#### Abstract

We derive the Lagrangian and the transformation laws of N=4 gauged supergravity coupled to matter multiplets whose  $\sigma$ -model of the scalars is  $\mathrm{SU}(1,1)/\mathrm{U}(1)\otimes \mathrm{SO}(6,6+n)/\mathrm{SO}(6)\otimes \mathrm{SO}(6+n)$  and which corresponds to the effective Lagrangian of the Type IIB string compactified on the  $T^6/\mathbb{Z}_2$  orientifold with fluxes turned on and in presence of n D3-branes. The gauge group is  $T^{12}\otimes G$  where G is the gauge group on the brane and  $T^{12}$  is the gauge group on the bulk corresponding to the gauged translations of the R-R scalars coming from the R-R four-form.

The N=4 bulk sector of this theory can be obtained as a truncation of the Scherk–Schwarz spontaneously broken N=8 supergravity. Consequently the full bulk spectrum satisfies quadratic and quartic mass sum rules, identical to those encountered in Scherk–Schwarz reduction gauging a flat group.

This theory gives rise to a no scale supergravity extended with partial super–Higgs mechanism.

#### 1 Introduction

In recent time, compactification of higher dimensional theories in presence of p-form fluxes [1]–[23] has given origin to new four–dimensional vacua with spontaneously broken supersymmetry and with vanishing vacuum energy. These models realize, at least at the classical level, the no–scale structure [24]–[26] of extended supergravities in an M or String theory setting [27]–[34] .

No–scale supergravities also arise from Scherk–Schwarz generalized dimensional reduction [35]–[37], where a flat group is gauged.

¿From a pure four-dimensional point of view all these models can be viewed as particular cases of gauged-extended supergravities (for recent reviews see [38]–[40]). The gauge couplings correspond to fluxes turned on<sup>1</sup>. This is so because for N > 1 supersymmetry a scalar potential is necessarily due to the presence of gauge symmetries. It has been shown that a common feature of all no-scale structures is that the complete gauge group of the theory contains a sector where "axionic" symmetries are gauged [41] –[47].

The Higgs effect in this sector is then tightly connected to the super–Higgs mechanism [48],[49]. The complete gauge group is usually larger than this sector and the additional gauge bosons are frequently associated to central charges of the supersymmetry algebra. For instance, in N=8 spontaneously broken supergravity à la Scherk–Schwarz, the translational part  $T_{\Lambda}$  is 27–dimensional and the extra sector  $T_0$  is one–dimensional, then completing a 28–dimensional flat group [35], [44]

$$[T_{\Lambda}, T_0] = f_{\Lambda 0}^{\Delta} T_{\Delta}; \quad [T_{\Lambda}, T_{\Sigma}] = 0; \quad \Lambda, \Sigma = 1...27$$
 (1.1)

This algebra is a 28-dimensional subalgebra of  $\mathfrak{e}_{7,7}$ . In the case of the IIB orientifold  $T^6/\mathbb{Z}_2$ , the translational part  $T_{\Lambda}$  is 12-dimensional, while the extra sector  $T_i$  are the Yang-Mills generators on the brane [8], [9], [50]

$$[T_{\Lambda}, T_i] = 0; \quad [T_{\Lambda}, T_{\Sigma}] = 0; \quad [T_i, T_j] = c_{ij}^{\ k} T_k; \quad \Lambda \Sigma = 1 \dots 12; \ i, j, k = 1 \dots dim G$$
(1.2)

What is common to these groups is that they must have a symplectic action on the vector field strengths and their dual [51]. This implies that they must be embedded in  $Sp(2n, \mathbb{R})$ , where  $n = 12 + \dim G$  in the orientifold case.

The particular choice of the embedding determines the structure of the gauged supergravity. In the case of the type IIB supergravity in presence of D3-branes, the strong requirement is that the original  $SL(2,\mathbb{R})$  symmetry acts linearly on the twelve bulk vectors  $(B_{\mu\Lambda}, C_{\mu L})$ ,  $\Lambda = 1...6$ , but acts as an electric magnetic duality on the vectors  $A^i_{\mu}$ , i = 1...n living on the D3-branes<sup>2</sup>.

Mathematically this corresponds to a very particular embedding of  $SL(2, \mathbb{R}) \times SO(6, 6+n)$  into  $Sp(24 + 2n, \mathbb{R})$ .

The relevant decomposition is

$$\mathfrak{so}(6,6+n) = \mathfrak{sl}(6,\mathbb{R})^0 + \mathfrak{so}(1,1)^0 + \mathfrak{so}(n)^0 + (\mathbf{15}',\mathbf{1})^{+2} + (\mathbf{15},\mathbf{1})^{-2} + (\mathbf{6}',\mathbf{n})^{+1} + (\mathbf{6},\mathbf{n})^{-1}$$
(1.3)

Note that in String and M theories the fluxes satisfy some quantization conditions [1]–[23]

 $<sup>^2(</sup>B_{\mu I}, C_{\mu I})$  are the  $SL(2, \mathbb{R})$  doublet N-S and R-R two-forms with one leg on space–time and one leg on the torus

where  $\mathfrak{so}(n) \supset Adj \, G_{(\dim n)}$  (note that if  $G = \mathrm{U}(N)$ , then  $n = N^2$ ). The symplectic embedding of the 12 + n vectors such that  $\mathrm{SL}(2,\mathbb{R})$  is diagonal on 12 vectors and off diagonal in the remaining Yang–Mills vectors on the branes, is performed in section 3. Interestingly, the full bulk sector of the  $T^6/\mathbb{Z}_2$  Type IIB orientifold can be related to a N = 4 truncation of the N = 8 spontaneously broken supergravity à la Scherk–Schwarz [35], [36]. This will be proven in detail in Section 8.

The U(4) R-symmetry of the Type IIB theory is identified with the U(4)  $\subset$  USp(8) of the N=8 theory, while  $SL(2,\mathbb{R})\times GL(6)$  is related to the subgroup of  $E_{6(6)}\times SO(1,1)\subset E_{7(7)}$ . The N=4 truncation is obtained by deleting the left-handed gravitino in the  $\overline{\bf 4}^{-\frac{1}{2}}$  and keeping the  ${\bf 4}^{+\frac{1}{2}}$  in the decomposition of the 8 of USp(8) into U(4) irreducible representations:  ${\bf 8} \longrightarrow \overline{\bf 4}^{-\frac{1}{2}} + {\bf 4}^{+\frac{1}{2}}$ .

The N=8 gravitino mass matrix (the **36** of USp(8)) decomposes as follows

$$36 \longrightarrow 1^0 + 15^0 + 10^{+1} + \overline{10}^{-1}$$
 (1.4)

and the representation  $\mathbf{10}^{+1}$  corresponds to the N=4 gravitino mass matrix of the orientifold theory [50], [57].

The vacuum condition of the N=8 Scherk–Schwarz model corresponds to the vanishing of a certain representation 42 of USp(8) [37], [44]. Its N=4 decomposition is

$$42 \longrightarrow 20^{0} + 1^{+2} + 1^{-2} + \overline{10}^{+1} + 10^{-1}$$
 (1.5)

and the vacuum condition of the N=4 orientifold theory corresponds to setting to zero [50], [57] the representation  $\mathbf{10}^{-1}$  (the other representations being deleted in the truncation).

This theory has a six-dimensional moduli space (6+6N, N) being the dimensional of the Cartan subalgebra of G, if the D3-brane coordinates are added) which is locally three copies of SU(1,1)/U(1) [45], [52], [50]. The spectrum depends on the overall scale  $\gamma = (R_1R_2R_3)^{-1} = e^{\frac{K}{2}}$ , where K is the Kähler potential of the moduli space. In units of this scale, if we call  $m_i$  (i = 1, 2, 3, 4) the four gravitino masses, the overall mass spectrum has a surprisingly simple form, and in fact it coincides with a particular truncation (to half of the states) of the N = 8 spectrum of Scherk-Schwarz spontaneously broken supergravity [36].

The mass spectrum satisfies the quadratic and quartic relations:

$$\sum_{J} (2J+1)(-1)^{2J} m_J^2 = 0$$

$$\sum_{J} (2J+1)(-1)^{2J} m_J^4 = 0$$
(1.6)

These relations imply that the one–loop divergent contribution to the vacuum energy is absent, in the field theory approximation [53], [54]. In the present investigation we complete the analysis performed in reference [57], [50]. In these previous works the part referring to the bulk sector of the theory and the vacua in presence of D3–branes degrees of freedom were obtained.

The paper is organized as follows:

In Section 2 we describe the N=4  $\sigma$ -model geometry of the bulk sector coupled to n D3-branes.

In Section 3 we give in detail the symplectic embedding which describes the bulk IIB theory coupled to D3-brane gauge fields.

In Section 4 the gauging of the N=4 theory is given.

In Section 5 the Lagrangian (up to four fermions terms) and the supersymmetry transformation laws (up to three fermions terms) are obtained.

In Section 6 the potential and its extrema are discussed.

In Section 7 the mass spectrum is given.

In section 8 we describe the embedding of our model in the N=8 supergravity and its relation with the Scherk–Schwarz compactification.

In Appendix A we describe the geometric method of the Bianchi identities in superspace in order to find the supersymmetry transformation laws on space—time.

In Appendix B we use the geometric method (rheonomic approach)in order to find a superspace Lagrangian which reduces to the space—time Lagrangian after suitable projection on the space—time.

In Appendix C we give a more detailed discussion of the freezing of the moduli when we reduce in steps  $N = 4 \longrightarrow 3, 2, 1, 0$  using holomorphic coordinates on the  $T^6$  torus.

In Appendix D we give some conventions.

# 2 The Geometry of the scalar sector of the $T^6/\mathbb{Z}_2$ orientifold in presence of D3-branes

#### 2.1 The $\sigma$ -model of the bulk supergravity sector

For the sake of establishing notations, let us first recall the physical content of the N=4 matter coupled supergravity theory.

The gravitational multiplet is

$$\{V_{\mu}^{a}; \psi_{A\mu}; \psi_{\mu}^{A}; A_{1\mu}^{I}; \chi^{A}; \chi_{A}; \phi_{1}; \phi_{2}\}$$
(2.1)

where  $\psi_{A\mu}$  and  $\psi_{\mu}^{A}$  are chiral and antichiral gravitini, while  $\chi^{A}$  and  $\chi_{A}$  are chiral and antichiral dilatini;  $V_{\mu}^{a}$  is the vierbein,  $A_{1\mu}^{I}$ ,  $I=1,\ldots 6$  are the graviphotons and the complex scalar fields  $\phi_{1}$ ,  $\phi_{2}$  satisfy the constraint  $\phi_{1}\overline{\phi}_{1}-\phi_{2}\overline{\phi}_{2}=1$ .

We also introduce 6 + n Yang–Mills vector multiplets, from which 6 will be considered as vector multiplets of the bulk, namely

$$\{A_{2\mu}^I; \lambda_A^I; \lambda^{IA}; s^r\} \tag{2.2}$$

where  $\lambda_A^I$  and  $\lambda^{IA}$  are respectively chiral and antichiral gaugini,  $A_{2\mu}^I$  are matter vectors and  $s^r$ ,  $r = 1, \dots 36$  are real scalar fields.

Correspondingly we denote the n vector multiplets, which microscopically live on the D3-branes, as

$$\{A^i_\mu; \, \lambda^i_A; \, \lambda^{iA}; \, q^I_i\} \tag{2.3}$$

where  $i = 1, \dots n$ .

It is well known that the scalar manifold of the N=4 supergravity coupled to 6+n vector multiplets is given by the coset space [55],[56]

$$\frac{\mathrm{SU}(1,1)}{\mathrm{U}(1)} \otimes \frac{\mathrm{SO}(6,6+n)}{\mathrm{SO}(6) \times \mathrm{SO}(6+n)}$$
 (2.4)

Denoting by  $w[\ ]$ , the weights of the fields under the U(1) factor of the U(4) R-symmetry, the weights of the chiral spinors are<sup>3</sup>

$$w[\psi_A] = \frac{1}{2}; \quad w[\chi^A] = \frac{3}{2}; \quad w[\lambda_{IA}] = -\frac{1}{2}; \quad w[\lambda_{iA}] = -\frac{1}{2}$$
 (2.5)

and for the SU(1,1)/U(1) scalars we have

$$w[\phi_1] = w[\phi_2] = -1; \quad w[\overline{\phi}_1] = w[\overline{\phi}_2] = 1$$
 (2.6)

Let us now describe the geometry of the coset  $\sigma$ -model.

For the SU(1,1)/U(1) factor of the N=4  $\sigma$ -model we use the following parameterization [57]:

$$S_{SU(1,1)} = \begin{pmatrix} \phi_1 & \overline{\phi}_2 \\ \phi_2 & \overline{\phi}_1 \end{pmatrix} \qquad (\phi_1 \overline{\phi}_1 - \phi_2 \overline{\phi}_2 = 1)$$
 (2.7)

Introducing the 2-vector

$$\begin{pmatrix} L^1 \\ L^2 \end{pmatrix} = \frac{1}{\sqrt{2}} \begin{pmatrix} \phi_1 + \phi_2 \\ -i(\phi_1 - \phi_2) \end{pmatrix}$$
 (2.8)

$$w[L^{\alpha}] = -1; \quad w[\overline{L}^{\alpha}] = 1$$
 (2.9)

the identity  $\phi_1 \overline{\phi}_1 - \phi_2 \overline{\phi}_2 = 1$  becomes:

$$L^{\alpha}\overline{L}^{\beta} - \overline{L}^{\alpha}L^{\beta} = i\epsilon^{\alpha\beta} \tag{2.10}$$

The indices  $\alpha = 1, 2$  are lowered by the Ricci tensor  $\epsilon_{\alpha\beta}$ , namely:

$$L_{\alpha} \equiv \epsilon_{\alpha\beta} L^{\beta} \tag{2.11}$$

A useful parametrization of the SU(1,1)/U(1) coset is in terms of the N–S, R–R string dilatons of Type IIB theory [50]

$$\frac{\phi_2}{\phi_1} = \frac{i-S}{i+S} \tag{2.12}$$

with  $S = ie^{\varphi} + C$ , from which follows, fixing an arbitrary U(1) phase:

$$S = -\frac{L^2}{L^1} (2.13)$$

$$\phi_1 = -\frac{1}{2}[i(e^{\varphi} + 1) + C]e^{-\frac{\varphi}{2}}$$
(2.14)

$$\phi_2 = \frac{1}{2}[i(e^{\varphi} - 1) + C]e^{-\frac{\varphi}{2}}$$
(2.15)

$$L^{1} = -\frac{i}{\sqrt{2}}e^{-\frac{\varphi}{2}} \tag{2.16}$$

$$L^{2} = -\frac{1}{\sqrt{2}} \left(e^{\frac{\varphi}{2}} - iCe^{-\frac{\varphi}{2}}\right) \tag{2.17}$$

 $<sup>^{3}</sup>$ Throughout the paper lower SU(4) indices belong to the fundamental representation, while upper SU(4) indices belong to its complex conjugate

Note that the physical complex dilaton S is U(1) independent.

We will also use the isomorphism  $SU(1,1) \sim SL(2,\mathbb{R})$  realized with the Cayley matrix  $\mathcal{C}$ 

$$C = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1\\ -i & i \end{pmatrix} \tag{2.18}$$

$$S_{\mathrm{SL}(2,R)} = \mathcal{C}S_{\mathrm{SU}(1,1)}\mathcal{C}^{-1} = \frac{1}{\sqrt{2}} \begin{pmatrix} L^1 + \overline{L}^1 & i(L^1 - \overline{L}^1) \\ L^2 + \overline{L}^2 & i(L^2 - \overline{L}^2) \end{pmatrix} \equiv \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix}$$
(2.19)

We note that the 2-vector  $(L^{\alpha} \overline{L}^{\alpha})$  transform as a vector of  $SL(2, \mathbb{R})$  on the left and SU(1, 1) on the right. Indeed:

$$\widetilde{S} = \mathcal{C}S_{\mathrm{SU}(1,1)} = \begin{pmatrix} L^1 & \overline{L}^1 \\ L^2 & \overline{L}^2 \end{pmatrix}$$
 (2.20)

The left-invariant Lie algebra valued 1-form of SU(1, 1) is defined by:

$$\theta \equiv S^{-1}dS = \begin{pmatrix} q & \overline{p} \\ p & -q \end{pmatrix} \tag{2.21}$$

where the coset connection 1-form q and the vielbein 1-form p are given by:

$$q = i\epsilon_{\alpha\beta} L^{\alpha} d\overline{L}^{\beta} \tag{2.22}$$

$$p = -i\epsilon_{\alpha\beta}L^{\alpha}dL^{\beta} \tag{2.23}$$

Note that we have the following relations

$$\nabla L^{\alpha} \equiv dL^{\alpha} + qL^{\alpha} = -\overline{L}^{\alpha} p \tag{2.24}$$

$$\nabla \overline{L}^{\alpha} \equiv d\overline{L}^{\alpha} - q\overline{L}^{\alpha} = -L^{\alpha}\overline{p} \tag{2.25}$$

To discuss the geometry of the  $SO(6, n)/SO(6) \times SO(6+n)$   $\sigma$ -model, it is convenient to consider first the case n=0, that is the case when only six out the 6+n vector multiplets are present (no D3-branes). This case was studied in reference [57].

In this case the coset reduces to  $\frac{SO(6,6)}{SO(6)\times SO(6)}$ ; with respect to the subgroup  $SL(6,\mathbb{R})\times SO(1,1)$  the SO(6,6) generators decompose as follows:

$$\mathfrak{so}(6,6) = \mathfrak{sl}(6,\mathbb{R})^0 + \mathfrak{so}(1,1)^0 + (\mathbf{15}',\mathbf{1})^{+2} + (\mathbf{15},\mathbf{1})^{-2}$$
 (2.26)

where the superscripts refer to the SO(1,1) grading. We work in the basis where the SO(6,6) invariant metric has the following form

$$\eta = \begin{pmatrix} \mathbf{0}_{6\times6} & \mathbf{1}_{6\times6} \\ \mathbf{1}_{6\times6} & \mathbf{0}_{6\times6} \end{pmatrix}$$
(2.27)

Thus, the generators in in the right hand side of (2.26) are:

$$\mathfrak{sl}(6,\mathbb{R}) : \begin{pmatrix} A & 0 \\ 0 & -A^T \end{pmatrix} \qquad ; \mathfrak{so}(1,1) : \begin{pmatrix} \mathbb{1} & 0 \\ 0 & -\mathbb{1} \end{pmatrix}$$
$$(\mathbf{15}',\mathbf{1})^{+2} : T_{[\Lambda\Sigma]} = \begin{pmatrix} 0 & t_{[\Lambda\Sigma]} \\ 0 & 0 \end{pmatrix} \qquad ; (\mathbf{15},\mathbf{1})^{-2} : (T_{[\Lambda\Sigma]})^T \qquad (2.28)$$

where we have defined:

$$t_{[\Lambda\Sigma]}^{\Gamma\Delta} = \delta_{\Lambda\Sigma}^{\Gamma\Delta}; \qquad \Lambda, \ \Sigma = 1, \dots, 6$$
 (2.29)

and A are the  $SL(6,\mathbb{R})$  generators. It is useful to split the scalar fields  $s^r$  into those which span the  $GL(6,\mathbb{R})/SO(6)_d$  submanifold and which parametrize the corresponding coset representative  $L_{GL(6,\mathbb{R})}$  from the axions parametrizing the  $15'^{+2}$  translations. We indicate them respectively with  $E = E^T \equiv E_{\Lambda}^I$ ,  $E^{-1} \equiv (E^{-1})_I^{\Lambda}$  symmetric  $6 \times 6$  matrices and with  $B = -B^T \equiv B^{\Lambda\Sigma}$ ,  $\Lambda$ ,  $\Sigma = 1, \ldots, 6$ ,  $I = 1, \ldots, 6$ . Note that the capital Greek indices refer to global GL(6) while the capital Latin indices refer to local  $SO(6)_{(d)}$  transformations. The coset representatives  $L_{GL(6,\mathbb{R})}$  and the full coset representative L can thus be constructed as follows:

$$L = \exp\left(-B^{\Lambda\Sigma}T_{[\Lambda\Sigma]}\right)L_{GL(6,\mathbb{R})} = \begin{pmatrix} E^{-1} & -BE\\ 0 & E \end{pmatrix}$$

$$L_{GL(6,\mathbb{R})} = \begin{pmatrix} E^{-1} & 0\\ 0 & E \end{pmatrix}$$
(2.30)

Note that the coset representatives L are orthogonal with respect to the metric (2.27), namely  $L^T \eta L = \eta$ .

The left invariant 1-form  $L^{-1}dL \equiv \Gamma$  satisfying  $d\Gamma + \Gamma \wedge \Gamma = 0$  turns out to be

$$\Gamma = \begin{pmatrix} EdE^{-1} & -EdBE \\ 0 & E^{-1}dE \end{pmatrix}$$
 (2.31)

As usual we can decompose the left invariant 1-form into the connection  $\Omega$ , plus the vielbein  $\mathcal{P}$ :

$$\Gamma = \Omega^H T_H + \mathcal{P}^K T_K \tag{2.32}$$

The matrices  $T_H$  are the generators of the isotropy group  $SO(6)_1 \times SO(6)_2$ , where we have indicated with  $SO(6)_1 \sim SU(4)$  the semisimple part of the R-symmetry group U(4) and with  $SO(6)_2$  the "matter group".

