taken as 2.0 GeV. The $h_1(1170)\pi$ and $a_1(1260)\pi$ channels were identified as the dominant decay modes for the b_2 hybrid state, which aligns with our findings in Table VII. However, the flux-tube model [22] predicts a much broader total width of 200–400 MeV for a b_2 state. Despite this discrepancy, the flux-tube model also supports the $h_1(1170)\pi$, $a_1(1260)\pi$, and $a_2(1320)\pi$ channels as the primary decay modes for the b_2 state.

The total decay width of $b_{2h}(2190)$ state, with $L_H = 2$, is predicted to be 89.7 MeV. This state could be observed in the $h_1(1170)\pi$, $a_1(1260)\pi$, $K_1(1400)K$, $f_1(1280)\rho$, $f_2(1270)\rho$, and $\omega_2(1D)\pi$ channels. The decay patterns of the $b_{2h}(2190)$ are similar to those of the $b_{2l}(2040)$, making it challenging to distinguish their mixing effects. However, the $a_2(1320)\pi$ channel is particularly noteworthy: it is a dominant decay mode for the $b_{2l}(2040)$, but contributes minimally to the $b_{2h}(2190)$. If future experiments discover two 2^{+-} isovector states, which may indicates the evidence of mixing between the b_{2l} and b_{2h} states.

C. The h_{2l} and h_{2h} states

The light isoscalar partners of the b_{2l} and b_{2h} states are expected to have nearly equal masses, as they are predominantly $(u\bar{u}+d\bar{d})g/\sqrt{2}$ states. Their decay properties have been investigated, and the results are summarized in Table VIII.

The $b_1(1235)\pi$, $a_1(1260)\rho$, and $\rho_2(1D)\pi$ channels are pre-

TABLE VIII: The partial and total widths of the h_{2l} and h_{2h} states with $J^{PC} = 2^{+-}$ (MeV).

channel	$h_{2l}(2040)$	$h_{2h}(2190)$			
$ ho\pi$	0.2	0.0	$b_1(1235)\pi$	11.4	35.8
$\omega\eta$	0.0	0.1	$a_1(1260)\rho$	14.1	59.6
$\omega \eta'$	0.0	0.0	$a_2(1320)\rho$	-	17.1
K^*K	0.0	0.1	$K_1(1270)K$	0.3	2.9
$\rho(1450)\pi$	1.3	1.4	$K_1(1400)K$	1.7	7.7
$\omega(1420)\eta$	0.0	0.1	$K_{2}^{*}(1430)K$	0.7	0.1
K(1460)K	0.0	0.2	$\rho_1(1D)\pi$	0.0	0.2
$K^{*}(1410)K$	0.0	0.1	$\rho_2(1D)\pi$	51.9	23.3
$h_1(1170)\eta$	1.8	6.6	$\rho_3(1D)\pi$	0.1	0.0
			Total	83.5	155.3

dicted to be the dominant decay modes for the h_{2l} state, with a total decay width of 83.5 MeV. Ref. [23] also supports the $b_1(1235)\pi$ as a primary decay channel for the h_{2l} state. Interestingly, the E852 experiment at the multi-particle spectrometer facility at Brookhaven National Laboratory (BNL) has reported a probable h_{2l} state around 2.0 GeV in 2005 [54]. Specifically, a strong signal of a resonance structure with exotic quantum numbers $I^G J^{PC} = 0^{-2^{+-}}$ was observed in the process $\pi^- + p \rightarrow h_2(0^{-2^{+-}}) + n \rightarrow b_1\pi n \rightarrow \omega\pi\pi n \rightarrow 5\pi n$. The properties of this h_2 state align well with the h_{2l} candidate in our framework. However, further experimental evidence is needed to confirm the existence of this state.

