# A Survey of Results on Random Random Walks on Finite Groups

Martin Hildebrand Department of Mathematics and Statistics University at Albany State University of New York Albany, NY 12222

November 2, 2018

#### Abstract

A number of papers have examined various aspects of "random random walks" on finite groups; the purpose of this article is to provide a survey of this work and to show, bring together, and discuss some of the arguments and results in this work. This article also provides a number of exercises. Some exercises involve straightforward computations; others involve proving details in proofs or extending results proved in the article. This article also describes some problems for further study.

### 1 Introduction

Random walks on the integers  $\mathbb Z$  are familiar to many students of probability. (See, for example, Ch. XIV of Feller, volume 1 [\[8\]](#page-35-0), Ch. XII of Feller, volume 2 [\[9\]](#page-35-1), or Ross [\[21\]](#page-36-0)). Such random walks are of the form  $X_0, X_1, X_2, \ldots$  where  $X_0 = 0$  and  $X_m = Z_1 + \ldots + Z_m$  where  $Z_1, Z_2, \ldots$  are independent, identically distributed random variables on  $\mathbb{Z}$ . A commonly studied random walk on  $\mathbb{Z}$ has  $P(Z_i = 1) = P(Z_i = -1) = 1/2$ . Various questions involving such random walks have been well studied. For example, one may ask what is the probability that there exists an  $m > 0$  such that  $X_m = 0$ . In the example with  $P(Z_i = 1) = P(Z_i = -1) = 1/2$ , it can be shown that this probability is 1. (See [\[8\]](#page-35-0), p. 360.) For another example, one can use the DeMoivre-Laplace Limit Theorem to get a good approximation of the distribution of  $X_m$  for large m.

One can examine random walks on sets other then  $\mathbb{Z}$ . For instance, there are random walks on  $\mathbb{Z}^2$  or  $\mathbb{Z}^3$ . A symmetric random walk on  $\mathbb{Z}^2$  has  $X_0 =$  $(0, 0)$  and  $P(Z_i = (1, 0)) = P(Z_i = (-1, 0)) = P(Z_i = (0, 1)) = P(Z_i = 0)$  $(0, -1)$  = 1/4 while a symmetric random walk on  $\mathbb{Z}^3$  has  $X_0 = (0, 0, 0)$ and  $P(Z_i = (1, 0, 0)) = P(Z_i = (-1, 0, 0)) = P(Z_i = (0, 1, 0)) = P(Z_i = 0)$  $(0, -1, 0) = P(Z_i = (0, 0, 1)) = P(Z_i = (0, 0, -1)) = 1/6$ . It can be shown for this random walk on  $\mathbb{Z}^2$ , the probability that there exists an  $m > 0$  such that  $X_m = (0,0)$  is 1 while for this random walk on  $\mathbb{Z}^3$ , the probability that there exists an  $m > 0$  such that  $X_m = (0, 0, 0)$  is less than 1. (See pp. 360-361 of [\[8\]](#page-35-0) for a description and proof. Feller attributes these results to Polya [\[19\]](#page-36-1) and computation of the probability in the walk on  $\mathbb{Z}^3$  to McCrea and Whipple [\[17\]](#page-36-2).)

One can similarly look at random walks on  $\mathbb{Z}_n$ , the integers modulo n, where  $n$  is a positive integer. Like the walks on the integers, the random walk is of the form  $X_0, X_1, X_2, \ldots$  where  $X_0 = 0$  and  $X_m = Z_1 + \ldots + Z_m$  where  $Z_1, Z_2, \ldots$  are i.i.d. random variables on  $\mathbb{Z}_n$ . One example of such a random walk has  $P(Z_i = 1) = P(Z_i = -1) = 1/2$  and n being an odd positive integer. This random walk on  $\mathbb{Z}_n$  corresponds to a finite Markov chain which is irreducible, aperiodic, and doubly stochastic. (For more details on this notation, see Ross [\[21\]](#page-36-0).) Thus the stationary probability for this Markov chain will be uniformly distributed on  $\mathbb{Z}_n$ . (If P is a probability uniformly distributed on  $\mathbb{Z}_n$ , then  $P(a) = 1/n$  for each  $a \in \mathbb{Z}_n$ .) Furthermore, after a large enough number of steps, the position of the random walk will be close to uniformly distributed on  $\mathbb{Z}_n$ .

One may consider other probabilities on  $\mathbb{Z}_n$  for  $Z_i$  in the random walk. For example, on  $\mathbb{Z}_{1000}$ , we might have  $P(Z_i = 0) = P(Z_i = 1) = P(Z_i = 1)$  $10) = P(Z_i = 100) = 1/4$ . Again Markov chain arguments can often show that the stationary distribution for the corresponding Markov chain will be uniformly distributed on  $\mathbb{Z}_n$  and that after a large enough number of steps, the position of the random walk will be close to uniformly distributed on  $\mathbb{Z}_{1000}$ . A reasonable question to ask is how large should m be to ensure that  $X_m$  is close to uniformly distributed.

One may generalize the notion of a random walk to an arbitrary finite group  $G$ . We shall suppose that the group's operation is denoted by mul-

tiplication. The random walk will be of the form  $X_0, X_1, X_2, \ldots$  where  $X_0$ is the identity element of G,  $X_m = Z_m Z_{m-1} \dots Z_2 Z_1$ , and  $Z_1, Z_2, \dots$  are i.i.d. random variables on  $G$ . (A random variable  $X$  on  $G$  is such that  $Pr(X = g) \ge 0$  for each  $g \in G$  and  $\sum_{g \in G} Pr(X = g) = 1$ . An alternate definition of a random walk on G has  $X_m = Z_1 Z_2 ... Z_{m-1} Z_m$  instead of  $X_m = Z_m Z_{m-1} \dots Z_2 Z_1$ . If G is not abelian, then the different definitions may correspond to different Markov chains. However, probabilities involving  $X_m$  alone do not depend on which definition we are using.

An example of a random walk on  $S_n$ , the group of all permutations on  $\{1,\ldots,n\}$ , has  $P(Z_i = e) = 1/n$  where e is the identity element and  $P(Z_i = \tau) = 2/n^2$  for each transposition  $\tau$ . Yet again, Markov chain arguments can show that after a large enough number of steps, this random walk will be close to uniformly distributed over all n! permutations in  $S_n$ . Again a reasonable question to ask is how large should  $m$  be to ensure that  $X_m$  is close to uniformly distributed over all the permutations in  $S_n$ . This problem is examined in Diaconis and Shahshahani [\[4\]](#page-35-2) and also is discussed in Diaconis [\[3\]](#page-35-3).

A number of works discuss various random walks on finite groups. A couple of overviews are Diaconis' monograph [\[3\]](#page-35-3) and Saloff-Coste's survey [\[22\]](#page-36-3).

In this article, we shall focus on "random random walks" on finite groups. To do so, we shall pick a probability for  $Z_i$  at random from a set of probabilities for  $Z_i$ . Then, given this probability for  $Z_i$ , we shall examine how close  $X_m$  is to uniformly distributed on G. To measure the distance a probability is from the uniform distribution, we shall use the variation distance. Often, we shall look at the average variation distance of the probability of  $X_m$  from the uniform distribution; this average is over the choices for the probabilities for  $Z_i$ . The next section will make these ideas more precise.

# 2 Notation

If  $P$  is a probability on  $G$ , we define the variation distance of  $P$  from the uniform distribution  $U$  on  $G$  by

$$
||P - U|| = \frac{1}{2} \sum_{s \in G} \left| P(s) - \frac{1}{|G|} \right|.
$$

Note that  $U(s) = 1/|G|$  for all  $s \in G$ .

EXERCISE. Show that  $||P - U|| \leq 1$ .

EXERCISE. Show that

$$
||P - U|| = \max_{A \subseteq G} |P(A) - U(A)|
$$

where  $A$  ranges over all subsets of  $G$ . (Note that  $A$  does not have to be a subgroup of  $G$ .)

A random variable X on G is said to have probability P if  $P(s) = Pr(X =$ s) for each  $s \in G$ .

If P and Q are probabilities on  $G$ , we define the *convolution* of P and  $Q$ by

$$
P * Q(s) = \sum_{t \in G} P(t)Q(t^{-1}s).
$$

Note that if  $X$  and  $Y$  are independent random variables on  $G$  with probabilities P and Q, respectively, then  $P * Q$  is the probability of the random variable XY on G.

If m is a positive integer and  $P$  is a probability on  $G$ , we define

$$
P^{*m} = P * P^{*(m-1)}
$$

where

$$
P^{*0}(s) = \begin{cases} 1 & \text{if } s = e \\ 0 & \text{otherwise} \end{cases}
$$

with e being the identity element of G. Thus if  $Z_1, \ldots, Z_m$  are i.i.d. random variables on  $G$  each with probability  $P$ , then  $P^{*m}$  is the probability of the random variable  $Z_m Z_{m-1} \dots Z_2 Z_1$  on  $G$ .

For example, on  $\mathbb{Z}_{10}$ , suppose  $P(0) = P(1) = P(2) = 1/3$ . Then  $P^{*2}(0) =$  $1/9, P^{*2}(1) = 2/9, P^{*2}(2) = 3/9, P^{*2}(3) = 2/9, P^{*2}(4) = 1/9, \text{ and } P^{*2}(s) =$ 0 for the remaining elements  $s \in \mathbb{Z}_{10}$ . Furthermore

$$
||P^{*2} - U|| = \frac{1}{2} \left( \left| \frac{1}{9} - \frac{1}{10} \right| + \left| \frac{2}{9} - \frac{1}{10} \right| + \left| \frac{3}{9} - \frac{1}{10} \right| + \left| \frac{2}{9} - \frac{1}{10} \right| + \left| \frac{1}{9} - \frac{1}{10} \right|
$$
  
+ 
$$
\left| 0 - \frac{1}{10} \right| + \left| 0 - \frac{1}{10} \right| \right)
$$
  
= 
$$
\frac{1}{2}
$$

EXERCISE. Let Q be a probability on  $\mathbb{Z}_{10}$ . Suppose  $Q(0) = Q(1) =$  $Q(4) = 1/3$ . Compute  $Q^{*2}$  and  $||Q^{*2} - U||$ .

EXERCISE. Consider the probability  $P$  in the previous example and the probability Q in the previous exercise. Compute  $P^{*4}$ ,  $Q^{*4}$ ,  $||P^{*4} - U||$ , and  $||Q^{*4} - U||.$ 

Let  $a_1, a_2, \ldots a_k \in G$ . Suppose  $p_1, \ldots, p_k$  are positive numbers which sum to 1. Let

$$
P_{a_1,...,a_k}(s) = \sum_{b=1}^{k} p_b \delta_{s,a_b}
$$

where

$$
\delta_{s,a_b} = \begin{cases} 1 & \text{if } s = a_b \\ 0 & \text{otherwise.} \end{cases}
$$

The random walk  $X_0, X_1, X_2, \ldots$  where  $Z_1, Z_2, \ldots$  are i.i.d. random variables on G with probability  $P_{a_1,...,a_k}$  is said to be supported on  $(a_1,...,a_k)$ .

If we know k and  $p_1, \ldots, p_k$ , then in theory we can find

$$
\|P_{a_1,\ldots,a_k}^{*m}-U\|
$$

for any k-tuple  $(a_1, \ldots, a_k)$  and positive integer m. Thus if we have some probability distribution for  $(a_1, \ldots, a_k)$ , we can in theory find

$$
E(||P_{a_1,...,a_k}^{*m} - U||)
$$

for each positive integer  $m$  since this variation distance is a function of the random k-tuple  $(a_1, \ldots, a_k)$ .

In a random random walk, a typical probability for  $Z_i$  will be  $P_{a_1,...,a_k}$ where  $p_1 = p_2 = \ldots = p_k = 1/k$  and  $(a_1, a_2, \ldots, a_k)$  chosen uniformly over all k-tuples with distinct elements of G. However, other probabilities for  $Z_i$ sometimes may be considered instead.