Since we are also interested in the connection of the diagonal subgroup  $SO(6)_{(d)}$ , we will use in the following two different basis for the generators, the first one that makes explicit the direct product structure of the isotropy group (Cartan basis) and the latter in which we identify the diagonal subgroup of the two factors (diagonal basis). We have respectively:

$$T_H = \begin{pmatrix} T_1 & 0 \\ 0 & T_2 \end{pmatrix} \qquad T'_H = \begin{pmatrix} T_{(v)} & T_{(a)} \\ T_{(a)} & T_{(v)} \end{pmatrix}$$
 (2.33)

where  $T_{(v)}$  is the generator of the diagonal  $SO(6)_{(d)}$  of  $SO(6)_1 \times SO(6)_2$  and  $T_{(a)}$  is the generator of the orthogonal complement. The two basis are related by

$$T_H' = D^{-1} T_H D (2.34)$$

where D is the matrix:

$$D = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1\\ 1 & -1 \end{pmatrix} \tag{2.35}$$

In the diagonal basis we can extract the connections  $\omega^{(d)}$  and  $\widehat{\omega}$  of the diagonal SO(6)<sub>(d)</sub> subgroup and of its orthogonal part by tracing with the  $T'_H$  generators or, more simply, by

decomposing  $L^{-1}dL$  into its antisymmetric part, giving the connection, and its symmetric part giving the vielbein. In the following we will write  $\Omega$  and  $\mathcal{P}$  as follows:

$$\Omega = \omega^{(d)} + \widehat{\omega} \tag{2.36}$$

$$\omega^{(d)} = \frac{1}{2} \begin{pmatrix} EdE^{-1} - dE^{-1}E & 0\\ 0 & EdE^{-1} - dE^{-1}E \end{pmatrix}$$
 (2.37)

$$\widehat{\omega} = \frac{1}{2} \begin{pmatrix} 0 & -EdBE \\ -EdBE & 0 \end{pmatrix}$$
 (2.38)

The vielbein  $\mathcal{P}$  is, by definition  $\mathcal{P} = \Gamma - \Omega$  so that we get

$$\Omega = \begin{pmatrix} \omega^{IJ} & -P^{[IJ]} \\ -P^{[IJ]} & \omega^{IJ} \end{pmatrix}; \qquad \mathcal{P} = \begin{pmatrix} P^{(IJ)} & -P^{[IJ]} \\ P^{[IJ]} & -P^{(IJ)} \end{pmatrix}$$
(2.39)

where

$$\omega^{IJ} = \frac{1}{2} (EdE^{-1} - dE^{-1}E)^{IJ}$$
 (2.40)

$$P^{(IJ)} = \frac{1}{2} (EdE^{-1} + dE^{-1}E)^{IJ}$$
 (2.41)

$$P^{[IJ]} = \frac{1}{2} (EdBE)^{IJ} \tag{2.42}$$

In particular:

$$\nabla^{(d)} E^I_{\Lambda} \equiv dE^I_{\Lambda} - E^I_{\Lambda} \omega_I^{\ J} = -E^J_{\Lambda} P^{(JI)}. \tag{2.43}$$

In this basis the Maurer-Cartan equation

$$d\Gamma + \Gamma \wedge \Gamma = 0 \tag{2.44}$$

take the form:

$$R^{(d)IJ} = -P^{(IK)} \wedge P^{(KJ)} \tag{2.45}$$

$$\nabla^{(d)} P^{[IJ]} = -P^{(IK)} \wedge P^{[KJ]} + P^{[IK]} \wedge P^{(KJ)}$$
(2.46)

$$\nabla^{(d)}P^{(IJ)} = 0 \tag{2.47}$$

where  $\nabla^{(d)}$  is the SO(6)<sub>d</sub> covariant derivative and  $R^{(d)}$  is the SO(6)<sub>d</sub> curvature:

$$R^{(d)IJ} = d\omega^{IJ} + \omega^{IK} \wedge \omega_K^{\ J} \tag{2.48}$$

The usual Cartan basis ( $T_H$ -basis) where the connection is block-diagonal and the vielbein is block off-diagonal is obtained by rotating  $\Gamma$  with the matrix D. We find:

$$\Gamma = \begin{pmatrix} \omega_1^{IJ} & -(P^{IJ})^T \\ -P^{IJ} & \omega_2^{IJ} \end{pmatrix} = \begin{pmatrix} \omega^{IJ} - P^{[IJ]} & P^{(IJ)} + P^{[IJ]} \\ P^{(IJ)} - P^{[IJ]} & \omega^{IJ} + P^{[IJ]} \end{pmatrix}$$
(2.49)

where  $\omega_1$  and  $\omega_2$  are the connections of SO(6)<sub>1</sub> and SO(6)<sub>2</sub> respectively, while  $-(P^{IJ})^T = P^{(IJ)} + P^{[IJ]}$  is the vielbein. In this case the the curvature of the SO(6,6)/SO(6)  $\otimes$  SO(6) manifold takes the form:

$$\mathcal{R} = \begin{pmatrix} R_1 & 0\\ 0 & R_2 \end{pmatrix} \tag{2.50}$$

where:

$$R_1^{IJ} \equiv d\omega_1^{IJ} + \omega_1^{IK} \wedge \omega_{1K}^{\ \ J} = -P^{KI} \wedge P_K^{\ \ J} \tag{2.51}$$

$$R_2^{IJ} \equiv d\omega_2^{IJ} + \omega_2^{IK} \wedge \omega_{2K}^{\ \ J} = -P^{IK} \wedge P_K^J \tag{2.52}$$

and the vanishing torsion equation is

$$\nabla P^{IJ} \equiv dP^{IJ} + P^{IK} \wedge \omega_{1K}^{\ J} + \omega_{2K}^{I} \wedge P^{KJ} = 0 \tag{2.53}$$

#### 2.2 Geometry of the $\sigma$ -model in presence of n D3-branes

We now introduce additional n Yang–Mills multiplets  $(A^i_\mu, \lambda^i_A, \lambda^{Ai}, q^i_I), I = 1 \dots 6, i = 1 \dots n.$ 

The isometry group is now  $SL(2,\mathbb{R}) \times SO(6,6+n)$  and the coset representative  $\mathbb{L}$  factorizes in the product of the  $\frac{SO(6,6+n)}{SO(6)\times SO(6+n)}$  coset representative L and the  $\frac{SL(2,\mathbb{R})}{SO(2)}$  coset representative S:

$$\mathbb{L} = SL \tag{2.54}$$

In the following we shall characterize the matrix form of the various SO(6, 6+n) generators in the  $\mathbf{12} + \mathbf{n}$  and define the embedding of  $SU(1,1) \otimes SO(6, 6+n)$  inside  $Sp(24+2n, \mathbb{R})$ . With respect to the subgroup  $SL(6, \mathbb{R}) \times SO(1,1) \times SO(n)$  the SO(6, 6+n) generators decompose as follows:

$$\mathfrak{so}(6,6+n) = \mathfrak{sl}(6,\mathbb{R})^0 + \mathfrak{so}(1,1)^0 + \mathfrak{so}(n)^0 + (\mathbf{15}',\mathbf{1})^{+2} + (\mathbf{15},\mathbf{1})^{-2} + (\mathbf{6}',\mathbf{n})^{+1} + (\mathbf{6},\mathbf{n})^{-1}$$
(2.55)

where the superscript refers to the  $\mathfrak{so}(1,1)$  grading. Let us choose for the 12 + n invariant metric  $\eta$  the following matrix :

$$\eta = \begin{pmatrix} 0_{6\times6} & \mathbb{1}_{6\times6} & 0_{6\times n} \\ \mathbb{1}_{6\times6} & 0_{6\times6} & 0_{6\times n} \\ 0_{n\times6} & 0_{n\times6} & -\mathbb{1}_{n\times n} \end{pmatrix}$$
(2.56)

where the blocks are defined by the decomposition of the 12 + m into 6 + 6 + m. The generators in the right hand side of (2.55) have the following form:

$$\mathfrak{sl}(6,\mathbb{R}): \begin{pmatrix} A & 0 & 0\\ 0 & -A^T & 0\\ 0 & 0 & 0 \end{pmatrix} \qquad ; \quad \mathfrak{so}(1,1): \begin{pmatrix} 1 & 0 & 0\\ 0 & -1 & 0\\ 0 & 0 & 0 \end{pmatrix}$$
 (2.57)

$$(\mathbf{15'}, \mathbf{1})^{+2} : T_{[\Lambda\Sigma]} = \begin{pmatrix} 0 & t_{[\Lambda\Sigma]} & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \qquad ; \ (\mathbf{15}, \mathbf{1})^{-2} : (T_{[\Lambda\Sigma]})^{T}$$
 (2.58)

$$(\mathbf{6}', \mathbf{n})^{+1} : T_{(\Lambda i)} = \begin{pmatrix} 0 & 0 & t_{(\Lambda i)} \\ 0 & 0 & 0 \\ 0 & (t_{(\Lambda i)})^T & 0 \end{pmatrix} ; (\mathbf{6}, \mathbf{n})^{-1} : (T_{(\Lambda i)})^T$$
 (2.59)

where we have used the following notation:

$$t_{[\Lambda\Sigma]}^{\Gamma\Delta} = \delta_{\Lambda\Sigma}^{\Gamma\Delta} \; ; \quad t_{(\Lambda_i)}^{\Sigma k} = \delta_{\Lambda}^{\Sigma} \delta_i^k \quad \Lambda, \Sigma = 1, \dots, 6 \; ; \quad i, k = 1, \dots, n$$
 (2.60)

As in the preceding case, we split the scalar fields into those which span the  $\frac{GL(6,\mathbb{R})}{SO(6)}$  submanifold and which parametrize the corresponding coset representative  $L_{GL(6,\mathbb{R})}$  from the axions parametrizing the  $(\mathbf{15}',\mathbf{1})^{+2}$  translations. We indicate them as before respectively with  $E=E^T\equiv E_\Lambda^I$ ,  $E^{-1}\equiv (E^{-1})_I^\Lambda$  and  $B=-B^T\equiv B^{\Lambda\Sigma}$ . In presence of D3-branes we have in addition the generators in the  $(\mathbf{6}',\mathbf{n})^{+1}$  that we parametrize with the  $6\times n$  matrices  $a\equiv a_i^\Lambda$  (in the following we will also use the notation  $q_i^I\equiv E_\Lambda^Ia_i^\Lambda$ ). The coset representatives  $L_{GL(6,\mathbb{R})}$  and L can thus be constructed as follows:

$$L = \exp\left(-B^{\Lambda\Sigma}T_{[\Lambda\Sigma]} + a^{\Lambda i}T_{(\Lambda i)}\right)L_{GL(6,\mathbb{R})} = \begin{pmatrix} E^{-1} & -CE & a \\ 0 & E & 0 \\ 0 & a^{T}E & 1 \end{pmatrix}$$

$$L_{GL(6,\mathbb{R})} = \begin{pmatrix} E^{-1} & 0 & 0 \\ 0 & E & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

$$C = B - \frac{1}{2}aa^{T}$$
 (2.61)

where the sum over repeated indices is understood and  $a \equiv a^{\Lambda i}$  are  $6 \times n$  matrices. As in the preceding case,  $E \equiv E_{\Lambda}^{I}$  and  $E^{-1} \equiv (E^{-1})_{I}^{\Lambda}$  are. Note that the coset representative L is orthogonal respect the metric  $\eta$ .

The left invariant 1-form  $\Gamma = L^{-1}dL$  turns out to be:

$$\Gamma = \begin{pmatrix} E dE^{-1} & -E[dB - \frac{1}{2}(da a^T - a da^T)]E & E da \\ \mathbf{0}_{6\times6} & E^{-1}dE & \mathbf{0}_{6\times n} \\ \mathbf{0}_{n\times6} & da^T E & \mathbf{1}_{n\times n} \end{pmatrix}$$
(2.62)

Proceeding as before we can extract, from the left invariant 1-form, the connection and the vielbein (2.32) in the basis where we take the diagonal subgroup  $SO(6)_d$  inside  $SO(6) \times SO(6+n)$ , where now  $T_H$  are the generators of  $SO(6)_1 \times SO(6)_2 \times SO(n)$ . It is sufficient to take the antisymmetric and symmetric part of  $\Gamma$  corresponding to the connection and the vielbein respectively. We find:

$$\Omega = \begin{pmatrix}
\omega^{IJ} & -P^{[IJ]} & P^{Ii} \\
-P^{[IJ]} & \omega^{IJ} & -P^{Ii} \\
-P^{iI} & P^{iI} & 0
\end{pmatrix}; \qquad \mathcal{P} = \begin{pmatrix}
P^{(IJ)} & -P^{[IJ]} & P^{Ii} \\
P^{[IJ]} & -P^{(IJ)} & P^{Ii} \\
P^{iI} & P^{iI} & 0
\end{pmatrix}$$
(2.63)

where

$$\omega^{IJ} = \frac{1}{2} (EdE^{-1} - dE^{-1}E)^{IJ}$$
(2.64)

$$P^{(IJ)} = \frac{1}{2} (EdE^{-1} + dE^{-1}E)^{IJ}$$
 (2.65)

$$P^{[IJ]} = \frac{1}{2} \{ E[dB - \frac{1}{2} (da \, a^T - a \, da^T)] E \}^{IJ}$$
 (2.66)

$$P^{Ii} = \frac{1}{2} E_{\Lambda}^{I} da^{\Lambda i} \tag{2.67}$$

¿From the Maurer-Cartan equations

$$d\Gamma + \Gamma \wedge \Gamma = 0 \tag{2.68}$$

we derive the expression of the curvatures and the equations expressing the absence of torsion in the diagonal basis:

$$\nabla^{(d)} P^{[IJ]} = -P^{(IK)} \wedge P^{[KJ]} + P^{[IK]} \wedge P^{(KJ)} + 2P^{I}_{i} \wedge P^{iJ}$$
 (2.69)

$$\nabla^{(d)}P^{iJ} = P^i_{\ I} \wedge P^{IJ} \tag{2.70}$$

while equations (2.45), (2.47) remain unchanged.

Note that, as it is apparent from equation (2.63), the connection of SO(n) is zero in this gauge:  $\omega^{ij} = 0$ . To retrieve the form of the connection in the Cartan basis it is sufficient to rotate  $\Omega$  and  $\mathcal{P}$ , given in equation (2.63), by the generalized D matrix (2.35)

$$D = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 & 0 \\ 1 & -1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \tag{2.71}$$

We find

$$\Omega = \begin{pmatrix}
\frac{\omega^{IJ} - P^{[IJ]}}{\mathbf{0}_{6\times 6}} & \mathbf{0}_{6\times n} \\
\mathbf{0}_{6\times 6} & \omega^{IJ} + P^{[IJ]} & P^{Ii} \\
\mathbf{0}_{n\times 6} & -P^{Ii} & \mathbf{0}_{n\times n}
\end{pmatrix}$$
(2.72)

$$\mathcal{P} = \begin{pmatrix} \mathbf{0}_{6\times6} & P^{(IJ)} + P^{[IJ]} & P^{Ii} \\ \hline P^{(IJ)} - P^{[IJ]} & \mathbf{0}_{6\times6} & \mathbf{0}_{6\times n} \\ P^{iI} & \mathbf{0}_{6\times n} & \mathbf{0}_{n\times n} \end{pmatrix}$$
(2.73)

$$R_{1}^{IJ} \equiv d\omega_{1}^{IJ} + \omega_{1}^{IK} \wedge \omega_{1K}^{J} = -P^{KI} \wedge P_{K}^{J} - 2P^{Ii} \wedge P^{iJ}$$
 (2.74)

$$R_2^{IJ} \equiv d\omega_2^{IJ} + \omega_2^{IK} \wedge \omega_{2K}^{J} = -P^{IK} \wedge P_K^{J} + 2P^{Ii} \wedge P^{iJ}$$
 (2.75)

and the vanishing torsion equation is

$$\nabla P^{IJ} \equiv dP^{IJ} + P^{IK} \wedge \omega_{1K}^{\ \ J} + \omega_{2}^{IK} \wedge P_{K}^{\ \ J} + 2P^{Ii} \wedge P_{i}^{J} = 0 \tag{2.76}$$

$$dP^{Ii} + \omega_1^{IJ} \wedge P_I^{i} + P^{(IJ)} \wedge P_I^{i} = 0 (2.77)$$

### 3 The symplectic embedding and duality rotations

Let us now discuss the embedding of the isometry group  $SL(2, \mathbb{R}) \times SO(6, 6 + n)$  inside  $Sp(24 + 2n, \mathbb{R})$ . We start from the embedding in which the SO(6, 6 + n) is diagonal<sup>4</sup>:

$$SO(6, 6+n) \stackrel{\iota}{\hookrightarrow} Sp(24+2n, \mathbb{R})$$

$$g \in SO(6, 6+n) \stackrel{\iota}{\longrightarrow} \iota(g) = \begin{pmatrix} g & 0 \\ 0 & (g^{-1})^T \end{pmatrix} \in Sp(24+2n, \mathbb{R})$$

$$S = \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} \in SL(2, \mathbb{R}) \stackrel{\iota}{\longrightarrow} \iota(S) = \begin{pmatrix} \alpha \mathbb{1} & -\beta \eta \\ -\gamma \eta & \delta \mathbb{1} \end{pmatrix} \in Sp(24+2n, \mathbb{R})$$

$$\alpha \delta - \beta \gamma = 1$$

$$(3.1)$$

<sup>&</sup>lt;sup>4</sup>The signs in the embedding  $\iota$  of  $SL(2,\mathbb{R})$  have been chosen in such a way that the action on the doublet charges in the final embedding  $\iota'$  were the same as S.

where each block of the symplectic matrices is a  $(12 + n) \times (12 + n)$  matrix. In this embedding a generic symplectic section has the following grading structure with respect to  $\mathfrak{so}(1,1)$ :

$$V_{\rm Sp} = \begin{pmatrix} v^{(+1)} \\ v^{(-1)} \\ v^{(0)} \\ u^{(-1)} \\ u^{(+1)} \\ u^{(0)} \end{pmatrix}$$
(3.2)

where  $v^{(\pm 1)}$  and  $u^{(\pm 1)}$  are six dimensional vectors while  $v^{(0)}$  and  $u^{(0)}$  have dimension n. Identifying the v's with the electric field strengths and the u's with their magnetic dual, we note that the embedding  $\iota$  (3.1) corresponds to the standard embedding where  $SL(2,\mathbb{R})$ acts as electric-magnetic duality while SO(6, 6 + n) is purely electric.

We are interested in defining an embedding  $\iota'$  in which the generators in the  $(\mathbf{15}',\mathbf{1})^{+2}$ act as nilpotent off diagonal matrices or Peccei–Quinn generators and the  $\mathrm{SL}(2,\mathbb{R})$  group has a block diagonal action on the  $v^{(\pm 1)}$  and  $u^{(\pm 1)}$  components and an off diagonal action on the  $v^{(0)}$  and  $u^{(0)}$  components.

Indeed, our aim is to gauge (at most) twelve of the fifteen translation generators in the representation  $(15', 1)^{+2}$  and a suitable subgroup  $G \subset SO(n)$ .

The symplectic transformation  $\mathcal{O}$  which realizes this embedding starting from the one in (3.1) is easily found by noticing that  $(v^{(+1)}, u^{(+1)})$  and  $(v^{(-1)}, u^{(-1)})$  transform in the  $(\mathbf{6}',\mathbf{2})^{+1}$  and  $(\mathbf{6},\mathbf{2})^{-1}$  with respect to  $\mathrm{GL}(6,\mathbb{R})\times\mathrm{SL}(2,\mathbb{R})$  respectively. Therefore we define the new embedding:

In this embedding the generic  $SL(2,\mathbb{R})$  element S has the following form:

embedding the generic 
$$SL(2,\mathbb{R})$$
 element  $S$  has the following form:
$$\iota'(S) = \begin{pmatrix} \delta \mathbb{1}_{6\times 6} & -\gamma \mathbb{1}_{6\times 6} & 0 & 0 & 0 & 0 \\ -\beta \mathbb{1}_{6\times 6} & \alpha \mathbb{1}_{6\times 6} & 0 & 0 & 0 & 0 \\ 0 & 0 & \alpha \mathbb{1}_{m\times m} & 0 & 0 & \beta \mathbb{1}_{m\times m} \\ 0 & 0 & 0 & \alpha \mathbb{1}_{6\times 6} & \beta \mathbb{1}_{6\times 6} & 0 \\ 0 & 0 & 0 & \gamma \mathbb{1}_{6\times 6} & \delta \mathbb{1}_{6\times 6} & 0 \\ 0 & 0 & \gamma \mathbb{1}_{m\times m} & 0 & 0 & \delta \mathbb{1}_{m\times m} \end{pmatrix}$$
we generic element of  $SO(6, 6+m)/SO(6) \times SO(6+m)$  takes the form

while the generic element of  $SO(6, 6+n)/SO(6) \times SO(6+n)$  takes the form

$$\iota'(L) = \begin{pmatrix} E & 0 & 0 & 0 & 0 & 0\\ 0 & E & 0 & 0 & 0 & 0\\ 0 & a^T E & 1 & 0 & 0 & 0\\ 0 & CE & -a & E^{-1} & 0 & 0\\ -CE & 0 & 0 & 0 & E^{-1} & -a\\ -a^T E & 0 & 0 & 0 & 0 & 1 \end{pmatrix}$$
(3.5)

The product  $\Sigma = \iota'(L)\iota'(S)$  of these two matrices gives the desired embedding in  $\operatorname{Sp}(24 + 2n, \mathbb{R})$  of the relevant coset. If we write the  $\operatorname{Sp}(24 + 2n, \mathbb{R})$  matrix in the form

$$\Sigma = \begin{pmatrix} A & B \\ C & D \end{pmatrix} \tag{3.6}$$

and define

$$f = \frac{1}{\sqrt{2}}(A - iB); \qquad h = \frac{1}{\sqrt{2}}(C - iD)$$
 (3.7)

we obtain [58]

$$f = \frac{1}{2} \begin{pmatrix} \delta E & -\gamma E & 0\\ -\beta E & \alpha E & 0\\ -\beta a^T E & \alpha a^T E & \alpha - i\beta \end{pmatrix}$$
(3.8)

$$h = \frac{1}{2} \begin{pmatrix} -\beta CE - i\alpha E^{-1} & \alpha CE - i\beta E^{-1} & -(\alpha - i\beta)a \\ -\delta CE - i\gamma E^{-1} & \gamma CE - i\delta E^{-1} & -(\gamma - i\delta)a \\ -\delta a^T E & \gamma a^T E & \gamma - i\delta \end{pmatrix}$$
(3.9)

The kinetic matrix of the vectors is defined as [51], [58]  $\mathcal{N} = h \cdot f^{-1}$  and we find

$$\mathcal{N} = \begin{pmatrix} -2iL^{1}\overline{L}^{1}E^{-1}E^{-1} & \frac{1}{2}aa^{T} - 2iL^{(1}\overline{L}^{2)}E^{-1}E^{-1} - 2iBL^{[1}\overline{L}^{2]} & -a \\ \frac{1}{2}aa^{T} - 2iL^{(2}\overline{L}^{1)}E^{-1}E^{-1} - 2iBL^{[2}\overline{L}^{1]} & -2iL^{2}\overline{L}^{2}E^{-1}E^{-1} + \frac{L^{2}}{L^{1}}aa^{T} & -\frac{L^{2}}{L^{1}}a \\ -a^{T} & -\frac{L^{2}}{L^{1}}a^{T} & \frac{L^{2}}{L^{1}} \end{pmatrix}$$

$$(3.10)$$

or in components

$$\mathcal{N}^{\Lambda\alpha\Sigma\beta} = -2iL^{(\alpha}\overline{L}^{\beta)}(E^{-1})^{\Lambda}_{I}(E^{-1})^{I\Sigma} + B^{\Lambda\Sigma}\epsilon^{\alpha\beta} - i(aa^{T})^{\Lambda\Sigma}L^{(\alpha}\left(\overline{L}^{\beta)} - L^{\beta)}\frac{\overline{L}^{1}}{L^{1}}\right)$$

$$\mathcal{N}^{\Lambda\alpha i} = -a^{\Lambda i}\frac{L^{\alpha}}{L^{1}}$$

$$\mathcal{N}^{ij} = \frac{L^{2}}{L^{1}}\delta^{ij}$$
(3.11)

where we have used the relation (2.10).

#### 4 The Gauging

Our aim is to gauge a group of the following form:

$$T_{12} \times G \subset SO(6, 6+n) \tag{4.1}$$

where  $T_{12}$  denote 12 of the  $(\mathbf{15'}, \mathbf{1})^{+2}$  Peccei–Quinn translations  $T_{[\Lambda\Sigma]}$  in SO(6,6) and the group G is in general a compact semisimple subgroup of SO(n) of dimension n. In particular if  $G = \mathrm{U}(N)$  we must have  $N^2 = n$ . The gauge group is a subgroup of the global symmetry group of the ungauged action whose algebra, for the choice of the symplectic embedding defined in the previous section, is:

$$\mathfrak{sl}(6,\mathbb{R})^0 + \mathfrak{so}(1,1)^0 + \mathfrak{so}(n)^0 + (\mathbf{15}',\mathbf{1})^{+2} + (\mathbf{6}',\mathbf{n})^{+1}$$
 (4.2)

We note that the maximal translation group  $T_{12}$  which can be gauged is of dimension twelve since the corresponding gauge vector fields are  $A_{\Lambda\alpha}$  belong to the  $(\mathbf{6}, \mathbf{2})^{-1}$  of  $\mathrm{GL}(6,\mathbb{R}) \times \mathrm{SL}(2,\mathbb{R})$ . Let us denote the gauge generators of the  $T_{12}$  factor by  $T^{\Lambda\alpha}$ , corresponding to the gauge vectors  $A_{\Lambda\alpha}$  and by  $T^i$   $(i=1,\ldots,n)$  those of the G factor associated with the vectors  $A_i$ . These two sets of generators are expressed in terms of the  $(\mathbf{15}',\mathbf{1})^{+2}$  generators  $T_{[\Lambda\Sigma]}$  and of the  $\mathrm{SO}(n)$  generators  $T_{[ij]}$  respectively by means of suitable embedding matrices  $f^{\Gamma\Sigma\Lambda\alpha}$  and  $c^{kij}$ :

$$T^{\Lambda\alpha} = f^{\Gamma\Sigma\Lambda\alpha} T_{[\Gamma\Sigma]}$$

$$T^{k} = c^{kij} T_{[ij]}$$
(4.3)

where  $c^{ijk}$  are the structure constants of G, with ijk completely antisymmetric. The constants  $f^{\Gamma\Sigma\Lambda\alpha}$  are totally antisymmetric in  $\Gamma\Sigma\Lambda$  as a consequence both of supersymmetry and gauge invariance or, in our approach, of the closure of the Bianchi identities. They transform therefore with respect to  $\mathrm{SL}(6,\mathbb{R})\times\mathrm{SO}(1,1)\times\mathrm{SL}(2,\mathbb{R})$  in the  $(\mathbf{20'},\mathbf{2})^{+3}$ . Note that  $f^{\Gamma\Sigma\Lambda\alpha}$  are the remnants in D=4 of the fluxes of the Type IIB three–forms.

