ABSTRACT

It is well-known that the standard no-ghost theorem is valid as long as the background has the light-cone directions. We prove the no-ghost theorem for the NSR string when only the timelike direction is flat. This is done by the BRST quantization, using the technique of Frenkel, Garland and Zuckerman and our previous results for the bosonic string. The theorem actually applies as long as the timelike direction is written as a $u(1)$ SCFT.

1 Introduction

In the last decade or so, strings on curved backgrounds have been discussed widely in various contexts. Some recent examples are AdS/CFT dualities, string on pp -wave backgrounds [1, 2], and time-dependent orbifolds [3, 4, 5, 6]. However, many discussion is limited to backgrounds with light-cone directions (*e.g.*, string on pp -wave backgrounds and time-dependent orbifolds). Otherwise, the technology is often limited to supergravities (*e.g.*, for AdS/CFT dualities).

This is due to the lack of the string theory on general backgrounds, especially the no-ghost theorem. As is well-known, string theory generally contains negative norm states (ghosts) from timelike oscillators. However, they do not appear as physical states. This is well-established for string theory in flat spacetime [7]-[26]. When the background spacetime is curved, things are not clear though. Standard proofs of the no-ghost theorem requires light-cone directions, *i.e.*, $d \geq 2$ if the background is written as $\mathbb{R}^{1,d-1} \times K$, where K is a unitary CFT. This is true both in the old covariant quantization (OCQ) and in the BRST quantization (Table 1)¹.

However, the source of ghosts is the timelike oscillators and the Fadeev-Popov ghosts. Thus, one would expect that no-ghost theorem is valid even for $d = 1$ as long as the timelike direction is intact. In fact, in our previous paper [27], we show the no-ghost theorem for $d \geq 1$ bosonic string based on the BRST quantization. We heavily used the previous results by Frenkel, Garland and Zuckerman (FGZ) [16]. The purpose of this paper is to extend the proof for the NSR string.

The proof by FGZ is different from the others. For example, the standard BRST quantization assumes $d \geq 2$ in order to prove the “vanishing theorem,” *i.e.*, the BRST cohomology is trivial except at the zero ghost number. However, FGZ’s proof of the vanishing theorem essentially does not require $d \geq 2$. Moreover, the power of the technique is not limited to the $d = 1$ case. This scheme is especially interesting because it does not even require that the timelike direction be flat; it admits an extension to more general curved backgrounds. As an example, we will discuss AdS_3 case in a separate paper [28].

Unfortunately, these points have not been appreciated well. This may be partly because the proof requires some mathematical backgrounds. It is one of our purposes here to explain FGZ’s proof to a broader audience in a more accessible manner.

In the next section, we briefly review the BRST quantization of the NSR string. Further details and our conventions are summarized in App. A and B. The reader who is familiar to the BRST quantization can directly go to the outline of our proof in Sec. 2.3. The presentation of the proof below is slightly different from our earlier paper [27], but the proof itself is very similar.

¹There are several attempts of the $d = 1$ proof in the old covariant quantization. For some discussion, see our first paper [27]. We will also discuss them thoroughly in our future paper [28].

Quantization	Approaches	Limitations
OCQ	DDF [7]	flat spacetime only
	á la Goddard-Thorn [8]	$d \geq 2$
BRST	á la Kato-Ogawa [9]	$d \geq 2$
	Asano-Natsuume [27]	$d \geq 1$

Table 1: Standard schemes for the no-ghost theorem.

2 Preliminary and Outline

2.1 The Assumptions

We make the following assumptions:

- (i). Our world-sheet theory consists of d free bosons X^μ and fermions ψ^μ ($\mu = 0, \dots, d-1$) with signature $(1, d-1)$ and a unitary SCFT K of central charge $\hat{c}_K = 10 - d$ ($\hat{c} = 2c/3$). Although we focus on the $d = 1$ case below, the extension to $1 \leq d \leq 10$ is straightforward.
- (ii). We assume that K is unitary and that all states in K lie in highest weight representations. From the Kac determinant (App. C), the weight of a highest weight state has $h^K > 0$ in the Neveu-Schwarz (NS) sector and $h^K > \hat{c}_K/16$ in the Ramond (R) sector. An example of K is a compact unitary SCFT, where its spectrum is discrete and bounded below. Another example is the transverse SCFT.
- (iii). The momentum of states is $k^\mu \neq 0$.

In App. A and B, we summarize our notations and conventions.

2.2 BRST Quantization

From our assumptions, the total L_m of the theory is given by

$$L_m = L_m^0 + L_m^g + L_m^K, \quad (1)$$

where L_m^0 , L_m^g , and L_m^K represent the Virasoro generators in the $\hat{c} = 1$ timelike sector, the FP-ghost sector, and the unitary SCFT K sector, respectively. In particular,

$$L_0 = \alpha' k^2 + L_0^{\text{osc}} \quad (2)$$

$$= \alpha' k^2 + N + L_0^K + a^0 + a^g, \quad (3)$$

where N is the total level number and a^0 (a^g) represents the normal ordering constant for the $\hat{c} = 1$ (FP-ghost) sector.

We will call the total Hilbert space $\mathcal{H}_{\text{total}}$. For the NS-sector, the physical state conditions are

$$Q|\text{phys}\rangle = 0 \quad (4)$$

as well as

$$b_0|\text{phys}\rangle = L_0|\text{phys}\rangle = 0. \quad (5)$$

The L_0 -condition follows from $0 = \{Q, b_0\}|\text{phys}\rangle = L_0|\text{phys}\rangle$. In addition, in the R-sector we impose

$$\beta_0|\text{phys}\rangle = G_0|\text{phys}\rangle = 0. \quad (6)$$

As in the L_0 -condition, the G_0 -condition follows from $0 = [Q, \beta_0]|\text{phys}\rangle = G_0|\text{phys}\rangle$.

Thus, we define the following subspaces of $\mathcal{H}_{\text{total}}$:

(i) *NS-sector*

$$\mathcal{H} = \{\phi \in \mathcal{H}_{\text{total}} : b_0\phi = 0\}, \quad (7a)$$

$$\hat{\mathcal{H}} = \mathcal{H}^{L_0} = \{\phi \in \mathcal{H}_{\text{total}} : b_0\phi = L_0\phi = 0\}. \quad (7b)$$

(ii) *R-sector*

$$\mathcal{H} = \{\phi \in \mathcal{H}_{\text{total}} : b_0\phi = \beta_0\phi = 0\}, \quad (8a)$$

$$\hat{\mathcal{H}} = \mathcal{H}^{L_0, G_0} = \{\phi \in \mathcal{H}_{\text{total}} : b_0\phi = \beta_0\phi = L_0\phi = G_0\phi = 0\}. \quad (8b)$$

Here, $*^{L_0}$ denotes the L_0 -invariant subspace: $F^{L_0} = F \cap \text{Ker}L_0$. (Similarly for $*^{L_0, G_0}$) We will consider the cohomology on $\hat{\mathcal{H}}$ since Q takes $\hat{\mathcal{H}}$ into itself from $\{Q, b_0\} = L_0$ and $[Q, L_0] = 0$. (For the R-sector, also use $[Q, \beta_0] = G_0$ and $\{Q, G_0\} = 0$.) The subspace \mathcal{H} will be useful in our proof of the vanishing theorem (Sec. 4).

The Hilbert space $\hat{\mathcal{H}}$ is classified according to mass eigenvalues. $\hat{\mathcal{H}}$ at a particular mass level will be often written as $\hat{\mathcal{H}}(k^2)$. For a state $|\phi\rangle \in \hat{\mathcal{H}}(k^2)$,

$$L_0|\phi\rangle = (\alpha'k^2 + L_0^{\text{osc}})|\phi\rangle = 0. \quad (9)$$

One can further take an eigenstate of the ghost number \hat{N}^g since $[L_0^{\text{osc}}, \hat{N}^g] = 0$. $\hat{\mathcal{H}}$ is decomposed by the eigenvalues of \hat{N}^g as

$$\hat{\mathcal{H}} = \bigoplus_{n \in \mathbf{Z}} \hat{\mathcal{H}}^n. \quad (10)$$

We decompose the BRST operator Q in terms of superconformal ghost zero modes:

$$Q = \hat{Q} + (\text{terms in } Q \text{ with superconformal ghost zero modes}). \quad (11)$$

See App. A for the explicit form of \hat{Q} . Then, for a state $|\phi\rangle \in \hat{\mathcal{H}}$,

$$Q|\phi\rangle = \hat{Q}|\phi\rangle. \quad (12)$$

Therefore, the physical state condition reduces to

$$\hat{Q}|\phi\rangle = 0. \quad (13)$$

Also, $\hat{Q}^2 = 0$ on $\hat{\mathcal{H}}$ from Eq. (12). Thus, $\hat{Q} : \hat{\mathcal{H}}^n \rightarrow \hat{\mathcal{H}}^{n+1}$ defines a BRST complex, which is called the *relative* BRST complex. So, we can define $\hat{\mathcal{H}}_c, \hat{\mathcal{H}}_e \subset \hat{\mathcal{H}}$ by

$$\hat{Q}\hat{\mathcal{H}}_c = 0, \quad \hat{\mathcal{H}}_e = \hat{Q}\hat{\mathcal{H}}, \quad (14)$$

and define the relative BRST cohomology of Q by

$$\hat{\mathcal{H}}_{\text{obs}} = \hat{\mathcal{H}}_c / \hat{\mathcal{H}}_e. \quad (15)$$

In terms of the cohomology group, $\hat{\mathcal{H}}_{\text{obs}}(k^2) = \bigoplus_{n \in \mathbf{Z}} H^n(\hat{\mathcal{H}}(k^2), \hat{Q}(k))$.