The total decay width of $h_{2h}(2190)$ state, with $L_H = 2$, is predicted to be 155.3 MeV. This state could be observed in the decay channels such as the $h_1(1170)\eta$, $b_1(1235)\pi$, $a_1(1260)\rho$, $a_2(1320)\rho$, $K_1(1400)K$, and $\rho_2(1D)\pi$. The decay patterns of the $b_{2h}(2190)$ are similar to those of the $b_{2l}(2040)$, making it challenging to distinguish their mixing effects based solely on the decay behaviors.

D. The h'_{2l} and h'_{2h} states

TABLE IX: The partial and total widths of the h'_{2l} and h'_{2h} states with $J^{PC} = 2^{+-}$ (MeV).

· · · ·	,				
channel	$h'_{2l}(2200)$	$h'_{2h}(2390)$			
<i>K</i> * <i>K</i>	0.1	0.0	K(1460)K	0.3	6.2
$\phi\eta$	0.0	0.0	$K^{*}(1410)K$	2.8	3.4
$\phi\eta'$	0.0	0.0	$\phi(1680)\eta$	-	0.2
$h'_1(1415)\eta$	0.7	3.6	$K^{*}(1680)K$	-	0.3
$K_1(1270)K$	2.3	14.5	$K_2(1770)K$	-	19.1
$K_1(1400)K$	18.1	47.6	$K_{2}^{*}(1780)K$	-	0.0
$K_2^*(1430)K$	9.4	1.1			
			Total	33.7	96.0

The strong decays of the h'_{2l} and h'_{2h} states are predicted in Table IX. According to our results, the h'_{2l} is likely to be a narrow hybrid state, predominantly decaying into the $K_1(1270)K$

and $K_2^*(1430)K$ channels. These findings are consistent with the results of Ref. [23].

In contrast, the h'_{2h} state is predicted to be broader, with its main decay channels including $K_1(1270)K$, $K_1(1400)K$, and $K_2(1770)K$. Investigating the h'_{2l} and h'_{2h} states in the $K_2^*(1430)K$ channel could provide insights into their mixing effects, similar to the case of the b_{2l} and b_{2h} states. We particularly emphasize the $K_2(1770)K$ channel for the h'_{2h} state. As an *s*-wave decay channel, its partial width is predicted to be 19.1 MeV. Similar results are observed for the b_{2l} , b_{2h} , h_{2l} , and h_{2h} states (see Tables VII and VIII).

IV. CONCLUSION AND OUTLOOK

Investigating hybrid mesons with the exotic J^{PC} quantum numbers is a crucial step toward establishing the complete spectrum of hybrid states. Since these hybrid mesons cannot mix with conventional $q\bar{q}$ mesons, their properties are easier to analyze. Currently, only the $\pi_1(1600)$ and $\eta_1(1855)$ with $J^{PC} = 1^{-+}$ have been definitively observed. However, evidence for states with $J^{PC} = 2^{+-}$ and $J^{PC} = 3^{-+}$ has also been reported in previous experiments [54, 62], indicating the potential for discovering more hybrid mesons with exotic quantum numbers in the future.

In this work, we focus on the mass spectrum and strong decays of hybrid mesons with $J^{PC} = 0^{+-}$ and $J^{PC} = 2^{+-}$ We developed a constituent gluon model in which the lowest excited gluonic field is approximated as a transverse electric (TE) gluon. In this scheme, the 0^{+-} and 2^{+-} hybrids can be interpreted as orbital excitations of the 1^{-+} hybrids. To describe the masses of hybrid mesons, we assume that the longrange confinement potential exists only between the quark and the TE gluon. Initially, we used a simple harmonic oscillator (SHO) potential to test the model. By solving the threebody Schrödinger equation, we found that the predicted excitation energies of the λ -mode are consistent with the results from other methods when interpreted as gluelump states. We then replaced the SHO potential with a linear confinement potential and included a Coulomb potential between the quarkantiquark pair. The resulting mass predictions for the 0^{+-} and 2^{+-} light hybrid states agree with lattice QCD results [57]. The hybrid potential model developed in Sec. II is fully compatible with the constituent gluon model [11].