We may identify the scalar fields of the theory with the elements of the coset representative L of  $SO(6,6+n)/SO(6) \times SO(6+n)$  namely,  $E_I^{\Lambda}$ ,  $B^{\Lambda\Sigma}$ ,  $a_i^{\Lambda}$ . The scalar field associated with the coset  $SL(2,\mathbb{R})/SO(2) \simeq SU(1,1)/U(1)$  is instead represented by the complex 2-vector  $L^{\alpha}$  satisfying the constraint (2.10).

The gauging can be performed in the usual way replacing the coordinates differentials with the gauge covariant differentials  $\nabla_{(q)}$ :

$$dL^{\alpha} \longrightarrow \nabla_{(g)}L^{\alpha} \equiv dL^{\alpha} \tag{4.4}$$

$$dE_I^{\Lambda} \longrightarrow \nabla_{(g)} E_I^{\Lambda} \equiv dE_I^{\Lambda} \tag{4.5}$$

$$dB^{\Lambda\Sigma} \longrightarrow \nabla_{(g)} B^{\Lambda\Sigma} = dB^{\Lambda\Sigma} + f^{\Lambda\Sigma\Gamma\alpha} A_{\Gamma\alpha}$$
 (4.6)

$$da_i^{\Lambda} \longrightarrow \nabla_{(g)} a_i^{\Lambda} = da_i^{\Lambda} + c_i^{jk} A_j a_k^{\Lambda}$$

$$\tag{4.7}$$

Note that  $f^{\Lambda\Sigma\Gamma\alpha}$  are the constant components of the translational Killing vectors in the chosen coordinate system, namely  $k^{\Lambda\Sigma|\Gamma\alpha} = f^{\Lambda\Sigma\Gamma\alpha}$  [57], where the couple  $\Lambda\Sigma$  are coordinate indices while  $\Gamma\alpha$  are indices in the adjoint representation of the gauge subgroup  $T_{12}$ ; in the same way the Killing vectors of the compact gauge subgroup G are given by  $k_i^{\Lambda|j} = c_i^{\ jk} a_k^{\Lambda}$  where the couple  $\Lambda i$  are coordinate indices, while jk are in the adjoint representation of G.

; From equations (4.4)–(4.7) we can derive the structure of the gauged left–invariant 1–form  $\hat{\Gamma}$ 

$$\hat{\Gamma} = \Gamma + \delta_{(T_{12})}\Gamma + \delta_{(G)}\Gamma \tag{4.8}$$

where  $\delta_{(T_{12})}\Gamma$  and  $\delta_{(G)}\Gamma$  are the shifts of  $\Gamma$  due to the gauging of  $T_{12}$  and G respectively. From these we can compute the shifts of the vielbein and of the connections. We obtain:

$$\hat{P}^{IJ} = P^{IJ} + \delta_{(T_{12})} P^{IJ} + \delta_G P^{IJ} \tag{4.9}$$

$$\hat{P}^{Ii} = P^{Ii} + \delta_{(T_{12})} P^{Ii} + \delta_G P^{Ii} \tag{4.10}$$

$$\hat{\omega}_{1,2}^{IJ} = \omega_{1,2} + \delta_{(T_{12})}\omega_{1,2}^{IJ} + \delta_G\omega_{1,2}^{IJ} \tag{4.11}$$

where

$$\delta_{(T_{12})}P^{IJ} = \frac{1}{2}E_{\Lambda}^{I}f^{\Lambda\Sigma\Gamma\alpha}A_{\Gamma\alpha}E_{\Sigma}^{J} \tag{4.12}$$

$$\delta_G P^{IJ} = \frac{1}{2} c^{ijk} E_{\Lambda}^I a_i^{\Lambda} A_j a_k^{\Sigma} E_{\Sigma}^J \tag{4.13}$$

$$\delta_{(T_{12})}P^{Ii} = 0 (4.14)$$

$$\delta_G P^{Ii} = \frac{1}{2} c^{ijk} E^I_{\Lambda} a^{\Lambda}_k A_j \tag{4.15}$$

$$\delta_{(T_{12})}\omega_1^{IJ} = -\delta_{(T_{12})}\omega_2^{IJ} = -\frac{1}{2}E_{\Lambda}^I f^{\Lambda\Sigma\Gamma\alpha} A_{\Gamma\alpha} E_{\Sigma}^J \tag{4.16}$$

$$\delta_G \omega_1^{IJ} = -\delta_G \omega_2^{IJ} = -\frac{1}{2} c^{ijk} E_\Lambda^I a_i^\Lambda A_j a_k^\Sigma E_\Sigma^J \tag{4.17}$$

Note that only the antisymmetric part of  $P^{IJ}$  is shifted, while the diagonal connection  $\omega_d = \omega_1 + \omega_2$  remains untouched. An important issue of the gauging is the computation of the "fermion shifts", that is of the extra pieces appearing in the supersymmetry transformation laws of the fermions when the gauging is turned on. Indeed the scalar potential can be computed from the supersymmetry of the Lagrangian as a quadratic form in the fermion shifts. The shifts have been computed using the (gauged) Bianchi identities in superspace as it is explained in Appendix A. We have:

$$\delta\psi_{A\mu}^{(shift)} = S_{AB}\gamma_{\mu}\varepsilon^{B} = -\frac{i}{48}(\overline{F}^{IJK-} + \overline{C}^{IJK-})(\Gamma_{IJK})_{AB}\gamma_{\mu}\epsilon^{B}$$
(4.18)

$$\delta \chi^{A(shift)} = N^{AB} \epsilon_B = -\frac{1}{48} (\overline{F}^{IJK+} + \overline{C}^{IJK+}) (\Gamma_{IJK})^{AB} \epsilon_B$$
 (4.19)

$$\delta \lambda_A^{I(shift)} = Z_A^{IB} \epsilon_B = \frac{1}{8} (F^{IJK} + C^{IJK}) (\Gamma_{JK})_A^B \epsilon_B$$
 (4.20)

$$\delta \lambda_{iA}^{(shift)} = W_{iA}^{\ B} \epsilon_B = \frac{1}{8} L_2 E_{\Lambda}^{\ J} E_{\Sigma}^{\ K} a^{\Lambda j} a^{\Sigma k} c_{ijk} (\Gamma_{JK})_A^{\ B} \epsilon_B$$
 (4.21)

where we have used the selfduality relation (see Appendix D for conventions)  $(\Gamma_{IJK})_{AB} = \frac{i}{3!} \epsilon_{IJKLMN} \Gamma_{AB}^{LMN}$  and introduced the quantities

$$F^{\pm IJK} = \frac{1}{2} \left( F^{IJK} \pm i * F^{IJK} \right) \tag{4.22}$$

$$C^{\pm IJK} = \frac{1}{2} \left( C^{IJK} \pm i \, {}^{*}C^{IJK} \right) \tag{4.23}$$

where

$$F^{IJK} = L^{\alpha} f_{\alpha}^{IJK}, \qquad f^{IJK\alpha} = f^{\Lambda \Sigma \Gamma \alpha} E_{\Lambda}^{I} E_{\Sigma}^{J} E_{\Gamma}^{K}, \qquad \overline{F}^{IJK} = \overline{L}^{\alpha} f_{\alpha}^{IJK}$$
(4.24)

and  $C^{IJK}$  are the boosted structure constants defined as

$$C^{IJK} = L_2 E_{\Lambda}^I E_{\Sigma}^J E_{\Gamma}^K a^{\Lambda i} a^{\Sigma j} a^{\Gamma k} c_{ijk}, \qquad \overline{C}^{IJK} = \overline{L}_2 E_{\Lambda}^I E_{\Sigma}^J E_{\Gamma}^K a^{\Lambda i} a^{\Sigma j} a^{\Gamma k} c_{ijk} \qquad (4.25)$$

while the complex conjugates of the self-dual and antiself-dual components are

$$(F^{\pm IJK})^* = \overline{F}^{\mp IJK}, \qquad (C^{\pm IJK})^* = \overline{C}^{\mp IJK}$$

$$(4.26)$$

For the purpose of the study of the potential, it is convenient to decompose the 24 dimensional representation of  $SU(4)_{(d)} \subset SU(4)_1 \times SU(4)_2$  to which  $\lambda_A^I$  belongs, into its irreducible parts, namely  $\mathbf{24} = \overline{\mathbf{20}} + \overline{\mathbf{4}}$ . Setting:

$$\lambda_A^I = \lambda_A^{I(\overline{20})} - \frac{1}{6} (\Gamma^I)_{AB} \lambda^{B(\overline{4})} \tag{4.27}$$

where

$$\lambda^{A(\overline{4})} = (\Gamma_I)^{AB} \lambda_B^I; \qquad (\Gamma_I)^{AB} \lambda_B^I(\overline{20}) = 0 \tag{4.28}$$

we get

$$\delta \lambda^{A(\overline{4})} = Z^{AB(\overline{4})} \epsilon_B = \frac{1}{8} (F^{+IJK} + C^{+IJK}) (\Gamma_{IJK})^{AB} \epsilon_B$$
 (4.29)

$$\delta \lambda_A^{I(\overline{20})} = Z_A^{I(\overline{20})B} \epsilon_B = \frac{1}{8} (F^{-IJK} + C^{-IJK}) (\Gamma_{JK})_A^B \epsilon_B$$
 (4.30)

## 5 Space-time Lagrangian

The space—time Lagrangian and the associated supersymmetry transformation laws, have been computed using the geometric approach in superspace. We give in the Appendices A and B a complete derivation of the main results of this section.

In the following, in order to simplify the notation, we have suppressed the "hats" to the gauged covariant quantities:  $\hat{\nabla} \to \nabla$ ;  $\hat{P} \to P$ ;  $\hat{\omega}_{1,2} \to \omega_{1,2}$ .

In particular, the gauged covariant derivatives on the spinors of the gravitational multiplet and of the Yang–Mills multiplets are defined as follows:

$$\nabla \psi_A = \mathcal{D}\psi_A + \frac{1}{2}q\psi_A - \frac{1}{4}(\Gamma_{IJ})_A^{\ B}\omega_1^{IJ}\psi_B \tag{5.1}$$

$$\nabla \chi^{A} = \mathcal{D}\chi^{A} + \frac{3}{2}q\chi^{A} - \frac{1}{4}(\Gamma_{IJ})^{A}_{B}\omega_{1}^{IJ}\chi^{B}$$
 (5.2)

$$\nabla \lambda_{IA} = \mathcal{D}\lambda_{IA} - \frac{1}{2}q\lambda_{IA} - \frac{1}{4}(\Gamma_{IJ})_A^B \omega_1^{IJ}\lambda_{IB} + \omega_2^{IJ}\lambda_{JA}$$
 (5.3)

$$\nabla \lambda_{iA} = \mathcal{D}\lambda_{iA} - \frac{1}{2}q\lambda_{iA} - \frac{1}{4}(\Gamma_{IJ})_A^{\ B}\omega_1^{IJ}\lambda_{iB}$$
 (5.4)

(5.5)

 $\nabla$  is the gauged covariant derivative with respect to all the connections that act on the field, while  $\mathcal{D}$  is the Lorentz covariant derivative acting on a generic spinor  $\theta$  as follows

$$\mathcal{D}\theta \equiv d\theta - \frac{1}{4}\omega^{ab}\gamma_{ab}\theta \tag{5.6}$$

The action of the U(1) connection q (2.22) appearing in the covariant derivative  $\nabla$  is defined as a consequence of the different U(1) weights of the fields (2.5).

The complete action is:

$$S = \int \sqrt{-g} \mathcal{L} d^4 x \tag{5.7}$$

where

$$\mathcal{L} = \mathcal{L}_{(kin)} + \mathcal{L}_{(Pauli)} + \mathcal{L}_{(mass)} - \mathcal{L}_{(potential)}$$
(5.8)

where

$$\mathcal{L}_{(kin)} = -\frac{1}{2}R - i\left(\mathcal{N}^{\Lambda\alpha\Sigma\beta}\mathcal{F}_{\Lambda\alpha}^{+\mu\nu}\mathcal{F}_{\Sigma\beta\mu\nu}^{+} - \overline{\mathcal{N}}^{\Lambda\alpha\Sigma\beta}\mathcal{F}_{\Lambda\alpha}^{-\mu\nu}\mathcal{F}_{\Sigma\beta\mu\nu}^{-}\right) +$$

$$-2i\left(\mathcal{N}^{i\Sigma\beta}\mathcal{F}_{i}^{+\mu\nu}\mathcal{F}_{\Sigma\beta\mu\nu}^{+} - \overline{\mathcal{N}}^{i\Sigma\beta}\mathcal{F}_{i}^{-\mu\nu}\mathcal{F}_{\Sigma\beta\mu\nu}^{-}\right) +$$

$$-i\left(\mathcal{N}^{ij}\mathcal{F}_{i}^{+\mu\nu}\mathcal{F}_{j\mu\nu}^{+} - \overline{\mathcal{N}}^{ij}\mathcal{F}_{i}^{-\mu\nu}\mathcal{F}_{j\mu\nu}^{-}\right) +$$

$$+\frac{2}{3}f^{\Lambda\Sigma\Gamma\gamma}\epsilon^{\alpha\beta}A_{\Gamma\gamma\mu}A_{\Sigma\beta\nu}F_{\Lambda\alpha\rho\sigma}\epsilon^{\mu\nu\rho\sigma} + \overline{p}_{\mu}p^{\mu} + \frac{1}{2}P_{\mu}^{IJ}P_{IJ}^{\mu} + P_{\mu}^{Ii}P_{Ii}^{\mu} +$$

$$+\frac{\varepsilon^{\mu\nu\rho\sigma}}{\sqrt{-g}}\left(\bar{\psi}_{\mu}^{A}\gamma_{\nu}\nabla_{\rho}\psi_{A\sigma} - \bar{\psi}_{A\mu}\gamma_{\nu}\nabla_{\rho}\psi_{\sigma}^{A}\right) - 2i\left(\bar{\chi}^{A}\gamma^{\mu}\nabla_{\mu}\chi_{A} + \bar{\chi}_{A}\gamma^{\mu}\nabla_{\mu}\chi^{A}\right) +$$

$$-i\left(\bar{\lambda}_{I}^{A}\gamma^{\mu}\nabla_{\mu}\lambda_{A}^{I} + \bar{\lambda}_{IA}\gamma^{\mu}\nabla_{\mu}\lambda^{IA}\right) - 2i\left(\bar{\lambda}_{i}^{A}\gamma^{\mu}\nabla_{\mu}\lambda_{A}^{i} + \bar{\lambda}_{iA}\gamma^{\mu}\nabla_{\mu}\lambda^{iA}\right)$$

$$(5.9)$$

where, using equations (2.23), (2.65), (2.66), (2.67) we have:

$$p_{\mu}\overline{p}^{\mu} = L_{\alpha}\overline{L}_{\beta}\partial_{\mu}L^{\alpha}\partial^{\mu}\overline{L}^{\beta}$$

$$P_{\mu}^{IJ}P_{IJ}^{\mu} = P_{\mu}^{(IJ)}P_{(IJ)}^{\mu} + P_{\mu}^{[IJ]}P_{[IJ]}^{\mu}$$

$$P_{\mu}^{(IJ)}P_{(IJ)}^{\mu} = -4\partial_{\mu}E_{\Lambda}^{I}\partial^{\mu}(E^{-1})_{I}^{\Lambda} = 4g_{\Lambda\Sigma}\partial_{\mu}(E^{-1})_{I}^{\Lambda}\partial^{\mu}(E^{-1})^{I\Sigma}$$

$$P_{\mu}^{[IJ]}P_{[IJ]}^{\mu} = \frac{1}{4}g_{\Lambda\Gamma}g_{\Sigma\Delta}\left(\nabla_{(g)\mu}B^{\Lambda\Sigma} - \frac{1}{2}a_{i}^{\Lambda}\overset{\leftrightarrow}{\nabla}_{(g)\mu}a^{i\Sigma}\right)\left(\nabla_{(g)}^{\mu}B^{\Gamma\Delta} - \frac{1}{2}a_{j}^{\Gamma}\overset{\leftrightarrow}{\nabla}_{(g)}^{\mu}a^{j\Delta}\right)$$

$$P_{\mu}^{IJ}P_{Ij}^{\mu} = g_{\Lambda\Sigma}\partial_{\mu}a_{i}^{\Lambda}\partial^{\mu}a^{\Sigma i}$$

$$(5.11)$$

and we have defined  $g_{\Lambda\Sigma} \equiv E_{I\Lambda}E_{\Sigma}^{I}$ ,  $\mathcal{F}^{\pm} = \frac{1}{2}(\mathcal{F} \pm i * \mathcal{F})$ 

$$\mathcal{L}_{(Pauli)} = -2p_{\mu}\bar{\chi}^{A}\gamma^{\nu}\gamma^{\mu}\psi_{A\nu} - P_{\mu}^{IJ}\Gamma_{I}^{AB}\bar{\lambda}_{JA}\gamma^{\nu}\gamma^{\mu}\psi_{B\nu} - 2P_{\mu}^{Ii}(\Gamma_{I})^{AB}\bar{\lambda}_{iA}\gamma^{\nu}\gamma^{\mu}\psi_{B\nu} + \\ -2Im\left(\mathcal{N}\right)^{\Lambda\alpha\Sigma\beta}\left[\mathcal{F}_{\Lambda\alpha}^{+\nu}\left(L_{\beta}E_{\Sigma}^{I}(\Gamma_{I})^{AB}\bar{\psi}_{A\mu}\psi_{B\nu} + 2i\overline{L}_{\beta}E_{\Sigma}^{I}(\Gamma_{I})^{AB}\bar{\chi}_{A}\gamma_{\nu}\psi_{B\mu} + \\ +2i\overline{L}_{\beta}E_{\Sigma}^{I}\bar{\lambda}_{A}^{I}\gamma_{\nu}\psi_{\mu}^{A} + \frac{1}{4}L_{\beta}E_{\Sigma}^{I}(\Gamma_{I})_{AB}\bar{\lambda}_{A}^{J}\gamma_{\mu\nu}\lambda^{JB} + \overline{L}_{\beta}E_{\Sigma}^{I}\bar{\lambda}_{A}^{I}\gamma_{\mu\nu}\chi_{A} + \\ + \frac{1}{2}L_{\beta}E_{\Sigma}^{I}(\Gamma_{I})_{AB}\bar{\lambda}^{iA}\gamma_{\mu\nu}\lambda_{i}^{B}\right)\right] + \\ -2Im\left(\mathcal{N}\right)^{i\Sigma\beta}\left[\mathcal{F}_{i}^{+\mu\nu}\left(L_{\beta}E_{\Sigma}^{I}(\Gamma_{I})^{AB}\bar{\psi}_{A\mu}\psi_{B\nu} + 2i\overline{L}_{\beta}E_{\Sigma}^{I}(\Gamma_{I})^{AB}\bar{\chi}_{A}\gamma_{\nu}\psi_{B\mu} + \\ +2i\overline{L}_{\beta}E_{\Sigma}^{I}\bar{\lambda}_{A}^{I}\gamma_{\nu}\psi_{\mu}^{A} + \frac{1}{4}L_{\beta}E_{\Sigma}^{I}(\Gamma_{I})_{AB}\bar{\lambda}_{J}^{A}\gamma_{\mu\nu}\lambda^{JB} + \overline{L}_{\beta}E_{\Sigma}^{I}\bar{\lambda}_{A}^{I}\gamma_{\mu\nu}\chi_{A} + \\ +2i\overline{L}_{\beta}E_{\Sigma}^{I}\bar{\lambda}_{A}^{I}\gamma_{\nu}\psi_{\mu}^{A} + \frac{1}{4}L_{\beta}E_{\Sigma}^{I}(\Gamma_{I})_{AB}\bar{\lambda}_{J}^{A}\gamma_{\mu\nu}\lambda^{JB} + \overline{L}_{\beta}E_{\Sigma}^{I}\bar{\lambda}_{A}^{I}\gamma_{\mu\nu}\chi_{A} + \\ +\frac{1}{2}L_{\beta}E_{\Sigma}^{I}(\Gamma_{I})_{AB}\bar{\lambda}^{iA}\gamma_{\mu\nu}\lambda_{i}^{B}\right) + \\ +\mathcal{F}_{\Sigma\beta}^{+\mu\nu}\left(E_{\Lambda}^{I}a_{i}^{\Lambda}L_{2}(\Gamma_{I})^{AB}\bar{\psi}_{A\mu}\psi_{B\nu} + 2iE_{\Lambda}^{I}a_{i}^{\Lambda}\bar{L}_{2}(\Gamma_{I})^{AB}\bar{\lambda}_{J}^{A}\gamma_{\mu\nu}\lambda^{JB} + \\ +2iE_{\Lambda}^{I}a_{i}^{\Lambda}\bar{L}_{2}\bar{\lambda}_{IA}\gamma_{\nu}\psi_{\mu}^{A} + 4i\overline{L}_{2}\bar{\lambda}_{iA}\gamma_{\nu}\psi_{\mu}^{A} + \frac{1}{4}L_{2}E_{\Sigma}^{I}a_{i}^{\Sigma}(\Gamma_{I})_{AB}\bar{\lambda}_{J}^{A}\gamma_{\mu\nu}\chi_{A}\right)\right] + \\ -2Im\left(\mathcal{N}\right)^{ij}\left[\mathcal{F}_{i}^{+\mu\nu}\left(E_{\Lambda}^{I}a_{j}^{\Lambda}L_{2}(\Gamma_{I})^{AB}\bar{\psi}_{A\mu}\psi_{B\nu} + 2iE_{\Lambda}^{I}a_{j}^{\Lambda}\bar{L}_{2}(\Gamma_{I})^{AB}\bar{\chi}_{A}\gamma_{\nu}\psi_{B\mu} + \\ +2iE_{\Lambda}^{I}a_{j}^{\Lambda}\bar{L}_{2}\bar{\lambda}_{I}^{I}\gamma_{\nu}\psi_{\mu}^{A} + 4i\overline{L}_{2}\bar{\lambda}_{jA}\gamma_{\nu}\psi_{\mu}^{A} + \frac{1}{4}L_{2}E_{\Sigma}^{I}a_{i}^{\Sigma}(\Gamma_{I})_{AB}\bar{\lambda}_{J}^{A}\gamma_{\mu\nu}\lambda^{JB}\right] + \\ +2iE_{\Lambda}^{I}a_{j}^{\Lambda}\bar{L}_{2}\bar{\lambda}_{A}^{I}\gamma_{\nu}\psi_{\mu}^{A} + 4i\overline{L}_{2}\bar{\lambda}_{jA}\gamma_{\nu}\psi_{\mu}^{A} + \frac{1}{4}L_{2}E_{\Sigma}^{I}a_{i}^{\Sigma}(\Gamma_{I})_{AB}\bar{\lambda}_{J}^{A}\gamma_{\mu\nu}\lambda^{J}\right] + \\ +2iE_{\Lambda}^{I}a_{j}^{\Lambda}\bar{L}_{2}\bar{\lambda}_{A}^{I}\gamma_{\mu\nu}\chi_{A} + \frac{1}{2}L_{2}E_{\Sigma}^{I}a_{i}^{\Sigma}(\Gamma_{I})_{AB}\bar{\lambda}_{J}^{A}\gamma_{\mu\nu}\lambda^{J}^{IB} + 2\overline{L}_{2}\bar{\lambda}_{i}^{A}\gamma_{\mu\nu}\chi_{A}\right] + \\ +2iE_{\Lambda}^{I}a_{j}^{\Lambda}\bar{L}_{2}^{\Lambda}\bar{L}_{2}^{\Lambda}\bar{L}_{2}^{\Lambda}\bar{L}_{2}^{\Lambda}$$

$$\mathcal{L}_{(mass)} = \left[ +2iS^{AB}\bar{\psi}_{A\mu}\gamma^{\mu\nu}\psi_{B\nu} - 4iN^{AB}\bar{\psi}_{\mu A}\gamma^{\mu}\chi_{B} - 2iZ_{IB}{}^{A}\bar{\psi}_{A\mu}\gamma^{\mu}\lambda^{IB} - 4iW_{iB}{}^{A}\bar{\psi}_{A\mu}\gamma^{\mu}\lambda^{iB} \right]$$

$$+6 \left( Q_{IB}^{A} \bar{\lambda}_{A}^{I} \chi^{B} + R_{iB}^{A} \bar{\lambda}_{A}^{i} \chi^{B} + T_{IJ}^{AB} \bar{\lambda}_{A}^{I} \lambda_{B}^{J} + U_{ij}^{AB} \bar{\lambda}_{A}^{i} \lambda_{B}^{j} + V_{Ij}^{AB} \bar{\lambda}_{A}^{I} \lambda_{B}^{j} \right) \right] + c.c.$$
(5.13)

$$\mathcal{L}_{(potential)} = \frac{1}{4} \left( -12S^{AB}S_{AB} + 4N^{AB}N_{AB} + 2Z_{IB}{}^{A}Z^{IB}{}_{A} + 4W_{iB}{}^{A}W^{iB}{}_{A} \right) (5.15)$$