2.3 The Outline of the Proof

The full proof of the no-ghost theorem is rather involved, so we give the outline here. The terminology appeared below is explained later. In general, the proof of the no-ghost theorem consists of 2 steps in the BRST quantization (Table 2).

- Step 1: The first is to show the *vanishing theorem*. The vanishing theorem states that the \hat{Q} -cohomology is trivial except at the zero ghost number. This is done by choosing an appropriate (bounded) *filtration* for your BRST operator \hat{Q} . A filtration allows us to use a simplified BRST operator Q_0 and we can first study the cohomology of Q_0 . If the Q_0 -cohomology is trivial, so is the \hat{Q} -cohomology; this is the reason why the filtration is so useful. However, the particular filtration used in standard proofs is also part of the reason why $d \geq 2$ in those proofs.
- Step 2: The second is to compute and compare the *index* and the *signature* of the cohomology group explicitly. If the index is equal to the signature, the no-ghost theorem holds provided the vanishing theorem is valid.

Step 1 and 2 themselves consist of several steps. For our approach, these are explained in Sec. 4.2 and 5.1, respectively.

However, in our approach, the matter Virasoro generators themselves play a very important role, and it is useful to have an additional step:

- Step 0: Write the matter Hilbert space in terms of products of two Verma modules, one for the $\hat{c} = 1$ SCFT and the other for the unitary SCFT K .

The step is useful particularly at Step 1.2 and is convenient when one discusses more general spacetime backgrounds.

Step 0:	Matter Hilbert space via Verma modules
	↓
Step 1:	The vanishing theorem using filtration (reason why $d \geq 2$ in standard proofs)
	↓
Step 2:	The no-ghost theorem

Table 2: The outline of the proof.

3 Step 0: Hilbert Space via Verma Modules

First step towards the no-ghost theorem is to map the timelike $\hat{c} = 1$ matter Fock space to Verma modules. This is essential for proving the vanishing theorem; in the language of FGZ, this means that the $\hat{c} = 1$ CFT is an “ \mathcal{L}_- -free module,” which is a prime assumption of the vanishing theorem (Theorem 1.12 of [16]). Moreover, expressing the Hilbert space in this general form is useful when one discusses CFTs other than the $\mathbb{R}^{1,0} \times K$ case.

Let $\mathcal{V}(\hat{c}, h)$ be a Verma module with highest weight h and central charge \hat{c} . Then,

Lemma 3.1. *There is an isomorphism between a Verma module and the $\hat{c} = 1$ matter Fock space:*

$$\sum_s \mathcal{F}(\alpha_{-m}^0, \psi_{-r}^0; s, k^0) \cong \mathcal{V}(1, h^0) \quad \text{if } (k^0)^2 > 0. \quad (16)$$

(The index s and its sum is relevant only to the R-sector. See App. B and C for notations.)²

The isomorphism is plausible from the defining formula of L_m^0 and G_r^0 ,

$$L_{-m}^0 = \sqrt{2\alpha'} k_0 \alpha_{-m}^0 + \dots, \quad (m \neq 0) \quad (17)$$

$$G_{-r}^0 = \sqrt{2\alpha'} k_0 \psi_{-r}^0 + \dots, \quad (18)$$

where $+\dots$ denotes terms with more than one oscillators. The above relations also suggest that the isomorphism fails at $k^0 = 0$. This is the reason why we require assumption (iii) in Sec. 2.1.

Proof of Lemma 3.1. The number of states of the Fock space $\sum_s \mathcal{F}(\alpha_{-m}^0, \psi_{-r}^0; s, k^0)$ and that of the Verma module $\mathcal{V}(1, h^0)$ are the same for a given level N . Thus, the Verma module furnishes a basis of the Fock space if all the states in a highest weight representation are

²At this stage, the Verma module implicitly defines an inner product on \mathcal{F} , which is the timelike part of \mathcal{H} . However, in the R-sector, the real inner product on $\tilde{\mathcal{H}}$ used in the no-ghost theorem is slightly different from the one by the Verma module (See App. B). This does not matter to the present discussion since here we only need to show that the states in the Verma module are linearly independent. We use the inner product on $\tilde{\mathcal{H}}$ given in App. B for the no-ghost theorem. Similar remark also applies to the expression (21).

linearly independent. This can be shown using the Kac determinant (App. C). For $\hat{c} = 1$, the Kac determinant does not vanish if

$$h^0 < 0(\text{NS}), 1/16(\text{R}), \quad (19)$$

so the states in the Verma module are linearly independent. Now, note that $h^0 = -\alpha'(k^0)^2 + a^0$, where $a^0 = 0(\text{NS}), 1/16(\text{R})$. Thus, Eq. (19) is valid for $(k^0)^2 > 0$. \square

The isomorphism is valid as long as $(k^0)^2 > 0$. Let us check what on-shell states actually appear in $\hat{\mathcal{H}}$. From assumption (ii) of Sec. 2.1 and the on-shell condition,

$$-h^0 (= \alpha'(k^0)^2 - a^0) = a^g + L_0^K + N, \quad (20a)$$

where

$$\text{NS} \begin{cases} a^0 = 0 \\ a^g = -\frac{1}{2} \\ h^K > 0 \end{cases}, \quad \text{R} \begin{cases} a^0 = \frac{1}{16} \\ a^g = -\frac{10}{16} \\ h^K > \frac{9}{16} \end{cases}. \quad (20b)$$

In the NS-sector, $\alpha'(k^0)^2 > -1/2$ from Eqs. (20). Also, $k^0 \neq 0$ from assumption (iii). The Fock spaces with $(k^0)^2 > 0$ are expressed by Verma modules. Those with $0 > \alpha'(k^0)^2 > -1/2$ are not. However, there is no state in this region. In the R-sector, one always has $(k^0)^2 > 0$.

To summarize, the matter part of the Hilbert space \mathcal{H} reduces to a sum of two Verma modules:

$$\mathcal{H}_{h^0, h^K} = \mathcal{V}(\hat{c} = 1, h^0 < 0) \otimes \mathcal{V}(\hat{c}^K = 9, h^K > 0) \quad (21)$$

for the NS-sector, and similarly for the R-sector.³ Throughout the discussion of the vanishing theorem in Sec. 4, we assume the above form of the Hilbert space. *Consequently, the vanishing theorem is valid not only for the $d = 1$ case but also for more general backgrounds as long as the matter Hilbert space takes the above form.*

4 Step 1: The Vanishing Theorem

4.1 Filtration and the Vanishing Theorem: General Discussion

We now state our vanishing theorem:

Theorem 4.1 (The Vanishing Theorem for String Theory). *The \hat{Q} -cohomology can be non-zero only at $\hat{N}^g = 0$, i.e.,*

$$H^n(\hat{\mathcal{H}}, \hat{Q}) = 0 \quad \text{for } n \neq 0 \quad (22)$$

if the matter part of \mathcal{H} can be decomposed as a sum of two Verma modules as in Eq. (21).

³See footnote 2.

To prove this, the notion of *filtration* is useful. However, a particular filtration used in standard proofs is part of the reason why $d \geq 2$.

A filtration is a procedure to break up \hat{Q} according to a quantum number N_f (filtration degree):

$$\hat{Q} = Q_0 + Q_1 + \cdots + Q_N, \quad (23)$$

where

$$[N_f, Q_m] = mQ_m. \quad (24)$$

In order that N_f takes $\hat{\mathcal{H}}$ into itself, a filtration also satisfies

$$[N_f, \hat{N}^g] = [N_f, L_0] = [N_f, G_0] = 0. \quad (25)$$

If $\hat{\mathcal{H}}$ can be nonzero only for a finite range of degrees, the filtration is called *bounded*.

The nilpotency of \hat{Q}^2 implies

$$\sum_{\substack{m,n \\ m+n=l}} Q_m Q_n = 0, \quad l = 0, \dots, 2N \quad (26)$$

since they have different values of N_f . In particular,

$$Q_0^2 = 0. \quad (27)$$

The point is that we can first study the cohomology of Q_0 . This is easier since Q_0 is often simpler than \hat{Q} . Knowing the cohomology of Q_0 then tells us about the cohomology of \hat{Q} . In fact, one can show the following lemma (for a bounded filtration):

Lemma 4.1. *If the Q_0 -cohomology is trivial, so is the \hat{Q} -cohomology.*

See, *e.g.*, Ref. [27] for the proof.

Note that the above lemma states only for trivial cohomology; nontrivial cohomology for Q is in general different from the Q_0 -cohomology. However, one can show that the Q_0 -cohomology is isomorphic to that of \hat{Q} if the Q_0 -cohomology is nontrivial for at most one filtration degree [30, 29]. Then, a standard proof proceeds to show that states in the nontrivial degree are in fact light-cone spectra, and thus there is no ghost in the \hat{Q} -cohomology [30]. We will not take this path to prove the no-ghost theorem. However, the vanishing theorem is useful in our approach as well.