For example, on  $\mathbb{Z}_5$ , suppose we let  $p_1 = p_2 = p_3 = 1/3$  and we choose  $(a_1, a_2, a_3)$  at random over all 3-tuples with distinct elements of  $\mathbb{Z}_5$ . Then

$$
E(\|P_{a_1,a_2,a_3}^{*m} - U\|) = \frac{1}{10} \left( \|P_{0,1,2}^{*m} - U\| + \|P_{0,1,3}^{*m} - U\| + \|P_{0,1,4}^{*m} - U\| + \|P_{0,2,3}^{*m} - U\| + \|P_{0,2,4}^{*m} - U\| + \|P_{0,3,4}^{*m} - U\| + \|P_{1,2,3}^{*m} - U\| + \|P_{1,2,4}^{*m} - U\| + \|P_{1,3,4}^{*m} - U\| + \|P_{2,3,4}^{*m} - U\| \right) .
$$

Note that we are using facts such as  $P_{0,1,2} = P_{2,1,0} = P_{1,2,0}$  since  $p_1 = p_2$  $p_3 = 1/3$ ; thus we averaged over 10 terms instead of over 60 terms.

We shall often write  $E(||P^{*m} - U||)$  instead of  $E(||P^{*m}_{a_1,\dots,a_k} - U||)$ .

Often times we shall seek upper bounds on  $E(\Vert P^{*m} - U \Vert)$ . Note that by Markov's inequality, if  $E(||P^{*m} - U||) \le u$ , then  $Pr(||P^{*m} - U|| \ge cu) \le$  $1/c$  for  $c > 1$  where the probability is over the same choice of the k-tuple  $(a_1, \ldots, a_k)$  as used in determining  $E(||P^{*m} - U||)$ .

Lower bounds tend to be found on  $||P^{*m} - U||$  for all  $a_1, \ldots, a_k$ , and we turn our attention to some lower bounds in the next section.

EXERCISE. Compute  $E(||P^{*4} - U||)$  if  $G = \mathbb{Z}_{11}$ ,  $k = 3$ ,  $p_1 = p_2 =$  $p_3 = 1/3$ , and  $(a_1, a_2, a_3)$  are chosen uniformly from all 3-tuples with distinct elements of G. It may be very helpful to use a computer to deal with the very tedious calculations; however, it may be instructive to be aware of the different values of  $||P^{*4} - U||$  for the different choices of  $a_1$ ,  $a_2$ , and  $a_3$ . In particular, what can you say about  $||P_{a_1,a_2,a_3}^{*4} - U||$  and  $||P_{0,a_2-a_1,a_3-a_1}^{*4} - U||$ ?

Throughout this article, there are a number of references to logarithms. Unless a base is specified, the expression log refers to the natural logarithm.

## 3 Lower bounds

### 3.1 Lower bounds on  $\mathbb{Z}_n$  with  $k=2$

In examining our lower bounds, we shall first look at an elementary case. Suppose  $G = \mathbb{Z}_n$ . We shall consider random walks supported on 2 points. The lower bound is given by the following:

**Theorem 1** Suppose  $p_1 = p_2 = 1/2$ . Let  $\epsilon > 0$  be given. There exists values  $c > 0$  and  $N > 0$  such that if  $n > N$  and  $m < cn^2$ , then

$$
||P_{a_1,a_2}^{*m} - U|| > 1 - \epsilon
$$

for all  $a_1$  and  $a_2$  in G with  $a_1 \neq a_2$ .

**Proof:** Let  $F_m = |\{i : 1 \le i \le m, Z_i = a_1\}|$ , and let  $S_m = |\{i : 1 \le i \le m, Z_i = a_1\}|$  $i \leq m, Z_i = a_2$ . In other words, if we perform m steps of the random walk supported on  $(a_1, a_2)$  on  $\mathbb{Z}_n$ , we add  $a_1$  exactly  $F_m$  times, and we add  $a_2$ exactly  $S_m$  times. Note that  $F_m + S_m = m$  and that  $X_m = F_m a_1 + S_m a_2$ . Observe that  $E(F_m) = m/2$ . Furthermore, observe that by the DeMoivre-Laplace Limit Theorem (see Ch. VII of [\[8\]](#page-35-0), for example), there are constants  $z_1$ ,  $z_2$ , and  $N_1$  such that if  $n > N_1$ , then  $Pr(m/2 - z_1\sqrt{m/4} < F_m <$ 

 $m/2 + z_2\sqrt{m/4}$  > 1 –  $\epsilon/2$ . Furthermore, there exists a constant c such that if  $m < cn^2$  and  $n > N_1$ , then  $(\epsilon/6)n \ge \sqrt{m/4}$  and  $Pr(m/2 - (\epsilon/6)n < F_m <$  $m/2 + (\epsilon/6)n > 1 - \epsilon/2$ . Let  $A_m = \{F_m a_1 + (m - F_m)a_2 : m/2 - (\epsilon/6)n <$  $F_m < m/2 + (\epsilon/6)n$ . Thus  $P^{*m}(A_m) > 1 - (\epsilon/2)$ . However,  $|A_m| \leq (\epsilon/3)n + 1$ . Thus if  $n > N_1$  and  $m < cn^2$ , then

$$
||P^{*m} - U|| > 1 - \frac{\epsilon}{2} - \left(\frac{\epsilon}{3} + \frac{1}{n}\right)
$$

$$
= 1 - \frac{5\epsilon}{6} - \frac{1}{n}
$$

Let  $N = \max(N_1, 6/\epsilon)$ . If  $n > N$  and  $m < cn^2$ , then  $||P^{*m} - U|| > 1 - \epsilon$ .  $\Box$ 

EXERCISE. Modify the above theorem and its proof to consider the case where  $0 < p_1 < 1$  is given and  $p_2 = 1 - p_1$ .

#### 3.2 Lower bounds on abelian groups with  $k$  fixed

Now let's turn our attention to a somewhat more general result. This result is a minor modification of a result of Greenhalgh [\[10\]](#page-35-4). Here the probability will be supported on elements  $a_1, a_2, \ldots, a_k$ . One similarity to the proof of the previous theorem is that we use the number of times in the random walk we choose  $Z_i$  to be  $a_1$ , the number of times we choose  $Z_i$  to be  $a_2$ , etc.

**Theorem 2** Let  $p_1 = p_2 = \ldots = p_k = 1/k$ . Suppose G is an abelian group of order n. Assume  $n \geq k \geq 2$ . Let  $\delta$  be a given value under 1/2. Then there exists a value  $\gamma > 0$  such that if  $m < \gamma n^{2/(k-1)}$ , then  $||P_{a_1,...,a_k}^{*m} - U|| > \delta$  for any k distinct values  $a_1, a_2, \ldots a_k \in G$ .

**Proof:** This proof slightly modifies an argument in Greenhalgh [\[10\]](#page-35-4). That proof, which only considered the case where  $G = \mathbb{Z}_n$ , had  $\delta = 1/4$  but considered a broader range of  $p_1, p_2, \ldots, p_k$ .

Since G is abelian,  $X_m$  is completely determined by the number of times  $r_i$  we pick each element  $a_i$ . Observe that  $r_1 + \ldots + r_k = m$ . Thus if  $g =$  $r_1a_1 + ... + r_ka_k$ , we get

$$
P^{*m}(g) \ge Q_m(\vec{r}) := \frac{m!}{\prod_{i=1}^k (r_i! k^{r_i})}
$$

where  $\vec{r} = (r_1, \ldots, r_k)$ . (Note that we may use  $P^{*m}$  instead of  $P_{a_1,\ldots,a_k}^{*m}$ .)

Suppose  $|r_i - m/k| \le \alpha_i \sqrt{m}$  for  $i = 1, ..., k$ . Then

$$
Pr(|r_i - m/k| \le \alpha_i \sqrt{m}, i = 1, ..., k) \ge 1 - \sum_{i=1}^k \frac{m(1/k)(1 - 1/k)}{\alpha_i^2 m}
$$

$$
= 1 - \sum_{i=1}^k \frac{(1/k)(1 - 1/k)}{\alpha_i^2}
$$

$$
> 2\delta
$$

where we assume  $\alpha_i$  are large enough constants to make the last inequality hold.

Let  $\vec{R} = \{\vec{r} : r_1 + \ldots + r_k = m \text{ and } |r_i - m/k] \leq \alpha_i \sqrt{m} \text{ for } i = 1, \ldots, k\},\$ and let  $A_m = \{r_1a_1 + \ldots + r_ka_k : (r_1, \ldots, r_k) \in \vec{R}\}\.$  Thus  $P^{*m}(A_m) > 2\delta$ .

Observe that, with  $\epsilon_m(\vec{r}) \to 0$  uniformly over  $\vec{r} \in \vec{R}$  as  $m \to \infty$ , we have, by Stirling's formula,

$$
Q_m(\vec{r})m^{(k-1)/2} = \frac{m^{(k-1)/2}e^{-m}m^m\sqrt{2\pi m}(1+\epsilon_m(\vec{r}))}{\prod_{i=1}^k k^{r_i}e^{-r_i}r_i^{r_i}\sqrt{2\pi r_i}}
$$
  

$$
= \frac{e^{-m}}{\exp(-\sum_{i=1}^k r_i)} \cdot \frac{m^m}{\prod_{i=1}^k (kr_i)^{r_i}} \cdot \frac{1}{\sqrt{\prod_{i=1}^k \left(\frac{r_i}{m}\right)}} \cdot \frac{1+\epsilon_m(\vec{r})}{(2\pi)^{(k-1)/2}}
$$
  

$$
= 1 \cdot \frac{1}{\prod_{i=1}^k (kr_i/m)^{r_i}} \cdot \frac{1}{\prod_{i=1}^k \sqrt{r_i/m}} \cdot \frac{1+\epsilon_m(\vec{r})}{(2\pi)^{(k-1)/2}}
$$

provided that all of the values  $r_1, \ldots, r_k$  are positive integers.

It can be shown that  $\prod_{i=1}^{k} \sqrt{r_i/m} \rightarrow (1/k)^{k/2}$  uniformly over  $\vec{r} \in \vec{R}$  as  $m \to \infty$ .

Now let  $x_i = r_i - m/k$ ; thus  $kr_i = kx_i + m$ . Note that  $x_1 + \ldots + x_k = 0$ since  $r_1 + \ldots + r_k = m$ . Observe that

$$
\prod_{i=1}^k \left(\frac{kr_i}{m}\right)^{r_i} = \prod_{i=1}^k \left(1 + \frac{kx_i}{m}\right)^{m/k + x_i}
$$
\n
$$
= \exp\left(\sum_{i=1}^k \left(\frac{m}{k} + x_i\right) \log\left(1 + \frac{kx_i}{m}\right)\right).
$$

Now observe

$$
\sum_{i=1}^{k} \left( \frac{m}{k} + x_i \right) \log \left( 1 + \frac{kx_i}{m} \right)
$$

$$
= \sum_{i=1}^{k} \left(\frac{m}{k} + x_i\right) \left(\frac{kx_i}{m} - \frac{k^2 x_i^2}{2m^2}\right) + f(m, x_1, \dots, x_k)
$$

$$
= \frac{k}{2m} \sum_{i=1}^{k} x_i^2 - \frac{k^2 \sum_{i=1}^{k} x_i^3}{2m^2} + f(m, x_1, \dots, x_k)
$$

where for some constant  $C_1 > 0$ ,  $|f(m, x_1, \ldots, x_k)| \leq C_1/\sqrt{m}$  for all  $\vec{r} \in \vec{R}$ . So for some constant  $C_2 > 0$ ,

$$
\left| f(m, x_1, \dots, x_k) - \frac{k^2 \sum_{i=1}^k x_i^3}{2m^2} \right| \le \frac{C_2}{\sqrt{m}}
$$

for all  $\vec{r} \in \vec{R}$ .