The structures appearing in  $\mathcal{L}_{(mass)}$  and  $\mathcal{L}_{(potential)}$  are given by

$$S_{AB} = -\frac{i}{48} (\overline{F}^{IJK-} + \overline{C}^{IJK-}) (\Gamma_{IJK})_{AB}$$
 (5.16)

$$N^{AB} = -\frac{1}{48} (\overline{F}^{IJK+} + \overline{C}^{IJK+}) (\Gamma_{IJK})^{AB}$$
 (5.17)

$$Z_A^{IB} = \frac{1}{8} (F^{IJK} + C^{IJK}) (\Gamma_{JK})_A^B$$
 (5.18)

$$W_{iA}^{B} = \frac{1}{8} L_2 q^{Jj} q^{Kk} c_{ijk} (\Gamma_{JK})_A^{B}$$
(5.19)

$$Q^{IA}_{B} = -\frac{1}{12} (F^{IJK} + C^{IJK}) (\Gamma_{JK})^{A}_{B}$$
 (5.20)

$$R^{iA}_{B} = -\frac{1}{24} L_2 q^{Jj} q^{Kk} c_{ijk} (\Gamma_{JK})^{A}_{B}$$
 (5.21)

$$T^{IJAB} = -\frac{1}{3}\delta^{IJ}N^{AB} + \frac{1}{12}(\overline{F}^{IJK} + \overline{C}^{IJK})(\Gamma_K)^{AB}$$
 (5.22)

$$U^{ijAB} = -\frac{2}{3}\delta^{ij}N^{AB} - \frac{1}{3}\overline{L}_2 q_k^I c^{ijk} (\Gamma_I)^{AB}$$

$$(5.23)$$

$$V^{IiAB} = -\frac{1}{3}c^{ijk}\overline{L}_2 q_j^I q_k^K (\Gamma_K)^{AB}$$

$$(5.24)$$

The Lagrangian is invariant under the following supersymmetry transformation laws:

$$\begin{split} \delta V_{\mu}^{a} &= -i \bar{\psi}_{A\mu} \gamma^{a} \varepsilon^{A} + c.c. \\ \delta A_{\Lambda \alpha \mu} &= -L_{\alpha} E_{\Lambda}^{I} (\Gamma_{I})^{AB} \bar{\psi}_{A\mu} \varepsilon_{B} + i L_{\alpha} E_{\Lambda}^{I} (\Gamma_{I})_{AB} \bar{\chi}^{A} \gamma_{\mu} \varepsilon^{B} + \\ &+ i L_{\alpha} E_{\Lambda I} \bar{\lambda}^{IA} \gamma_{\mu} \varepsilon_{A} + c.c. \\ \delta A_{i\mu} &= -L_{2} E_{\Lambda}^{I} a_{i}^{\Lambda} (\Gamma_{I})^{AB} \bar{\psi}_{A\mu} \varepsilon_{B} + i L_{2} E_{\Lambda}^{I} a_{i}^{\Lambda} (\Gamma_{I})_{AB} \bar{\chi}^{A} \gamma_{\mu} \varepsilon^{B} + \\ &+ i L_{2} E_{\Lambda I} a_{i}^{\Lambda} \bar{\lambda}^{IA} \gamma_{\mu} \varepsilon_{A} + 2i L_{2} \bar{\lambda}_{i}^{A} \gamma_{\mu} \varepsilon_{A} + c.c. \\ p_{\beta} \delta L^{\beta} &\equiv 2 \bar{\chi}_{A} \varepsilon^{A} \Longrightarrow \delta L^{\alpha} = 2 \overline{L}^{\alpha} \bar{\chi}_{A} \varepsilon^{A} \\ \delta_{K}^{I} E_{\Lambda}^{J)} \delta(E^{-1})^{\Lambda K} &= -(\Gamma^{(I)})^{AB} \bar{\lambda}_{A}^{J)} \varepsilon_{B} + c.c. \\ \frac{1}{2} E_{\Lambda}^{I} E_{\Sigma}^{J} (\delta B^{\Lambda \Sigma} - \delta a_{i}^{I\Lambda} a^{\Sigma | i}) &= (\Gamma^{I)})^{AB} \bar{\lambda}_{A}^{J} \varepsilon_{B} + c.c. \\ \frac{1}{2} E_{\Lambda}^{I} E_{\Sigma}^{J} (\delta B^{\Lambda \Sigma} - \delta a_{i}^{I\Lambda} a^{\Sigma | i}) &= (\Gamma^{I})^{AB} \bar{\lambda}_{A}^{J} \varepsilon_{B} + c.c. \\ \delta \psi_{\mu A} &= \mathcal{D}_{\mu} \varepsilon_{A} - \overline{L}^{\alpha} (E^{-1})_{I}^{\Lambda} (\Gamma^{I})_{AB} \mathcal{F}_{\Lambda \alpha | \mu \nu}^{-} \gamma^{\nu} \varepsilon^{B} + S_{AB} \gamma_{\mu} \varepsilon^{B} \\ \delta \chi^{A} &= \frac{i}{2} \overline{p}_{\mu} \gamma^{\mu} \varepsilon^{A} + \frac{i}{4} \overline{L}^{\alpha} (E^{-1})_{I}^{\Lambda} (\Gamma^{I})^{AB} \mathcal{F}_{\Lambda \alpha | \mu \nu}^{-} \gamma^{\mu \nu} \varepsilon_{B} + N^{AB} \varepsilon_{B} \\ \delta \lambda_{IA} &= \frac{i}{2} (\Gamma^{J})_{AB} P_{JI | \mu} \gamma^{\mu} \varepsilon^{B} - \frac{i}{2} L^{\alpha} (E^{-1})_{I}^{\Lambda} \mathcal{F}_{\Lambda \alpha | \mu \nu}^{-} \gamma^{\mu \nu} \varepsilon_{A} + Z_{IA}^{B} \varepsilon_{B} \end{split}$$

$$\delta\lambda_{iA} = \frac{i}{2} (\Gamma^{J})_{AB} P_{Ji|\mu} \gamma^{\mu} \varepsilon^{B} + \frac{1}{4} \frac{1}{\overline{L}_{2}} \mathcal{F}_{i|\mu\nu}^{-} \gamma^{\mu\nu} \varepsilon_{A} + \frac{1}{4} \frac{1}{\overline{L}_{2}} a_{i}^{\Lambda} \mathcal{F}_{2\Lambda|\mu\nu}^{-} \gamma^{\mu\nu} \varepsilon_{A} + W_{iA}^{B} \varepsilon_{B}$$

$$(5.25)$$

where we have defined

$$q_i^I = E_{\Lambda}^I a_I^{\Lambda} \tag{5.26}$$

### 6 The scalar potential and its extrema

From the expression of the potential given in the Lagrangian (5.15) and using the fermionic shifts given in equations (5.16)–(5.19), one obtains that the potential is given by a sum of two terms, each being a square modulus, namely:

$$V = \frac{1}{12} |F^{IJK-} + C^{IJK-}|^2 + \frac{1}{8} |L_2 c_{ijk} q^{jJ} q^{kK}|^2$$
(6.1)

where  $F^{IJK-}$  and  $C^{IJK-}$  were defined in equations (4.22) and (4.23) and  $q_i^I$  in equation (5.26).

In the first term  $F^{IJK-}$  represents the contribution to the potential of the bulk fields, while  $C^{IJK-}$  is the contribution from the D-branes sector. On the other hand the second term is the generalization of the potential already present in the super Yang–Mills theory [50].

We note that using the decomposition given in equations (4.29),(4.30), namely:

$$Z_A^{IB} = Z_A^{IB(\overline{20})} - \frac{1}{6} (\Gamma^I)_A^C Z_{CB}^{(\overline{4})}$$
(6.2)

in equation (5.15), the contribution of the gravitino shift  $S_{AB}$  cancels exactly against the contribution  $Z_{AB}^{(4)}$  of the representation  $\overline{\mathbf{4}}$  of the gaugino; furthermore, since  $Z_A^{IB(\overline{20})}$  is proportional to  $N_{AB}$ , the bulk part of the potential is proportional to  $N_{AB}N^{BA}$ .

We now discuss the extrema of this potential. Since V is positive semidefinite, its extrema are given by the solution of V = 0, that is

$$L_2 c_{ijk} q^{jJ} q^{kK} = 0, \quad F^{IJK-} + C^{IJK-} = 0$$
 (6.3)

In absence of fluxes  $F^{IJK} = 0$ , the only solution is that the  $q^{jJ}$  belong to the Cartan subalgebra of G, then  $C^{IJK} = 0$ , but all the moduli of the orientifold are not stabilized as well as the  $L_{\alpha}$ . In this case the moduli space is

$$\frac{\mathrm{SU}(1,1)}{\mathrm{U}(1)} \times \frac{\mathrm{SO}(6,6+N)}{\mathrm{SO}(6) \times \mathrm{SO}(6+N)} \tag{6.4}$$

where N is the dimension of the Cartan subalgebra of G.

In presence of fluxes,  $F^{IJK} \neq 0$  we have, besides  $q^{jJ}$  belonging to the Cartan subalgebra of G, also  $F^{IJK-} = 0$ . We now show that this condition freezes the dilaton field S and several moduli of  $GL(6)/SO(6)_d$ . We note that the equation  $F^{IJK-} = 0$  can be rewritten as:

$$L^{1}f_{1}^{IJK-} + L^{2}f_{2}^{IJK-} = 0 \Longrightarrow \frac{f_{1}^{IJK-}}{f_{2}^{IJK-}} = -\frac{L^{2}}{L^{1}} \equiv S$$
 (6.5)

so that S must be a constant. We set:

$$S = i\alpha \to \frac{L^2}{L^1} = -i\alpha \Longrightarrow \frac{\phi_2}{\phi_1} = \frac{1-\alpha}{1+\alpha}$$
 (6.6)

where  $\alpha$  is a complex constant and  $\Re \alpha \equiv e^{\varphi_0} > 0$  Equation (6.5) becomes:

$$f_1^{\Lambda\Sigma\Delta} = +\Re\alpha * f_2^{\Lambda\Sigma\Delta} - \Im\alpha f_2^{\Lambda\Sigma\Delta} \tag{6.7}$$

We rewrite this equation using  $f_{1,2}^{IJK-} = \frac{1}{2} \left( f_{1,2}^{IJK} - i * f_{1,2}^{IJK} \right)$  and by replacing the SO(6) indices I, J, K with GL(6) indices via the coset representatives  $E_{\Lambda}^{I}$ ; we find:

$$f_1^{\Lambda\Sigma\Gamma} + \Im \alpha f_2^{\Lambda\Sigma\Gamma} = \frac{1}{3!} \Re \alpha \ det E^{-1} \epsilon^{\Lambda\Sigma\Gamma\Delta\Pi\Omega} g_{\Delta\Delta'} g_{\Pi\Pi'} g_{\Omega\Omega'} f_2^{\Delta'\Pi'\Omega'}$$
 (6.8)

where  $g^{\Lambda\Sigma} \equiv E_I^{\Lambda} E^{\Sigma I}$  is the (inverse) moduli metric of  $T^6$  in  $GL(6)/SO(6)_d$ .

It is convenient to analyze equation (6.8) using the complex basis defined in Appendix C. In this basis only 4 fluxes (together with their complex conjugates) corresponding to the eigenvalues of the gravitino mass matrix, are different from zero.

Going to the complex basis where each Greek index decomposes as  $\Lambda = (i, \bar{\imath}), i = 1, 2, 3$  [57] and lowering the indices on both sides, one obtains an equation relating a (p, q) form on the l.h.s (p, q = 0, 1, 2, 3; p + q = 3) to a combination of (p', q') forms on the r.h.s. Requiring that all the terms with  $p' \neq p, q' \neq q$  are zero and that the r.h.s. of equation (6.8) be a constant, on is led to fix different subsets of the  $g^{\Lambda\Sigma}$  moduli, depending on the residual degree of supersymmetry.

Suppose now that we have N=3 unbroken supersymmetry, that is  $m_1=m_2=m_3=0$ ,  $m_4 \propto |f^{123}| \neq 0$  (see Appendix C). The previous argument, concerning (p,q)-forms, allows us to conclude that all the components  $g_{i,j}$  and  $g_{i\bar{j}}$  are zero, so that at the N=3 minimum we have:

$$g_{\Lambda\Sigma} \longrightarrow \begin{pmatrix} g_{i\bar{\jmath}} & 0\\ 0 & g_{\bar{\imath}j} \end{pmatrix}$$
 (6.9)

In the N=2 case we have  $m_2=m_3=0$ ,  $m_1\propto |f^{1\overline{23}}|\neq 0$ ,  $m_4\propto |f^{123}|\neq 0$  and a careful analysis of equation (6.8) shows that, besides the previous frozen moduli, also the  $g_{1\overline{2}}$ ,  $g_{1\overline{3}}$  components are frozen.

Finally, in the N=1 case we set one of the masses equal to zero, say  $m_2=0$ , and  $m_1 \propto |f^{1\overline{23}}| \neq 0$ ,  $m_3 \propto |f^{12\overline{3}}| \neq 0$   $m_4 \propto |f^{12\overline{3}}| \neq 0$ ; in this case the only surviving moduli are the diagonal ones, namely  $g_{i\overline{\imath}}$ , so that, using the results given in Appendix C, also the real components of  $g_{\Lambda\Sigma}$  are diagonal

$$g_{\Lambda\Sigma} \longrightarrow \text{diag}\{e^{2\varphi_1}, e^{2\varphi_2}, e^{2\varphi_3}, e^{2\varphi_1}, e^{2\varphi_2}, e^{2\varphi_3}\}$$
 (6.10)

the exponentials representing the radii of the manifold  $T_{(14)}^2 \times T_{(25)}^2 \times T_{(36)}^2$ . In terms of the vielbein  $E_{\Lambda}^I$  we have:

$$E_{\Lambda}^{I} = \text{diag}(e^{\varphi_{1}}, e^{\varphi_{2}}, e^{\varphi_{3}}, e^{\varphi_{1}}, e^{\varphi_{2}}, e^{\varphi_{3}})$$
 (6.11)

Finally, when all the masses are different from zero (N = 0), no further condition on the moduli is obtained.

Note that in every case equation (6.8) reduces to the  $SL(2,\mathbb{R}) \times GL(6,\mathbb{R})$  non covariant constraint among the fluxes:

$$f_1^{\Lambda\Sigma\Gamma} + \Im \alpha f_2^{\Lambda\Sigma\Gamma} = \frac{1}{3!} \Re \alpha \ \epsilon^{\Lambda\Sigma\Gamma\Delta\Pi\Omega} f_2^{\Delta\Pi\Omega}$$
 (6.12)

In the particular case  $\alpha = 1$ , which implies  $\varphi = C = 0$ , from equations (6.5), (6.6), we obtain:

$$f_1^{-\Lambda\Sigma\Delta} = if_2^{-\Lambda\Sigma\Delta} \tag{6.13}$$

In this case the minimum of the scalar potential is given by

$$\phi_2 = 0 \Longrightarrow |\phi_1| = 1 \tag{6.14}$$

or, in terms of the  $L^{\alpha}$  fields,  $L^1 = \frac{1}{\sqrt{2}}$ ,  $L^2 = -\frac{i}{\sqrt{2}}$  (up to an arbitrary phase). Furthermore (6.7) reduces to the duality relation:

$$f_1^{\Lambda\Sigma\Delta} = \frac{1}{3!} \epsilon^{\Lambda\Sigma\Delta\Gamma\Pi\Omega} f_2^{\Gamma\Pi\Omega} \tag{6.15}$$

which is the  $SL(2,\mathbb{R}) \times GL(6)$  non covariant constraint imposed in [43].

Let us now discuss the residual moduli space in each case. For this purpose we introduce, beside the metric  $g^{\Lambda\Sigma}$ , also the 15 axions  $B^{\Lambda\Sigma}$  with enlarge  $GL(6)/SO(6)_d$  to  $SO(6,6)/SO(6) \times SO(6)$  (using complex coordinates  $B^{\Lambda\Sigma} = (B^{i\bar{\jmath}}, B^{ij} = -B^{ji})$ .

Since we have seen that for N=1,0, the frozen moduli from  $F^{IJK-}=0$  are all the  $g^{i\bar{\jmath}}$  and  $g^{ij}$  except the diagonal ones  $g^{i\bar{\imath}}$ , correspondingly, in the  $B^{\Lambda\Sigma}$  sector, all  $B^{ij}$  and  $B^{i\bar{\jmath}}$  are frozen, except the diagonal  $B^{i\bar{\imath}}$ , and they are eaten by the 12 bosons through the Higgs mechanism. Indeed the three diagonal  $B^{i\bar{\imath}}$  are inert under gauge transformation (see Appendix C). The metric moduli space is  $(O(1,1))^3$  which, adding the axions, enlarges to the coset space  $(U(1,1)/U(1)\times U(1))^3$ . Adding the Yang-Mills moduli in the D3-brane sector, the full moduli space of a generic vacuum with completely broken supersymmetry, or N=1 supersymmetry contains 6+6N moduli which parametrize three copies of  $U(1,1+N)/U(1)\times U(1+N)$ .

Let us consider now the situation of partial supersymmetry breaking ( for a more detailed discussion see Appendix C). For N=3 supersymmetry the equation  $F^{IJK-}=0$  freezes all  $g^{ij}$  moduli but none of the  $g^{i\bar{\jmath}}$ . The relevant moduli space of metric  $g^{i\bar{\jmath}}$  is nine dimensional and given by  $GL(3,\mathbb{C})/U(3)$ . Correspondingly there are six massive vectors whose longitudinal components are the  $B^{ij}$  axions. Adding the nine uneaten  $B^{i\bar{\jmath}}$  axions the total moduli space is  $U(3,3)/U(3)\times U(3)$ . Further adding the 6N Cartan moduli, the complete moduli space is  $U(3,3+N)/U(3)\times U(3+N)$ .

For N=2 unbroken supersymmetry the equation  $F^{IJK-}=0$  fixes all  $g^{ij}$  and  $g^{i\bar{\jmath}}$  except the diagonal ones and  $g^{2\bar{3}}$ . The moduli space of the metric is  $\mathrm{SO}(1,1)\times\mathrm{GL}(2,\mathbb{C})/\mathrm{U}(2)$ . There are 10 massive vectors which eat all  $B^{ij}$  moduli and  $B^{i\bar{\jmath}}$  except the diagonal ones and  $B^{2\bar{3}}$ ; the complete moduli space enlarges to  $\mathrm{SU}(1,1)/\mathrm{U}(1)\times\mathrm{SU}(2,2)/\mathrm{SU}(2)\times\mathrm{SU}(2)\times\mathrm{U}(1)$ . This space is the product of the one–dimensional Kähler manifold and the two–dimensional quaternionic manifold as required by N=2 supergravity. By further adding the 6N Cartan moduli, the moduli space enlarges to  $\mathrm{SU}(1,1+N)/\mathrm{U}(1)\times\mathrm{SU}(1+N)\times\mathrm{SU}(2,2+N)/\mathrm{SU}(2)\times\mathrm{SU}(2+N)\times\mathrm{U}(1)$ .

Finally in the case of N=1 unbroken supersymmetry, the frozen moduli are the same as in the N=0 case, and the moduli space is indeed the product of three copies of Kähler–Hodge manifolds, as appropriate to chiral multiplets.

#### 7 The mass spectrum

The spectrum of this theory contains 128 states (64 bosons and 64 fermions) coming from the bulk states of IIB supergravity and  $16N^2$  states coming from the n D3-branes. The brane sector is N=4 supersymmetric. Setting  $\alpha=1$ , the bulk part has a mass spectrum which has a surprisingly simple form.

In units of the overall factor  $\frac{\sqrt{2}}{24}e^{\frac{K}{2}}$ ,  $K=2\varphi_1+2\varphi_2+2\varphi_3$  being the Kähler potential of the moduli space  $\left(\frac{SU(1,1)}{U(1)}\right)^3$ , one finds<sup>5</sup>:

#### **Fermions**

(4) 
$$spin \frac{3}{2}$$
  $|m_i|$   $i = 1, 2, 3, 4$   
2(4)  $spin \frac{1}{2}$   $|m_i|$   
(16)  $spin \frac{1}{2}$   $|m_i \pm m_j \pm m_k|$   $i < j < k$ 

$$2(4) \quad spin \frac{1}{2} \qquad |m_i|$$

(16) 
$$spin \frac{1}{2} |m_i \pm m_j \pm m_k| \quad i < j < k$$

#### Bosons

$$(12) \quad spin \, 1 \qquad |m_i \pm m_j| \qquad i < j$$

(6) 
$$spin 0$$
  $m = 0$ 

(6) 
$$spin 0$$
  $m = 0$   
(12)  $spin 0$   $|m_i \pm m_j|$ 

(8) 
$$spin 0$$
  $|m_1 \pm m_2 \pm m_3 \pm m_4|$ 

where  $m_i$ ,  $i=1,\ldots 4$  is the modulus of the complex eigenvalues of the matrix  $f_1^{IJK-}(\Gamma_{IJK})_{AB}$ evaluated at the minimum.

Note that in the case  $\alpha \neq 1$  all the masses  $m_i$  acquire an  $\alpha$ -dependent extra factor due to the relation

$$\overline{F}^{IJK-} = -\sqrt{2}(\Re\alpha)^{\frac{1}{2}} f_2^{IJK-} = i\sqrt{2} \frac{(\Re\alpha)^{\frac{1}{2}}}{\alpha} f_1^{IJK-}$$
 (7.1)

so that all the spectrum is rescaled by a factor  $g(\alpha) \equiv \sqrt{2} \frac{(\Re \alpha)^{\frac{1}{2}}}{\alpha}$ .

This spectrum is identical (in suitable units) to a truncation (to half of the states) of the mass spectrum of the N=8 spontaneously broken supergravity à la Scherk-Schwarz [35]-[37].

The justification of this statement in given in the next section.

We now note some properties of the spectrum. For arbitrary values of  $m_i$  the spectrum satisfies the quadratic and quartic mass relations

$$\sum_{J} (2J+1)(-1)^{2J} m_J^{2k} = 0 \quad k = 1, 2$$
(7.2)

Note that, in proving the above relations, the mixed terms for k=1 are of the form  $m_i m_j$ and they separately cancel for bosons and fermions, due to the symmetry  $m_i \longrightarrow -m_i$  of the spectrum. On the other hand, for k=2 the mixed terms  $m_i^2 m_i^2$  are even in  $m_i$  and

<sup>&</sup>lt;sup>5</sup>Note that we have corrected a mistake in the spin 1 mass formula (5.21)–(5.23) as given in reference [57]

thus cancel between bosons and fermions.

If we set some of the  $m_i = 0$  we recover the spectrum of N = 3, 2, 1, 0 supersymmetric phases.

If we set  $|m_i| = |m_j|$  for some i, j we recover some unbroken gauge symmetries. This is impossible with the N=3 phase (when  $m_2=m_3=m_4=0$ ) but it is possible in the  $N\leq 2$  phases. For instance in the N=2 phase, for  $m_3=m_4=0$  and  $|m_1|=|m_2|$  there is an additional massless vector multiplet, while in the N=1 phase, for  $m_4=0$ ,  $|m_1|=|m_2|=|m_3|$  there are three massless vector multiplets and finally for the N=0 phase and all  $|m_i|$  equal, there are six massless vectors.