Now, we have to find an appropriate filtration and show that the Q_0 -cohomology is trivial if $\hat{N}^g \neq 0$. This completes the proof of the vanishing theorem. The standard proof of the theorem uses the following filtration [9, 29, 30]: ⁴

$$N_f^{(\text{KO})} = \sum_{\substack{m=-\infty \\ m \neq 0}}^{\infty} \frac{1}{m} \alpha_{-m}^- \alpha_m^+ + \hat{N}^g. \quad (28)$$

⁴The \hat{N}^g piece is not really necessary. We include this to make the filtration degree non-negative.

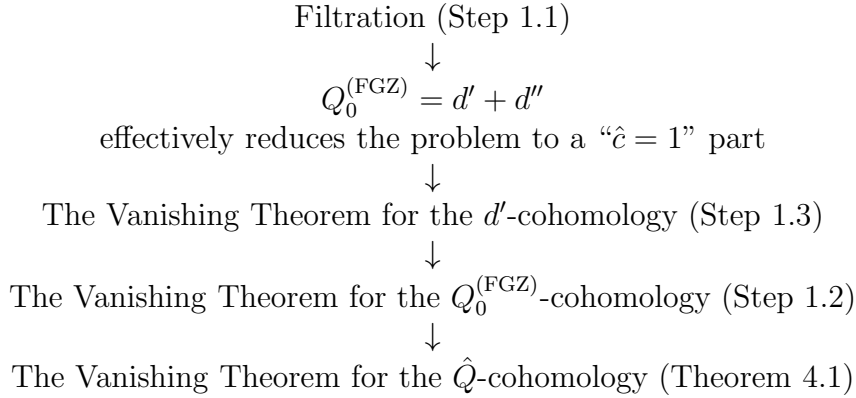

Table 3: The outline of the proof of the vanishing theorem for $d = 1$.

The degree $N_f^{(\text{KO})}$ counts the number of α^+ minus the number of α^- excitations. So, this filtration assumes two flat directions, and we have to take a different approach for $d = 1$.

4.2 The Outline of Step 1

Since we want to show the no-ghost theorem for $d = 1$, we cannot use $N_f^{(\text{KO})}$ as our filtration degree. Fortunately, the structure of our Hilbert space (21) enables us to prove the vanishing theorem using a different filtration [16, 24, 26]. The proof of the vanishing theorem consists of three steps (Table 3):

- Step 1.1: Apply our filtration á la Frenkel, Garland, and Zuckerman. With FGZ’s filtration, Q_0 can be further decomposed as a sum of two differentials, d' and d'' . This decomposition is crucial for the proof; it effectively reduces the problem to a “ $\hat{c} = 1$ ” SCFT, which contains the timelike part, the b and β ghost part. This is the reason why the proof does not require $d \geq 2$.
- Step 1.2: If the d' -cohomology is trivial, so is the Q_0 -cohomology. This follows from a Künneth formula. Then, the \hat{Q} -cohomology is trivial as well from Lemma 4.1.
- Step 1.3: Now, the problem is reduced to the d' -cohomology. Show the vanishing theorem for the d' -cohomology.

In this approach, the matter Virasoro generators themselves play a role similar to that of the light-cone oscillators in Kato-Ogawa’s approach. In this section, we prove the theorem using the technique of Refs. [16, 24, 26], but for more mathematically rigorous discussion, consult the original references.

Operators	fdeg
c_m	$ m $
b_m	$- m $
γ_r	$ r $
β_r	$- r $
L_m^0	m
G_r^0	r
L_m^K	0
G_r^K	0

Table 4: Filtration degrees to each modes for the vanishing theorem.

4.3 Step 1.1: Filtration

Our filtration is given by

$$N_f^{(\text{FGZ})} = -L_0^0 + \sum_{m>0} m(N_m^c - N_m^b) + \sum_{r>0} r(N_r^\gamma - N_r^\beta). \quad (29)$$

The filtration assigns the degrees in Table 4 to the operators. FGZ's filtration is originally given for the $d = 26$ bosonic string, and it was later extended to the flat $d = 10$ NSR string [24, 26]. We can apply this filtration to our problem since it does not require $d \geq 2$ in principle.

The operator $N_f^{(\text{FGZ})}$ satisfies conditions (25) and the degree of each term in \hat{Q} is non-negative. Because the eigenvalue of L_0^{osc} is bounded below from Eqs. (3) and (9), the total number of oscillators for a given mass level is bounded. Thus, the degree for the states is bounded for each mass level. Note that the unitarity of K is essential for the filtration to be bounded.

The degree zero part of \hat{Q} is given by

$$Q_0^{(\text{FGZ})} = d' + d'', \quad (30a)$$

$$d' = \sum_{m>0} c_m L_{-m}^0 + \sum_{r>0} \gamma_r G_{-r}^0 + \sum_{m,n>0} \frac{1}{2}(m-n)b_{-m-n}c_m c_n \\ + \sum_{m,r>0} \frac{1}{2}(2r-m)\beta_{-m-r}c_m \gamma_r - \sum_{m,r>0} b_{-m-r}\gamma_m \gamma_r, \quad (30b)$$

$$d'' = - \sum_{m,n>0} \frac{1}{2}(m-n)c_{-m}c_{-n}b_{m+n} \\ - \sum_{m,r>0} \frac{1}{2}(2r-m)\beta_{m+r}c_{-m}\gamma_{-r} - \sum_{m,r>0} b_{m+r}\gamma_{-m}\gamma_{-r}. \quad (30c)$$

Note that d' (d'') includes only $c_{m>0}$ and $\gamma_{r>0}$ ($b_{m>0}$ and $\beta_{r>0}$). Also, the matter part is

included in d' only. The importance of the filtration is that $Q_0^{(\text{FGZ})}$ naturally breaks up into two differentials d' and d'' further. To see this, break \mathcal{H} as follows:

$$\mathcal{H} = \mathcal{V}(1, h^0) \otimes \mathcal{F}(b_{-m}, c_{-m}, \beta_{-r}, \gamma_{-r}) \otimes \mathcal{H}_K \quad (31a)$$

$$= \mathcal{F}^{\hat{c}=1} \otimes \mathcal{F}(c_{-m}, \gamma_{-r}) \otimes \mathcal{H}_K. \quad (31b)$$

Here, $\mathcal{F}^{\hat{c}=1} = \mathcal{V}(1, h^0) \otimes \mathcal{F}(b_{-m}, \beta_{-r})$. The Hilbert spaces \mathcal{H} , $\mathcal{F}^{\hat{c}=1}$, and $\mathcal{F}(c_{-m}, \gamma_{-r})$ are decomposed according to the ghost number $\hat{N}^g = n$:

$$\mathcal{H}^n = \left(\bigoplus_{\substack{n=c-b \\ c, b \geq 0}} \mathcal{F}^{\hat{c}=1^{-b}} \otimes \mathcal{F}^c(c_{-m}, \gamma_{-r}) \right) \otimes \mathcal{H}_K, \quad (32)$$

where

$$b = N^b + N^\beta, \quad (33a)$$

$$c = N^c + N^\gamma. \quad (33b)$$

Then, the differentials act as follows:

$$Q_0^{(\text{FGZ})} : \mathcal{H}^n \rightarrow \mathcal{H}^{n+1}, \quad (34a)$$

$$d' : \mathcal{F}^{\hat{c}=1^n} \rightarrow \mathcal{F}^{\hat{c}=1^{n+1}}, \quad (34b)$$

$$d'' : \mathcal{F}^n(c_{-m}, \gamma_{-r}) \rightarrow \mathcal{F}^{n+1}(c_{-m}, \gamma_{-r}), \quad (34c)$$

and $d'^2 = d''^2 = 0$. Thus, $\mathcal{F}^{\hat{c}=1^n}$ and $\mathcal{F}^n(c_{-m}, \gamma_{-r})$ are complexes with differentials d' and d'' . Note that $Q_0^{(\text{FGZ})}$ is the differential for \mathcal{H}^n as well as for $\hat{\mathcal{H}}^n$. We consider the cohomology on \mathcal{H}^n for the time being, but eventually relate it to the cohomology on $\hat{\mathcal{H}}^n$.

4.4 Step 1.2: Reduce the Problem to the d' -cohomology

The property that $Q_0^{(\text{FGZ})}$ is the sum of two differentials d' and d'' has an important consequence. This reduces the problem to the “ $\hat{c} = 1$ ” part only; we show that the vanishing theorem holds for the $Q_0^{(\text{FGZ})}$ -cohomology *if* the theorem holds for the d' -cohomology. Then, in the next subsection, we see that this assumption for d' -cohomology certainly holds.