Thus for some constant  $\alpha > 0$  and some integer  $M > 0$ , we have

$$
Q_m(\vec{r})m^{(k-1)/2} \ge \alpha
$$

for all  $\vec{r} \in \vec{R}$  and  $m \geq M$ . (We may also assume that M is large enough that  $m/k > \alpha_i \sqrt{m}$  if  $m \ge M$ . Thus if  $m \ge M$ , we have  $r_i > 0$  for all  $\vec{r} \in \vec{R}$ .) Now suppose that

$$
\frac{\alpha}{m^{(k-1)/2}} \ge \frac{2}{n}
$$

Thus if  $g \in A_m$ ,  $P^{*m}(g) \ge \alpha/m^{(k-1)/2} \ge 2/n$  and  $P^{*m}(g)-(1/n) \ge P^{*m}(g)/2$ . Thus  $P^{*m}(A_m) - U(A_m) \ge 0.5P^{*m}(A_m) > \delta$ , and so

$$
\|P^{*m}_{a_1,\ldots,a_k}-U\|>\delta
$$

if  $m \leq (\alpha/2)^{2/(k-1)} n^{2/(k-1)}$  and  $m \geq M$ . The following exercise shows that the above reasoning suffices if  $M \leq (\alpha/2)^{2/(k-1)} n^{2/(k-1)}$ , i.e.  $n \geq$  $(2/\alpha)M^{(k-1)/2}.$ 

EXERCISE. If P and Q are probabilities on G, show that  $||P * Q - U|| \le$  $||P - U||$ . Use this result to show that if  $m_2 \geq m_1$ , then  $||P^{*m_2} - U|| \leq$  $||P^{*m_1} - U||.$ 

For smaller values of  $n \geq k$ , observe that  $||P^{*0} - U|| = 1 - 1/n > \delta$ , and we may choose  $\gamma_1$  such that  $\gamma_1 N^{2/(k-1)} < 1$  where  $N = (2/\alpha) M^{(k-1)/2}$ . Let  $\gamma = \min(\gamma_1, (\alpha/2)^{2/(k-1)})$ . Note that this value  $\gamma$  does not depend on which abelian group G we chose.  $\Box$ 

EXERCISE. Extend the previous theorem and proof to deal with the case where  $p_1, \ldots, p_k$  are positive numbers which sum to 1.

EXERCISE. Extend the previous theorem and proof to deal with the case where  $\delta$  is a given value under 1. (Hint: If  $\delta < 1/b$  where  $b > 1$ , replace "2 $\delta$ " by " $b\delta$ " and replace " $2/n$ " by an appropriate multiple of  $1/n$ .)

### 3.3 Some lower bounds with  $k$  varying with the order of the group

Now let's look at some lower bounds when  $k$  varies with n. The following theorem is a rephrasing of a result of Hildebrand [\[14\]](#page-35-5).

**Theorem 3** Let G be an abelian group of order n. If  $k = \lfloor (\log n)^a \rfloor$  where  $a < 1$  is a constant, then for each fixed positive value b, there exists a function  $f(n)$  such that  $f(n) \to 1$  as  $n \to \infty$  and  $||P^{*m}_{a_1,...,a_k} - U|| \ge f(n)$  for each  $(a_1, \ldots, a_k) \in G^k$  where  $m = \lfloor (\log n)^b \rfloor$ .

**Proof:** The proof also is based on material in [\[14\]](#page-35-5). In the first m steps of the random walk, each value  $a_i$  can be picked either 0 times, 1 time, ..., or  $\lfloor (\log n)^b \rfloor$  times. Since the group is abelian, the value  $X_m$  depends only on the number of times each  $a_i$  is picked in the first m steps of the random walk. So after m steps, there are at most  $(1 + \lfloor (\log n)^b \rfloor)^k$  different possible values for  $X_m$ . The following exercise implies the theorem.

EXERCISE. Prove the following. If  $k = \lfloor (\log n)^a \rfloor$  and  $a < 1$  is a constant, then

$$
\frac{(1 + \lfloor (\log n)^b \rfloor)^k}{n} \to 0
$$

as  $n \to \infty$ .

Note that the function  $f$  may depend on  $b$  but does not necessarily depend on which abelian group G we chose.  $\Box$ 

The following lower bound, mentioned in [\[14\]](#page-35-5), applies for any group  $G$ .

**Theorem 4** Let G be any group of order n. Suppose k is a function of n. Let  $\epsilon > 0$  be given. If

$$
m = \lfloor \frac{\log n}{\log k} \rfloor (1 - \epsilon),
$$

then  $||P_{a_1,...,a_k}^{*m} - U|| \ge f(n)$  for each  $(a_1,...,a_k) \in G^k$  and some  $f(n)$  such that  $f(n) \to 1$  as  $n \to \infty$ .

**Proof:** Note that  $X_m$  has at most  $k^m$  possible values and that  $k^m \leq n^{1-\epsilon}$ . Thus  $||P_{a_1,...,a_k}^{*m} - U|| \ge 1 - (n^{1-\epsilon}/n)$ . Let  $f(n) = 1 - (n^{1-\epsilon}/n)$ .

If  $k = \lfloor (\log n)^a \rfloor$  and  $a > 1$  is constant, then the previous lower bound can be made slightly larger for abelian groups. The following theorem is a rephrasing of a result in Hildebrand [\[14\]](#page-35-5).

**Theorem 5** Let G be an abelian group of order n. Suppose  $k = \lfloor (\log n)^a \rfloor$ where  $a > 1$  is a constant. Let  $\epsilon > 0$  be given. Suppose  $p_1 = \ldots = p_k = 1/k$ . Suppose

$$
m = \lfloor \frac{a}{a-1} \frac{\log n}{\log k} (1 - \epsilon) \rfloor.
$$

Then for some  $f(n)$  such that  $f(n) \to 1$  as  $n \to \infty$ ,  $||P_{a_1,...,a_k}^{*m} - U|| \ge f(n)$ for all  $(a_1, \ldots, a_k)$  such that  $a_1, \ldots, a_k$  are distinct elements of G.

**Proof:** The proof of this theorem is somewhat trickier than the previous couple of proofs and is based on a proof in [\[14\]](#page-35-5). We shall find functions  $g(n)$ and  $h(n)$  such that  $g(n) \to 0$  and  $h(n) \to 0$  as  $n \to \infty$  and the following holds. Given  $(a_1, \ldots, a_k) \in G^k$ , there exists a set  $A_m$  such that  $P_{a_1,\ldots,a_k}^{*m}(A_m)$  $1 - g(n)$  while  $U(A_m) < h(n)$ .

To find such a set  $A_m$ , we use the following proposition.

**Proposition 1** Let  $R = \{j : 1 \leq j \leq m \text{ and } Z_j = Z_i \text{ for some } i < j \}.$ Then there exist functions  $f_1(n)$  and  $f_2(n)$  such that  $f_1(n) \to 0$  as  $n \to \infty$ ,  $f_2(n) \rightarrow 0$  as  $n \rightarrow \infty$ , and  $Pr(|R| > f_1(n)m) < f_2(n)$ .

**Proof:** First note  $Pr(Z_j = Z_i \text{ for some } i < j) \leq (j-1)/k$ . Thus  $\sum_{j=1}^m Pr(Z_j = Z_i \text{ for some } i < j) < m^2/k$ . Thus  $E(|R|) < m^2/k$ . Thus by Markov's inequality,

$$
Pr(|R| > f_1(n)m) < \frac{m^2/k}{f_1(n)m} = \frac{m}{f_1(n)k}
$$

for any function  $f_1(n) > 0$ . Since  $m/k \to 0$  as  $n \to \infty$ , we can find a function  $f_1(n) \to 0$  as  $n \to \infty$  such that  $f_2(n) := m/(f_1(n)k) \to 0$  as  $n \to \infty$ .  $f_1(n) \to 0$  as  $n \to \infty$  such that  $f_2(n) := m/(f_1(n)k) \to 0$  as  $n \to \infty$ .

Let  $A_m = \{Z_m Z_{m-1} \dots Z_1 \text{ such that } |\{j : 1 \le j \le m \text{ and } Z_j = Z_i \text{ for } j \le m \}$ some  $i < j$   $\leq f_1(n)m$ . So by construction,

$$
P_{a_1,...,a_k}^{*m}(A_m) \ge 1 - f_2(n).
$$

Now let's consider  $U(A_m)$ . There are  $k^m$  different choices overall for  $Z_1, Z_2, \ldots, Z_m$ . Observe that for each  $X_m \in A_m$ , there is at least one way to obtain it after m steps of the random walk such that the values  $Z_1, \ldots, Z_k$  have  $m - \lfloor f_1(n)m \rfloor$  distinct values. Rearranging these distinct values does not change the value  $X_m$  since G is abelian. Thus each  $X_m$  is obtained by at least  $(m - \lfloor f_1(n)m \rfloor)!$  different choices in the walk. Thus  $A_m$  has at most  $k^m/(m - \lceil f_1(n)m \rceil)!$  different values. The following exercise completes the proof of the theorem.

EXERCISE. Show that for the values  $m$  and  $k$  in this theorem and for any function  $f_1(n) > 0$  such that  $f_1(n) \to 0$  as  $n \to \infty$ ,

$$
\frac{k^m/(m-\lceil f_1(n)m\rceil)!}{n}\to 0
$$

as  $n \to \infty$ . (Hint: Use Stirling's formula to show that  $(m - \lfloor f_1(n)m \rfloor)!$  is  $n^{(1-\epsilon)(1-g_1(n))/(a-1)}$  for some function  $g_1(n) \to 0$  as  $n \to \infty$ , and search for terms which are insignificant when one expresses  $k^m$  in terms of n.)

 $\Box$ 

Note that the function  $f(n)$  in the previous theorem does not have to depend on the which group  $G$  of order  $n$  we have.

# 4 Upper bounds

We now turn our attention to upper bounds for the random random walks on finite groups. Usually these bounds will refer to the expected value of the variation distance after m steps. This expected value, as noted in an earlier section, is over the choice of the k-tuple  $(a_1, \ldots, a_k)$ . First we shall look at a lemma frequently used for upper bounds involving random walks on finite groups as well as random random walks on finite groups.

### 4.1 The Upper Bound Lemma of Diaconis and Shahshahani

This lemma uses techniques from Fourier analysis on finite groups. A more extensive summary of this technique appears in Diaconis [\[3\]](#page-35-3). There are a number of sources which describe Fourier analysis on finite groups (e.g. Terras [\[25\]](#page-36-4)) and representation theory of finite groups (e.g. Serre [\[23\]](#page-36-5) or Simon [\[24\]](#page-36-6)).

A representation  $\rho$  of a finite group G is a function from G to  $GL_n(\mathbb{C})$ such that  $\rho(st) = \rho(s)\rho(t)$  for all  $s, t \in G$ ; the value n is called the degree of the representation and is denoted  $d_{\rho}$ . For example, if  $j \in \{0, 1, \ldots, n-1\}$ ,

then  $\rho_j(k) = \left[e^{2\pi i jk/n}\right]$  for  $k \in \mathbb{Z}_n$  is a representation of  $\mathbb{Z}_n$ . For any group G, the representation  $\rho(s) = [1]$  for all  $s \in G$  is called the trivial representation. A representation is said to be irreducible if there is no proper nontrivial subspace W of  $\mathbb{C}^n$  (where  $n = d_\rho$ ) such that  $\rho(s)W \subseteq W$  for all  $s \in G$ . If there exists an invertible complex matrix A such that  $A\rho_1(s)A^{-1} = \rho_2(s)$  for all  $s \in G$ , then the representation  $\rho_1$  and  $\rho_2$  are said to be equivalent. It can be shown that each irreducible representation is equivalent to a unitary representation. We shall assume that when we pick an irreducible representation up to equivalence, we pick a unitary representation. It can be shown that  $|G| = \sum_{\rho} d_{\rho}^2$  where the sum is over all irreducible representations of G up to equivalence.

We define the Fourier transform

$$
\hat{P}(\rho) = \sum_{s \in G} P(s)\rho(s).
$$

The following lemma, known as the Upper Bound Lemma, is due to Diaconis and Shahshahani [\[4\]](#page-35-2) and is frequently used in studying probability on finite groups. The description here is based on the description in Diaconis [\[3\]](#page-35-3).

**Lemma 1** Let P be a probability on a finite group  $G$  and  $U$  be the uniform distribution on G. Then

$$
||P-U||^2 \leq \frac{1}{4}\sum_{\rho}^* d_{\rho} Tr(\hat{P}(\rho)\hat{P}(\rho)^*)
$$

where the sum is over all non-trivial irreducible representations  $\rho$  up to equivalence and ∗ of a matrix denotes its conjugate transpose.

### 4.2 Upper bounds for random random walks on  $\mathbb{Z}_n$ where  $n$  is prime

<span id="page-12-0"></span>A result shown in Hildebrand [\[14\]](#page-35-5) (and based upon a result in [\[13\]](#page-35-6)) is the following.

**Theorem 6** Suppose k is a fixed integer which is at least 2. Let  $p_i$ ,  $i =$  $1, \ldots, k$  be such that  $p_i > 0$  and  $\sum_{i=1}^k p_i = 1$ . Let  $\epsilon > 0$  be given. Then for some values N and  $\gamma > 0$  (where N and  $\gamma$  may depend on  $\epsilon, k, p_1, \ldots, p_k$ , but not  $n$ ),

$$
E(||P_{a_1,\ldots,a_k}^{*m}-U||)<\epsilon
$$

for  $m = \lfloor \gamma n^{2/(k-1)} \rfloor$  for prime numbers  $n > N$ . The expectation is over a uniform choice of k-tuples  $(a_1, \ldots, a_k) \in G^k$  such that  $a_1, \ldots, a_k$  are all distinct.