The spectrum of the D3-brane sector has an enhanced (N=4) supersymmetry, so when the gauge group is spontaneously broken to its Cartan subalgebra  $\mathrm{U}(N) \longrightarrow \mathrm{U}(1)^N$ , N(N-1) charged gauge bosons become massive and they are  $\frac{1}{2}$  BPS saturated multiplets of the N=4 superalgebra with central charges (the fermionic sector for the brane gaugini is discussed at the end of Section 8). The residual N Cartan multiplets remain massless and their scalar partners complete the 6+6N dimensional moduli space of the theory, that is classically given by three copies of  $\frac{\mathrm{SU}(1,1+N)}{\mathrm{U}(1)\times\mathrm{SU}(1,1+N)}$ . Adding all these facts together we may say that the spectrum is classified by the following

Adding all these facts together we may say that the spectrum is classified by the following quantum numbers  $(q, e_i)$ , where q are "charges" of the bulk gauge group, namely  $|m_i|$ ,  $|m_i \pm m_j|$ ,  $|m_i \pm m_j \pm m_k|$ ,  $|m_i \pm m_j \pm m_k \pm m_\ell|$  and  $e_i$  are the N-1 charges of the SU(N) root-lattice. In the supergravity spectrum there is a sector of the type (q, 0) (the 128 states coming from the bulk) and a sector of the type  $(0, e_i)$  (the sector coming from the D3-brane).

## 8 Embedding of the N=4 model with six matter multiplets in the N=8

There are two inequivalent ways of embedding the N=4 model with an action which is invariant under global  $SL(2,\mathbb{R}) \times GL(6,\mathbb{R})$ , within the N=8 theory. They correspond to the two different embeddings of the  $SL(2,\mathbb{R}) \times GL(6,\mathbb{R})$  symmetry of the N=4 action inside  $E_{7(7)}$  which is the global symmetry group of the N=8 field equations and Bianchi identities.

The N=8 model describes the low energy limit of Type II superstring theory compactified on a six torus  $T^6$ . As shown in [60, 61, 62] the ten dimensional origin of the 70 scalar fields of the model can be characterized group theoretically once the embeddings of the isometry group  $SO(6,6)_T$  of the moduli space of  $T^6$  and of the duality groups of higher dimensional maximal supergravities are specified within  $E_{7(7)}$ . This analysis makes use of the solvable Lie algebra representation which consists in describing the scalar manifold as a solvable group manifold generated by a solvable Lie algebra of which the scalar fields are the parameters. The solvable Lie algebra associated with  $E_{7(7)}$  is defined by its Iwasawa decomposition and is generated by the seven Cartan generators and by the 63 shift generators corresponding to all the positive roots. In this representation the Cartan subalgebra is parametrized by the scalars coming from the diagonal entries of the internal metric while all the other scalar fields are in one to one correspondence with the  $E_{7(7)}$  positive roots. We shall represent the  $E_{7(7)}$  Dynkin diagram as in figure 1. The positive roots are expressed as combinations  $\alpha = \sum_{i=1}^{7} n^i \alpha_i$  of the simple roots in which

Figure 1:  $E_{7(7)}$  Dynkin diagram. The empty circles denote  $SO(6,6)_T$  roots, while the filled circle denotes the  $SO(6,6)_T$  spinorial weight.

Figure 2:  $SL(2,\mathbb{R}) \times SO(6,6)_T$  and  $SL(2,\mathbb{R}) \times SO(6,6)$  Dynkin diagrams. The root  $\alpha$  is the  $E_{7(7)}$  highest root while  $\beta$  is  $\alpha_3 + 2\alpha_4 + \alpha_5 + 2\alpha_6 + \alpha_7$ . The group  $SL(2,\mathbb{R})_{IIB}$  is the symmetry group of the ten dimensional type IIB theory.

the positive integers  $n^i$  define the grading of the root  $\alpha$  with respect to  $\alpha_i$ . The isometry group of the  $T^6$  moduli space  $SO(6,6)_T$  is defined by the sub-Dynkin diagram  $\{\alpha_i\}_{i=1,\dots,6}$  while the Dynkin diagram of the duality group  $E_{11-D(11-D)}$  of the maximal supergravity in dimension D > 4 is obtained from the  $E_{7(7)}$  Dynkin diagram by deleting the simple roots  $\{\alpha_1, \dots, \alpha_{D-4}\}$ . Using these conventions in Table 1 [62] the correspondence between the 63 non dilatonic scalar fields deriving from dimensional reduction of type IIB theories and positive roots of  $E_{7(7)}$  is illustrated. In this framework the R-R scalars, for instance, are defined by the positive roots which are spinorial with respect to  $SO(6,6)_T$ , i.e. which have grading  $n^7 = 1$  with respect to the spinorial simple root  $\alpha_7$ . On the contrary the NS-NS scalars are defined by the roots with  $n^7 = 0, 2$ .

Let us first discuss the embedding of the  $SL(2,\mathbb{R})\times SO(6,6)$  duality group of our model within  $E_{7(7)}$ . In the solvable Lie algebra language the Peccei–Quinn scalars parametrize the maximal abelian ideal of the solvable Lie algebra generating the scalar manifold. As far as the manifold  $SO(6,6)/SO(6) \times SO(6)$  is concerned, this abelian ideal is 15 dimensional and is generated by the shift operators corresponding to positive SO(6,6) roots with grading one with respect to the simple root placed at one of the two symmetric ends of the corresponding Dynkin diagram D<sub>6</sub>. Since in our model the Peccei–Quinn scalars are of R-R type, the SO(6,6) duality group embedded in  $E_{7(7)}$  does not coincide with  $SO(6,6)_T$ . Indeed one of its symmetric ends should be a spinorial root of  $SO(6,6)_T$ . Moreover the  $SL(2,\mathbb{R})$  group commuting with SO(6,6) should coincide with the  $SL(2,\mathbb{R})_{IIB}$  symmetry group of the ten dimensional type IIB theory, whose Dynkin diagram consists in our formalism of the simple root  $\alpha_7$ . This latter condition uniquely determines the embedding of SO(6,6) to be the one defined by  $D_6 = \{\alpha_1, \alpha_2, \alpha_3, \alpha_4, \alpha_5, \beta\}$ , where  $\beta = \alpha_3 + 2\alpha_4 + \alpha_5$  $\alpha_5 + 2\alpha_6 + \alpha_7$  is the spinorial root (see figure 2). On the other hand the 20 scalar fields parametrizing the manifold  $SL(6,\mathbb{R})/SO(6)$  are all of NS-NS type (they come from the components of the  $T^6$  metric). This fixes the embedding of  $SL(6,\mathbb{R})$  within  $E_{7(7)}$  which we shall denote by  $SL(6,\mathbb{R})_1$ : its Dynkin diagram is  $\{\alpha_1,\alpha_2,\alpha_3,\alpha_4,\alpha_5\}$ . The Peccei-Quinn scalars are then defined by the positive roots with grading one with respect to the spinorial end  $\beta$  of D<sub>6</sub> which is not contained in  $SL(6,\mathbb{R})_1$ . In table 1 the scalar fields in  $SO(1,1) \times SL(6,\mathbb{R})_1/SO(6)$  which are not dilatonic (i.e. do not correspond to diagonal entries of the  $T^6$  metric) correspond to the  $SL(6,\mathbb{R})_1$  positive roots which are characterized by  $n^6 = n^7 = 0$  and are the off-diagonal entries of the internal metric. The Peccei-Quinn scalars on the other hand correspond to the roots with grading one with respect to  $\beta$ , which in Table 1 are those with  $n^6 = 2$ ,  $n^7 = 1$  and indeed, as expected, are identified with the internal components of the type IIB four form.

The above analysis based on the microscopic nature of the scalars present in our model has led us to select one out of two inequivalent embeddings of the  $SL(6,\mathbb{R})$  group within  $E_{7(7)}$  which we shall denote by  $SL(6,\mathbb{R})_1$  and  $SL(6,\mathbb{R})_2$ . The former corresponds to the  $A_5$  Dynkin diagram running from  $\alpha_1$  to  $\alpha_5$  while the latter to the  $A_5$  diagram running from  $\beta$  to  $\alpha_5$ . The  $SL(6,\mathbb{R})_1$  symmetry group of our N=4 Lagrangian is uniquely defined as part of the maximal subgroup  $SL(3,\mathbb{R}) \times SL(6,\mathbb{R})_1$  of  $E_{7(7)}$  (in which  $SL(3,\mathbb{R})$  represents an enhancement of  $SL(2,\mathbb{R})_{IIB}$  [60]) with respect to which the relevant  $E_{7(7)}$  representations branch as follows:

$$\mathbf{56} \ \rightarrow \ (\mathbf{1}, \mathbf{20}) + (\mathbf{3}', \mathbf{6}) + (\mathbf{3}, \mathbf{6}') \tag{8.1}$$

$$\mathbf{133} \rightarrow (\mathbf{8}, \mathbf{1}) + (\mathbf{3}, \mathbf{15}) + (\mathbf{3}', \mathbf{15}') + (\mathbf{1}, \mathbf{35}) \tag{8.2}$$

Moreover with respect to the  $SO(3) \times SO(6)$  subgroup of  $SL(3, \mathbb{R}) \times SL(6, \mathbb{R})_1$  the relevant SU(8) representations branch in the following way:

$$egin{array}{lll} 8 & 
ightarrow & (\mathbf{2},\mathbf{4}) \ 56 & 
ightarrow & (\mathbf{2},\mathbf{20}) + (\mathbf{4},\overline{\mathbf{4}}) \ 63 & 
ightarrow & (\mathbf{1},\mathbf{15}) + (\mathbf{3},\mathbf{1}) + (\mathbf{3},\mathbf{15}) \ 70 & 
ightarrow & (\mathbf{1},\mathbf{20}) + (\mathbf{3},\mathbf{15}) + (\mathbf{5},\mathbf{1}) \end{array}$$

The group  $GL(6,\mathbb{R})_2$  on the other hand is contained inside both  $SL(8,\mathbb{R})$  and  $E_{6(6)} \times O(1,1)$  as opposite to  $GL(6,\mathbb{R})_1$ . As a consequence of this it is possible in the N=8 theory to choose electric field strengths and their duals in such a way that  $SL(2,\mathbb{R}) \times GL(6,\mathbb{R})_2$  is contained in the global symmetry group of the action while this is not the case for the group  $SL(2,\mathbb{R}) \times GL(6,\mathbb{R})_1 \subset SL(3,\mathbb{R}) \times SL(6,\mathbb{R})_1$ . Indeed as it is apparent from eq. (8.1) the electric/magnetic charges in the **56** of  $E_{7(7)}$  do not branch with respect to  $SL(6,\mathbb{R})_1$  into two 28 dimensional reducible representations as it would be required in order for  $SL(6,\mathbb{R})_1$  to be contained in the symmetry group of the Lagrangian. On the other hand the group  $SL(2,\mathbb{R}) \times O(1,1) \times SO(6) \subset SL(3,\mathbb{R}) \times SL(6,\mathbb{R})_1$  can be contained in the symmetry group of the N=8 action for a certain choice of the electric and magnetic field strengths<sup>6</sup>, since with respect to it the **56** branches as follows (the grading as usual refers to the O(1,1) factor):

$$\mathbf{56} \rightarrow (\mathbf{1}, \mathbf{10})_0 + (\mathbf{1}, \overline{\mathbf{10}})_0 + (\mathbf{1}, \mathbf{6})_{+2} + (\mathbf{1}, \mathbf{6})_{-2} + (\mathbf{2}, \mathbf{6})_{+1} + (\mathbf{2}, \mathbf{6})_{-1}$$
(8.4)

In truncating to the N=4 model the charges in the  $(\mathbf{1},\mathbf{10})_0+(\mathbf{1},\overline{\mathbf{10}})_0+(\mathbf{1},\mathbf{6})_{+2}+(\mathbf{1},\mathbf{6})_{-2}$  are projected out and the symmetry group of the Lagrangian is enhanced to  $\mathrm{SL}(2,\mathbb{R})\times\mathrm{GL}(6,\mathbb{R})_1$ .

## 8.1 The masses in the N=4 theory with gauged Peccei-Quinn isometries and USp(8) weights

As we have seen, in the N=4 theory with gauged Peccei–Quinn isometries, the parameters of the effective action at the origin of the scalar manifold are encoded in the tensor  $f_{\alpha}^{IJK}$ . The condition for the origin to be an extremum of the potential, when  $\alpha=1$ , constrains the fluxes in the following way:

$$f_1^{-IJK} - if_2^{-IJK} = 0 (8.5)$$

therefore all the independent gauge parameters will be contained in the combination  $f_1^{-IJK} + if_2^{-IJK}$  transforming in the  $\mathbf{10}^{+1}$  with respect to U(4) and in its complex conjugate which belongs to the  $\overline{\mathbf{10}}^{-1}$ . Using the gamma matrices each of these two tensors can be mapped into  $4 \times 4$  symmetric complex matrices:

$$B_{AB} = (f_1^{-IJK} + if_2^{-IJK}) \Gamma^{IJK}_{AB} \in \mathbf{10}^{+1}$$

$$\overline{B}^{AB} = (f_1^{+IJK} - if_2^{+IJK}) \Gamma_{IJK}^{AB} \in \overline{\mathbf{10}}^{-1}$$
(8.6)

<sup>&</sup>lt;sup>6</sup>Actually this property holds for the whole  $SL(3,\mathbb{R}) \times SO(6)$ 

where the matrix  $B_{AB}$  is proportional to the gravitino mass matrix  $S_{AB}$ . If we denote by  $A_A{}^B$  a generic generator of  $\mathfrak{u}(4)$  we may formally build the representation of a generic  $\mathfrak{usp}(8)$  generator in the 8:

$$\begin{pmatrix} A_A{}^B & B_{AC} \\ -\overline{B}^{DB} & -A_C{}^D \end{pmatrix} \in \mathfrak{usp}(8)$$
(8.7)

The U(1) group in U(4) is generated by  $A_A{}^B = \mathrm{i}\,\delta_A{}^B$ . Under a U(4) transformation  $\mathcal{A}$  the matrix B transforms as follows:

$$B \rightarrow \mathcal{A}B\mathcal{A}^t$$
 (8.8)

Therefore using U(4) transformations the off diagonal generators in the  $\mathfrak{usp}(8)/\mathfrak{u}(4)$  can be brought to the following form

$$\begin{pmatrix} \mathbf{0} & B^{(d)} \\ -B^{(d)} & \mathbf{0} \end{pmatrix} \equiv m_i H_i$$

$$B^{(d)} = \operatorname{diag}(m_1, m_2, m_3, m_4) \quad m_i > 0$$
(8.9)

where the phases and thus the signs of the  $m_i$  were fixed using the U(1)<sup>4</sup> transformations inside U(4) and  $H_i$  denote a basis of generators of the  $\mathfrak{usp}(8)$  Cartan subalgebra. The gravitino mass matrix represents just the upper off diagonal block of the  $\mathfrak{usp}(8)$  Cartan generators in the 8.

As far as the vectors are concerned we may build the  $\mathfrak{usp}(8)$  generators in the **27** in much the same way as we did for the gravitini case, by using the  $\mathfrak{u}(4)$  generators in the **15** and in the  $\mathbf{6} + \mathbf{6}$  to form the diagonal  $15 \times 15$  and  $12 \times 12$  blocks of a  $27 \times 27$  matrix.

$$\begin{pmatrix} A_{15\times15} & K_{15\times12} \\ K_{12\times15} & A_{12\times12} \end{pmatrix} \in \mathfrak{usp}(8)$$
 (8.10)

Here  $A_{15\times15}\equiv A^{\Lambda\Sigma}_{\Gamma\Delta}$ ,  $A_{12\times12}\equiv A^{\Lambda\alpha}_{\Gamma\beta}$  while  $K_{15\times12}\equiv K^{\Lambda\Sigma|\Gamma\alpha}=f^{\Lambda\Sigma\Gamma\alpha}$  and  $K_{12\times15}=-K^T_{15\times12}$ .

The vector mass matrix is:

$$M_{\text{(vector)}}^2 \propto K_{15\times12}^t K_{15\times12} \tag{8.11}$$

By acting by means of U(4) on the rectangular matrix  $K_{15\times12}$  it is possible to reduce it to the upper off-diagonal part of a generic element of the  $\mathfrak{usp}(8)$  Cartan subalgebra:

$$K_{15\times 12} = \begin{pmatrix} a_1 & 0 & \dots & 0 \\ 0 & a_2 & 0 & \dots & 0 \\ \vdots & & \ddots & & \vdots \\ \vdots & & \ddots & \vdots \\ 0 & \dots & \dots & 0 & a_{12} \\ 0 & 0 & \dots & \dots & 0 \\ 0 & 0 & \dots & \dots & 0 \\ 0 & 0 & \dots & \dots & 0 \end{pmatrix}$$

$$a_{\ell} = |m_i \pm m_j| \quad 1 \le i < j \le 4 \; ; \; m_i \ge 0 \tag{8.12}$$

Using equation (8.11) we may read the mass eigenvalues for the vectors which are just  $a_{\ell}$ . The above argument may be extended also to the gaugini and the scalars as discussed in the next Section.

## 8.2 Duality with a truncation of the spontaneously broken N=8 theory from Scherk–Schwarz reduction

As discussed in the previous sections the microscopic interpretation of the fields in our N=4 model is achieved by its identification, at the ungauged level, with a truncation of the N=8 theory describing the field theory limit of IIB string theory on  $T^6$ . To this end the symmetry group of the N=4 action is interpreted as the  $SL(2,\mathbb{R})\times GL(6,\mathbb{R})_1$ inside the  $SL(3,\mathbb{R}) \times SL(6,\mathbb{R})_1$  maximal subgroup of  $E_{7(7)}$ , which is the natural group to consider when interpreting the four dimensional theory from the type IIB point of view, since the  $SL(3,\mathbb{R})$  factor represents an enhancement of the type IIB symmetry group  $SL(2,\mathbb{R})_{IIB} \times SO(1,1)$ , where SO(1,1) is associated to the  $T^6$  volume, while  $SL(6,\mathbb{R})_1$  is the group acting on the moduli of the  $T^6$  metric. A different microscopic interpretation of the ungauged N=4 theory would follow from the identification of its symmetry group with the group  $SL(2,\mathbb{R}) \times GL(6,\mathbb{R})_2$  contained in both  $E_{6(6)} \times O(1,1)$  and  $SL(8,\mathbb{R})$ subgroups of  $E_{7(7)}$ , where, although the  $SL(2,\mathbb{R})$  factor is still  $SL(2,\mathbb{R})_{IIB}$ , the fields are naturally interpreted in terms of dimensionally reduced M-theory since  $GL(6,\mathbb{R})_2$  this time is the group acting on the moduli of the  $T^6$  torus from D=11 to D=5. At the level of the N=4 theory the  $SL(6,\mathbb{R})_1$  and the  $SL(6,\mathbb{R})_2$  are equivalent, while their embedding in  $E_{7(7)}$  is different and so is the microscopic interpretation of the fields in the corresponding theories. Our gauged model is obtained by introducing in the model with  $SL(2,\mathbb{R}) \times GL(6,\mathbb{R})_1$  manifest symmetry a gauge group characterized by a flux tensor transforming in the  $(2,20)^{+3}$ . It is interesting to notice that if the symmetry of the ungauged action were identified with  $SL(2,\mathbb{R}) \times GL(6,\mathbb{R})_2$  formally we would have the same N=4 gauged model, but, as we are going to show, this time we could interpret it as a truncation to N=4 of the spontaneously broken N=8 theory deriving from a Scherk-Schwarz reduction from D=5. The latter, as mentioned in the introduction, is a gauged N=8 theory which is completely defined once we specify the gauge generator  $T_0 \in \mathfrak{e}_{6.6}$  to be gauged by the graviphoton arising from the five dimensional metric. The gauging (couplings, masses etc...) is therefore characterized by the 27 representation of  $T_0$ , namely by the flux matrix  $f_{r,0}^s$   $(r,s=1,\ldots,27)$ , element of  $\mathrm{Adj}(\mathfrak{e}_{6,6})=78$  [47]. Decomposing this representation with respect to  $SL(2,\mathbb{R}) \times SL(6,\mathbb{R})_2$  we have:

$$78 \rightarrow (3,1) + (1,35) + (2,20) \tag{8.13}$$

The representation (2,20) defines the gaugings in which we choose:

$$T_0 \in \frac{\mathfrak{e}_{6,6}}{\mathfrak{sl}(2,\mathbb{R}) + \mathfrak{sl}(6,\mathbb{R})_2} \tag{8.14}$$

These generators can be either compact or non-compact. However, it is known that only for compact  $T_0$  the gauged N=8 theory is a "no-scale" model with a Minkowski vacuum at the origin of the moduli space (flat gaugings). Let us consider the relevant branchings of  $E_{7(7)}$  representations with respect to  $SL(2, \mathbb{R}) \times SL(6, \mathbb{R})_2$ :

$$\begin{array}{l} {\bf 56} \ \rightarrow \ ({\bf 2},{\bf 6}')_{+1} + ({\bf 2},{\bf 6})_{-1} + ({\bf 1},{\bf 15}')_{-1} + ({\bf 1},{\bf 15})_{+1} + ({\bf 1},{\bf 1})_{-3} + ({\bf 1},{\bf 1})_{+3} \\ {\bf 133} \ \rightarrow \ ({\bf 3},{\bf 1})_0 + ({\bf 1},{\bf 1})_0 + ({\bf 1},{\bf 35})_0 + ({\bf 2},{\bf 20})_0 + ({\bf 2},{\bf 6})_{+2} + ({\bf 2},{\bf 6}')_{-2} + ({\bf 1},{\bf 15}')_{+2} + ({\bf 1},{\bf 15})_{-2} \end{array}$$

where the  $(\mathbf{2}, \mathbf{6})_{-1} + (\mathbf{1}, \mathbf{15}')_{-1}$  in the first branching denote the vectors deriving from five dimensional vectors while  $(\mathbf{1}, \mathbf{1})_{-3}$  is the graviphoton. The truncation to N = 4 is achieved

at the bosonic level by projecting the **56** into  $(\mathbf{2}, \mathbf{6}')_{+1} + (\mathbf{2}, \mathbf{6})_{-1}$  and the **133** into the adjoint of  $SL(2, \mathbb{R}) \times SO(6, 6)$ , namely  $(\mathbf{3}, \mathbf{1})_0 + (\mathbf{1}, \mathbf{1})_0 + (\mathbf{1}, \mathbf{15})_0 + (\mathbf{1}, \mathbf{15}')_{+2} + (\mathbf{1}, \mathbf{15})_{-2}$ .

If we chose  $T_0$  within  $(\mathbf{2}, \mathbf{20})$  as a  $27 \times 27$  generator it has only non vanishing entries  $f^{\Lambda\Sigma\Gamma\alpha}$  in the blocks  $(\mathbf{1}, \mathbf{15}') \times (\mathbf{2}, \mathbf{6}')$  and  $(\mathbf{2}, \mathbf{6}') \times (\mathbf{1}, \mathbf{15}')$  and inspection into the couplings of these theories shows that the truncation to N=4 is indeed consistent and that we formally get the N=4 gauged theory considered in this paper with six matter multiplets. Moreover the extremality condition  $f_1^{-IJK} - \mathrm{i} f_2^{-IJK} = 0$  discussed in the previous section coincides with the condition on  $T_0$  to be compact:

$$f_1^{-IJK} - if_2^{-IJK} = 0 \Leftrightarrow T_0 \in \frac{\mathfrak{usp}(8)}{\mathfrak{so}(2) + \mathfrak{so}(6)}$$
  $(N = 8 \text{ flat gauging})$ 

After restricting the  $(\mathbf{2}, \mathbf{20})$  generators  $T_0$  to  $\mathfrak{usp}(8)$  they will transform in the  $\mathbf{10}^{+1} + \overline{\mathbf{10}}^{-1}$  with respect to  $\mathrm{SO}(2) \times \mathrm{SO}(6)$ ,  $\mathbf{10}^{+1}$  being the same representation as the gravitino mass matrix. In the previous section the itinerary just described from the N=8 to the N=4 theory was followed backwards: we have reconstructed the  $27 \times 27 \, \mathfrak{usp}(8)$  matrix  $T_0$  starting from the symmetry  $\mathfrak{u}(4)$  of the ungauged N=4 action and the fluxes  $f_{\alpha}^{IJK}$  defining the gauging.