First, decompose a $Q_0^{(\text{FGZ})}$ -closed state ϕ^n into a sum of products of ϕ_1^{-b} and ϕ_2^{n+b} with $b \geq 0$ and $n + b \geq 0$:

$$\phi^n = \sum_{b, n+b \geq 0} \phi_1^{-b} \phi_2^{n+b}. \quad (35)$$

The superscripts denote their ghost numbers. Suppose that every ϕ_1 is d' -exact for nonzero b :

$$\phi_1^{-b} = d' \chi_1^{-b-1}, \quad b > 0. \quad (36)$$

As a consequence, for ϕ^n with $n < 0$,

$$\begin{aligned}\phi^n &= \sum_{b \geq -n > 0} \phi_1^{-b} \phi_2^{n+b} \\ &= \sum d' \chi_1^{-b-1} \phi_2^{n+b}.\end{aligned}\tag{37}$$

Then, ϕ_2 is d'' -closed since

$$0 = Q_0^{(\text{FGZ})} \phi^n = \sum d' \chi_1^{-b-1} (-)^b (d'' \phi_2^{n+b}).\tag{38}$$

So, each term in the sum (35) can be written as

$$\begin{aligned}\phi_1 \phi_2 &= (d' \chi_1) \phi_2 \\ &= (d' \chi_1) \phi_2 + (-)^{b+1} \chi_1 d'' \phi_2 \\ &= Q_0^{(\text{FGZ})} (\chi_1 \phi_2) \quad \text{for } n < 0.\end{aligned}\tag{39}$$

Thus, ϕ is in fact $Q_0^{(\text{FGZ})}$ -exact. To summarize, we have shown that

$$\text{If } \phi_1^{-b} \text{ is } d'\text{-exact for } b > 0, \phi^n \text{ is } Q_0^{(\text{FGZ})}\text{-exact for } n < 0.$$

We can understand this as a consequence of a Künneth formula. The Künneth formula relates the cohomology group of \mathcal{H} to those of $\mathcal{F}^{\hat{c}=1^n}$ and $\mathcal{F}(c_{-m}, \gamma_{-r})$:

$$H^n(\mathcal{H}) = \bigoplus_{\substack{n=c-b \\ c, b \geq 0}} H^{-b}(\mathcal{F}^{\hat{c}=1^n}) \otimes H^c(\mathcal{F}(c_{-m}, \gamma_{-r})) \otimes \mathcal{H}_K.\tag{40}$$

If $H^{-b}(\mathcal{F}^{\hat{c}=1^n}) = 0$ for $b > 0$,

$$H^n(\mathcal{H}) = \bigoplus_{n=c} H^0(\mathcal{F}^{\hat{c}=1^n}) \otimes H^c(\mathcal{F}(c_{-m}, \gamma_{-r})) \otimes \mathcal{H}_K,\tag{41}$$

which leads to $H^n(\mathcal{H}) = 0$ for $n < 0$ because $c \geq 0$. Then, $H^n(\mathcal{H})^{L_0} = 0$ for $n < 0$.

The cohomology group we need is $H^n(\hat{\mathcal{H}})$, not $H^n(\mathcal{H})^{L_0}$. However, Lian and Zuckerman have shown that

$$H^n(\mathcal{H}^{L_0}) \cong H^n(\mathcal{H})^{L_0}.\tag{42}$$

For the R-sector, $\hat{\mathcal{H}} = \mathcal{H}^{L_0, G_0}$. From the above result, it can be also shown that $H^n(\mathcal{H}^{G_0}) = 0$ for $n < 0$. See pages 325-326 of Ref. [24]. Thus,

$$H^n(\hat{\mathcal{H}}, Q_0^{(\text{FGZ})}) = 0 \quad \text{if } n < 0,\tag{43}$$

and using Lemma 4.1,

$$H^n(\hat{\mathcal{H}}, \hat{Q}) = H^n(\hat{\mathcal{H}}, Q_0^{(\text{FGZ})}) = 0 \quad \text{if } n < 0.\tag{44}$$

We will later prove the Poincaré duality theorem, $H^n(\hat{\mathcal{H}}, \hat{Q}) = H^{-n}(\hat{\mathcal{H}}, \hat{Q})$ (Lemma 5.1). Therefore,

$$H^n(\hat{\mathcal{H}}, \hat{Q}) = 0 \quad \text{if } n \neq 0. \quad (45)$$

This is our vanishing theorem.

Actually, from Eq. (41), $H^n(\mathcal{H})$ does not include a state with $b, c \neq 0$. Thus, we have established a stronger statement:

Theorem 4.2 (FP-Ghost Decoupling Theorem). *Physical states do not contain Fadeev-Popov ghosts if \mathcal{H} is decomposed as in Eq. (21).*

Although the theorem itself is not necessary to establish the no-ghost theorem, it is useful to establish, *e.g.*, the BRST-OCQ equivalence [28].

To summarize, the problem of the \hat{Q} -cohomology is reduced to the one of the $Q_0^{(\text{FGZ})}$ -cohomology by Lemma 4.1, and we see in this subsection that the problem is further reduced to the one of the d' -cohomology. Thus, our problem now is

Lemma 4.2 (The Vanishing Theorem for the “ $\hat{c} = 1$ ” Part). *The d' -cohomology can be non-zero only at zero ghost number, i.e., $H^{-b}(\mathcal{F}_{\hat{c}=1}) = 0$ if $b > 0$.*

We prove the lemma in the next subsection.

4.5 Step 1.3: The Vanishing Theorem for the d' -cohomology

We now show the vanishing theorem for the “ $\hat{c} = 1$ ” part (Lemma 4.2). The proof is straightforward using Step 0 and an argument given in [26].

Proof of Lemma 4.2. From Step 0, a state $|\phi\rangle \in \mathcal{F}_{\hat{c}=1}$ can be written as

$$|\phi\rangle = \beta_{-r_1} \dots \beta_{-r_K} b_{-i_1} \dots b_{-i_L} G_{-\gamma_1}^0 \dots G_{-\gamma_N}^0 L_{-\lambda_1}^0 \dots L_{-\lambda_M}^0 |h^0\rangle, \quad (46)$$

where

$$\begin{aligned} 0 < r_1 \leq r_2 \leq \dots \leq r_K, \\ 0 < i_1 < i_2 < \dots < i_L, \\ 0 \leq \gamma_1 < \gamma_2 < \dots < \gamma_N, \\ 0 < \lambda_1 \leq \lambda_2 \leq \dots \leq \lambda_M. \end{aligned} \quad (47)$$

Note that the states in $\mathcal{F}_{\hat{c}=1}$ all have nonpositive ghost number: $\hat{N}^g|\phi\rangle = -(K + L)|\phi\rangle$.

We define a new filtration degree $N_f^{(\text{FK})}$ as

$$N_f^{(\text{FK})}|\phi\rangle = -(K + L + M + N)|\phi\rangle, \quad (48)$$

Operators	fdeg
c_m	1
b_{-m}	-1
γ_r	1
β_{-r}	-1
L_{-m}^0	-1
G_{-r}^0	-1

Table 5: Filtration degrees to each modes (for $m, r > 0$) for Lemma 4.2.

which corresponds to the assignments in Table 5. The operator $N_f^{(\text{FK})}$ satisfies conditions (25). Note that the filtration is not “consistent” with the Virasoro algebra: if one applies the rule to $[L_m^0, L_n^0] = (m-n)L_{m+n}^0 + \dots$, the degree of the left-hand side is -2 , whereas the degree of the right-hand side is -1 . This means that the filtration degree of a state $|\phi\rangle$ can be determined only *after* one specifies the ordering of the Virasoro generators. Here, we take the above ordering. Similarly, d' cannot be decomposed in itself; the degrees of d' are determined after one chooses a state $|\phi\rangle$ and arranges $d'|\phi\rangle$ in the above ordering. In general, the degree of d' is always non-negative, so we would like to extract the lowest degree, the degree zero part d'_0 of d' . Note that

$$d'|\phi\rangle = \left(\sum_{m>0} c_m L_{-m}^0 + \sum_{r>0} \gamma_r G_{-r}^0 \right) |\phi\rangle + (N_f^{(\text{FK})} > 0 \text{ terms}). \quad (49)$$

So, the d'_0 -part comes only from the first term. The first term may still include $N_f^{(\text{FK})} > 0$ terms; the d'_0 -part can be extracted only after one arranges the first term in the above ordering. In practice, this is easy and one just has to put operators in the correct position. Since Virasoro generators do not commute, extra terms may appear, but these extra terms do not contribute to the degree zero part. ⁵

Since we want a bounded filtration, break up $\mathcal{F}_{\hat{c}=1}$ according to L_0 eigenvalue l_0 :

$$\mathcal{F}_{\hat{c}=1} = \bigoplus_{l_0} \mathcal{F}_{\hat{c}=1}^{l_0}, \quad (50)$$

where

$$\mathcal{F}_{\hat{c}=1}^{l_0} = \mathcal{F}_{\hat{c}=1} \cap \text{Ker}(L_0 - l_0). \quad (51)$$

Then, the above filtration is bounded for each $\mathcal{F}_{\hat{c}=1}^{l_0}$ since $\mathcal{F}_{\hat{c}=1}^{l_0}$ is finite dimensional.

⁵This paragraph corrects a misleading argument in the analogous proof for the bosonic string (Lemma 4.1) in Ref. [27].