**Proof:** This presentation is based upon the ideas in the proof in [\[14\]](#page-35-5). First the result of the following exercise means that we may use the Upper Bound Lemma.

EXERCISE. Suppose that given  $\epsilon' > 0$ , there exists values  $\gamma' > 0$  and N' (which may depend on  $\epsilon', k, p_1, \ldots, p_k$ , but not on n) such that

$$
E(||P_{a_1,...,a_k}^{*m} - U||^2) < \epsilon'
$$

if  $m = \lfloor \gamma' n^{2/(k-1)} \rfloor$  and n is a prime which is greater than N' where the expectation is as in Theorem [6.](#page-12-0) Then Theorem [6](#page-12-0) holds.

The following proposition is straightforward, and its proof is left to the reader. Note that by abuse of notation, we view the Fourier transform in this proposition as a scalar instead of as a 1 by 1 matrix.

#### Proposition 2

$$
|\hat{P}_{a_1,\dots,a_k}(j)|^2 = \left(\sum_{i=1}^k p_i^2\right) + 2 \sum_{1 \le i_1 < i_2 \le k} p_{i_1} p_{i_2} \cos(2\pi (a_{i_1} - a_{i_2})j/n)
$$

where  $\hat{P}_{a_1,...,a_k}(j) = \hat{P}_{a_1,...,a_k}(\rho_j)$ .

In the rest of the proof of Theorem [6,](#page-12-0) we shall assume  $j \neq 0$  since the  $j = 0$  term corresponds to the trivial representation, which is not included in the sum in the Upper Bound Lemma.

Let's deal with the case  $k = 2$  now. We see that

$$
\hat{P}_{a_1,a_2}(j) = (1 - 2p_1p_2) + 2p_1p_2\cos(2\pi(a_1 - a_2)j/n).
$$

Note that  $(a_1 - a_2)j \mod n$  runs through  $1, 2, \ldots, n - 1$ . Thus

$$
\sum_{j=1}^{n-1} |\hat{P}_{a_1,a_2}(j)|^{2m} = \sum_{j=1}^{n-1} (1 - 2p_1p_2 + 2p_1p_2\cos(2\pi j/n))^m
$$
  

$$
\leq 2 \sum_{j=1}^{\lfloor (n-1)/2 \rfloor} \exp(-cj^2 m/n^2)
$$

$$
\leq 2\sum_{j=1}^{\infty} \exp(-cjm/n^2)
$$

$$
= 2\frac{\exp(-cm/n^2)}{1-\exp(-cm/n^2)}
$$

for some constant  $c > 0$ . (This argument is similar to one in Chung, Diaconis, and Graham [\[1\]](#page-35-7).) For some  $\gamma > 0$ , if  $m = \lfloor \gamma n^2 \rfloor$ , then  $||P_{a_1,a_2}^{*m} - U|| < \epsilon$  for sufficiently large primes n uniformly over all  $a_1, a_2 \in \mathbb{Z}_n$  with  $a_1 \neq a_2$ .

From now on in the proof of Theorem [6,](#page-12-0) we assume  $k \geq 3$ . Note that  $|\hat{P}_{a_1,...,a_k}(j)|^2 \ge 0$  and that if  $\cos(2\pi (a_{i_1} - a_{i_2})j/n) \le 0.99$  for some  $i_1$  and  $i_2$ with  $1 \leq i_1 < i_2 \leq k$ , then  $|\hat{P}_{a_1,...,a_k}(j)|^2 \leq b_1 := 1 - 0.02 \min_{i_1 \neq i_2} p_{i_1} p_{i_2}$ .

EXERCISE. If  $m = \lfloor \gamma n^{2/(k-1)} \rfloor$  where  $\gamma > 0$  is a constant, show that  $\lim_{n\to\infty} nb_1^m = 0.$ 

Thus we need to focus on values of  $a_1, \ldots, a_k$  such that  $\cos(2\pi(a_{i_1}$  $a_{i_2}$ ) $j(n) > 0.99$  for all  $i_1$  and  $i_2$  with  $1 \le i_1 < i_2 \le k$ . In doing so, we'll focus on the case where  $i_1 = 1$ .

Let  $g_n(x) = x_0$  where  $x_0 \in (-n/2, n/2]$  and  $x \equiv x_0 \pmod{n}$ . Thus  $\cos(2\pi x/n) = \cos(2\pi g_n(x)/n)$ . The following lemma looks at the probability that

$$
(g_n((a_1-a_2)j)/n,\ldots,g_n((a_1-a_k)j)/n)
$$

<span id="page-14-0"></span>falls in a given  $(k - 1)$ -dimensional "cube" of a given size.

**Lemma 2** Suppose  $k \geq 3$  is constant. Let  $\epsilon > 0$  be given. Then there exists a value  $N_0$  such that if  $n > N_0$  and n is prime, then

$$
P\left(m_i(\epsilon/2)^{1/(k-1)}n^{(k-2)/(k-1)}/(2n) \le g_n((a_1 - a_i)j)/n
$$
  
\n
$$
\le (m_i + 1)(\epsilon/2)^{1/(k-1)}n^{(k-2)/(k-1)}/(2n), i = 2,... k
$$
  
\n
$$
\le \frac{1.1(\epsilon/2)}{2^{k-1}n}
$$

for each  $(m_2, ..., m_k) \in \mathbb{Z}^{k-1}$  and  $j \in \{1, ..., n-1\}$ .

**Proof:** Observe that if n is prime and odd, then  $g_n((a_1 - a_i)j)$  may be any of the values  $(-n+1)/2, \ldots, -2, -1, 1, 2, \ldots, (n-1)/2$  except for those values taken by  $g_n((a_1 - a_{i'})j)$  for  $i' < i$ . Furthermore, different values of  $a_i$  correspond to different values of  $g_n((a_1 - a_i)j)$ . Note that this statement need not hold if n were not prime or if j were 0.

On the interval [a, b], there are at most  $b - a + 1$  integers. Thus on the interval

$$
\left[\frac{m_i(\epsilon/2)^{1/(k-1)}n^{(k-2)/(k-1)}}{2}, \frac{(m_i+1)(\epsilon/2)^{1/(k-1)}n^{(k-2)/(k-1)}}{2}\right],
$$

there are at most  $1 + (\epsilon/2)^{1/(k-1)} n^{(k-2)/(k-1)}/2$  possible values of  $g_n((a_1-a_i)j)$ .

Thus the probability in the statement of the lemma is less than or equal to  $k=1$ 

$$
\frac{\left(1 + \frac{\left(\epsilon/2\right)^{1/(k-1)} n^{(k-2)/(k-1)}/2\right)^{k-1}}{(n-1)(n-2)\dots(n-k+1)} \sim \frac{\left(\epsilon/2\right)}{2^{k-1} n}
$$

where  $f(n) \sim g(n)$  means  $\lim_{n\to\infty} f(n)/g(n) = 1$ . The lemma follows.  $\Box$ 

EXERCISE. Explain why the proof of the previous lemma fails if  $k = 2$ (even though this failure is not acknowledged in [\[14\]](#page-35-5)).

Next we wish to find an upper bound on  $|\tilde{P}_{a_1,...,a_k}(j)|^{2m}$  for  $(g_n((a_1$  $a_2)j)/n, \ldots, g((a_1-a_k)j)/n)$  in each such  $(k-1)$ -dimensional "cube". Note that there is a constant  $c_1 \in (0,1]$  such that if  $\cos(2\pi k_1/n) > 0.99$ , then  $\cos(2\pi k_1/n) \leq 1 - (c_1/2)(g_n(k_1))^2/n^2$ . Now let  $\ell_n$  be largest positive integer  $\ell$  such that

$$
\cos\left(2\pi\left(\frac{\ell(\epsilon/2)^{1/(k-1)}n^{(k-2)/(k-1)}}{2n}\right)\right) > 0.99
$$

and

$$
\frac{\ell(\epsilon/2)^{1/(k-1)}n^{(k-2)/(k-1)}}{2n} < \frac{1}{4}
$$

Now observe that if  $m_i \in [-\ell_n - 1, \ell_n]$  and

$$
\frac{m_i(\epsilon/2)^{1/(k-1)}n^{(k-2)/(k-1)}}{2n} \leq \frac{g_n((a_1 - a_i)j)}{n}
$$
  

$$
\leq \frac{(m_i + 1)(\epsilon/2)^{1/(k-1)}n^{(k-2)/(k-1)}}{2n},
$$

then

$$
\cos(2\pi(a_{i_1}-a_{i_2})j/n) \leq \max\left(0.99, 1-c_1\frac{(\min(|m_i|, |m_i+1|))^2(\epsilon/2)^{2/(k-1)}}{8n^{2/(k-1)}}\right).
$$

Thus

$$
E(|\hat{P}_{a_1,...,a_k}(j)|^{2m})
$$

$$
\leq b_1^m + \sum_{m_i \in [-\ell_n - 1, \ell_n], i = 2, \dots, k} \frac{1.1(\epsilon/2)}{2^{k-1}n}
$$
  
 
$$
\times \left(1 - c_1 (\min_{i_1 \neq i_2} p_{i_1} p_{i_2}) \sum_{i=2}^k \frac{(\min(|m_i|, |m_i + 1|))^2 (\epsilon/2)^{2/(k-1)}}{4n^{2/(k-1)}}\right)^m
$$
  
\n
$$
= b_1^m + 2^{k-1} \sum_{m_i \in [0, \ell_n], i = 2, \dots, k} \frac{1.1(\epsilon/2)}{2^{k-1}n}
$$
  
\n
$$
\times \left(1 - c_1 (\min_{i_1 \neq i_2} p_{i_1} p_{i_2}) \sum_{i=2}^k \frac{m_i^2 (\epsilon/2)^{2/(k-1)}}{4n^{2/(k-1)}}\right)^m.
$$

Since

$$
\frac{m_i^2(\epsilon/2)^{2/(k-1)}}{4n^{2/(k-1)}} < \frac{1}{16} \;,
$$

 $c_1 \leq 1$ , and  $\min_{i_1 \neq i_2} p_{i_1} p_{i_2} \leq 1/k$ , we may conclude that

$$
c_1 \left( \min_{i_1 \neq i_2} p_{i_1} p_{i_2} \right) \sum_{i=2}^k \frac{m_i^2 (\epsilon/2)^{2/(k-1)}}{4n^{2/(k-1)}} < 1.
$$

Thus for some constant  $c_2 > 0$ ,

$$
\left(1 - c_1 \left(\min_{i_1 \neq i_2} p_{i_1} p_{i_2}\right) \sum_{i=2}^k \frac{m_i^2 (\epsilon/2)^{2/(k-1)}}{4n^{2/(k-1)}}\right)^m \le \exp\left(-mc_2 \sum_{i=2}^k \frac{m_i^2 (\epsilon/2)^{2/(k-1)}}{4n^{2/(k-1)}}\right).
$$

Thus

$$
E(|\hat{P}_{a_1,\ldots,a_k}(j)|^{2m})
$$
  
\n
$$
\leq b_1^m + \sum_{m_i \in [0,\ell_n], i=2,\ldots,k} 1.1 \frac{\epsilon}{2n} \exp\left(-mc_2 \sum_{i=2}^k m_i^2 \frac{(\epsilon/2)^{2/(k-1)}}{4n^{2/(k-1)}}\right)
$$
  
\n
$$
\leq b_1^m + \sum_{m_i \in [0,\infty), i=2,\ldots,k} 1.1 \frac{\epsilon}{2n} \exp\left(-mc_2 \sum_{i=2}^k m_i \frac{(\epsilon/2)^{2/(k-1)}}{4n^{2/(k-1)}}\right)
$$
  
\n
$$
= b_1^m + \left(\frac{1.1\epsilon}{2n}\right) / \left(1 - \exp\left(-mc_2 \frac{(\epsilon/2)^{2/(k-1)}}{4n^{2/(k-1)}}\right)\right)^{k-1}.
$$

For some constant  $\gamma > 0$  and  $m = |\gamma n^{2/(k-1)}|$ ,

$$
\lim_{n \to \infty} \left( 1 - \exp \left( -mc_2 \frac{(\epsilon/2)^{2/(k-1)}}{4n^{2/(k-1)}} \right) \right)^{k-1} \ge 0.7.
$$

Thus

$$
E(|\hat{P}_{a_1,...,a_k}(j)|^{2m}) \le b_1^m + \frac{0.9\epsilon}{n} < \frac{\epsilon}{n}
$$

for sufficiently large  $n$ , and the theorem follows from the Upper Bound Lemma.  $\Box$ 

### 4.3 Random random walks on  $\mathbb{Z}_n$  where *n* is not prime

Dai and Hildebrand [\[2\]](#page-35-8) generalized the result of Theorem [6](#page-12-0) to the case where n need not be prime. One needs to be cautious in determining which values to pick for  $a_1, \ldots, a_k$ . For example, if n is even and  $a_1, \ldots, a_k$  are all even, then  $X_m$  can never be odd. For another example, if n is even and  $a_1, \ldots, a_k$ are all odd, then  $X_m$  is never odd if m is even and  $X_m$  is never even if m is odd. In both cases,  $||P_{a_1,...,a_k}^{*m} - U|| \nrightarrow 0$  as  $m \rightarrow \infty$ . Furthermore, if you choose  $(a_1, \ldots, a_k)$  uniformly from  $G^k$ , there is a  $1/2^k$  probability that  $a_1, \ldots, a_k$  are all even and a  $1/2^k$  probability that  $a_1, \ldots, a_k$  are all odd.