In Sec. III, we systematically investigated the strong decays of 0^{+-} and 2^{+-} light hybrid mesons using the constituent gluon model. The main decay properties of these hybrids are summarized as follows:

1. The b_0 and h'_0 states are likely to be broad, with predicted total decay widths exceeding 300 MeV (see Table VI). If the h_0 lies below the threshold of the K(1460)K channel (an *s*-wave decay channel), its total width is predicted to be around 80 MeV. However, if the K(1460)K channel is accessible, the h_0 could also become a broad state. This makes the experimental search for 0^{-+} light hybrids particularly challenging.

- 2. The b_{2l} and h_{2l} states are expected to be relatively narrow, with predicted widths of less than 100 MeV. The dominant decay modes for the b_{2l} state are $a_1(1260)\pi$, $a_2(1320)\pi$, and $\omega_2(1D)\pi$. For the h_{2l} state, the $\rho_2(1D)\pi$ channel, as an *s*-wave decay, has the largest partial width, while the $b_1(1235)\pi$ and $a_1(1260)\rho$ channels also play significant roles.
- 3. The b_{2h} and h_{2h} states are predicted to have total decay widths of approximately 90–150 MeV. The b_{2h} state primarily decays into $h_1(1170)\pi$, $a_1(1260)\pi$, $K_1(1400)K$, $f_1(1280)\rho$, and $f_2(1270)\rho$ channels. As the isoscalar partner of b_{2h} , the h_{2h} mainly decays into $b_1(1235)\pi$, $a_1(1260)\rho$, $a_2(1320)\rho$, and $\rho_2(1D)\pi$ channels.
- 4. The h'_{2l} state is expected to be a narrow resonance, with a predicted decay width of only 33.7 MeV. Experimental searches for this state could focus on the $K_1(1400)K$ and $K_2^*(1430)K$ channels. The h'_{2h} state, with a predicted width of 96.0 MeV, primarily decays into $K_1(1270)K$, $K_1(1400)K$, and $K_2(1770)K$ channels.

In this work, we have studied the masses and strong decays of 0⁺⁻ and 2⁺⁻ hybrid mesons using an unified set of model parameters. Finally, we suggest potential experimental processes for discovering these states. Since signals of 2⁺⁻ and 3⁻⁺ hybrids have been observed in $\pi^- p$ inelastic scattering, the COMPASS experiment is well-positioned to discover 0⁺⁻ and 2⁺⁻ hybrid states in the near future. Although J/ψ radiative decays are forbidden for 0⁺⁻ and 2⁺⁻ states due to *C*-parity conservation, the BESIII collaboration could still search for these states. For example, the $\pi_1(1600)\pi \rightarrow \eta'\pi\pi$ [63]. Similarly, the b_{2l} and b_{2h} states could be discovered in the processes $\chi_{c1} \rightarrow \rho + b_2$ (*p*-wave) and $J/\psi \rightarrow \pi + b_2$ (*d*-wave), while the h_{2l} and h_{2h} states could be found in $\chi_{c1} \rightarrow \omega + h_2$ (*p*-wave).

Appendix A: Solving Eq. (12) by variational method

Here, we provide details on solving the three-body Schrödinger equation, i.e., Eq. (12), using the variational method. We focus on the ground state to illustrate how the expectation value of the Hamiltonian in Eq. (12) is obtained. The final result is given by Eq. (14).

First, we express the wave function of a ground hybrid state in momentum space as

$$\Psi_{00,00}(\boldsymbol{p}_{\rho}, \boldsymbol{p}_{\lambda}) = \frac{1}{\pi^{3/2} \beta_{\rho}^{3/2} \beta_{\lambda}^{3/2}} e^{-\frac{p_{\rho}^{2}}{2\beta_{\rho}^{2}} - \frac{p_{\lambda}^{2}}{2\beta_{\lambda}^{2}}}, \qquad (A1)$$

which corresponds to Eq. (13) in configuration space. We define the following Jacobi coordinates (see Fig. 2):

$$\boldsymbol{\rho} = \boldsymbol{r}_q - \boldsymbol{r}_{\bar{q}}, \quad \boldsymbol{\lambda} = \boldsymbol{r}_g - \frac{\boldsymbol{r}_q + \boldsymbol{r}_{\bar{q}}}{2}. \tag{A2}$$