We first consider the d'_0 -cohomology on $\mathcal{F}_{\hat{c}=1}^{l_0}$ for each l_0 . Define an operator Γ such as

$$\begin{aligned} \Gamma|\phi\rangle = & \\ & \sum_{l=1}^M \beta_{-r_1} \cdots \beta_{-r_K} b_{-\lambda_l} (b_{-i_1} \cdots b_{-i_L}) L_{-\lambda_1}^0 \cdots \widehat{L_{-\lambda_l}^0} \cdots L_{-\lambda_M}^0 G_{-r_1}^0 \cdots G_{-r_N}^0 |h^0\rangle \\ & + \sum_{l=1}^N (-)^{L+l-1} \beta_{-r_l} (\beta_{-r_1} \cdots \beta_{-r_K}) b_{-\lambda_l} \cdots b_{-i_L} L_{-\lambda_1}^0 \cdots L_{-\lambda_M}^0 G_{-r_1}^0 \cdots \widehat{G_{-r_l}^0} \cdots G_{-r_N}^0 |h^0\rangle, \end{aligned} \quad (52)$$

where $\widehat{L_{-\lambda_l}^0}$ and $\widehat{G_{-r_l}^0}$ mean that the term is missing (When $M = 0$ or $N = 0$, $\Gamma|\phi\rangle \stackrel{\text{def}}{=} 0$). Then, it is straightforward to show that

$$\{d'_0, \Gamma\}|\phi\rangle = (K + L + M + N)|\phi\rangle. \quad (53)$$

The operator Γ is called a *homotopy operator* for d'_0 . Its significance is that the d'_0 -cohomology is trivial except for $K + \cdots + N = 0$. If $|\phi\rangle$ is closed, then

$$|\phi\rangle = \frac{\{d'_0, \Gamma\}}{K + \cdots + N}|\phi\rangle = \frac{1}{K + \cdots + N} d'_0 \Gamma |\phi\rangle. \quad (54)$$

Thus, a closed state $|\phi\rangle$ is actually an exact state if $K + \cdots + N \neq 0$. Therefore, the d'_0 -cohomology is trivial for $\hat{N}^g < 0$ since $\hat{N}^g = -(K + L)$. And now, again using Lemma 4.1, the d' -cohomology $H^n(\mathcal{F}_{\hat{c}=1}^{l_0})$ is trivial if $n < 0$.

Because $[d', L_0] = 0$, we can define

$$H^n(\mathcal{F}_{\hat{c}=1}^{l_0})^{l_0} = H^n(\mathcal{F}_{\hat{c}=1}) \cap \text{Ker}(L_0 - l_0). \quad (55)$$

Furthermore, as in Eq. (42), the isomorphism

$$H^n(\mathcal{F}_{\hat{c}=1})^{l_0} \cong H^n(\mathcal{F}_{\hat{c}=1}^{l_0}) \quad (56)$$

can be established. Consequently, $H^n(\mathcal{F}_{\hat{c}=1}) = 0$ if $n < 0$. \square

5 Step 2: The No-Ghost Theorem

Having shown the vanishing theorem, it is straightforward to show the no-ghost theorem:

Theorem 5.1 (The No-Ghost Theorem). $\hat{\mathcal{H}}_{\text{obs}}$ is a positive definite space when $1 \leq d \leq 10$.

The calculation below is essentially the same as the one in Refs. [24, 26], but we repeat it here for completeness.

5.1 The Outline of Step 2

In order to prove the theorem, the notion of *signature* is useful. For a vector space V with an inner product, we can choose a basis e_a such that

$$\langle e_a | e_b \rangle = \delta_{ab} C_a, \quad (57)$$

where $C_a \in \{0, \pm 1\}$. Then, the signature of V is defined as

$$\text{sign}(V) = \sum_a C_a, \quad (58)$$

which is independent of the choice of e_a . Note that if $\text{sign}(V) = \dim(V)$, all the C_a are 1, so V has positive definite norm.

So, the statement of the no-ghost theorem is equivalent to ⁶

$$\text{sign}(V_i^{\text{obs}}) = \dim(V_i^{\text{obs}}). \quad (59)$$

This can be replaced as a more useful form

$$\sum_i e^{-\lambda \alpha' m_i^2} \text{sign}(V_i^{\text{obs}}) = \sum_i e^{-\lambda \alpha' m_i^2} \dim(V_i^{\text{obs}}), \quad (60)$$

where λ is a constant or

$$\text{tr}_{\text{obs}} q^{L_0^{\text{osc}}} C = \text{tr}_{\text{obs}} q^{L_0^{\text{osc}}}, \quad (61)$$

where $q = e^{-\lambda}$ and we have used the on-shell condition (9). The operator C gives eigenvalues C_a .

Equation (61) is not easy to calculate; however, the following relation is straightforward to prove:

$$\text{tr} q^{L_0^{\text{osc}}} C = \text{tr} q^{L_0^{\text{osc}}} (-)^{\hat{N}^{\text{g}}}. \quad (62)$$

Here, the trace is taken over V_i and we take a basis which diagonalizes $(-)^{\hat{N}^{\text{g}}}$. Then, we can prove Eq. (61) by 3 steps in Table 6. Note that the trace weighted by $(-)^{\hat{N}^{\text{g}}}$ is an *index*.

The index is very similar to a partition function or a *character* of a Virasoro algebra, but there is an important difference. The index sums over the on-shell states only. In flat spacetime, the mass-shell condition can be always satisfied by suitably choosing k^μ , so the index takes the same form as the character with weight $(-)^{\hat{N}^{\text{g}}}$ (apart from a zero-mode contribution $q^{\alpha' k^2}$). In general, this is not the case though [28].

⁶In this section, we also write $V_i^{\text{obs}} = \hat{\mathcal{H}}_{\text{obs}}(k^2)$ and $V_i = \hat{\mathcal{H}}(k^2)$, where the subscript i labels different mass levels.

$$\begin{array}{ccc}
\mathrm{tr}_{\mathrm{obs}} q^{L_0^{\mathrm{osc}}} C & \text{No-Ghost Theorem} & \mathrm{tr}_{\mathrm{obs}} q^{L_0^{\mathrm{osc}}} \\
& \stackrel{=}{=} & \\
\text{Step 2.2 } \Downarrow & & \Downarrow \text{Step 2.1} \\
\mathrm{tr} q^{L_0^{\mathrm{osc}}} C & \text{Step 2.3} & \mathrm{tr} q^{L_0^{\mathrm{osc}}} (-)^{\hat{N}^{\mathrm{g}}} \\
& \stackrel{\leftrightarrow}{=} &
\end{array}$$

Table 6: Strategy to prove the no-ghost theorem.

5.2 Step 2.1

Proof of Step 2.1. At each mass level, states φ_m in V_i are classified into two kinds of representations: BRST singlets $\phi_{\bar{a}} \in V_i^{\mathrm{obs}}$ and BRST doublets (χ_a, ψ_a) , where $\chi_a = \hat{Q}\psi_a$. The ghost number of χ_a is the ghost number of ψ_a plus 1. Therefore, $(-)^{\hat{N}^{\mathrm{g}}}$ causes these pairs of states to cancel in the index and only the singlets contribute:

$$\mathrm{tr} q^{L_0^{\mathrm{osc}}} (-)^{\hat{N}^{\mathrm{g}}} = \mathrm{tr}_{\mathrm{obs}} q^{L_0^{\mathrm{osc}}} (-)^{\hat{N}^{\mathrm{g}}} \quad (63)$$

$$= \mathrm{tr}_{\mathrm{obs}} q^{L_0^{\mathrm{osc}}}. \quad (64)$$

We have used the vanishing theorem on the last line. \square

5.3 Step 2.2

Proof of Step 2.2. At a given mass level, the matrix of inner products among $|\varphi_m\rangle$ takes the form

$$\langle \varphi_m | \varphi_n \rangle = \begin{pmatrix} \langle \chi_a | \\ \langle \psi_a | \\ \langle \phi_{\bar{a}} | \end{pmatrix} (|\chi_b\rangle, |\psi_b\rangle, |\phi_{\bar{b}}\rangle) = \begin{pmatrix} 0 & M & 0 \\ M^\dagger & A & B \\ 0 & B^\dagger & D \end{pmatrix}. \quad (65)$$

We have used $\hat{Q}^\dagger = \hat{Q}$, $\langle \chi | \chi \rangle = \langle \chi | \hat{Q} | \psi \rangle = 0$ and $\langle \chi | \phi \rangle = \langle \psi | \hat{Q} | \phi \rangle = 0$. If M were degenerate, there would be a state χ_a which is orthogonal to all states in V_i . Thus, the matrix M should be nondegenerate. (Similarly, the matrix D should be nondegenerate as well.) So, a change of basis

$$\begin{aligned}
|\chi'_a\rangle &= |\chi_a\rangle, \\
|\psi'_a\rangle &= |\psi_a\rangle - \frac{1}{2}(M^{-\dagger}A)_{ba}|\chi_b\rangle, \\
|\phi'_{\bar{a}}\rangle &= |\phi_{\bar{a}}\rangle - (M^{-\dagger}B)_{b\bar{a}}|\chi_b\rangle,
\end{aligned} \quad (66)$$

sets $A = B = 0$. Finally, going to a basis,

$$\begin{aligned} |\chi''_a\rangle &= \frac{1}{\sqrt{2}}(|\chi'_a\rangle + M_{ba}^{-1}|\psi'_b\rangle), \\ |\psi''_a\rangle &= \frac{1}{\sqrt{2}}(|\chi'_a\rangle - M_{ba}^{-1}|\psi'_b\rangle), \\ |\phi''_a\rangle &= |\phi'_a\rangle, \end{aligned} \tag{67}$$

the inner product $\langle \varphi''_m | \varphi''_n \rangle$ becomes block-diagonal:

$$\langle \varphi''_m | \varphi''_n \rangle = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & D \end{pmatrix}. \tag{68}$$