The following exercises develop a useful condition.

EXERCISE. Let  $a_1, \ldots, a_k \in \{0, \ldots, n-1\}$ . Prove that the subgroup of  $\mathbb{Z}_n$  generated by  $\{a_2-a_1, a_3-a_1, \ldots, a_k-a_1\}$  is  $\mathbb{Z}_n$  if and only if  $(a_2-a_1, a_3-a_1)$  $a_1, \ldots, a_k - a_1, n) = 1$  where  $(b_1, \ldots, b_\ell)$  is the greatest common divisor of  $b_1, \ldots, b_\ell$  in  $\mathbb{Z}$ .

EXERCISE. Prove that  $||P_{a_1,...,a_k}^{*m} - U|| \to 0$  as  $m \to \infty$  if and only if the subgroup of  $\mathbb{Z}_n$  generated by  $\{a_2 - a_1, \ldots, a_k - a_1\}$  is  $\mathbb{Z}_n$ . (Hint:  $X_m$  equals m times  $a_1$  plus some element of this subgroup.)

<span id="page-17-0"></span>The main result of [\[2\]](#page-35-8) is

**Theorem 7** Let  $k \geq 2$  be a constant integer. Choose the set  $S := \{a_1, \ldots, a_k\}$ uniformly from all subsets of size k from  $\mathbb{Z}_n$  such that  $(a_2 - a_1, \ldots, a_k$  $a_1, n) = 1$  and  $a_1, \ldots, a_k$  are all distinct. Suppose  $p_1, \ldots, p_k$  are positive constants with  $\sum_{i=1}^{k} p_i = 1$ . Then  $E(||P_{a_1,...,a_k}^{*m} - U||) \rightarrow 0$  as  $n \rightarrow \infty$  where  $m := m(n) \geq \sigma(n)n^{2/(k-1)}$  and  $\sigma(n)$  is any function with  $\sigma(n) \to \infty$  as  $n \to \infty$ . The expected value comes from the choice of the set S.

The case  $k = 2$  can be handled in a manner similar to the case  $k = 2$ for *n* being prime. So we assume  $k \geq 3$ . Also, we shall let  $\epsilon > 0$  be such that  $1/(k-1) + (k+1)\epsilon < 1$  throughout the proof of Theorem [7.](#page-17-0) As in the proof of Theorem [6,](#page-12-0) we can use the Upper Bound Lemma to bound  $E(||P_{a_1,\ldots,a_k}^{*m} - U||^2)$ . We may write P instead of  $P_{a_1,\ldots,a_k}$ .

We shall consider 3 categories of values for  $j$ . The proofs for the first and third categories use ideas from [\[2\]](#page-35-8). The proof for the second category at times diverges from the proof in [\[2\]](#page-35-8); the ideas in this alternate presentation were discussed in personal communications between the authors of [\[2\]](#page-35-8).

<span id="page-18-1"></span>The first category has  $J_1 := \{j : (j, n) > n^{(k-2)/(k-1)+\epsilon} \text{ and } 1 \le j \le n-1\}.$ In this case, we have the following lemma.

**Lemma 3**  $\sum_{j\in J_1} |\hat{P}(j)|^{2m} \to 0$  as  $n \to \infty$  for  $m \geq \sigma(n)n^{2/(k-1)}$  where  $\sigma(n) \to \infty$  as  $n \to \infty$ . For a given  $\sigma(n)$ , this convergence is uniform over all choices of the set S where  $a_1, \ldots, a_k$  are distinct and  $(a_2-a_1, \ldots, a_k-a_1, n)$  = 1.

**Proof of Lemma:** Observe that if n divides  $ja_h - ja_1$  for all  $h = 2, \ldots, k$ , then *n* would divide *j* since  $(a_2 - a_1, \ldots, a_k - a_1, n) = 1$ . So for some value  $h \in \{2, \ldots, k\}, n$  does not divide  $ja_h - ja_1$ . Let  $\omega = e^{2\pi i/n}$ . Thus, with this value of  $h$ , we get

$$
|\hat{P}(j)| = |p_1\omega^{ja_1} + ... + p_k\omega^{ja_k}|
$$
  
\n
$$
\leq 1 - 2\min(p_1, p_h) + \min(p_1, p_h)|\omega^{ja_1} + \omega^{ja_h}|
$$
  
\n
$$
= 1 - 2\min(p_1, p_h)(1 - |\cos(\pi j(a_h - a_1)/n)|)
$$
  
\n
$$
\leq 1 - ca^2/n^2
$$

where  $a := (j, n)$  and  $c > 0$  is a constant not depending on S. To see the last inequality, observe that since  $j(a_h - a_1) \not\equiv 0 \pmod{n}$ , we get  $(j/a)(a_h - a_1)$  $a_1 \not\equiv 0 \pmod{n/a}$  and  $(j/a)(a_h - a_1) \in \mathbb{Z}$ . Thus  $|\cos(\pi j(a_h - a_1)/n)| \leq$  $\cos(\pi a/n)$ .

The proof of the lemma is completed with the following exercise.

EXERCISE. Show that for m in the lemma and with  $a > n^{(k-2)/(k-1)+\epsilon}$ , we get  $(1 - ca^2/n^2)^m < c_1 \exp(-n^{2\epsilon})$  for some constant  $c_1 > 0$  and  $n(1$  $ca^2/n^2$ <sup>2*m*</sup>  $\rightarrow$  0 as  $n \rightarrow \infty$ .

<span id="page-18-0"></span>The next category of values of j is  $J_2 := \{j : (j,n) < n^{(k-2)/(k-1)-\epsilon} \text{ and }$  $1 \leq j \leq n-1$ .

✷

**Lemma** 4  $\sum_{j\in J_2} E(|\hat{P}(j)|^{2m}) \to 0$  if  $m \ge \sigma(n)n^{2/(k-1)}$  where  $\sigma(n) \to \infty$  as  $n \to \infty$  where the expectation is as in Theorem [7.](#page-17-0)

<span id="page-19-0"></span>To prove this lemma, we use the following.

**Lemma 5**  $\sum_{j\in J_2} E(|\hat{P}(j)|^{2m}) \to 0$  if  $m \ge \sigma(n)n^{2/(k-1)}$  where  $\sigma(n) \to \infty$  as  $n \to \infty$  where the expectation is over a uniform choice of  $(a_1, \ldots, a_k) \in G^k$ .

Proof of Lemma [5:](#page-19-0) Although Dai and Hildebrand [\[2\]](#page-35-8) used a different method, the proof of this lemma can proceed in a manner similar to the proof of Theorem [6](#page-12-0) for  $k > 3$ ; however, one must be careful in proving the analogue of Lemma [2.](#page-14-0) Note in particular that instead of ranging over  $-(n-1)/2, \ldots, -2, -1, 1, 2, \ldots, (n-1)/2$ , the value  $g_n((a_1 - a_i)j)$  ranges over multiples of  $(j, n)$  in  $(-n/2, n/2]$ . Furthermore, distinct values of  $a_i$ need not lead to distinct values of  $g_n((a_1 - a_i)j)$ .

EXERCISE. Show that Lemma [2](#page-14-0) still holds if n is not prime but  $j \in J_2$ and  $(a_1, \ldots, a_k)$  are chosen uniformly from  $G^k$ . Then show Lemma [5](#page-19-0) holds.  $\Box$ 

To complete the proof of Lemma [4,](#page-18-0) note that if  $d$  is a divisor of  $n$  and  $(a_1, \ldots, a_k)$  is chosen uniformly from  $G^k$ , then the probability that d divides all of  $a_2 - a_1, \ldots, a_k - a_1$  is  $1/d^{k-1}$ . Thus, given n, the probability  $\sum_{d=2}^{\infty} d^{-(k-1)} \leq (\pi^2/6) - 1 < 1$  if  $k \geq 3$ . Also observe that the probability that  $a_2 - a_1, \ldots, a_k - a_1$  have a common divisor greater than 1 is at most that a duplication exists on  $a_1, \ldots, a_k$  approaches to 0 as  $n \to \infty$ .

<span id="page-19-1"></span>EXERCISE. Show that these conditions and Lemma [5](#page-19-0) imply Lemma [4.](#page-18-0)  $\Box$ 

The last category of values for j is  $J_3 := \{j : n^{(k-2)/(k-1)-\epsilon} \leq (j,n) \leq \epsilon \}$  $n^{(k-2)/(k-1)+\epsilon}$  and  $1 \leq j \leq n-1$ .

**Lemma 6**  $\sum_{j\in J_3} E(|\hat{P}(j)|^{2m}) \to 0$  if  $m \ge \sigma(n)n^{2/(k-1)}$  with  $\sigma(n) \to \infty$  as  $n \to \infty$  and with the expectation as in Theorem [7.](#page-17-0)

**Proof:** Since  $||P_{a_1,a_2,...,a_k}^{*m} - U|| = ||P_{0,a_2-a_1,...,a_k-a_1}^{*m} - U||$ , we may assume without loss of generality that  $a_1 = 0$ . Hence we assume  $(a_2, \ldots, a_k, n) = 1$ . Let  $\langle x \rangle$  denote the distance of x from the nearest multiple of n. If  $\langle ja_\ell \rangle$  $n^{(k-2)/(k-1)+\epsilon}$ , then by reasoning similar to that in the proof of Lemma [3,](#page-18-1) we may conclude that  $|\hat{P}(j)|^{2m} < c_1 \exp(-n^{2\epsilon})$  for some constant  $c_1 > 0$ . Otherwise  $\langle ja_\ell \rangle \leq n^{(k-2)/(k-1)+\epsilon}$  for  $\ell = 2, \ldots k$ ; let B be the number of  $(k-1)$ 1)-tuples  $(a_2, \ldots, a_k)$  satisfying this condition. Since  $(j, n) \leq n^{(k-2)/(k-1)+\epsilon}$ , we may conclude by Proposition [3](#page-20-0) below that for some positive constant  $c_2$ , we have  $B < c_2(n^{(k-2)/(k-1)+\epsilon})^{k-1}$ . Thus

$$
E(|\hat{P}(j)|^{2m}) < c_1 \exp(-n^{2\epsilon}) + \frac{B}{Tn^{k-1}b(n)}
$$

where  $T := 1 - \sum_{d=2}^{\infty} d^{-(k-1)}$  and  $b(n)$  is the probability that  $(a_2, \ldots, a_k)$ when chosen at random from  $G^{k-1}$  has no 0 coordinates and no pair of coordinates with the same value. Note that  $b(n) \to 1$  as  $n \to \infty$ . Thus  $E(|\hat{P}(j)|^{2m}) < c_1 \exp(-n^{2\epsilon}) + c_3 n^{(k-1)\epsilon-1}$  for some constant  $c_3 > 0$ .