As far as the fermions are concerned, we note that in the N=8 theory, the gravitini in the 8 of USp(8) decompose under SO(2) × SO(6)<sub>2</sub>  $\subset$  USp(8) as

$$8 \longrightarrow 4^{+\frac{1}{2}} + \overline{4}^{-\frac{1}{2}} \tag{8.15}$$

so that a vector in the 8 can be written as

$$V^{a} = \begin{pmatrix} v_{A}^{(+\frac{1}{2})} \\ v^{A(-\frac{1}{2})} \end{pmatrix} \qquad A, B = 1, \dots 8; \quad a, b = 1, \dots 8$$
 (8.16)

From equation (8.7) we see that the off diagonal generators in the coset  $\frac{\text{USp(8)}}{\text{U(4)}}$  belong to the U(4) representation  $\mathbf{10}^{+1} + \overline{\mathbf{10}}^{-1}$  among which we find the symplectic invariant

$$\mathbf{C}_{ab} = \begin{pmatrix} \mathbf{0}_{4\times4} & \mathbb{1}_{4\times4} \\ -\mathbb{1}_{4\times4} & \mathbf{0}_{4\times4} \end{pmatrix} \tag{8.17}$$

The basic quantities which define the fermionic masses and the gradient flows equations of the N=4 model (in absence of D3-brane couplings) are the symmetric matrices

$$S_{AB} = -\frac{i}{48} (\overline{F}^{IJK-} + \overline{C}^{IJK-}) (\Gamma_{IJK})_{AB}$$
(8.18)

$$N_{AB} = -\frac{1}{48} (F^{IJK-} + C^{IJK-}) (\Gamma_{IJK})_{AB}$$
 (8.19)

that belong to the representations  $\mathbf{10}^{+1}$ ,  $\mathbf{10}^{-1}$  of U(4) respectively. Note that they have opposite U(1)<sub>R</sub> weight

$$w[S_{AB}] = -w[N_{AB}] = 1 (8.20)$$

If we indicate with  $\lambda_A^{(\overline{4})}$ ,  $\lambda_{IA}^{(\overline{20})}$  the  $\overline{\mathbf{4}}$ ,  $\overline{\mathbf{20}}$  irreducible representations of the  $\mathbf{24}$   $\lambda_A^I$  bulk gaugini, the weights of the left handed gravitini, dilatini and gaugini as given in equation (2.5) give in this case

$$w[\psi_A] = \frac{1}{2}; \quad w[\chi^A] = \frac{3}{2}; \quad w[\lambda_{IA}^{(\overline{20})}] = -\frac{1}{2}; \quad w[\lambda^{A(\overline{4})}] = -\frac{1}{2}; \quad w[\lambda_A^i] = -\frac{1}{2}$$
 (8.21)

From equations (5.13), (5.15), (5.16)–(5.24) it follows that, by suitable projection on the irreducible representations  $\overline{4}$ ,  $\overline{20}$ , the following mass matrices associated to the various bilinears either depend on the  $S_{AB}$  or  $N_{AB}$  matrices, according to the following scheme<sup>7</sup>:

$$\chi^{A(\overline{4})}\chi^{B(\overline{4})} \longrightarrow 0$$
(8.22)

$$\chi^{A(\overline{4})} \lambda_{IB}^{(\overline{20})} \longrightarrow S^{AB}$$
(8.23)

$$\chi^{A(\overline{4})} \lambda^{B(\overline{4})} \longrightarrow N_{AB}$$
(8.24)

$$\chi^{A(\overline{4})}\lambda^{B(\overline{4})} \longrightarrow N_{AB}$$

$$\lambda^{(\overline{20})}_{IA}\lambda^{(\overline{20})}_{JB} \longrightarrow S_{AB}$$

$$\lambda^{A(\overline{4})}\lambda^{B(\overline{4})} \longrightarrow S_{AB}$$

$$(8.24)$$

$$(8.25)$$

$$\lambda^{A(\overline{4})}\lambda^{B(\overline{4})} \longrightarrow S_{AB}$$

$$(8.26)$$

$$\lambda^{A(\overline{4})}\lambda^{B(\overline{4})} \longrightarrow S_{AB}$$
 (8.26)

$$\lambda^{A(4)}\lambda^{B(4)} \longrightarrow S_{AB}$$

$$\lambda^{A(\overline{4})}\lambda^{(\overline{20})}_{IB} \longrightarrow N^{AB}$$

$$\psi_{A}\chi^{(4)}_{B} \longrightarrow N^{AB}$$

$$\psi_{A}\lambda^{(4)}_{B} \longrightarrow S^{AB}$$

$$\psi_{A}\lambda^{IB(20)}_{B} \longrightarrow N_{AB}$$

$$\psi_{A}\psi_{B} \longrightarrow S^{AB}$$

$$\psi_A \chi_B^{(4)} \longrightarrow N^{AB}$$
 (8.28)

$$\psi_A \lambda_B^{(4)} \longrightarrow S^{AB}$$
 (8.29)

$$\psi_A \lambda^{IB(20)} \longrightarrow N_{AB}$$
 (8.30)

$$\psi_A \psi_B \longrightarrow S^{AB}$$
 (8.31)

$$\lambda_A^i \lambda_B^j \longrightarrow N^{AB}$$
 (8.32)

All these assignments come from the fact that  $S_{AB}$ ,  $N_{AB}$  are in the  $\mathbf{10}^{+1}$   $\mathbf{10}^{-1}$  representations of U(4) and the mass matrices must have grading opposite to the bilinear fermions, since the Lagrangian has zero grading. Indeed, from the group theoretical decomposition we find, for each of the listed bilinear fermions

$$\overline{\mathbf{4}}^{\frac{3}{2}} \times \overline{\mathbf{4}}^{\frac{3}{2}} \quad \not\supset \quad \mathbf{10}^{\pm 1} \tag{8.33}$$

$$\overline{\mathbf{4}}^{\frac{3}{2}} \times \overline{\mathbf{20}}^{-\frac{1}{2}} \supset \mathbf{10}^{+1}$$
 (8.34)

$$\overline{\mathbf{4}}^{\frac{3}{2}} \times \overline{\mathbf{4}}^{-\frac{1}{2}} \supset \overline{\mathbf{10}}^{+1}$$
 (8.35)

$$\overline{20}^{-\frac{1}{2}} \times \overline{20}^{-\frac{1}{2}} \supset 10^{-1} + \overline{10}^{-1}$$
 (8.36)

$$\overline{4}^{-\frac{1}{2}} \times \overline{4}^{-\frac{1}{2}} \supset \overline{10}^{-1}$$
 (8.37)

$$\overline{4}^{-\frac{1}{2}} \times \overline{20}^{-\frac{1}{2}} \supset 10^{-1}$$
 (8.38)

$$4^{\frac{1}{2}} \times 4^{-\frac{3}{2}} \supset 10^{-1}$$
 (8.39)

$$\mathbf{4}^{\frac{1}{2}} \times \mathbf{4}^{\frac{1}{2}} \supset \mathbf{10}^{+1}$$
 (8.40)

$$\mathbf{4}^{\frac{1}{2}} \times \mathbf{20}^{\frac{1}{2}} \supset \overline{\mathbf{10}}^{+1} \tag{8.41}$$

$$\mathbf{4}^{\frac{1}{2}} \times \mathbf{4}^{\frac{1}{2}} \supset \mathbf{10}^{+1}$$
 (8.42)

$$\mathbf{4}^{-\frac{1}{2}} \times \mathbf{4}^{-\frac{1}{2}} \supset \mathbf{10}^{-1}$$
 (8.43)

The decomposition of the  $\overline{\bf 20}^{-\frac{1}{2}} \times \overline{\bf 20}^{-\frac{1}{2}}$  implies that in principle we have both  $S_{AB}$  and  $N^{AB}$  appearing in the  $\lambda_{IA}^{(\overline{20})}\lambda_{JB}^{(\overline{20})}$  mass term. However an explicit calculation shows that the representation  $\mathbf{10}^{-1}$ , corresponding to  $N_{AB}$  is missing.

The above assignments are consistent with the Scherk-Schwarz truncation of N=8

<sup>&</sup>lt;sup>7</sup>We remind that  $(S^{AB}, N^{AB})$  have opposite U(1) weights, since they transform in the complex conjugate representation with respect to  $(S_{AB}, N_{AB})$ .

supergravity [37], where the two matrices  $Q_{5ab}$ ,  $P_{5abcd}$  contain the  $10, \overline{10}$  of SU(4) of the N=4 theory. More explicitly:

$$Q_{5ab} \longrightarrow (S_{AB}, S^{AB})$$
  
 $P_{5abcd} \longrightarrow (N_{AB}, N^{AB})$ 

which is consistent with the fact that, on the vacuum,  $P_{5abcd} = 0$  in the Scherk-Schwarz N=8 model and  $N_{AB}=0$  in our N=4 orientifold model.

Let us consider now the decomposition of the dilatino in the 48 of USp(8) under U(4). We get:

$$\chi_{abc} \longrightarrow \chi_{ABC} \oplus \chi^{AB}{}_{C} + h.c.$$
(8.44)

corresponding to

$$48 \longrightarrow \overline{4} + \overline{20} + 4 + 20 \tag{8.45}$$

We may then identify the chiral dilatino and gaugino as follows:

$$\chi^{A} = \epsilon^{ABCD} \chi_{BCD}; \qquad \lambda_{C}^{I(\overline{20})} = (\Gamma^{I})_{AB} \chi^{AB}_{C}$$
 (8.46)

Moreover the decomposition  $\mathbf{8} \longrightarrow \mathbf{4}^{+\frac{1}{2}} + \overline{\mathbf{4}}^{-\frac{1}{2}}$  identifies  $\mathbf{4}^{+\frac{1}{2}}$  with  $\lambda_A^{I(4)}$  and  $\overline{\mathbf{4}}^{-\frac{1}{2}}$  with  $\lambda^{IA(\overline{4})}$  as they come from the **C**-trace part or the threefold antisymmetric product  $8 \times 8 \times 8$ . These results are consistent with the explicit reduction appearing in reference [37]. Indeed the mass term of reference [37] are of the following form <sup>8</sup>

$$Q_{5ab}\bar{\psi}_{\mu}^{'a}\gamma^{\mu\rho}\psi_{\rho}^{'b} \tag{8.47}$$

$$Q_{5ab}\bar{\psi}_{\mu}^{'a}\gamma^{\mu\rho}\psi_{\rho}^{'b}$$

$$Q_{5ab}\bar{\zeta}^{'a}\zeta^{'b}$$

$$Q_{5ab}\bar{\psi}_{\mu}^{'a}\gamma^{\mu}\zeta^{'b}$$

$$(8.48)$$

$$(8.49)$$

$$Q_{5ab}\bar{\psi}_{\mu}^{'a}\gamma^{\mu}\zeta^{'b} \tag{8.49}$$

$$Q_{5a}^{\phantom{5a}e}\bar{\chi}^{\prime abc}\chi^{\prime}_{\phantom{\prime}ebc} \tag{8.50}$$

$$Q_{5a}^{\phantom{5a}e}\bar{\chi}'^{abc}\chi'_{\phantom{bc}ebc}$$

$$P_{5}^{abcd}\bar{\psi}'_{\mu a}\gamma^{\mu}\gamma^{5}\chi'_{\phantom{bcd}}$$

$$(8.50)$$

$$(8.51)$$

$$P_5^{abcd} \overline{\zeta}_a' \gamma^5 \chi_{bcd}' \tag{8.52}$$

The term (8.47) gives rise to the mass term of the gravitino  $S^{AB}\bar{\psi}_{A\mu}\gamma^{\mu\nu}\psi_{B\nu}$ ; the term  $N^{AB}\psi_{A\nu}\gamma^{\mu}\chi_{B}$  and the term  $Z_{A}^{I}{}^{B}\bar{\psi}_{A\mu}\gamma^{\mu}\lambda^{IB}$  are obtained by reduction of the structures (8.49), (8.51) via the decompositions (8.39), (8.40). The mass term of the bulk gaugini  $T_{LI}^{AB}\bar{\lambda}_A^I\lambda_B^J$  is reconstructed from the terms (8.48), (8.50), (8.52) through the decompositions (8.37), (8.36), (8.38). Finally, the mass term  $Q_A^{I}{}^B \bar{\chi}^A \lambda_B^I$  is obtained by reducing equation (8.50), (8.52) via the decomposition (8.48), (8.50).

In conclusion we see that our theory can be thought as a truncation of the Scherk-Schwarz N=8 supergravity. Once the Goldstino  $\bar{\lambda}^{A(\overline{4})}$  is absorbed to give mass to the gravitino  $\psi_{A\mu}$  the spin  $\frac{1}{2}$  mass matrix is given by the entries  $\left(\chi\chi,\,\chi\lambda^{(\overline{20})},\,\lambda^{(\overline{20})}\lambda^{(\overline{20})}\right)$ . Therefore the full spin  $\frac{1}{2}$  mass spectrum is the truncation of the Scherk–Schwarz N=8 spin  $\frac{1}{2}$  to this sectors.

This justifies the results for the mass spectrum given in Section 7. Analogous considerations can be done for the scalar sector.

<sup>&</sup>lt;sup>8</sup>Note that the terms (8.48), (8.49) do not appear explicitly in the Lagrangian of reference [37] but they would appear after diagonalization of the fermionic kinetic terms.

We conclude by arguing that there is a duality between two microscopically different theories:

[type IIB on an orientifold with fluxes] 
$$\leftrightarrow$$
  $\begin{bmatrix} N=4 \text{ truncation of } N=8 \text{ theories} \\ \text{spontaneously broken à la Scherk-Schwarz} \end{bmatrix}$ 

since they are described by the same N=4 four dimensional effective field theory.

Finally we consider the fermionic bilinear involving D3-brane gaugini  $\lambda_A^i$ . From the structure of the matrices  $W_{iA}^{\ B}$ ,  $R_{iA}^{\ B}$ ,  $V_{AB}^{Ii}$ , equations (5.19), (5.21), (5.24), we notice that they vanish when the D3-brane coordinates commute (i.e. the scalars  $q_i^I$  are in the Cartan subalgebra of G).

The diagonal mass  $U_{AB}^{ij}$  (5.23) has a gravitational part  $\delta^{ij}N_{AB}$  which vanishes on the vacuum while the second term is non vanishing for those gaugini which are not in the Cartan subalgebra of G. Indeed, for G = SU(N), there are exactly N(N-1) ( $\frac{1}{2}$  BPS) vector multiplets which become massive when SU(N) is spontaneously broken to  $U(1)^{N-1}$ .

# Appendix A: The solution of the Bianchi Identities and the supersymmetry transformation laws.

In this Appendix we describe the geometric approach for the derivation of the N=4 supersymmetry transformation laws of the physical fields.

The first step to perform is to extend the physical fields to superfields in N=4 superspace: that means that the space–time 1-forms  $\omega^{a\,b},\,V^a,\psi^A,\,\psi_A,\,A_{\Lambda\alpha},\,A_i$  and the space–time zero–forms  $\chi^A,\,\chi_A,\,\lambda_A^I,\,\lambda^{IA},\,\lambda_A^i,\,\lambda^{IA},\,L^\alpha,\,E_{\Lambda I},\,B^{\Lambda\Sigma},\,a_i^\Lambda$  are promoted to one–superforms and zero–superforms in N=4 superspace, respectively.

As a consequence the superforms must depend on the superspace coordinates  $\{x^{\mu}; \theta_{A}^{\alpha}\}$  (where  $x^{\mu}$ ,  $\mu = 1, 2, 3, 4$  are the ordinary space–time coordinates and  $\theta_{A}^{\alpha}$ ,  $\alpha = 1, 2, 3, 4$ , A = 1, 2, 3, 4 are anticommuting fermionic coordinates ) in such a way that projected on the space–time submanifold (i.e. setting  $\theta_{A}^{\alpha} = 0$ ,  $d\theta_{A}^{\alpha} = 0$ ) they correspond to the ordinary physical fields.

A basis of one-forms on the superspace is given by  $\{V^a, \psi_A^{\alpha}\}$ , a = 1, 2, 3, 4; here  $V^a$  are the vierbein, and  $\psi_A^{\alpha}$  are the fermionic vielbein identified with the gravitini fields.

The appropriate definition for the super–curvatures (or super–field strengths)of the superfield p–forms in the N=4 superspace is<sup>9</sup> as follows (we omit for simplicity the sign of wedge product):

$$R^{ab} = d\omega^{ab} - \omega_c^a \omega^{cb} \tag{A.1}$$

$$T^a = \mathcal{D}V^a - i\bar{\psi}_A\gamma^a\psi^A = 0 \tag{A.2}$$

$$F_{\Lambda\alpha} = dA_{\Lambda\alpha} - \frac{1}{2} L_{\alpha} E_{\Lambda}^{I}(\Gamma_{I})^{AB} \bar{\psi}_{A} \psi_{B} - \frac{1}{2} \overline{L}_{\alpha} E_{\Lambda}^{I}(\Gamma_{I})_{AB} \bar{\psi}^{A} \psi^{B}$$
(A.3)

$$F_{i} = dA_{i} - \frac{1}{2}L_{2}q_{i}^{I}(\Gamma_{I})^{AB}\bar{\psi}_{A}\psi_{B} - \frac{1}{2}\overline{L}_{2}q_{i}^{I}(\Gamma_{I})_{AB}\bar{\psi}^{A}\psi^{B}$$
(A.4)

$$\rho_A = \mathcal{D}\psi_A + \frac{1}{2}q\psi_A - 2Q_A^B\psi_B \tag{A.5}$$

$$\nabla \chi^A = \mathcal{D}\chi^A - \frac{3}{2}q\chi^A - 2Q_B^A\chi^B \tag{A.6}$$

$$\nabla \lambda_{IA} = \mathcal{D}\lambda_{IA} - \frac{1}{2}q\lambda_{IA} - 2Q_A^B\lambda_{IB} + \omega_2^{IJ}\lambda_{JA}$$
(A.7)

$$\nabla \lambda_{iA} = \mathcal{D}\lambda_{iA} - \frac{1}{2}q\lambda_{iA} - 2Q_A^B\lambda_{iB} \tag{A.8}$$

$$p = -i\epsilon_{\alpha\beta}L^{\alpha}dL^{\beta} \tag{A.9}$$

$$P^{IJ} = -\frac{1}{2} (EdE^{-1} + dE^{-1}E)^{IJ} + \frac{1}{2} \{ E[\nabla B - \frac{1}{2} (\nabla a \, a^T - a \, \nabla a^T)]E \}^{IJ}$$
 (A.10)

$$P^{Ii} = \frac{1}{2} E_{\Lambda}^{I} \nabla a^{\Lambda i} \tag{A.11}$$

 $\nabla$  is the covariant derivative with respect to all the connections that act on the field, including the gauge contribution, while  $\mathcal{D}$  is the Lorentz covariant derivative acting on a generic vector  $A^a$  and a generic spinor  $\theta$  respectively as follows

$$\mathcal{D}A^a \equiv dA^a - \omega^{ab}A_b; \qquad \mathcal{D}\theta \equiv d\theta - \frac{1}{4}\omega^{ab}\gamma_{ab}\theta$$
 (A.12)

The coefficients appearing in front of the U(1) connection q correspond to the different U(1) weights of the fields as shown in equation (2.5).

 $Q_B^A$  is the R-symmetry SU(4)<sub>1</sub> connection, that in terms of the gauged SO(6)<sub>1</sub> connection  $\omega_1^{IJ}$  reads as  $Q_B^A = \frac{1}{8}(\Gamma_{IJ})_A{}^B\omega_1^{IJ}$  (see Appendix D for details).

Equation (A.2) is a superspace constraint imposing the absence of supertorsion, on the N=4 superspace.

Note that the definition of the "curvatures" has been chosen in such a way that in absence

<sup>&</sup>lt;sup>9</sup>Here and in the following by "curvatures" we mean not only two–forms, but also the one–forms defined as covariant differentials of the zero–form superfields

of vector multiplets the equations by setting  $R^{ab} = T^a = \rho^A = \rho_A = F^I = 0$ , I = 1, ..., 6 give the Maurer-Cartan equations of the N = 4 Poincaré superalgebra dual to the N = 4 superalgebra of (anti)-commutators, (the 1-forms  $\omega^{ab}, V^a, \psi^A, \psi_A, A^I$  are dual to the corresponding generators of the supergroup).

By d-differentiating the supercurvatures definition (A.1)–(A.11), one obtains the Bianchi identities that are their integrability conditions:

$$\begin{split} \mathcal{R}^{ab}V_b + i\bar{\psi}_A\gamma^a\rho^A + i\bar{\psi}^A\gamma^a\rho_A &= 0 \\ \mathcal{D}R^{ab} &= 0 \\ \nabla F_{\Lambda\alpha} - L_\alpha E_\Lambda^I(\Gamma_I)^{AB}\bar{\psi}_A\rho_B - \overline{L}_\alpha E_\Lambda^I(\Gamma_I)_{AB}\bar{\psi}^A\rho^B + \frac{1}{2}\nabla L_\alpha E_\Lambda^I(\Gamma_I)^{AB}\bar{\psi}_A\psi_B + \\ + \frac{1}{2}\nabla\overline{L}_\alpha E_\Lambda^I(\Gamma_I)_{AB}\bar{\psi}^A\psi^B + \frac{1}{2}L_\alpha\nabla E_\Lambda^I(\Gamma_I)^{AB}\bar{\psi}_A\psi_B + \frac{1}{2}\overline{L}_\alpha\nabla E_\Lambda^I(\Gamma_I)_{AB}\bar{\psi}^A\psi^B &= 0 \\ \nabla F_i - L_2q_i^I(\Gamma_I)^{AB}\bar{\psi}_A\rho_B - \overline{L}_2q_i^I(\Gamma_I)_{AB}\bar{\psi}^A\rho^B + \frac{1}{2}\nabla L_2q_i^I(\Gamma_I)^{AB}\bar{\psi}_A\psi_B + \\ + \frac{1}{2}\nabla\overline{L}_2q_i^I(\Gamma_I)_{AB}\bar{\psi}^A\psi^B + \frac{1}{2}L_2\nabla q_i^I(\Gamma_I)^{AB}\bar{\psi}_A\psi_B + \frac{1}{2}\overline{L}_2\nabla q_i^I(\Gamma_I)_{AB}\bar{\psi}^A\psi^B &= 0 \\ \nabla \rho_A + \frac{1}{4}\mathcal{R}^{ab}\gamma_{ab}\psi_A - \frac{1}{2}R\psi_A + 2R_A^B\psi_B &= 0 \\ \nabla^2\chi^A + \frac{1}{4}\mathcal{R}^{ab}\gamma_{ab}\chi^A + \frac{3}{2}R\chi^A + 2R_B^A\chi^B &= 0 \\ \nabla^2\lambda_{IA} + \frac{1}{4}\mathcal{R}^{ab}\gamma_{ab}\lambda_{IA} + \frac{1}{2}R\lambda_{IA} + 2R_A^B\lambda_{IB} - R_{2IJ}\lambda_A^J &= 0 \\ \nabla^D = 0 \\ \nabla P &= 0 \\ \nabla P^{IJ} + \frac{1}{2}E_\Lambda^I(f^{\Lambda\Sigma\Gamma\alpha}F_{\Gamma\alpha} + c^{ijk}a_i^\Lambda a_k^\Sigma F_j)E_\Sigma^J &= 0 \\ \nabla P^{Ii} + \frac{1}{2}a_k^\Lambda E_\Lambda^Ic^{ijk}F_j &= 0 \end{split} \tag{A.13}$$

Here  $R_A^B = \frac{1}{8} (\Gamma_{IJ})_A{}^B R_1^{IJ}$  is the gauged SU(4) curvature with

$$R_1^{IJ} = d\omega_1^{IJ} + \omega^{IK} \wedge \omega_K^{J} - \frac{1}{2} E_{\Lambda}^{I} f^{\Lambda \Sigma \Gamma \alpha} F_{\Gamma \alpha} E_{\Sigma}^{J}$$
 (A.14)

and R = dq is the U(1) curvature.

The solution can be obtained as follows: first of all one requires that the expansion of the curvatures along the intrinsic p-forms basis in superspace namely:  $V^a, V^a \wedge V^b, \psi, \psi \wedge V^b, \psi \wedge \psi$ , is given in terms only of the physical fields (rheonomy). This insures that no new degree of freedom is introduced in the theory.