Therefore, BRST doublets again make no net contribution:

$$\text{tr } q^{L_0^{\text{osc}}} C = \text{tr}_{\text{obs}} q^{L_0^{\text{osc}}} C. \tag{69}$$

This proves Step 2.2. \square

One can indeed check that M and D are nondegenerate. The inner product in V_i is written as the product of inner products in $\mathcal{F}(\alpha_{-m}^0, \psi_{-r}^0; s, k^0)$, superconformal ghost sector and \mathcal{H}_K . The inner product in $\mathcal{F}(\alpha_{-m}^0, \psi_{-r}^0; s, k^0)$ is easily seen to be diagonal and nondegenerate. For the ghost sector, the inner product becomes diagonal and nondegenerate as well by taking the basis

$$\begin{aligned} p_m &= \frac{1}{\sqrt{2}}(b_m + c_m), & m_m &= \frac{1}{\sqrt{2}}(b_m - c_m), \\ p_r &= \frac{1}{\sqrt{2}}(\gamma_r + \beta_r), & m_r &= \frac{1}{\sqrt{2}}(\gamma_r - \beta_r), \end{aligned} \tag{70}$$

whose (anti-)commutation relations are

$$\begin{aligned} \{p_m, p_n\} &= \delta_{m+n}, & \{p_m, m_n\} &= 0, & \{m_m, m_n\} &= -\delta_{m+n}, \\ [p_r^\dagger, p_s] &= \delta_{r-s}, & [p_r^\dagger, m_s] &= 0, & [m_r^\dagger, m_s] &= -\delta_{r-s}, \end{aligned} \tag{71}$$

where $\delta_{m+n} = \delta_{m+n,0}$. For the SCFT K sector, \mathcal{H}_K is assumed to have a positive-definite inner product. Therefore, the matrix $\langle \varphi_m | \varphi_n \rangle$ is nondegenerate. Consequently, the matrices M and D are also nondegenerate.

The inner product is nonvanishing only between the states with opposite ghost numbers. Since D is nondegenerate, BRST singlets of opposite ghost number must pair up. We have therefore established the Poincaré duality theorem as well:

Lemma 5.1 (Poincaré Duality). *BRST singlets of opposite ghost number must pair up, i.e.,*

$$H^{\hat{N}^{\text{g}}}(\hat{\mathcal{H}}, \hat{Q}) = H^{-\hat{N}^{\text{g}}}(\hat{\mathcal{H}}, \hat{Q}). \tag{72}$$

5.4 Step 2.3

Proof of Step 2.3. We prove Eq. (62) by explicitly calculating the both sides.

In order to calculate the left-hand side of Eq. (62), take an orthonormal basis of definite $N_{m,r}^p$, $N_{m,r}^m$ [the basis (5.3)], $N_{m,r}^0$ and a basis of \mathcal{H}_K . Then, $C = (-)^{N_m^m + N_r^m + N_m^0 + N_r^0}$. Similarly, for the right-hand side, take an orthonormal basis of definite N_m^b , N_m^c , N_r^β , N_r^γ , $N_{m,r}^0$ and an orthonormal basis of \mathcal{H}_K .

From these relations, the left-hand side of Eq. (62) becomes

$$\begin{aligned}
& \text{tr } q^{L_0^{\text{osc}}} C \\
&= \left\{ \begin{array}{l} 1 \quad (\text{NS}) \\ \frac{1}{2} \times 2 \quad (\text{R}) \end{array} \right\} \times q^{\frac{2\nu-9}{16}} \prod_{m,r>0} \left(\sum_{N_m^p=0}^1 q^{mN_m^p} \right) \left(\sum_{N_m^m=0}^1 q^{mN_m^m} (-)^{N_m^m} \right) \left(\sum_{N_m^0=0}^{\infty} q^{mN_m^0} (-)^{N_m^0} \right) \\
&\quad \times \left(\sum_{N_r^p=0}^{\infty} q^{rN_r^p} \right) \left(\sum_{N_r^m=0}^{\infty} q^{rN_r^m} (-)^{N_r^m} \right) \left(\sum_{N_r^0=0}^1 q^{rN_r^0} (-)^{N_r^0} \right) \text{tr}_{\mathcal{H}_K} q^{L_0^K} \\
&= q^{\frac{2\nu-9}{16}} \prod_{m,r} (1+q^m)(1-q^m)(1+q^m)^{-1}(1-q^r)^{-1}(1+q^r)^{-1}(1-q^r) \text{tr}_{\mathcal{H}_K} q^{L_0^K} \\
&= q^{\frac{2\nu-9}{16}} \prod_{m,r} \frac{1-q^m}{1+q^r} \text{tr}_{\mathcal{H}_K} q^{L_0^K}. \tag{73}
\end{aligned}$$

When $q = e^{2\pi i\tau}$, one can rewrite it as

$$\text{tr } q^{L_0^{\text{osc}}} C = \begin{cases} \sqrt{\frac{\eta^3}{\vartheta_{00}(0,\tau)}} q^{L_0^K - \frac{\hat{c}K}{16}} & (\text{NS}) \\ \sqrt{\frac{2\eta^3}{\vartheta_{10}(0,\tau)}} q^{L_0^K - \frac{\hat{c}K}{16}} & (\text{R}) \end{cases}, \tag{74}$$

where $\vartheta_{ab}(\nu, \tau)$ is the theta function with characteristics and $\eta(\tau)$ is the Dedekind eta function. The right-hand side becomes

$$\begin{aligned}
& \text{tr } q^{L_0^{\text{osc}}} (-)^{\hat{N}^g} \\
&= q^{\frac{2\nu-9}{16}} \prod_{m,r>0} \left(\sum_{N_m^b=0}^1 q^{mN_m^b} (-)^{N_m^b} \right) \left(\sum_{N_m^c=0}^1 q^{mN_m^c} (-)^{N_m^c} \right) \left(\sum_{N_m^0=0}^{\infty} q^{mN_m^0} \right) \\
&\quad \times \left(\sum_{N_r^\beta=0}^{\infty} q^{rN_r^\beta} (-)^{N_r^\beta} \right) \left(\sum_{N_r^\gamma=0}^{\infty} q^{rN_r^\gamma} (-)^{N_r^\gamma} \right) \left(\sum_{N_r^0=0}^1 q^{rN_r^0} \right) \text{tr}_{\mathcal{H}_K} q^{L_0^K} \\
&= q^{\frac{2\nu-9}{16}} \prod_{m,r} (1-q^m)(1-q^m)(1-q^m)^{-1}(1+q^r)^{-1}(1+q^r)^{-1}(1+q^r) \text{tr}_{\mathcal{H}_K} q^{L_0^K} \\
&= q^{\frac{2\nu-9}{16}} \prod_{m,r} \frac{1-q^m}{1+q^r} \text{tr}_{\mathcal{H}_K} q^{L_0^K}. \tag{75}
\end{aligned}$$

This proves Eq. (62). \square

Acknowledgments

We would like to thank Vijay Balasubramanian, Mirjam Cvetič, Yang-Hui He, Mitsuhiro Kato, Asad Naqvi, Burt Ovrut and Joe Polchinski for useful discussions. M.N. would like to thank theoretical high energy physics group at Univ. of Pennsylvania for the kind hospitality where parts of this work was carried out. The research of M.N. was supported in part by the Grant-in-Aid for Scientific Research (13740167) and the Oversea Research Fellowship from the Ministry of Education, Culture, Sports, Science and Technology, Japan..

A Some Basics

We follow the notations and conventions of Refs. [24, 30] (These references occasionally use different conventions; in this case, the conventions of Ref. [30] supersede the ones of Ref. [24].) The basic (anti-)commutation relations are

$$[\alpha_m^\mu, \alpha_n^\nu] = m\delta_{m+n} \eta^{\mu\nu}, \quad \{\psi_r^\mu, \psi_s^\nu\} = \delta_{r+s} \eta^{\mu\nu}, \quad (76)$$

$$\{b_m, c_n\} = \delta_{m+n}, \quad [\gamma_r, \beta_s] = \delta_{r+s}, \quad (77)$$

and $\delta_m = \delta_{m,0}$.

The super-Virasoro algebra is given by

$$[L_m, L_n] = (m-n)L_{m+n} + \frac{\hat{c}}{8}(m^3 - m)\delta_{m+n}, \quad (78)$$

$$\{G_r, G_s\} = 2L_{r+s} + \frac{\hat{c}}{8}(4r^2 - 1)\delta_{r+s}, \quad (79)$$

$$[L_m, G_r] = \frac{m-2r}{2}G_{m+r}, \quad (80)$$

where $\hat{c} = 2c/3$.