Let D be the number of divisors of n. By Proposition [4](#page-20-1) below,  $D < c_4 n^{\epsilon}$ for some positive constant  $c_4$ . Also, if a divides  $n$ , then there are at most  $n/a$  natural numbers in  $[1, n-1]$  with  $(j, n) = a$ . For  $j \in J_3$ ,

$$
\frac{n}{a} \le \frac{n}{n^{(k-2)/(k-1)-\epsilon}} = n^{1/(k-1)+\epsilon}.
$$

Thus

$$
\sum_{j \in J_3} E(|\hat{P}(j)|^{2m}) \le c_4 n^{\epsilon} n^{1/(k-1)+\epsilon} (c_1 \exp(-n^{2\epsilon}) + c_3 n^{(k-1)\epsilon-1}) \to 0
$$

as  $n \to \infty$  if  $m > n^{2/(k-1)}\sigma(n)$ . Note that we used  $1/(k-1) + (k+1)\epsilon < 1$  here. here.  $\Box$ 

We need two propositions mentioned above.

<span id="page-20-0"></span>**Proposition 3** If  $(j, n) \leq b$  with  $j \in \{1, \ldots, n-1\}$ , then the number of values a in  $0, 1, \ldots, n-1$  such that  $\langle ja \rangle \leq b$  is less than or equal to 3b.

<span id="page-20-1"></span>The proof of this proposition may be found in [\[2\]](#page-35-8) or may be done as an exercise.

**Proposition 4** For any  $\epsilon$  with  $0 < \epsilon < 1$ , there is a positive constant  $c = c(\epsilon)$ such that  $d(n) \leq cn^{\epsilon}$  for any natural number n where  $d(n)$  is the number of divisors of n.

**Proof:** Suppose  $n = p_1^{a_1}$  $i_1^{a_1} \ldots p_r^{a_r}$  where  $p_1, \ldots, p_r$  are distinct prime numbers and  $a_1, \ldots, a_r$  are positive integers. Then  $d(n) = (a_1+1)(a_2+1)\ldots(a_r+1)$ 1). Note that  $a_1, a_2, \ldots$  here are not the values selected from  $\mathbb{Z}_n$  and  $p_1, p_2, \ldots$ are not probabilities! Let  $M = e^{1/\epsilon}$ . If  $p_i > M$ , then  $(p_i^{a_i})^{\epsilon} \ge ((e^{1/\epsilon})^{a_i})^{\epsilon} =$ 

 $e^{a_i} \geq 1 + a_i$ . If  $p_i \leq M$ , then  $(p_i^{a_i})^{\epsilon} \geq 2^{a_i \epsilon} = e^{\epsilon a_i \log 2} \geq 1 + \epsilon a_i \log 2 \geq$  $\epsilon(\log 2)(1 + a_i)$ . Thus

$$
n^{\epsilon} = \left(\prod_{i=1}^{r} p_i^{a_i}\right)^{\epsilon}
$$
  
\n
$$
= \left(\prod_{p_i \le M} p_i^{a_i}\right)^{\epsilon} \times \left(\prod_{p_i > m} p_i^{a_i}\right)^{\epsilon}
$$
  
\n
$$
\ge \prod_{p_i \le M} \epsilon(\log 2)(1 + a_i) \times \prod_{p_i > M} (1 + a_i)
$$
  
\n
$$
\ge (\epsilon \log 2)^M \prod_{i=1}^{r} (1 + a_i)
$$

since  $\epsilon \log 2 < 1$ . Thus  $n^{\epsilon} \ge (\epsilon \log 2)^M d(n)$  and  $d(n) \le cn^{\epsilon}$  where  $c =$  $(\epsilon \log 2)^{-M}$ .

EXERCISE. Give a rough idea of what c is if  $\epsilon = 0.1$ . (Hint: It's ridiculously large!)

PROBLEM FOR FURTHER STUDY. Give an argument so that Lemma [6](#page-19-1) or Theorem [7](#page-17-0) does not need such a ridiculously large constant.

#### 4.4 Dou's version of the Upper Bound Lemma

The Upper Bound Lemma of Diaconis and Shahshahani is particularly useful for random walks on abelian groups or random walks where  $P$  is constant on conjugacy classes of G. Dou [\[5\]](#page-35-9) has adapted this lemma to a form which is useful for some random random walks. This form was used in [\[5\]](#page-35-9) to study some random random walks on various abelian groups, and Dou and Hildebrand [\[6\]](#page-35-10) extended some results in [\[5\]](#page-35-9) involving random random walks on abelian groups. Dou's lemma is the following.

<span id="page-21-0"></span>**Lemma 7** Let  $Q$  be a probability on a group  $G$  of order n. Then for any positive integer m,

$$
4||Q^{*m} - U||^2 \le \sum_{\Omega} nQ(x_1) \dots Q(x_{2m}) - \sum_{G^{2m}} Q(x_1) \dots Q(x_{2m})
$$

where  $G^{2m}$  is the set of all  $2m$ -tuples  $(x_1, \ldots, x_{2m})$  with  $x_i \in G$  and  $\Omega$ is the subset of  $G^{2m}$  consisting of all  $2m$ -tuples such that  $x_1x_2...x_m =$  $x_{m+1}x_{m+2}...x_{2m}$ .

**Proof:** The proof presented here uses arguments given in [\[5\]](#page-35-9) and [\[6\]](#page-35-10). Label all the non-equivalent irreducible representations of G by  $\rho_1, \ldots, \rho_h$ . Assume  $\rho_h$  is the trivial representation and the representations are all unitary. Let  $\chi_1, \ldots, \chi_h$  be the corresponding characters and  $d_1, \ldots, d_h$  be the corresponding degrees. Note that  $\rho_i(x)^* = (\rho_i(x))^{-1} = \rho_i(x^{-1})$  for all  $x \in G$ since  $\rho_i$  is unitary. Thus

$$
\hat{Q}(\rho_i)^m = \sum_{x_1,\dots,x_m} Q(x_1) \dots Q(x_m) \rho_i(x_1 \dots x_m)
$$

and

$$
(\hat{Q}(\rho_i)^m)^* = \sum_{x_{m+1},...,x_{2m}} Q(x_{m+1}) \dots Q(x_{2m}) \rho_i((x_{m+1} \dots x_{2m})^{-1}))
$$

Thus if  $s = (x_1 \dots x_n)(x_{m+1} \dots x_{2m})^{-1}$ , we get

$$
\sum_{i=1}^{h-1} d_i Tr(\hat{Q}(\rho_i)^m (\hat{Q}(\rho_i)^m)^*) = \sum_{i=1}^{h-1} \sum_{G^{2m}} Q(x_1) \dots Q(x_{2m}) d_i \chi_i(s)
$$
  
= 
$$
\sum_{G^{2m}} Q(x_1) \dots Q(x_{2m}) \sum_{i=1}^{h-1} d_i \chi_i(s)
$$

Note that  $d_h \chi_h(s) = 1$  for all  $s \in G$  and

$$
\sum_{i=1}^{h} d_i \chi_i(s) = \begin{cases} n & \text{if } s = e \\ 0 & \text{otherwise} \end{cases}
$$

where  $e$  is the identity element of  $G$ . The lemma follows from the Upper Bound Lemma.  $\Box$ 

To use this lemma, we follow some notation as in [\[5\]](#page-35-9) and [\[6\]](#page-35-10). We say a  $2m$ tuple  $(x_1, \ldots, x_{2m})$  is of size i if the set  $\{x_1, \ldots, x_{2m}\}$  has i distinct elements. An *i*-partition of  $\{1, \ldots, 2m\}$  is a set of *i* disjoint subsets  $\tau = \{\Delta_1, \ldots, \Delta_i\}$ such that  $\Delta_1 \cup \ldots \cup \Delta_i = \{1, \ldots, 2m\}$ . An *i-partition* of the number 2m is an *i*-tuple of integers  $\pi = (p_1, \ldots, p_i)$  such that  $p_1 \geq \ldots \geq p_i \geq 1$  and  $\sum_{j=1}^{i} p_j = 2m.$ 

Note that each 2m-tuple in  $G^{2m}$  of size i gives rise to an i-partition of 2m in a natural way. For  $1 \leq j \leq i$ , let  $\Delta_i \subset \{1, \ldots, 2m\}$  be a maximal subset of indices for which the corresponding coordinates are the same. Then

 $\Delta_1, \ldots, \Delta_i$  form an *i*-partition of  $\{1, \ldots, 2m\}$ ; we call this *i*-partition the type of the 2m-tuple. If  $|\Delta_1| \geq ... \geq |\Delta_i|$ , then  $\pi = (|\Delta_1|, ..., |\Delta_i|)$  is an *i*-partition of 2m, and we say the type  $\tau$  corresponds to  $\pi$ .

EXAMPLE. If  $\nu = (0, 11, 5, 5, 1, 3, 0, 5) \in \mathbb{Z}_{12}^8$ , then the type of  $\nu$  is  $\tau = \{\{3, 4, 8\}, \{1, 7\}, \{2\}, \{5\}, \{6\}\}\$ and the corresponding 5-partition of the number 8 is  $\pi = (3, 2, 1, 1, 1).$ 

Now suppose that  $\tau = {\Delta_1, \ldots, \Delta_i}$  is a type corresponding to a partition  $\pi$  of 2m. Let  $N_{\pi}(\tau)$  be the number of 2m-tuples in  $\Omega$  of type  $\tau$ .

<span id="page-23-1"></span>A little thought should give the following lemma.

**Lemma 8**  $N_{\pi}(\tau)$  is the number of *i*-tuples  $(y_1, \ldots, y_i)$  with distinct coordinates in G that are solutions to the induced equation obtained from  $x_1 \ldots x_m =$  $x_{m+1} \ldots x_{2m}$  by substituting  $y_j$  for  $x_\ell$  if  $\ell \in \Delta_j$ .

EXAMPLE. If  $\tau = \{\{3, 4, 8\}, \{1, 7\}, \{2\}, \{5\}, \{6\}\}\,$ , then this equation is  $y_2y_3y_1^2 = y_4y_5y_2y_1.$ 

EXERCISE. Suppose  $\nu = (0, 3, 4, 1, 5, 1, 4, 5, 3, 3) \in \mathbb{Z}_{12}^{10}$ . Find the type  $\tau$  of  $\nu$ . Then find the value i and the induced equation described in the previous lemma.

We can adapt Lemma [7](#page-21-0) to prove the following lemma. The lemma and its proof are minor modification of some material presented in [\[5\]](#page-35-9) and [\[6\]](#page-35-10). In particular, the argument in [\[5\]](#page-35-9) covered a broader range of probabilities Q.

<span id="page-23-0"></span>**Lemma 9** Suppose  $(a_1, \ldots, a_k)$  are chosen uniformly from all k-tuples with distinct elements of G. Also suppose that  $Q(a_i) = 1/k$ . Then

$$
E(||Q^{*m} - U||^2) \le \sum_{i=1}^{\min(k, 2m)} \sum_{\pi \in P(i)} \frac{1}{k^{2m}} \frac{[k]_i}{[n]_i} \sum_{\tau \in T(\pi)} (n N_{\pi}(\tau) - [n]_i)
$$

where  $[n]_i = n(n-1)...(n-i+1)$ ,  $P(i)$  is the set of all *i*-partitions of  $2m$ , and  $T(\pi)$  is the set of all types which correspond to  $\pi$ .

**Proof:** Suppose  $\pi$  is an *i*-partition of 2*m*. A 2*m*-tuple of  $\pi$  is defined to be a 2m-tuple whose type corresponds to  $\pi$ , Let  $D_1(\pi)$  be the set of all 2m-tuples of  $\pi$  in  $\Omega$ , and let  $D_2(\pi)$  be the set of all 2m-tuples of  $\pi$  in  $G^{2m}$ . Thus  $|D_1(\pi)| = \sum_{\tau \in T(\pi)} N_{\pi}(\tau)$  and  $|D_2(\pi)| = \sum_{\tau \in T(\pi)} M_{\pi}(\tau)$  where  $M_{\pi}(\tau)$ is the number of 2m-tuples of type  $\tau$  in  $G^{2m}$  where  $\pi$  is the corresponding *i*-partition of the number 2m. It can readily be shown that  $M_{\pi}(\tau) = [n]_i$ .