The expectation values of the following terms in the Hamiltonian of Eq. (12) can be calculated directly:

$$\langle \Psi_{00,00} | \frac{\mathbf{p}_{\rho}^2}{2m_{\rho}} + \frac{\mathbf{p}_{\lambda}^2}{2m_{\lambda}} + \frac{1}{6} \frac{\alpha_s}{\rho} | \Psi_{00,00} \rangle = \frac{3}{4} \left(\frac{\beta_{\rho}^2}{m_{\rho}} + \frac{\beta_{\lambda}^2}{m_{\lambda}} \right) + \frac{\alpha_s \beta_{\rho}}{3\sqrt{\pi}}.$$

Calculating the expectation value of the term " $9b(r_1 + r_2)/8$ " in Eq. (12) requires additional techniques. To this end, we define the following Jacobi coordinates:

$$\rho' = \boldsymbol{r}_1 = \boldsymbol{r}_g - \boldsymbol{r}_q, \quad \boldsymbol{\lambda}' = \boldsymbol{r}_{\bar{q}} - \frac{m_q \boldsymbol{r}_q + m_g \boldsymbol{r}_g}{m_q + m_g}.$$
(A3)

The transformation between (ρ, λ) and (ρ', λ') is given by

$$\begin{pmatrix} \boldsymbol{\rho} \\ \boldsymbol{\lambda} \end{pmatrix} = \begin{pmatrix} -\epsilon & -1 \\ 1 - \frac{\epsilon}{2} & -\frac{1}{2} \end{pmatrix} \begin{pmatrix} \boldsymbol{\rho}' \\ \boldsymbol{\lambda}' \end{pmatrix},$$

where $\epsilon = \frac{m_g}{m_q + m_g}$. The determinant of the matrix in Eq. (A4) is equal to 1, ensuring that " $\iint d^3 \rho d^3 \lambda = \iint d^3 \rho' d^3 \lambda'$ ". Using Eq. (A4), the wave function of the ground hybrid state, i.e., Eq. (13), can be rewritten as

$$\Psi_{00,00}(\rho',\lambda') = \frac{\beta_{\rho}^{3/2} \beta_{\lambda}^{3/2}}{\pi^{3/2}} e^{-A\rho'^2 + B\rho' \cdot \lambda' - C\lambda'^2}.$$
 (A5)

Here, we define

$$A = \frac{1}{2} \left(\epsilon^2 \beta_\rho^2 + \xi^2 \beta_\lambda^2 \right), \quad B = -\epsilon \beta_\rho^2 + \frac{\xi}{2} \beta_\lambda^2, \quad C = \frac{\beta_\rho^2}{2} + \frac{\beta_\lambda^2}{8},$$

where $\xi = 1 - \frac{\epsilon}{2}$. The expectation value

$$\langle \Psi_{00,00}(\boldsymbol{\rho}',\boldsymbol{\lambda}')|rac{9b}{8}r_1|\Psi_{00,00}(\boldsymbol{\rho}',\boldsymbol{\lambda}')
angle,$$

can now be calculated directly. The expectation value of " $9br_2/8$ " is obtained similarly. Combining these results, the energy of the ground state (Eq. (14)) is derived. We can also calculate the energy of the 1ρ excited states, yielding

$$E_{01,00} = \frac{5\beta_{\rho}^2}{4m_{\rho}} + \frac{3\beta_{\lambda}^2}{4m_{\lambda}} + \frac{3b\left(\beta_{\lambda}^2 + 3\beta_{\rho}^2\right)}{2\sqrt{\pi}\beta_{\rho}\beta_{\lambda}\sqrt{\beta_{\lambda}^2 + 4\beta_{\rho}^2}} + \frac{2\alpha_s\beta_{\rho}}{9\sqrt{\pi}} + c'_H.$$