The $d = 1$ matter part of the super-Virasoro generators are given by

$$L_m^0 = -\frac{1}{2} \sum_{n \in \mathbf{Z}} \circ \alpha_{m-n}^0 \alpha_n^0 \circ - \frac{1}{4} \sum_{r \in \mathbf{Z} + \nu} (2r - m) \circ \psi_{m-r}^0 \psi_r^0 \circ + a^0 \delta_m, \quad (81)$$

$$G_r^0 = - \sum_{n \in \mathbf{Z}} \alpha_n^0 \psi_{r-n}^0, \quad (82)$$

where $a^0 = 0(\text{NS}), 1/16(\text{R})$ and $\nu = 1/2(\text{NS}), 0(\text{R})$. The Noether current for spacetime translation gives $\alpha_0^0 = \sqrt{2\alpha'k^0}$. The superconformal ghost part is given by

$$L_m^g = \sum_{n \in \mathbf{Z}} (m+n) \circ b_{m-n} c_n \circ + \sum_{r \in \mathbf{Z} + \nu} \frac{1}{2} (m+2r) \circ \beta_{m-r} \gamma_r \circ + a^g \delta_m, \quad (83)$$

$$G_r^g = - \sum_{n \in \mathbf{Z}} \left\{ \frac{1}{2} (2r+n) \beta_{r-n} c_n + 2b_n \gamma_{r-n} \right\}, \quad (84)$$

where $a^g = -1/2(\text{NS}), -5/8(\text{R})$.

The ghost number operator \hat{N}^g counts the number of c, γ minus the number of b, β excitations:

$$\hat{N}^g = \sum_{m>0} (c_{-m}b_m - b_{-m}c_m) - \sum_{r>0} (\gamma_{-r}\beta_r + \beta_{-r}\gamma_r) \quad (85)$$

$$= \sum_{m>0} (N_m^c - N_m^b) + \sum_{r>0} (N_r^\gamma - N_r^\beta). \quad (86)$$

The operator \hat{N}^g is related to the standard ghost number operator N^g as

$$N^g = \hat{N}^g + c_0b_0 - (1 - 2\nu)\gamma_{-\nu}\beta_\nu - \nu. \quad (87)$$

The ghost zero modes will not matter to our discussion. Note that the operator \hat{N}^g is also normalized so that $\hat{N}^g|0_g\rangle = 0$. ($|0_g\rangle$ denotes a ghost ground state. See App. B.)

The BRST operator is

$$Q = \sum_m c_{-m}(L_m^0 + L_m^K) + \sum_r \gamma_{-r}(G_r^0 + G_r^K) - \sum_{m,n} \frac{1}{2}(n-m) \circ b_{-m-n}c_m c_n \circ + \sum_{m,r} \left\{ \frac{1}{2}(2r-m) \circ \beta_{-m-r}c_m \gamma_r \circ - \circ b_{-m} \gamma_{m-r} \gamma_r \circ \right\} + a^g c_0 \quad (88)$$

with the part from the unitary SCFT K . The BRST operator can be decomposed in terms of ghost zero modes as follows:

$$Q = \begin{cases} \hat{Q} + c_0L_0 + b_0M & (\text{NS}) \\ \hat{Q} + c_0L_0 + b_0M + \gamma_0G_0 + \beta_0N - \gamma_0^2b_0 & (\text{R}) \end{cases}, \quad (89)$$

where $M = -2\sum_{m>0}(mc_{-m}c_m + \gamma_{-m}\gamma_m)$, $N = \frac{3}{2}\sum_{r>0}c_{-r}\gamma_r$, and \hat{Q} is the collection of the terms in Q without b_0, c_0, β_0 , and γ_0 .

B Hilbert Spaces, Ground States, and Inner Products

We first describe the Hilbert spaces $\mathcal{H}_{\text{total}}$, \mathcal{H} , and $\hat{\mathcal{H}}(k^2)$ more explicitly. In particular, we need an appropriate inner product on $\hat{\mathcal{H}}(k^2)$ to establish the no-ghost theorem.

The raising operators are $\alpha_{-m}^\mu, \psi_{-r}^\mu, b_{-m}, c_{-m}, \beta_{-r}$, and γ_{-r} ($m, r > 0$). For zero modes, we define that p_μ, b_0 , and β_0 are grouped with the lowering operators and x^μ, c_0 , and γ_0 with the raising operators in $\mathcal{H}_{\text{total}}$. In the ghost sector, the ground state is given by $|\downarrow\rangle$, where

$$b_0|\downarrow\rangle = 0, \quad |\uparrow\rangle = c_0|\downarrow\rangle. \quad (90)$$

In the superconformal ghost sector, the ground state is given by

(i) NS-sector:

$$\beta_r |\frac{1}{2}\rangle = 0, \quad r > 0, \quad (91)$$

$$\gamma_r |\frac{1}{2}\rangle = 0, \quad r > 0. \quad (92)$$

(ii) R-sector:

$$\beta_r |1\rangle = 0, \quad r \geq 0, \quad (93)$$

$$\gamma_r |1\rangle = 0, \quad r > 0. \quad (94)$$

The matter R ground states $|s, k\rangle$ are given by a representation of the gamma matrix algebra of ψ_0^μ . It has 32-dimensional in $d = 10$ and 2-dimensional in $d = 1$; they are labeled by s .

The Hilbert space \mathcal{H} is a subspace of $\mathcal{H}_{\text{total}}$ and it is defined by the condition $b_0 = 0$ (and $\beta_0 = 0$ in R-sector) as in Eqs. (7) and (8). So, it is represented as

$$\mathcal{H} = \begin{cases} \mathcal{F}(\alpha_{-m}^\mu, \psi_{-r}^\mu; k) \otimes \mathcal{F}(b_{-m}, c_{-m}, \beta_{-r}, \gamma_{-r}; \downarrow, \frac{1}{2}) \otimes \mathcal{H}_K & \text{(NS)} \\ \mathcal{F}(\alpha_{-m}^\mu, \psi_{-r}^\mu; s, k) \otimes \mathcal{F}(b_{-m}, c_{-m}, \beta_{-r}, \gamma_{-r}; \downarrow, 1) \otimes \mathcal{H}_K & \text{(R)} \end{cases} \quad (95)$$

Here, $\mathcal{F}(\alpha_{-m}^\mu, \psi_{-r}^\mu; k)$ is a Fock space spanned by all α_{-m}^μ and ψ_{-r}^μ ($m, r > 0$) on the matter ground state $|k\rangle = e^{ikx}|0\rangle$ (and similarly for the others). A state in \mathcal{H}_K is constructed by Verma modules of K on a highest weight state $|h^K\rangle$.

In the NS-sector, $\hat{\mathcal{H}}(k^2)$ is given by imposing L_0 -condition on \mathcal{H} :

$$\hat{\mathcal{H}}(k^2) = (\mathcal{F}(\alpha_{-m}^\mu, \psi_{-r}^\mu; s, k) \otimes \mathcal{F}(b_{-m}, c_{-m}, \beta_{-r}, \gamma_{-r}; 0_g) \otimes \mathcal{H}_K)^{L_0}. \quad (96)$$

where $|0_g\rangle$ denotes the ghost ground state $|\downarrow, \frac{1}{2}\rangle$. The inner product in the space $\hat{\mathcal{H}}(k^2)$ is given by

$$\langle 0, I; k, 0_g || 0, I'; k, 0_g \rangle = \delta_{II'} \quad (97)$$

with the hermiticity property,

$$\begin{aligned} (\alpha_m^\mu)^\dagger &= \alpha_{-m}^\mu, & b_m^\dagger &= b_{-m}, & c_m^\dagger &= c_{-m}, \\ (\psi_r^\mu)^\dagger &= \psi_{-r}^\mu, & \beta_r^\dagger &= -\beta_{-r}, & \gamma_r^\dagger &= \gamma_{-r}. \end{aligned} \quad (98)$$

Here I labels the states of the unitary SCFT K . We take the basis I to be orthonormal. Note that the above hermiticity is consistent with the hermiticity of the BRST charge Q on the inner product $\langle || \rangle$. The relation of this inner product $\langle || \rangle$ with that $\langle | \rangle$ in $\mathcal{H}_{\text{total}}$ is

$$\langle 0, I; k, \uparrow, \frac{1}{2} | 0, I'; k', \downarrow, \frac{1}{2} \rangle = 2\pi\delta(k^2 - k'^2) \langle 0; k, 0_g, I || 0; k', 0_g, I' \rangle. \quad (99)$$

We write $\langle \dots || \dots \rangle$ as $\langle \dots | \dots \rangle$ in this paper.