Observe from Lemma [7](#page-21-0) that

$$
4E(||Q^{*m} - U||^2) \leq \sum_{i=1}^{2m} \sum_{\pi \in P(i)} \left( \sum_{(x_1, \dots, x_{2m}) \in D_1(\pi)} nE(Q(x_1) \dots Q(x_{2m})) - \sum_{(x_1, \dots, x_{2m}) \in D_2(\pi)} E(Q(x_1) \dots Q(x_{2m})) \right).
$$

Now let's consider  $E(Q(x_1)...Q(x_{2m}))$ . This expectation depends only on the size i of  $(x_1, \ldots, x_{2m})$ . The probability that a given *i*-tuple  $(y_1, \ldots, y_i)$ with distinct elements of G is contained in a random sample of G is  $[k]_i/[n]_i$ . Thus

$$
E(Q(x_1)\dots Q(x_{2m})) = \frac{1}{k^{2m}} \frac{[k]_i}{[n]_i}
$$

Note that if the size of  $(x_1, \ldots, x_{2m})$  is greater than k, then  $Q(x_1) \ldots Q(x_{2m})$ must be 0.

Thus

$$
\sum_{x \in D_1(\pi)} nE(Q(x_1) \dots Q(x_{2m})) = \frac{1}{k^{2m}} \frac{[k]_i}{[n]_i} \sum_{\tau \in T(\pi)} nN_{\pi}(\tau)
$$

and

$$
\sum_{x \in D_2(\pi)} E(Q(x_1) \dots Q(x_{2m})) = \frac{1}{k^{2m}} \frac{[k]_i}{[n]_i} \sum_{\tau \in T(\pi)} M_{\pi}(\tau)
$$

$$
= \frac{1}{k^{2m}} \frac{[k]_i}{[n]_i} \sum_{\tau \in T(\pi)} [n]_i
$$

The lemma follows by substitution and easy algebra.  $\Box$ 

Next we consider a result in Dou [\[5\]](#page-35-9). The next theorem and its proof essentially come from [\[5\]](#page-35-9) but use a simpler and less general expression for the probability P.

We assume that G is an abelian group with n elements such that  $n =$  $n_1 \dots n_t$  where  $n_1 \geq \dots \geq n_t$  are prime numbers,  $t \leq L$  for some value L not depending on *n*, and  $n_1 \leq An_t$  for some value A not depending on *n*.

<span id="page-24-0"></span>Theorem 8 Suppose G satisfies the conditions in the previous paragraph and  $k > 2L + 1$  is constant. Suppose  $(a_1, \ldots, a_k)$  is chosen uniformly from k-tuples with distinct elements of G. Then for some function  $f(n) \to 0$  as  $n \to \infty$  (with  $f(n)$  not depending on the choice of G)

$$
E(\|P^{*m}_{a_1,...,a_k} - U\|) \le f(n)
$$

where  $m = c(n)n^{2/(k-1)}$  where  $c(n) \to \infty$  as  $n \to \infty$  and  $p_1 = \ldots = p_k = 1/k$ so that  $P_{a_1,\dots,a_k}(s) = 1/k$  if  $s = a_i$  for some i in  $1,\dots,k$ .

**Proof:** Without loss of generality, we may assume that

$$
c(n) < n^{(1/L)-(2/(k-1))} A^{-1+(1/L)}.
$$

We may use Lemma [9.](#page-23-0) Let

$$
B_1 = \sum_{i=1}^{k-1} \sum_{\pi \in P(i)} \frac{1}{k^{2m}} \frac{[k]_i}{[n]_i} \sum_{\tau \in T(\pi)} (n N_{\pi}(\tau) - [n]_i).
$$

It can be readily shown from Lemma [8](#page-23-1) that  $nN_{\pi}(\tau) - [n]_i \leq n[n]_i$ . Thus

$$
B_1 \leq \sum_{i=1}^{k-1} \sum_{\pi \in P(i)} \frac{1}{k^{2m}} \frac{[k]_i}{[n]_i} \sum_{\tau \in T(\pi)} n[n]_i
$$

$$
= \frac{1}{k^{2m}} n \sum_{i=1}^{k-1} [k]_i S_{2m,i}
$$

where  $S_{2m,i}$  is a Stirling number of the second kind; this number is the number of ways to place  $2m$  labeled balls in i unlabeled boxes such that there are no empty boxes.

EXERCISE. Show that  $(k-1)^{2m} = \sum_{i=1}^{k-1} [k-1]_i S_{2m,i}$ . (Hint: The left side is the number of ways to place  $2m$  labeled balls in  $k-1$  labeled boxes where some boxes may be empty.)

Observe that  $[k]_i = k[k-1]_i/(k-i) \leq k[k-1]_i$  if  $i \leq k-1$ . Thus  $B_1 \leq k(1/k^{2m})n(k-1)^{2m} \to 0$  as  $n \to \infty$  for the specified m.

Now let

$$
B_2 = \sum_{\tau} \frac{1}{k^{2m}} \frac{[k]_k}{[n]_k} (n N_{\pi}(\tau) - [n]_k)
$$

where the sum is over all k-tuples  $\tau$ , i.e. the set of all k-partitions of the set  $\{1, 2, \ldots, 2m\}$ . We use the following lemma (which, along with is proof, is based upon [\[5\]](#page-35-9)).

**Lemma 10** If G is an abelian group satisfying the conditions for Theorem [8](#page-24-0) and  $m = c(n)n^{2/(k-1)}$  where  $c(n) \to \infty$  as  $n \to \infty$  such that

$$
c(n) < n^{(1/L)-(2/(k-1))} A^{-1+(1/L)},
$$

then for each k-type  $\tau$ , either  $N_{\pi}(\tau) = [n]_k$  or  $N_{\pi}(\tau) \leq [n]_{k-1}$ . If  $T_1 =$  ${k - \text{types } \tau | N_{\pi}(\tau) = [n]_{k}}$  and  $T_2 = {k - \text{types } \tau | N_{\pi}(\tau) \leq [n]_{k-1}}$ , then  $|T_1| + |T_2| = S_{2m,k}$  and

$$
|T_1| \le \kappa_{m,k} := \sum_{r_1 + \ldots + r_k = m, r_1, \ldots, r_k \ge 0} {m \choose r_1, \ldots, r_k}^2
$$

Proof: We start with an exercise.

EXERCISE. Show that the conditions on G and the restrictions on  $c(n)$ imply that  $m < n_t$ .

By Lemma [8,](#page-23-1)  $N_{\pi}(\tau)$  is the number of k-tuples  $(y_1, \ldots, y_k)$  with distinct coordinates such that  $\lambda_1 y_1 + \ldots + \lambda_k y_k = 0$  for some integers  $\lambda_1, \ldots, \lambda_k$  with  $|\lambda_i| \leq m < n_t$ . Note that here we are using the fact that G is abelian. Also note that  $\lambda_i$  is the number of times  $y_i$  is substituted for  $x_j$  with  $1 \leq j \leq m$ minus the number of times  $y_i$  is substituted for  $x_j$  with  $m + 1 \leq j \leq 2m$ ; in other words,  $\lambda_i = |\Delta_i \cap \{1, ..., m\}| - |\Delta_i \cap \{m+1, ..., 2m\}|$ . If  $\lambda_1 =$ ... =  $\lambda_k = 0$ , then  $N_{\pi}(\tau) = [n]_k$ ; otherwise if  $\lambda_j \neq 0$  for some j, then  $y_j$  is solvable in terms of the other variables in  $y_1, \ldots, y_k$  since  $m < p_t$  and thus  $N_{\pi}(\tau) \leq [n]_{k-1}$ . Thus we may conclude that  $\lambda_1 = \ldots = \lambda_k = 0$  if and only if  $\tau = {\Delta'_1 \cup \Delta''_1, \ldots, \Delta'_k \cup \Delta''}$  where  $\tau' = {\Delta'_1, \ldots, \Delta'_k}$  and  $\tau'' = {\Delta''_1, \ldots, \Delta''_k}$ are k-types of  $\{1, \ldots, m\}$  and  $\{m+1, \ldots, 2m\}$  respectively with  $|\Delta'_i| = |\Delta''_i|$ for  $i = 1, 2, ..., k$ . The inequality  $|T_1| \leq \kappa_{m,k}$  is elementary. The equality  $|T_1| + |T_2| = S_{2m,k}$  follows quickly from the definitions of  $S_{2m,k}$ ,  $T_1$ , and  $T_2$ . The lemma is thus proved.

Thus  $B_2 \leq B_{2,1} + B_{2,2}$  where

$$
B_{2,1} = \sum_{\tau \in T_1} \frac{1}{k^{2m}} \frac{[k]_k}{[n]_k} (n-1)[n]_k
$$

and

$$
B_{2,2} = \sum_{\tau \in T_2} \frac{1}{k^{2m}} \frac{[k]_k}{[n]_k} [n]_{k-1} (k-1).
$$

Note that in defining  $B_{2,2}$ , we used the fact that  $n[n]_{k-1}-[n]_k=[n]_{k-1}(k-1)$ . Now observe that

$$
B_{2,2} \le (k-1) \frac{1}{k^{2m}} [k]_k |T_2|/(n-k+1)
$$
  
\n
$$
\le (k-1) \frac{1}{k^{2m}} [k]_k S_{2m,k}/(n-k+1)
$$
  
\n
$$
\le (k-1) \frac{1}{k^{2m}} k^{2m}/(n-k+1)
$$

since  $S_{2m,k} \leq k^{2m}/k!$  because  $k^{2m}$  is the no more than the number of ways to place  $2m$  labeled balls in k labeled boxes where no box is left empty. Thus  $B_{2,2} \to 0$  as  $n \to \infty$ .

We also have

$$
B_{2,1} \leq \frac{1}{k^{2m}} [k]_k (n-1)|T_1|
$$
  
\n
$$
\leq \frac{1}{k^{2m}} [k]_k (n-1) \kappa_{m,k}
$$
  
\n
$$
\leq \frac{1}{k^{2m}} [k]_k (n-1) c_0 k^{2m} / m^{(k-1)/2}
$$

since an appendix of [\[5\]](#page-35-9) proves  $\kappa_{m,k} \leq c_0 k^{2m} / m^{(k-1)/2}$  for some positive constant  $c_0$ . Thus for some value c which may depend on k but not n, we get  $B_{2,1} \leq c(n-1)/m^{(k-1)/2}$ . The theorem follows.

PROBLEM FOR FURTHER STUDY. The restrictions on G in Theo-rem [8](#page-24-0) seem excessive, but we used the fact that  $m < n_t$  to bound  $|T_1|$ . Perhaps arguments can be made for a broader range of G to deal with some cases where we do not have this fact. Indeed, similar squares of multinomial coefficients, along with some additional terms, appear in the argument which Dai and Hildebrand [\[2\]](#page-35-8) use to prove Lemma [5](#page-19-0) described earlier; this proof might serve as a starting point for a possible proof of an extension of Theorem [8.](#page-24-0)

It should be noted that Greenhalgh [\[11\]](#page-35-11) has also used arguments involving squares of such multinomial coefficients to prove results similar to Theorem [6.](#page-12-0)

Further results using these techniques appear in Dou and Hildebrand [\[6\]](#page-35-10). In particular, the following two theorems are shown there; their proofs will not be presented here.

**Theorem 9** Suppose G is an arbitrary finite group of order n and  $k =$  $\lfloor (\log n)^a \rfloor$  where  $a > 1$  is constant. Let  $\epsilon > 0$  be given. Suppose  $(a_1, \ldots, a_k)$  is chosen uniformly from k-tuples with distinct elements of G. Then for some function  $f(n) \to 0$  as  $n \to \infty$  (with  $f(n)$  not depending on the choice of G),

$$
E(\|P^{*m}_{a_1,...,a_k} - U\|) \le f(n)
$$

if

$$
m = m(n) > \frac{a}{a-1} \frac{\log n}{\log k} (1 + \epsilon).
$$

**Theorem 10** Suppose G is an arbitrary finite group of order n. Also suppose  $k = \lfloor a \log n \rfloor$  and  $m = \lfloor b \log n \rfloor$  where a and b are constants with  $a > e^2$ ,  $b < a/4$ , and  $b \log(eb/a) < -1$ . Suppose  $(a_1, \ldots, a_k)$  is chosen uniformly from k-tuples with distinct elements of G. Then for some function  $f(n) \to 0$ as  $n \to \infty$  (with  $f(n)$  not depending on the choice of G),

<span id="page-28-0"></span>
$$
E(||P_{a_1,...,a_k}^{*m} - U||) \le f(n).
$$

Roichman [\[20\]](#page-36-7) uses spectral arguments to get results similar to these theorems and to extend them to symmetric random walks where at each step one multiplies either by  $a_i$  or by  $a_i^{-1}$  $i^{-1}$  (with probability 1/2 each) where i is chosen uniformly from  $\{1, \ldots, k\}$ .