Secondly one writes down such expansion in a form which is compatible with all the symmetries of the theory, that is: covariance under U(1) and  $SO_d(6) \otimes SO(n)$ , Lorentz transformations and reparametrization of the scalar manifold. Besides it is very useful to take into account the invariance under the following rigid rescalings of the fields (and their corresponding curvatures):

$$(\omega^{ab}, A_{\Lambda\alpha}, E_{\Lambda}^I, B^{\Lambda\Sigma}, a_i^{\Lambda}) \to (\omega^{ab}, A_{\Lambda\alpha}, E_{\Lambda}^I, B^{\Lambda\Sigma}, a_i^{\Lambda})$$
 (A.15)

$$V^a \to \ell V^a$$
 (A.16)

$$(\psi^A, \psi_A) \to \ell^{\frac{1}{2}}(\psi^A, \psi_A) \tag{A.17}$$

(A.27)

$$(\lambda_{iA}, \lambda_A^I, \chi^A) \to \ell^{-\frac{1}{2}}(\lambda_{iA}, \lambda_A^I, \chi^A) \tag{A.18}$$

Indeed the first three rescalings and the corresponding ones for the curvatures leave invariant the definitions of the curvatures and the Bianchi identities. The last one follows from the fact that in the solution for the  $\sigma$  – model vielbeins p,  $P^{IJ}$ ,  $P^{Ii}$  the spin  $\frac{1}{2}$ fermions must appear contracted with the gravitino 1-form.

Performing all the steps one finds the final parametrizations of the superspace curvatures, namely:

$$F_{\Lambda\alpha} = \mathcal{F}_{\Lambda\alpha}^{ab} V_a V_b + i (\overline{L}_{\alpha} E_{\Lambda}^I (\Gamma_I)^{AB} \overline{\chi}_A \gamma_a \psi_B + L_{\alpha} E_{\Lambda}^I (\Gamma_I)_{AB} \overline{\chi}^A \gamma_a \psi^B + \\ + L_{\alpha} E_{\Lambda}^I \overline{\lambda}_I^A \gamma_a \psi_A + \overline{L}_{\alpha} E_{\Lambda}^I \overline{\lambda}_{IA} \gamma_a \psi^A) V^a \qquad (A.19)$$

$$F_i = \mathcal{F}_i^{ab} V_a V_b + i (\overline{L}_2 q_i^I (\Gamma_I)^{AB} \overline{\chi}_A \gamma_a \psi_B + L_2 q_i^I (\Gamma_I)_{AB} \overline{\chi}^A \gamma_a \psi^B + \\ + L_2 q_i^I \overline{\lambda}_I^A \gamma_a \psi_A + \overline{L}_2 q_i^I \overline{\lambda}_{IA} \gamma_a \psi^A + 2L_2 \overline{\lambda}_i^A \gamma_a \psi_A + 2\overline{L}_2 \overline{\lambda}_{iA} \gamma_a \psi^A) V^a \qquad (A.20)$$

$$\rho_A = \rho_{Aab} V^a V^b - \overline{L}^{\alpha} (E^{-1})_I^{\Lambda} (\Gamma^I)_{AB} \mathcal{F}_{\Lambda\alpha}^{-ab} \gamma_b \psi^B V_a + \\ + \epsilon_{ABCD} \chi^B \overline{\psi}^C \psi^D + S_{AB} \gamma_a \psi^B V^a \qquad (A.21)$$

$$\nabla \chi^A = \nabla \chi_a^A V^a + \frac{i}{2} \overline{p}_a \gamma^a \psi^A + \frac{i}{4} \overline{L}^{\alpha} (E^{-1})_I^{\Lambda} (\Gamma^I)^{AB} \mathcal{F}_{\Lambda\alpha}^{-ab} \gamma_{ab} \psi_B + N^{AB} \psi_B \qquad (A.22)$$

$$\nabla \lambda_{IA} = \nabla \lambda_{IAa} V^a + \frac{i}{2} (\Gamma_I)_{AB} P_a^{II} \gamma^a \psi^B - \frac{i}{2} L^{\alpha} (E^{-1})_I^{\Lambda} \mathcal{F}_{\Lambda\alpha}^{-ab} \gamma_{ab} \psi_A + Z_{IA}^B \psi_B (A.23)$$

$$\nabla \lambda_{iA} = \nabla \lambda_{iAa} V^a + \frac{i}{2} (\Gamma_I)_{AB} P_a^{II} \gamma^a \psi^B - \frac{1}{4} \overline{L}_2 q_i^I (E^{-1})_I^{\Lambda} \mathcal{F}_{\Lambda\alpha}^{-ab} \gamma_{ab} \psi_A + \\ + \frac{1}{4} \overline{L}_2 \mathcal{F}_i^{-ab} \gamma_{ab} \psi_A + W_{iA}^B \psi_B \qquad (A.24)$$

$$p = p_a V^a + 2 \overline{\chi}_A \psi^A \qquad (A.25)$$

$$P^{IJ} = P_a^{IJ} V^a + (\Gamma^I)^{AB} \overline{\lambda}_A^I \psi_B + (\Gamma^I)_{AB} \overline{\lambda}_I^{IA} \psi^B \qquad (A.26)$$

$$P^{II} = P_a^{II} V^a + (\Gamma^I)^{AB} \overline{\lambda}_A^I \psi_B + (\Gamma^I)_{AB} \overline{\lambda}_I^{IA} \psi^B \qquad (A.27)$$

The previous parametrizations are given up to three fermions terms, except equation (A.21) where the term with two gravitini has been computed; in fact this term is in principle involved in the computation of the gravitino shift but by explicit computation its contribution vanishes.

As promised the solution for the curvatures is given as an expansion along the 2-form basis  $(V \wedge V, V \wedge \psi, \psi \wedge \psi)$  or the 1-form basis  $(V, \psi)$  with coefficients given in terms of the physical fields.

It is important to stress that the components of the field strengths along the bosonic vielbeins are not the space-time field strengths since  $V^a = V^a_\mu dx^\mu + V^a_\alpha d\theta^\alpha$  where  $(V_{\mu}^{a}, V_{\alpha}^{a})$  is a submatrix of the super-vielbein matrix  $E^{I} \equiv (\overset{\mu}{V}{}^{a}, \psi)$ . The physical field strengths are given by the expansion of the forms along the  $dx^{\mu}$ -differentials and by restricting the superfields to space-time ( $\theta = 0$  component). For example, from the parametrization (A.19), expanding along the  $dx^{\mu}$ -basis one finds:

$$F^{\Lambda}_{\mu\nu} = F^{\Lambda}_{ab}V^{a}_{[\mu}V^{b}_{\nu]} + i\overline{L}_{\alpha}E^{I}_{\Lambda}(\Gamma_{I})^{AB}\bar{\chi}_{A}\gamma_{[\mu}\psi_{\nu]B} + iL_{\alpha}E^{I}_{\Lambda}(\Gamma_{I})_{AB}\bar{\chi}^{A}\gamma_{[\mu}\psi^{B}_{\nu]} + iL_{\alpha}E^{I}_{\Lambda}\bar{\lambda}^{A}_{I}\gamma_{[\mu}\psi_{\nu]A} + i\overline{L}_{\alpha}E^{I}_{\Lambda}\bar{\lambda}_{IA}\gamma_{[\mu}\psi^{A}_{\nu]}$$
(A.28)

where  $F_{\mu\nu}^{\Lambda}$  is defined by the expansion of eq. (A.3) along the  $dx^{\mu}$ -differentials. When all the superfields are restricted to space—time we may treat the  $V_{\mu}^{a}$  vielbein as the usual 4-dimensional invertible matrix converting intrinsic indices in coordinate indices and we see that the physical field-strength  $\mathcal{F}_{\Lambda\alpha\mu\nu}$  differs from  $F_{\Lambda\alpha\,ab}V^a_{[\mu}V^b_{\nu]}\equiv \tilde{F}_{\Lambda\alpha\mu\nu}$  by a set of spinor currents ( $\tilde{F}_{\Lambda\alpha\mu\nu}$  is referred to as the supercovariant field–strength).

Analougous considerations hold for the other field-strengths components along the bosonic vielbeins.

Note that the solution of the Bianchi identities also implies a set of differential constraints on the components along the bosonic vielbeins which are to be identified, when the fields are restricted to space—time only, with the equations of motion of the theory. Indeed the analysis of the Bianchi identities for the fermion fields give such equations (in the sector containing the 2-form basis  $\bar{\psi}_A \gamma^a \psi^A$ ). Further the superspace derivative along the  $\psi_A$  ( $\psi^A$ ) directions, which amounts to a supersymmetry transformation, yields the equations of motion of the bosonic fields. Indeed the closure of the Bianchi identities is equivalent to the closure of the N=4 supersymmetry algebra on the physical fields and we know that in general such closure implies the equations of motion.

The determination of the superspace curvatures enables us to write down the N=4SUSY transformation laws. Indeed we recall that from the superspace point of view a supersymmetry transformation is a Lie derivative along the tangent vector:

$$\epsilon = \bar{\epsilon}^A \, \vec{D}_A + \bar{\epsilon}_A \, \vec{D}^A \tag{A.29}$$

where the basis tangent vectors  $\vec{D}_A$ ,  $\vec{D}^A$  are dual to the gravitino 1-forms:

$$\vec{D}_A(\psi^B) = \vec{D}^A(\psi_B) = \mathbf{1} \tag{A.30}$$

and 1 is the unit in spinor space.

Denoting by  $\mu^I$  and  $R^I$  the set of one-forms  $(V^a, \psi_A, \psi^A, A_{\Lambda\alpha}, A_i)$  and of two-forms  $\left(T^a=0,\,\rho_A,\,\rho^A,\,F_{\Lambda\alpha},F_i\right)$  respectively, one has:

$$\ell \mu^{I} = (i_{\epsilon}d + di_{\epsilon}) \mu^{I} \equiv (D\epsilon)^{I} + i_{\epsilon}R^{I}$$
(A.31)

where D is the derivative covariant with respect to the N=4 Poincaré superalgebra and  $i_{\epsilon}$  is the contraction operator along the tangent vector  $\epsilon$ .

In our case:

$$(D\epsilon)^{a} = -i \left( \bar{\psi}_{A} \gamma^{a} \epsilon^{A} + \bar{\psi}^{A} \gamma^{a} \epsilon_{A} \right)$$

$$(D\epsilon)^{\alpha} = \nabla \epsilon^{\alpha}$$

$$(A.32)$$

$$(D\epsilon)^{\alpha} = \nabla \epsilon^{\alpha} \tag{A.33}$$

$$(D\epsilon)_{\Lambda\alpha} = (D\epsilon)_i = 0 \tag{A.34}$$

(here  $\alpha$  is a spinor index)

For the 0-forms which we denote shortly as  $\nu^{I}$  we have the simpler result:

$$\ell_{\epsilon} = i_{\epsilon} d\nu^{I} = i_{\epsilon} \left( \nabla \nu^{I} - connection \, terms \right) \tag{A.35}$$

Using the parametrizations given for  $R^I$  and  $\nabla \nu^I$  and identifying  $\delta_{\epsilon}$  with the restriction of  $\ell_{\epsilon}$  to space-time it is immediate to find the N=4 susy laws for all the fields. The explicit formulae are given by the equations (5.25).

## Appendix B: Derivation of the space time Lagrangian from the geometric approach

In Appendix A we have seen how to reconstruct the N=4 susy transformation laws of the physical fields from the solution of the Bianchi identities in superspace.

In principle, since the Bianchi identities imply the equations of motion, the Lagrangian could also be completely determined. However this would be a cumbersome procedure.

In this Appendix we give a short account of the construction of the Lagrangian on space—time from a geometrical Lagrangian in superspace. Note that while the solution of the Bianchi identities is completely equivalent to the ordinary "Superspace approach" (apart from notations and a different emphasis on the group—theoretical structure), the geometric approach for the construction of the Lagrangian is completely different from the usual superspace approach via integration in superspace

In the geometric (rheonomic) approach the superspace action is a 4-form in superspace integrated on a 4-dimensional (bosonic) hypersurface  $\mathcal{M}^4$  locally embedded in superspace

$$\mathcal{A} = \int_{\mathcal{M}^4 \subset \mathcal{SM}} \mathcal{L} \tag{B.1}$$

where  $\mathcal{SM}$  is the superspace manifold. Provided we do not introduce the Hodge duality operator in the construction of  $\mathcal{L}$  the equations of motions derived from the generalized variational principle  $\delta \mathcal{A} = 0$  are 3–form or 4–form equations independent from the particular hypersurface  $\mathcal{M}^4$  on which we integrate and they are therefore valid in all superspace. (Indeed in the variational principle we have also to vary the hypersurface which can always compensated by a diffeomorphism of the fields if the Lagrangian is written olnly in terms of differential forms).

These superspace equations of motion can be analyzed along the 3-form basis. The components of the equations obtained along bosonic vielbeins give the differential equations for the fields which, identifying  $\mathcal{M}^4$  with space—time, are the ordinary equations of motion of the theory. The components of the same equations along 3-forms containing at least one gravitino ("outer components") give instead algebraic relations which identify the components of the various "supercurvatures" in the outer directions in terms of the physical fields along the bosonic vierbeins (rhenomy principle).

Actually if we have already solved the Bianchi identities this requirement is equivalent to identify the outer components of the curvatures obtained from the variational principle with those obtained from the Bianchi identities.

There are simple rules which can be used in order to write down the most general Lagrangian compatible with this requirement.

The implementation of these rules is described in detail in the literature [59] to which we refer the interested reader. Actually one writes down the most general 4-form as a sum of terms with indeterminate coefficients in such a way that  $\mathcal{L}$  be a scalar with respect to all the symmetry transformations of the theory (Lorentz invariance, U(1), SO(6)<sub>d</sub>  $\otimes$  SO(n) invariance, invariance under the rescaling (A.18). Varying the action and comparing the outer equations of motion with the actual solution of the Bianchi identities one then fixes all the undetermined coefficients.

Let us perform the steps previously indicated. The most general Lagrangian has the following form: (we will determine the complete Lagrangian up to four fermion terms):

$$\mathcal{L}_{kinetic} = \mathcal{R}^{ab}V^{c}V^{d}\epsilon_{abcd} + a_{1}(\bar{\psi}_{A}\gamma_{a}\rho^{A}V^{a} - \bar{\psi}^{A}\gamma_{a}\rho_{A}V^{a}) + [a_{2}(\bar{\chi}^{A}\gamma^{a}\nabla\chi_{A} + \bar{\chi}_{A}\gamma^{a}\nabla\chi^{A}) + a_{3}(\bar{\lambda}^{IA}\gamma^{a}\nabla\lambda_{IA} + \bar{\lambda}_{IA}\gamma^{a}\nabla\lambda^{IA}) + a_{6}(\bar{\lambda}^{iA}\gamma^{a}\nabla\lambda_{iA} + \bar{\lambda}_{iA}\gamma^{a}\nabla\lambda^{iA})V^{b}V^{c}V^{d}\epsilon_{abcd} + a_{4}[\mathbf{p}^{a}(\bar{p} - 2\bar{\chi}^{A}\psi_{A}) + \mathbf{\bar{p}}^{a}(p - 2\bar{\chi}_{A}\psi^{A}) - \frac{1}{4}\mathbf{\bar{p}}_{f}\mathbf{p}^{f}V^{a}]V^{b}V^{c}V^{d}\epsilon_{abcd} + a_{5}[\mathbf{P}_{a}^{IJ}(P^{IJ} - (\Gamma^{I})^{AB}\bar{\lambda}_{A}^{J}\psi_{B} - (\Gamma^{I})_{AB}\bar{\lambda}^{JA}\psi^{B}) - \frac{1}{8}\mathbf{P}_{f}^{IJ}\mathbf{P}^{IJf}V^{a}]V^{b}V^{c}V^{d}\epsilon_{abcd} + a_{7}[\mathbf{P}_{a}^{Ii}(P^{Ii} - (\Gamma^{I})^{AB}\bar{\lambda}_{A}^{i}\psi_{B} - (\Gamma^{I})_{AB}\bar{\lambda}^{iA}\psi^{B}) - \frac{1}{8}\mathbf{P}_{f}^{Ii}\mathbf{P}^{Iif}V^{a}]V^{b}V^{c}V^{d}\epsilon_{abcd} + a_{7}[\mathbf{P}_{a}^{Ii}(P^{Ii} - (\Gamma^{I})^{AB}\bar{\lambda}_{A}^{i}\psi_{B} - (\Gamma^{I})_{AB}\bar{\lambda}^{iA}\psi^{B}) - \frac{1}{8}\mathbf{P}_{f}^{Ii}V^{a}}V^{b}V^{c}V^{d}\psi^{B} + a_{7}[\mathbf{P}_{a}^{Ii}(P^{Ii} - (\Gamma^{I})^{AB}\bar{\lambda}_{A}^{i}\psi_{B} - (\Gamma^{I})_{AB}\bar{\lambda}^{iA}\psi^{A}) - \frac{1}{8}\mathbf{P}_{f}^{Ii}V^{a}}V^{b}V^{c}V^{d}\psi^{B} + a_{7}[\mathbf{P}_{a}^{Ii}(P^{Ii} - (\Gamma^{I})^{AB}\bar{\lambda}_{A}^{i}\psi^{A} - (\Gamma^{I})_{AB}\bar{\lambda}^{iA}\psi^{A} + a_{7}[\mathbf{P}_{a}^{Ii}(P^{Ii} - (\Gamma^{I})^{AB}\bar{\lambda}^{iA}\psi^{A} - (\Gamma^{I})_{AB}\bar{\lambda}^{iA}\psi^{A} + a_{7}[\mathbf{P}_{a}^{Ii}(P^{Ii} - (\Gamma^{I})^{AB}\bar{\lambda}^{iA}\psi^{A} - (\Gamma^{I})_{AB}\bar{\lambda}^{iA}\psi^{A} - (\Gamma^{I}$$

$$\mathcal{L}_{Pauli} = b_{1}[p\bar{\chi}^{A}\gamma_{ab}\psi_{A} - \bar{p}\bar{\chi}_{A}\gamma_{ab}\psi^{A}]V^{a}V^{b} + \\ +b_{2}P^{IJ}[(\Gamma^{I})^{AB}\bar{\lambda}_{A}^{J}\gamma_{ab}\psi_{B} - (\Gamma^{I})_{AB}\bar{\lambda}^{JA}\gamma_{ab}\psi^{B})V^{a}V^{b} + \\ +b_{3}P^{Ii}[(\Gamma^{I})^{AB}\bar{\lambda}_{A}^{i}\gamma_{ab}\psi_{B} - (\Gamma^{I})_{AB}\bar{\lambda}^{iA}\gamma_{ab}\psi^{B})V^{a}V^{b} + \\ +F_{\Lambda\alpha}[c_{1}(\overline{N}^{\Lambda\alpha\Sigma\beta}L_{\beta}E_{\Sigma}^{I}(\Gamma_{I})^{AB}\bar{\psi}_{A}\psi_{B} + N^{\Lambda\alpha\Sigma\beta}\overline{L}_{\beta}E_{\Sigma}^{I}(\Gamma_{I})_{AB}\bar{\psi}^{A}\psi^{B}) + \\ +c_{2}(N^{\Lambda\alpha\Sigma\beta}L_{\beta}E_{\Sigma}^{I}(\Gamma_{I})^{AB}\bar{\chi}_{A}\gamma_{a}\psi_{B} + \overline{N}^{\Lambda\alpha\Sigma\beta}L_{\beta}E_{\Sigma}^{I}(\Gamma_{I})_{AB}\bar{\chi}^{A}\gamma_{a}\psi^{B})V^{a} + \\ +c_{3}(N^{\Lambda\alpha\Sigma\beta}L_{\beta}E_{\Sigma}^{I}\bar{\lambda}_{A}^{I}\gamma_{a}\psi_{A} + \overline{N}^{\Lambda\alpha\Sigma\beta}\overline{L}_{\beta}\bar{\lambda}_{IA}\gamma_{a}\psi^{A})V^{a}] + \\ +F_{\Lambda\alpha}[c_{4}(\overline{N}^{\Lambda\alpha i}L_{2}q_{i}^{I}(\Gamma_{I})^{AB}\bar{\psi}_{A}\psi_{B} + N^{\Lambda\alpha i}\overline{L}_{2}q_{i}^{I}(\Gamma_{I})_{AB}\bar{\psi}^{A}\psi^{B}) + \\ +c_{5}(N^{\Lambda\alpha i}L_{2}q_{i}^{I}\bar{\lambda}_{A}^{I}\gamma_{a}\psi_{A} + \overline{N}^{\Lambda\alpha i}\overline{L}_{2}q_{i}^{I}(\Gamma_{I})_{AB}\bar{\chi}^{A}\gamma_{a}\psi^{B})V^{a} + \\ +c_{6}(N^{\Lambda\alpha i}L_{2}q_{i}^{I}\bar{\lambda}_{A}^{I}\gamma_{a}\psi_{A} + \overline{N}^{\Lambda\alpha i}\overline{L}_{2}q_{i}^{I}\bar{\lambda}_{IA}\gamma_{a}\psi^{A})V^{a} + \\ +c_{7}(N^{\Lambda\alpha i}L_{2}\bar{\lambda}_{i}^{A}\gamma_{a}\psi_{A} + \overline{N}^{\Lambda\alpha i}\overline{L}_{2}\bar{\lambda}_{iA}\gamma_{a}\psi^{A})V^{a} + \\ +c_{7}(N^{\Lambda\alpha i}L_{2}\bar{\lambda}_{i}^{A}\gamma_{a}\psi_{A} + \overline{N}^{\Lambda\alpha i}\overline{L}_{2}\bar{\lambda}_{iA}\gamma_{a}\psi^{A})V^{a} + \\ +c_{7}(N^{\Lambda\alpha i}L_{2}\bar{\lambda}_{i}^{A}\gamma_{a}\psi_{A} + \overline{N}^{\Lambda\alpha i}\bar{L}_{2}\bar{\lambda}_{iA}\gamma_{a}\psi^{A})V^{a} + \\ +c_{7}(N^{\Lambda\alpha i}L_{2}\bar{\lambda}_{iA}^{A}\gamma_{a}\psi_{A} + \overline{N}^{\Lambda\alpha i}\bar{\lambda}_{A}^{A}\bar{\lambda}_{A}^{A}\bar{\lambda}_{A}^{A}\bar{\lambda}_{A}^{A}\bar{\lambda}_$$

$$+c_{6}(\mathcal{N}^{ij}L_{2}q_{j}^{I}\bar{\lambda}_{I}^{A}\gamma_{a}\psi_{A} + \overline{\mathcal{N}}^{ij}\overline{L}_{2}q_{j}^{I}\bar{\lambda}_{IA}\gamma_{a}\psi^{A})V^{a} + +c_{7}(\mathcal{N}^{ij}L_{2}\bar{\lambda}_{j}^{A}\gamma_{a}\psi_{A} + \overline{\mathcal{N}}^{ij}\overline{L}_{2}\bar{\lambda}_{jA}\gamma_{a}\psi^{A})V^{a}] + more terms$$
(B.3)

$$\mathcal{L}_{gauge} = g_{1}(\bar{\psi}_{A}\gamma_{ab}\psi_{B}S^{AB} - \bar{\psi}^{A}\gamma_{ab}\psi^{B}S_{AB})V^{a}V^{b} + g_{2}(\bar{\psi}_{A}\gamma^{a}\chi_{B}N^{AB} + \bar{\psi}^{A}\gamma^{a}\chi^{B}N_{AB})V^{b}V^{c}V^{d}\epsilon_{abcd} + g_{3}(\bar{\psi}_{A}\gamma^{a}\lambda^{IB}Z_{IB}^{\ A} + \bar{\psi}^{A}\gamma^{a}\lambda_{B}^{I}Z_{IA}^{\ A})V^{b}V^{c}V^{d}\epsilon_{abcd} + g_{4}(\bar{\psi}_{A}\gamma^{a}\lambda^{iB}W_{iB}^{\ A} + \bar{\psi}^{A}\gamma^{a}\lambda_{B}^{i}W_{iA}^{\ B})V^{b}V^{c}V^{d}\epsilon_{abcd} + (\bar{\lambda}_{I}^{A}\chi_{B}Q_{A}^{IB} + \bar{\lambda}_{IA}\chi^{B}Q_{B}^{IA} + \bar{\lambda}_{i}^{A}\chi_{B}M_{A}^{iB} + \bar{\lambda}_{iA}\chi^{B}M_{B}^{iA})V^{a}V^{b}V^{c}V^{d}\epsilon_{abcd} + (\bar{\lambda}_{IA}\lambda_{JB}T^{IJAB} + \bar{\lambda}^{IA}\lambda^{JB}T_{IJAB} + \bar{\lambda}_{iA}\lambda_{jB}U^{ijAB} + \bar{\lambda}^{i}\lambda^{jB}U_{ijAB})V^{a}V^{b}V^{c}V^{d}\epsilon_{abcd} + (\bar{\lambda}_{IA}\lambda_{JB}T^{IJAB} + \bar{\lambda}^{IA}\lambda^{JB}T_{IJAB} + \bar{\lambda}^{IA}\lambda^{JB}T_{IJAB} + \bar{\lambda}^{IA}\lambda^{JB}U^{ijAB} + \bar{\lambda}^$$

$$\mathcal{L}_{torsion} = T_a V^a V^b (t_1 \bar{\chi}^A \gamma_b \chi_a + t_2 \bar{\lambda}_{IA} \gamma_b \lambda^{IA} + t_3 \bar{\lambda}_{iA} \gamma_b \lambda^{iA})$$
(B.5)

Note that in equation (B.3) the statement "+ more terms" means Pauli terms containing currents made out spin  $\frac{1}{2}$  bilinears which can not be computed in this geometric approach without knowledge of the four fermion couplings. However these terms have been included in the space–time Lagrangian given in Section 5 by imposing the invariance of the space–time Lagrangian under supersymmetry transformations.