On the other hand, in the R-sector, the space $\hat{\mathcal{H}}(k^2)$ is given by $\hat{\mathcal{H}}(k^2) = \mathcal{H}^{L_0, G_0}$. The L_0 -condition is the same as the NS-sector and it just gives the space $\mathcal{H}^{L_0}(k^2)$ by imposing the condition $\alpha'k^2 + L_0^{\text{osc}} = 0$ on \mathcal{H} . To obtain $\hat{\mathcal{H}}(k^2)$, we have to impose the condition $G_0 = 0$ on

\mathcal{H}^{L_0} further. The dimension of $\hat{\mathcal{H}}(k^2)$ is half of the space $\mathcal{H}^{L_0}(k^2)$. This is verified as follows: First, note that G_0 defines a complex on \mathcal{H}^{L_0} since $G_0^2 = 0$ in \mathcal{H}^{L_0} . If $|\phi\rangle$ is a G_0 -closed state, $G_0|\phi\rangle = 0$, then by using the relation $\{G_0, \psi_0^0/\alpha_0^0\} = 1$,

$$|\phi\rangle = \left\{ G_0, \frac{\psi_0^0}{\alpha_0^0} \right\} |\phi\rangle = G_0 \left(\frac{\psi_0^0}{\alpha_0^0} |\phi\rangle \right). \quad (100)$$

Namely, ψ_0^0/α_0^0 is the homotopy operator for G_0 and $|\phi\rangle$ is G_0 -exact. Thus, \mathcal{H}^{L_0} has no G_0 -singlets and only G_0 -doublets exist. The G_0 -daughter states contribute to $\hat{\mathcal{H}}(k^2)$ whereas the G_0 -parent states do not. Since the number of daughter states is equal to the number of parent states, the space $\hat{\mathcal{H}}(k^2)$ has half the states of $\mathcal{H}^{L_0}(k^2)$. Note that these daughter states can be written as $\hat{\mathcal{H}} = G_0\mathcal{H}^{L_0}$.

Now we specify the base and the inner product of $\hat{\mathcal{H}}(k^2)$ when $d = 1$. In this case, 2-dimensional fermion zero mode vector is represented, *e.g.*, by $|\pm, k\rangle$ with $|+, k\rangle = \psi_0^0|-, k\rangle$. Define a ‘world-sheet fermion number operator’ f which counts the number of all world-sheet fermions *without* ψ_0^0 in a state $|\phi\rangle \in \mathcal{H}^{L_0}(k^2)$. [Hence $(-)^f |\pm\rangle = |\pm\rangle$.] The exclusion of the zero mode is the difference from the world-sheet fermion number used in the GSO projection. In \mathcal{H}_K , where states are represented by Verma module of K , the fermion number is defined by the number of G_{-r}^K ’s ($r \geq 0$). Using this operator, we divide the space $\mathcal{H}^{L_0}(k^2)$ into two spaces \mathcal{H}^0 and \mathcal{H}^1 as

$$\mathcal{H}^a = \{|\phi; \pm, k\rangle | (-)^f = a\}, \quad (101)$$

where $a = 0$ or 1 . Note that $\dim \mathcal{H}^0 = \dim \mathcal{H}^1 (= \dim \hat{\mathcal{H}})$.

As remarked earlier, $\hat{\mathcal{H}} = G_0\mathcal{H}^{L_0}$. One can show that all the states within $G_0\mathcal{H}^0$ are independent. Likewise, the states in $G_0\mathcal{H}^1$ are independent, and actually $G_0\mathcal{H}^0 = G_0\mathcal{H}^1$. So, one can take either $G_0\mathcal{H}^0$ or $G_0\mathcal{H}^1$ as a base of $\hat{\mathcal{H}}$. We set the non-degenerate inner product of each of these spaces by the inner product of \mathcal{H}^0 or \mathcal{H}^1 which is defined by

$$\langle 0, I; s, k, 0_g | 0, I'; s', k, 0_g \rangle = \delta_{ss'} \delta_{II'} \quad (102)$$

with the hermiticity property Eqs. (98), where $|0_g\rangle$ denotes the ghost ground state $|\downarrow, 1\rangle$. Our construction of the Hilbert space and the inner product is essentially the same as Ref. [24].

We can check that the structure (dimension of \mathcal{H}^a , signature, and index) of these two spaces $G_0\mathcal{H}^a$ ($a = 0, 1$) under the above inner product are exactly the same. Thus, we perform the calculation concerning the no-ghost theorem in Sec. 5 as follows:

1. First, consider the space $\mathcal{H}^{L_0}(k^2)$ with the inner product Eq. (102).
2. Then, calculate the dimension and the signature in the space \mathcal{H}^{L_0} .
3. Finally, divide these results by 2. This gives the correct results on $\hat{\mathcal{H}}(k^2)$.

Note that the assumption $\alpha_0^0 = \sqrt{2\alpha'}k^0 \neq 0$ is crucial in the above discussion.

C Kac Determinant

For a $\mathcal{N} = 1$ superconformal algebra, a Verma module $\mathcal{V}(\hat{c}, h)$ consists of all states of the form

$$|h, \{\lambda\}\rangle = G_{-\gamma_1} G_{-\gamma_2} \dots G_{-\gamma_N} L_{-\lambda_1} L_{-\lambda_2} \dots L_{-\lambda_M} |h\rangle, \quad (103)$$

where $0 \leq \gamma_1 < \gamma_2 < \dots < \gamma_N$ and $0 < \lambda_1 \leq \lambda_2 \leq \dots \leq \lambda_M$. Here, each G_{-r} acts at most once since $G_{-r}^2 = L_{-2r} + \hat{c}(4r^2 - 1)/16$.

Consider the matrix of inner products for the states at level N :

$$\mathcal{M}_{\{\lambda\}, \{\lambda'\}}^N(\hat{c}, h) = \langle h, \{\lambda\} | h, \{\lambda'\} \rangle, \quad \sum_i \gamma_i + \lambda_i = N. \quad (104)$$

The Kac determinant is then given by

$$\det[\mathcal{M}^N(\hat{c}, h)]_{\text{NS}} = K_N \prod_{1 \leq rs \leq 2N} (h - h_{r,s})^{P_{\text{NS}}(N-rs/2)}, \quad (105a)$$

$$\det[\mathcal{M}^N(\hat{c}, h)]_{\text{R}} = (h - \frac{\hat{c}}{16})^{P_{\text{R}}(N)/2} K_N \prod_{1 < rs \leq 2N} (h - h_{r,s})^{P_{\text{R}}(N-rs/2)}, \quad (105b)$$

where K_N is a positive constant, $r, s =$ positive integer and $r - s =$ even (NS), odd (R). We normalized $\langle h | h \rangle = 1$. The multiplicity of the roots $P_{\text{NS,R}}(k)$ is given by

$$\prod_{n=1}^{\infty} \frac{1 + q^{n-1/2}}{1 - q^n} = \sum_{k=0}^{\infty} P_{\text{NS}}(k) q^k, \quad (106a)$$

$$\prod_{n=1}^{\infty} \frac{1 + q^{n-1}}{1 - q^n} = \sum_{k=0}^{\infty} P_{\text{R}}(k) q^k. \quad (106b)$$

The zeros of the Kac determinant are at

$$h_{r,s} = \frac{\hat{c} - 1 + \epsilon}{16} + \frac{1}{4}(r\alpha_+ + s\alpha_-)^2, \quad (107)$$

where $\epsilon = 0$ (NS), 1 (R) and

$$\alpha_{\pm} = \frac{1}{4}(\sqrt{1 - \hat{c}} \pm \sqrt{9 - \hat{c}}). \quad (108)$$

In addition, the determinant vanishes at $h = \hat{c}/16$ in the R-sector.

D Some Useful Commutators

In this appendix, we collect some useful commutators:

$$\begin{aligned}
[L_m, \alpha_n^\nu] &= -n\alpha_{m+n}^\nu, & [L_m, \psi_r^\nu] &= -\frac{1}{2}(m+2r)\psi_{m+r}^\nu, \\
[L_m, b_n] &= (m-n)b_{m+n}, & [L_m, c_n] &= (-2m-n)c_{m+n}, \\
[L_m, \beta_r] &= \frac{1}{2}(m-2r)\beta_{m+r}, & [L_m, \gamma_r] &= -\frac{1}{2}(3m+2r)\gamma_{m+r}, \\
[Q, L_m] &= 0, & \{Q, G_r\} &= 0, \\
[Q, \alpha_m^\nu] &= -\sum_n mc_n\alpha_{m-n}^\nu - \sum_r m\gamma_{-r}\psi_{m+r}^\nu, & \{Q, \psi_r^\nu\} &= \sum_s \gamma_{-s}\alpha_{r+s}^\nu - \sum_s \frac{1}{2}(s+2r)c_{-s}\psi_{r+s}, \\
\{Q, b_m\} &= L_m, & \{Q, c_m\} &= -\sum_n nc_{-n}c_{m+n} - \sum_s \gamma_{-s}\gamma_{m+s}, \\
[Q, \beta_r] &= G_r, & [Q, \gamma_r] &= -\sum_s \frac{1}{2}(3s-r)c_{r-s}\gamma_s, \\
[G_r, \alpha_m^\nu] &= -m\psi_{r+m}^\nu, & \{G_r, \psi_s^\nu\} &= \alpha_{r+s}^\nu, \\
\{G_r, b_m\} &= -\frac{1}{2}(2r-m)\beta_{r+m}, & \{G_r, c_m\} &= -2\gamma_{r+m}, \\
[G_r, \beta_s] &= -2b_{r+s}, & [G_r, \gamma_s] &= \frac{1}{2}(3r+s)c_{r+s}, \\
[N^g, b_m] &= -b_m, & [N^g, c_m] &= c_m, \\
[N^g, \beta_r] &= -\beta_r, & [N^g, \gamma_r] &= \gamma_r, \\
[N^g, L_m] &= 0, & [N^g, Q] &= Q, \\
[N^g, G_r] &= 0.
\end{aligned}$$