The introduction of the auxiliary 0-forms  $\mathbf{p}^a$ ,  $\mathbf{P}_a^{IJ}$ ,  $\mathbf{F}_{\Lambda\alpha}^{\pm ab}$ ,  $\mathbf{F}_i^{\pm ab}$  is a trick which avoids the use of the Hodge operator for the construction of the kinetic terms for the vectors and scalar fields which otherwise would spoil the validity of the 3-form equations of motion in all superspace; indeed the equation of of motion of these auxiliary 0-forms identifies them with the components of the physical field-strengths  $p^a$ ,  $P_a^{IJ}$ ,  $F_{\Lambda\alpha}^{\pm ab}$ ,  $F_i^{\pm ab}$  along the bosonic vielbeins  $V^a$  thus reconstructing the usual kinetic terms on space-time.

The  $\mathcal{L}_{torsion}$ -term has been constructed in such a way as to give  $T^a = 0$ .

Performing the variation of all the fields one fixes all the undetermined coefficients, namely:

$$a_{1} = 4; \quad a_{2} = -\frac{4}{3}i; \quad a_{3} = -\frac{2}{3}i; \quad a_{4} = \frac{2}{3}; \quad a_{5} = \frac{2}{3}; \quad a_{6} = -\frac{4}{3}i;$$

$$a_{7} = \frac{4}{3}; \quad c_{1} = -2; \quad c_{2} = -4i; \quad c_{3} = -4i; \quad c_{4} = -2; \quad c_{5} = -4i;$$

$$c_{6} = -4i; \quad c_{7} = -8i; \quad b_{1} = 4i; \quad b_{2} = 2i; \quad b_{3} = 4i;$$

$$g_{1} = -4; \quad g_{2} = -\frac{8}{3}i; \quad g_{3} = -\frac{4}{3}i; \quad g_{4} = -\frac{8}{3}i;$$

$$t_{1} = -4; \quad t_{2} = -2; \quad t_{3} = -4; \quad a = -4$$
(B.6)

In order to obtain the space–time Lagrangian the last step to perform is the restriction of the 4–form Lagrangian from superspace to space–time. Namely we restrict all the terms to the  $\theta = 0$ ,  $d\theta = 0$  hypersurface  $\mathcal{M}^4$ . In practice one first goes to the second order formalism by identifying the auxiliary 0–form fields as explained before. Then one

expands all the forms along the  $dx^{\mu}$  differentials and restricts the superfields to their lowest  $(\theta = 0)$  component. Finally the coefficients of:

$$dx^{\mu} \wedge dx^{\nu} \wedge dx^{\rho} \wedge dx^{\sigma} = \frac{\epsilon^{\mu\nu\rho\sigma}}{\sqrt{g}} \left( \sqrt{g} d^{4} x \right)$$
 (B.7)

give the Lagrangian density written in Section 5. The overall normalization of the space—time action has been chosen such as to be the standard one for the Einstein term. (To conform to the usual definition of the Riemann tensor  $R^{ab}_{\phantom{ab}cd}$  we have set  $R^{ab} = -\frac{1}{2}R^{ab}_{\phantom{ab}cd}V^cV^d$ ).

## Appendix C: The moduli of $T^6$ in real and complex coordinates

In this appendix we give a more detailed discussion of the extrema of the potential using a complex basis for the  $GL(6,\mathbb{R})$  indices for the moduli of the  $T^6$  torus.

Let us consider the basis vectors  $\{e_{\Lambda}\}$ ,  $(\Lambda = 1 \dots 6)$  of the fundamental representation of  $GL(6,\mathbb{R})$ . We introduce a complex basis  $\{E_i, \overline{E}_i\}$  with i = 1, 2, 3 or, to avoid confusion on indices, i = x, y, z in the following way:

$$e_1 + ie_4 = E_x; e_2 + ie_5 = E_y; e_3 + ie_6 = E_z$$
 (C.1)

$$e_1 - ie_4 = \overline{E}_x; \ e_2 - ie_5 = \overline{E}_y; \ e_3 - ie_6 = \overline{E}_z$$
 (C.2)

The axion fields and the (inverse) metric of  $T^6$  can then be written using (anti)holomorphic indices  $i, j, \bar{\imath}, \bar{\jmath}$  as follows:

$$B^{\Lambda\Sigma} \longrightarrow B^{ij}, B^{i\bar{\jmath}}, B^{\bar{\imath}\bar{\jmath}}, B^{\bar{\imath}\bar{\jmath}}$$
 (C.3)

$$g^{\Lambda\Sigma} \longrightarrow g^{ij}, g^{i\overline{\jmath}}, g^{\overline{\imath}j}, g^{\overline{\imath}\overline{\jmath}}$$
 (C.4)

(C.5)

In particular, the fluxes  $f_1^{\Lambda\Sigma\Gamma}\equiv f^{\Lambda\Sigma\Gamma}$  are given by

$$f^{xyz} = \frac{1}{8} \{ f^{123} - f^{156} + f^{246} - f^{345} + i \left( f^{123} - f^{156} + f^{246} - f^{345} \right) \} \quad (C.6)$$

$$f^{x\overline{yz}} = \frac{1}{8} \{ f^{123} - f^{156} - f^{246} + f^{345} + i \left( f^{123} - f^{156} - f^{246} + f^{345} \right) \} \quad (C.7)$$

$$f^{xy\overline{z}} = \frac{1}{8} \{ f^{123} + f^{156} - f^{246} - f^{345} + i \left( f^{123} + f^{156} - f^{246} - f^{345} \right) \} \quad (C.8)$$

$$f^{x\overline{y}k} = \frac{1}{8} \{ f^{123} + f^{156} + f^{246} + f^{345} + i \left( f^{123} + f^{156} + f^{246} + f^{345} \right) \}$$
 (C.9)

while

$$f^{x\overline{x}y} = f^{x\overline{x}z} = f^{y\overline{y}x} = f^{y\overline{y}z} = f^{z\overline{z}x} = f^{z\overline{z}y} = 0$$
 (C.10)

and therefore, the twenty entries of  $f_1^{\Lambda\Sigma\Delta}$  are reduced to eight.

In this holomorphic basis the gravitino mass eigenvalues assume the rather simple form:

$$m_1 \equiv |\mu_1 + i\mu_1'| = \frac{1}{6|L^2|} |f^{x\overline{y}\overline{z}}|$$
 (C.11)

$$m_2 \equiv |\mu_2 + i\mu_2'| = \frac{1}{6|L^2|} |f^{x\overline{y}z}|$$
 (C.12)

$$m_3 \equiv |\mu_3 + i\mu_3'| = \frac{1}{6|L^2|} |f^{xy\overline{z}}|$$
 (C.13)

$$m_4 \equiv |\mu_4 + i\mu_4'| = \frac{1}{6|L^2|} |f^{xyz}|$$
 (C.14)

We note that the three axions  $B^{\Lambda\Sigma}=\{B_{14},\,B_{25},\,B_{36}\}\equiv\{-2iB_{x\overline{x}},\,-2iB_{y\overline{y}},\,-2iB_{z\overline{z}}\}$  are inert under  $T_{12}$ –gauge transformations, since we have 15 axions but only 12 bulk vectors. When we consider the truncation to the N=3 theory we expect that only 9 complex scalar fields become massless moduli parametrizing  $\mathrm{SU}(3,3)/\mathrm{SU}(3)\times\mathrm{SU}(3)\times\mathrm{U}(1)$ . Moreover, it is easy to see that if we set e.g.  $\mu_1=\mu_2=\mu_3=0$  ( $\mu_1'=\mu_2'=\mu_3'=0$ ) which implies  $f^{345}=f^{156}=-f^{123}=-f^{246}$  (\* $f^{345}=f^{156}=-f^{123}=-f^{246}$ ) in the N=3 theory, we get that also the 6 fields  $B^{12}-B^{45},\,B^{13}-B^{46},\,B^{24}-B^{15},\,B^{34}-B^{16},\,B^{23}-B^{56},\,B^{35}-B^{26}$  are inert under gauge transformations.

In holomorphic coordinates, the translational gauging implies that the differential of the axionic fields become covariant and they are given by:

$$\nabla_{(g)}B^{ij} \equiv dB^{ij} + (\Re f^{ijk1})A_{k1} + (\Re f^{ij\overline{k}1})A_{\overline{k}1} + (\Im f^{ijk2})A_{k2} + (\Im f^{ij\overline{k}2})A_{\overline{k}2}(C.15)$$

$$\nabla_{(g)}B^{i\overline{j}} \equiv dB^{i\overline{j}} + (\Re f^{i\overline{j}k1})A_{k1} + (\Re f^{i\overline{j}\overline{k}1})A_{\overline{k}1} + (\Im f^{i\overline{j}k2})A_{k2} + (\Im f^{i\overline{j}\overline{k}2})A_{\overline{k}2}(C.16)$$

Since in the  $N=4 \longrightarrow N=3$  truncation the only surviving massless moduli fields are  $B_{i\bar{\jmath}}+ig_{i\bar{\jmath}}$ , then the 3+3 axions  $\{B_{ij}, B_{\bar{\imath}\bar{\jmath}}\}$  give mass to 6 vectors, while  $\delta B_{i\bar{\jmath}}$  must be zero. We see from equation (C.16) we see that we must put to zero the components

$$f^{i\overline{j}k} = f^{i\overline{j}\overline{k}} = f^{ij\overline{k}} = 0 \tag{C.17}$$

while

$$f^{ijk} \equiv f \epsilon^{ijk} \neq 0 \tag{C.18}$$

Looking at the equations (C.11) we see that these relations are exactly the same which set  $\mu_1 + i\mu'_1 = \mu_2 + i\mu'_2 = \mu_3 + i\mu'_3 = 0$  and  $\mu_4 + i\mu'_4 \neq 0$ , confirming that the chosen complex structure corresponds to the N=3 theory. Note that the corresponding  $g^{i\bar{\jmath}}$  fields partners of  $B^{i\bar{\jmath}}$  in the chosen complex structure parametrize the coset  $O(1,1) \times SL(3,\mathbb{C})/SU(3)$ . Actually the freezing of the holomorphic  $g^{ij}$  gives the following relations among the components in the real basis of  $g^{\Lambda\Sigma}$ :

$$g^{14} = g^{25} = g^{36} = 0 (C.19)$$

$$g^{11} - g^{44} = 0$$
,  $g^{22} - g^{55} = 0$ ,  $g^{33} - g^{66} = 0$  (C.20)

$$g^{12} - g^{45} = 0$$
,  $g^{13} - g^{46} = 0$ ,  $g^{23} - g^{56} = 0$  (C.21)

$$g^{15} + g^{24} = 0$$
,  $g^{16} + g^{34} = 0$ ,  $g^{26} + g^{35} = 0$  (C.22)

The freezing of the axions  $B^{ij}$  in the holomorphic basis give the analogous equations:

$$B^{12} - B^{45} = 0$$
,  $B^{13} - B^{46} = 0$ ,  $B^{23} - B^{56} = 0$  (C.23)

$$B^{15} + B^{42} = 0$$
,  $B^{16} + B^{43} = 0$ ,  $B^{26} + B^{53} = 0$  (C.24)

$$B^{14} = B^{25} = B^{36} = 0 (C.25)$$

The massless  $g^{i\bar{j}}$  and  $B^{i\bar{j}}$  are instead given by the following combinations:

$$g^{x\overline{x}} = \frac{1}{2}(g^{11} + g^{44}), \quad g^{y\overline{y}} = \frac{1}{2}(g^{22} + g^{55}), \quad g^{z\overline{z}} = \frac{1}{2}(g^{33} + g^{66})$$
 (C.26)

$$B^{x\overline{x}} = \frac{i}{2}B^{14}, \quad B^{y\overline{y}} = \frac{i}{2}B^{25}, \quad B^{z\overline{z}} = \frac{i}{2}B^{36}$$
 (C.27)

$$g^{x\overline{y}} = \frac{1}{2}(g^{12} + ig^{15}), \quad g^{x\overline{z}} = \frac{1}{2}(g^{13} + ig^{16}), \quad g^{y\overline{z}} = \frac{1}{2}(g^{23} + ig^{26})$$
 (C.28)

$$B^{x\overline{y}} = \frac{1}{2}(B^{12} + iB^{15}), \quad B^{x\overline{z}} = \frac{1}{2}(B^{13} + iB^{16}), \quad B^{y\overline{z}} = \frac{1}{2}(B^{23} + iB^{26}) \quad (C.29)$$

$$B^{xx} = B^{yy} = B^{zz} = 0 (C.30)$$

Let us now consider the reduction  $N=4 \longrightarrow N=2$  for which the relevant moduli space is  $\mathrm{SU}(2,2)/\left(\mathrm{SU}(2)\times\mathrm{SU}(2)\times\mathrm{U}(1)\right)\otimes\mathrm{SU}(1,1)/\mathrm{U}(1)$ . Setting  $\mu_2+i\mu_2'=\mu_3+i\mu_3'=0$  we find:

$$f^{x\overline{y}z} = f^{xy\overline{z}} = 0 \tag{C.31}$$

which, in real components implies:

$$f^{123} + f^{156} = 0;$$
  $f^{246} + f^{345} = 0$  (C.32)

and analogous equations for their Hodge dual. This implies that in the N=2 phase two more axions are gauge inert namely  $B^{23}+B^{56}=2B^{23}$  and  $B^{26}+B^{35}=2B^{26}$  or, in holomorphic components,  $B^{y\bar{z}}$ . The remaining fields are  $g^{14}, g^{25}, g^{36}, g^{23}, g^{26}$  and  $B^{14}, B^{25}, B^{36}, B^{23}, B^{26}$ , the last ones parametrize the coset  $SO(1,1) \times SO(2,2)/SO(2) \times SO(2)$ .

If we now consider the truncation  $N=4\longrightarrow N=1$  the relevant coset manifold is  $(\mathrm{SU}(1,1)/\mathrm{U}(1))^3$  which contains 3 complex moduli. To obtain the corresponding complex structure, it is sufficient to freeze  $g^{i\overline{\jmath}}$ ,  $B^{i\overline{\jmath}}$  with  $i\neq j$ . In particular the  $\mathrm{SU}(1,1)^3$  can be decomposed into  $\mathrm{O}(1,1)^3\otimes^s T^3$  where the three  $\mathrm{O}(1,1)$  and the three translations  $T^3$  are parametrized by  $g^{x\overline{x}}$ ,  $g^{y\overline{y}}$ ,  $g^{z\overline{z}}$  and  $B^{x\overline{x}}$ ,  $B^{y\overline{y}}$ ,  $B^{z\overline{z}}$  respectively.

These axions are massless because of equation (C.10) (Note that the further truncation  $N=1 \longrightarrow N=0$  does not alter the coset manifold  $SU(1,1)^3$  since we have no loss of massless fields in this process). In this case we may easily compute the moduli dependence of the gravitino masses. Indeed,  $O(1,1)^3$ , using equations (C.20), (C.26), will have as coset representative the matrix

$$E_{\Lambda}^{I} = \begin{pmatrix} e^{\varphi_{1}} & 0 & 0 & 0 & 0 & 0\\ 0 & e^{\varphi_{2}} & 0 & 0 & 0 & 0\\ 0 & 0 & e^{\varphi_{3}} & 0 & 0 & 0\\ 0 & 0 & 0 & e^{\varphi_{1}} & 0 & 0\\ 0 & 0 & 0 & 0 & e^{\varphi_{2}} & 0\\ 0 & 0 & 0 & 0 & 0 & e^{\varphi_{3}} \end{pmatrix}$$
(C.33)

where we have set  $g_{11}=e^{2\varphi_1},\ g_{22}=e^{2\varphi_2},\ g_{33}=e^{2\varphi_3}$ , the exponentials representing the radii of the manifold  $T_{(14)}^2\times T_{(25)}^2\times T_{(36)}^2$ .

We see that in the gravitino mass formula the vielbein  $E_{\Lambda}^{I}$  reduces to the diagonal components of the matrix (C.33) A straightforward computation then gives:

$$S_{AB}\overline{S}^{AB} = \frac{2}{(48)^2} e^{(2\varphi_1 + 2\varphi_2 + 2\varphi_3)} \begin{pmatrix} m_1^2 & 0 & 0 & 0\\ 0 & m_2^2 & 0 & 0\\ 0 & 0 & m_3^2 & 0\\ 0 & 0 & 0 & m_4^2 \end{pmatrix}$$
(C.34)

We note that in the present formulation where we have used a contravariant  $B^{\Lambda\Sigma}$  as basic charged fields, the gravitino mass depends on the  $T^6$  volume. However if we made use of the dual 4-form  $C_{\Lambda\Sigma\Gamma\Delta}$ , as it comes from Type IIB string theory, then the charge coupling would be given in terms of  ${}^*f^{\alpha}_{\Lambda\Sigma\Gamma}$  and the gravitino mass matrix would be trilinear in  $E^{\Lambda}_I$  instead of  $E^{I}_{\Lambda}$ . Therefore all our results can be translated in the new one by replacing  $R_i \to R_i^{-1}$ .

## Appendix D: Conventions

We realize the isomorphism between the two fold antisymmetric representation of SU(4) and the fundamental of SO(6) using the  $4 \times 4$   $\Gamma$ -matrix  $(\Gamma^I)_{AB} = -(\Gamma^I)_{BA}$ . We have used the following representation

$$\Gamma^{1} = \begin{pmatrix}
0 & 0 & 0 & 1 \\
0 & 0 & 1 & 0 \\
0 & -1 & 0 & 0 \\
-1 & 0 & 0 & 0
\end{pmatrix} \qquad \Gamma^{4} = \begin{pmatrix}
0 & 0 & 0 & i \\
0 & 0 & -i & 0 \\
0 & i & 0 & 0 \\
-i & 0 & 0 & 0
\end{pmatrix}$$

$$\Gamma^{2} = \begin{pmatrix}
0 & 0 & -1 & 0 \\
0 & 0 & 0 & 1 \\
1 & 0 & 0 & 0 \\
0 & -1 & 0 & 0
\end{pmatrix} \qquad \Gamma^{5} = \begin{pmatrix}
0 & 0 & i & 0 \\
0 & 0 & 0 & i \\
-i & 0 & 0 & 0 \\
0 & -i & 0 & 0
\end{pmatrix}$$

$$\Gamma^{3} = \begin{pmatrix}
0 & 1 & 0 & 0 \\
-1 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 \\
0 & 0 & -1 & 0
\end{pmatrix} \qquad \Gamma^{6} = \begin{pmatrix}
0 & -i & 0 & 0 \\
i & 0 & 0 & 0 \\
0 & 0 & 0 & i \\
0 & 0 & -i & 0
\end{pmatrix}$$

Note that their anticommutator is  $\{\Gamma_I, \overline{\Gamma}_J\} = -\delta_{IJ}$ , where the complex conjugation acts as

$$(\Gamma^I)^{AB} = (\overline{\Gamma}^I)_{AB} = \frac{1}{2} \epsilon^{ABCD} (\Gamma^I)_{CD}$$
 (D.2)

We define

$$(\Gamma^{IJ})_A{}^B = \frac{1}{2} \left[ (\Gamma^{[I]})_{AC} (\Gamma^{J]})^{CB} \right]$$
 (D.3)

$$(\Gamma^{IJK})_{AB} = \frac{1}{3!} \left[ (\Gamma^I)_{AC} (\Gamma^J)^{CD} (\Gamma^K)_{DB} + perm. \right]$$
 (D.4)

Here the matrices  $(\Gamma^{IJK})_{AB}$  are symmetric and satisfy the relation

$$(\Gamma^{IJK})_{AB} = \frac{i}{6} \varepsilon^{IJKLMN} (\Gamma_{LMN})_{AB}$$
 (D.5)

In this representation, the following matrices are diagonal:

$$\Gamma^{123} = \begin{pmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{pmatrix}$$

$$\Gamma^{156} = \begin{pmatrix}
-1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & -1
\end{pmatrix}$$

$$\Gamma^{246} = \begin{pmatrix}
-1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & -1 & 0 \\
0 & 0 & 0 & -1
\end{pmatrix}$$

$$\Gamma^{345} = \begin{pmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & -1 & 0 \\
0 & 0 & 0 & -1
\end{pmatrix}$$
(D.6)

as well as the matrices  $\Gamma^{456}$ ,  $\Gamma^{234}$ ,  $\Gamma^{135}$  and  $\Gamma^{126}$  related with them through the relation (D.5).

We define for a generic tensor

$$T_{...IJ...} = \dots \frac{1}{2} (\Gamma_I)^{AB} \frac{1}{2} (\Gamma_J)^{CD} \dots T_{...[AB] [CD]...}$$

$$T_{...[AB] [CD]...} = \dots \frac{1}{2} (\Gamma^I)_{AB} \frac{1}{2} (\Gamma^J)_{CD} \dots T_{...IJ...}$$
(D.7)

so that

$$E_{\Lambda}^{I}(E^{-1})_{I}^{\Sigma} = E_{\Lambda}^{AB}(E^{-1})_{AB}^{\Sigma} = \delta_{\Lambda}^{\Sigma}$$
(D.8)

$$E_{\Lambda}^{I}(E^{-1})_{J}^{\Lambda} = \delta_{I}^{J} \iff E_{\Lambda}^{AB}(E^{-1})_{CD}^{\Lambda} = \delta_{CD}^{AB} \tag{D.9}$$

In particular we need to convert the SO(6)<sub>1</sub> indices of  $\omega_1^{IJ}$  into SU(4) R-symmetry indices as they appear in the covariant derivative on spinors. For this purpose we apply the previous definition (D.7) to the connection  $\omega_1^{IJ}$  defining

$$\omega^{AB}_{CD} \equiv \frac{1}{4} (\Gamma_I)^{AB} (\Gamma_J)_{CD} \,\omega_1^{IJ} \tag{D.10}$$

then we introduce the connection  $Q^A_B$  defined as

$$\omega^{AB}_{CD} \equiv \delta^{[A}_{[C}Q^{B]}_{D]} \tag{D.11}$$

and thus

$$Q_D^A = -\frac{1}{2}\omega_{BD}^{AB} = \frac{1}{8}(\Gamma_{IJ})_D^A \omega_1^{IJ}$$
 (D.12)

One can easily realize that given the definition of the  $SO(6)_1$  curvature as

$$R_1^{IJ} \equiv d\omega_1^{IJ} + \omega_{1K}^I \wedge \omega_1^{KJ} \tag{D.13}$$

one finds for consistence that

$$R_{B}^{A} \equiv dQ_{B}^{A} - 2Q_{C}^{A} \wedge Q_{B}^{C} = \frac{1}{8} (\Gamma_{IJ})_{B}^{A} R_{1}^{IJ}$$
 (D.14)

As a consequence, the covariant derivative acting on spinors turns out to be

$$D\theta_A = d\theta_A - 2Q^A_B\theta_B = d\theta_A - \frac{1}{4}(\Gamma_{IJ})^A_B \omega_1^{IJ}\theta_B$$
 (D.15)

theory on  $T^6$  ( $C^{(0)}$ ,  $C^{(2)} \equiv C_{ij}$  and  $C^{(4)} \equiv C_{ijkl}$ ) and positive roots of  $E_{7(7)}$  according to the solvable Lie algebra formalism. The N=4 Peccei–Quinn scalars correspond to roots with grading 1 with respect to  $\beta$ , namely those with  $n^6=2$  and  $n^7=1$  which are marked by an arrow in the table.