### 4.5 Extensions of a result of Erdös and Rényi

Some early results involving probability on finite groups appear in an article of Erdös and Rényi  $[7]$ . In it, they give the following theorem.

**Theorem 11** Suppose  $k \geq 2 \log_2 n + 2 \log_2(1/\epsilon) + \log_2(1/\delta)$  and  $J = (a_1, \ldots, a_k)$ is a random k-tuple of elements from an abelian group G of order n. If  $b \in G$ , let  $V_k(b)$  be the number of  $(\epsilon_1, \ldots, \epsilon_k) \in \{0,1\}^k$  such that  $b = \epsilon_1 a_1 + \ldots + \epsilon_k a_k$ . Then

$$
Pr\left(\max_{b \in G} \left| V_k(b) - \frac{2^k}{n} \right| \le \epsilon \frac{2^k}{n} \right) > 1 - \delta.
$$

Near the end of their paper, Erdös and Rényi note that this theorem can be generalized to non-abelian groups  $G_n$  of order n by counting the number of ways an element b can be written in the form  $b = a_{i_1} a_{i_2} \dots a_{i_r}$  where  $1 \leq i_1 < i_2 < \ldots < i_r \leq k$  and  $0 \leq r \leq k$ . They find it unnatural to assume that if  $i < j$  that  $a_i$  would have to appear before  $a_j$ . They also assert that if we "do not consider only such products in which  $i_1 < i_2 < \ldots < i_r$ , then the situation changes completely. In this case the structure of the group  $G_n$ becomes relevant."

Further results by Pak [\[18\]](#page-36-8) and Hildebrand [\[15\]](#page-36-9) built upon this result in [\[7\]](#page-35-12) and its extension to non-abelian groups to get results for random "lazy" random walks on arbitrary finite groups. These "lazy" random walks are such that at each step, there's a large probability that the walk stays at the same group element. These results, despite the assertion of [\[7\]](#page-35-12), do not depend on the structure of the group  $G$  and involve products of the form  $a_{i_1}a_{i_2}\ldots a_{i_r}$  where  $i_1, i_2, \ldots, i_r$  need not be in increasing order and may be repeated.

For the next two theorems, which come from [\[15\]](#page-36-9), we use the following notation. If  $J = (a_1, \ldots, a_k) \in G^k$ , then

$$
P(s) = P_J(s) = \frac{1}{2k} |\{i : a_i = s\}| + \frac{1}{2} \delta_{\{s = e\}}
$$

<span id="page-29-0"></span>where  $\delta_{\{s=e\}}$  is 1 if s is the identity e of G and 0 otherwise. Note that this expression is different from the expression  $P_{a_1,\dots,a_k}(s)$  in the rest of this article.

**Theorem 12** Suppose  $a > 1$  and  $\epsilon > 0$  are given. Let  $k = \lceil a \log_2 n \rceil$ . Suppose  $m = m(n) > (1 + \epsilon)a \log(a/(a - 1)) \log_2 n$ . Then for some function  $f_1(n) \to 0$  as  $n \to \infty$  (where  $f_1(n)$  does not depend on which group G of order n is being considered),  $E(||P^{*m} - U||) \le f_1(n)$  as  $n \to \infty$  where J is chosen uniformly from  $G^k$ .

<span id="page-29-1"></span>**Theorem 13** Suppose  $k = \log_2 n + f(n)$  where  $f(n) \to \infty$  as  $n \to \infty$  and  $f(n)/\log_2 n \to 0$  as  $n \to \infty$ . Let  $\epsilon > 0$  be given. If  $m = m(n) > (1 +$  $\epsilon$ )(log<sub>2</sub> n)(log(log<sub>2</sub> n)), then for some function  $f_2(n) \to 0$  as  $n \to \infty$  (where  $f_2(n)$  does not depend on which group G of order n is being considered),  $E(||P^{*m} - U||) \le f_2(n)$  where *J* is chosen uniformly from  $G^k$ .

<span id="page-29-2"></span>The proofs of Theorems [12](#page-29-0) and [13](#page-29-1) use the following variation of Theo-rem [11.](#page-28-0) In it, note that  $g^0$  is the identity element of G.

**Lemma 11** Let  $J = (a_1, \ldots, a_k)$ . Suppose  $j \leq k$ . Let  $Q_J(s)$  be the probability that  $s = a_1^{\epsilon_1} a_2^{\epsilon_2}$  $\epsilon_2^{e_2} \ldots \alpha_j^{e_j}$  where  $\epsilon_1, \epsilon_2, \ldots, \epsilon_j$  are i.i.d. uniform on  $\{0, 1\}$ . If J is chosen uniformly from all k-tuples  $(a_1, \ldots, a_k)$  of elements of G, then  $Pr(||Q_J - U|| \le \epsilon) \ge 1 - \delta$  for each  $j \ge \log_2 n + 2\log_2(1/\epsilon) + \log_2(1/\delta)$ .

**Proof:** This proof follows [\[15\]](#page-36-9) and extends a proof in [\[7\]](#page-35-12). Let  $V_j(s) = 2^j Q_j(s)$ . Observe that

$$
4||Q_J - U||^2 = \left(\sum_{s \in G} \left| \frac{V_j(s)}{2^j} - \frac{1}{n} \right| \right)^2
$$
  
 
$$
\leq n \sum_{s \in G} \left(\frac{V_j(s)}{2^j} - \frac{1}{n}\right)^2
$$

by the Cauchy-Schwarz inequality; this argument is very similar to part of the proof of the Upper Bound Lemma described in Chapter 3 of Diaconis [\[3\]](#page-35-3).

Thus

$$
Pr(2||Q_J - U|| > \epsilon) \le Pr\left(n \sum_{s \in G} \left(\frac{V_j(s)}{2^j} - \frac{1}{n}\right)^2 > \epsilon^2\right)
$$
  
=  $Pr\left(\sum_{s \in G} \left(V_j(s) - \frac{2^j}{n}\right)^2 > \frac{\epsilon^2 2^{2j}}{n}\right).$ 

It can be shown (as on p. 130 of [\[7\]](#page-35-12) extended to non-abelian groups) that

$$
E\left(\sum_{s\in G}\left(V_j(s)-\frac{2^j}{n}\right)^2\right)=2^j\left(1-\frac{1}{n}\right)
$$

where the expectation comes from choosing  $J$  uniformly from all  $k$ -tuples  $(a_1, \ldots, a_k)$  of elements of G.

Thus by Markov's inequality, we get

$$
Pr(||Q_J - U|| > \epsilon) \le Pr(2||Q_J - U|| > \epsilon)
$$
  

$$
\le \frac{2^j (1 - (1/n))}{\epsilon^2 2^{2j}/n}
$$
  

$$
\le \frac{n}{\epsilon^2 2^j} \le \delta.
$$

 $\Box$ 

We say that a family of probability distributions  $R_J$  depending on  $J \in G^k$ is  $(\alpha, \beta)$ -good in variation distance if  $Pr(||R_J - U|| > \alpha) \leq \beta$  where the probability is over a uniform choice of all  $k$ -tuples for  $J$ . Thus Lemma [11](#page-29-2) shows that  $a_1^{\epsilon_1}$  $a_1^{\epsilon_1} \dots a_j^{\epsilon_j}$ <sup> $\epsilon_j$ </sup> is  $(\epsilon, \delta)$ -good in variation distance if  $j \geq \log_2 n + 2\log_2(1/\epsilon) +$  $\log_2(1/\delta)$ .

Theorems [12](#page-29-0) and [13](#page-29-1) look at the variation distance from the uniform distribution of a probability distribution of

$$
a_{i_1}^{\epsilon_1}a_{i_2}^{\epsilon_2}\ldots a_{i_m}^{\epsilon_m}
$$

where  $i_1, \ldots, i_m$  are i.i.d. uniform on  $\{1, \ldots, k\}, \epsilon_1, \ldots, \epsilon_m$  are i.i.d. uniform on  $\{0, 1\}$ , and  $(i_1, \ldots, i_m)$  and  $(\epsilon_1, \ldots, \epsilon_m)$  are independent. Using Lemma [11](#page-29-2) to examine this distribution requires considerable care.

First let's consider the case where  $i_1, \ldots, i_m$  are all given and consist of at least j distinct values. Suppose also that the value  $\epsilon_{\ell}$  is given if  $i_{\ell} = i_{\ell'}$  for some  $\ell' < \ell$  or if  $\{i_1, \ldots, i_{\ell-1}\}$  has at least j distinct values; in other words,  $\epsilon_{\ell}$ is given if  $i_{\ell}$  appeared earlier in the m-tuple  $(i_1, \ldots, i_m)$  or if  $i_{\ell}$  is not among the first j distinct values in this m-tuple. We assume that the remaining j values from  $\epsilon_1, \ldots, \epsilon_m$  are i.i.d. uniform on  $\{0, 1\}$ . For example, if  $j = 5$ ,  $k = 7$ , and  $m = 9$ , such an expression may look like

$$
a_3^{\epsilon_1} a_4^{\epsilon_2} a_2^{\epsilon_3} a_4^1 a_1^{\epsilon_5} a_3^1 a_6^{\epsilon_7} a_7^0 a_2^1
$$

where  $\epsilon_1$ ,  $\epsilon_2$ ,  $\epsilon_3$ ,  $\epsilon_5$ , and  $\epsilon_7$  are i.i.d. uniform on  $\{0, 1\}$ .

To use Lemma [11](#page-29-2) to examine such expressions, we need to consider the "pulling through" technique described in Pak [\[18\]](#page-36-8) and subsequently in Hilde $brand$   $|15|$ .

Proposition 5 Suppose  $h = a_1^{\epsilon_1}$  $a_1^{\epsilon_1} \dots a_\ell^{\epsilon_\ell}$  $\frac{\epsilon_{\ell}}{\ell}xa_{\ell+1}^{\epsilon_{\ell+1}}\ldots a_j^{\epsilon_j}$  where  $\epsilon_1,\ldots,\epsilon_j$  are each in  $\{0,1\}$  and x is a fixed function of  $a_1, \ldots, a_\ell$ . Then

$$
h = a_1^{\epsilon_1} \dots a_\ell^{\epsilon_\ell} \left( a_{\ell+1}^x \right)^{\epsilon_{\ell+1}} \dots \left( a_j^x \right)^{\epsilon_j} x
$$

where  $g^x := xgx^{-1}$ . Furthermore if  $a_1, \ldots, a_j$  are i.i.d. uniform on G, then  $a_1, \ldots, a_\ell, a_{\ell+1}^x, \ldots, a_j^x$  are i.i.d. uniform on  $G$ .

**Proof:** The alternate expression for h can be readily verified. Note that since x does not depend on  $a_{\ell+1}$  and since  $a_1, \ldots, a_{\ell}, a_{\ell+1}$  are i.i.d. uniform on G, the expression  $xa_{\ell+1}x^{-1}$  will be uniform on G independent of  $a_1, \ldots, a_\ell$ . Continuing in the same way completes the proof of the proposition.  $\Box$ 

This proposition can be used repeatedly. For example, if

$$
h = a_3^{\epsilon_1} a_4^{\epsilon_2} a_2^{\epsilon_3} a_4^1 a_1^{\epsilon_5} a_3^1 a_6^{\epsilon_7} a_7^0 a_2^1,
$$

then

$$
h = a_3^{\epsilon_1} a_4^{\epsilon_2} a_2^{\epsilon_3} (a_1^{a_4})^{\epsilon_5} (a_6^{a_4 a_3})^{\epsilon_7} a_4 a_3 a_7^0 a_2^1.
$$

Furthermore, if  $a_3$ ,  $a_4$ ,  $a_2$ ,  $a_1$ , and  $a_6$  are i.i.d. uniform on G, then so are  $a_3$ ,  $a_4, a_2, a_1^{a_4}$  $a_4^{a_4}$ , and  $a_6^{a_4 a_3}$  $a_4^{a_4a_3}$ . Also note that if  $a_1, \ldots, a_7$  are given and  $\epsilon_1, \epsilon_2, \epsilon_3$ ,  $\epsilon_5$ , and  $\epsilon_7$  are i.i.d. uniform on  $\{0, 1\}$ , then the probabilities P and Q given by  $P(s) = Pr(s = a_3^{\epsilon_1} a_4^{\epsilon_2} a_2^{\epsilon_3})$  $\frac{\epsilon_3}{2}(a_1^{a_4})$  $\binom{a_4}{1}$ <sup> $\epsilon_5$ </sup> $\left(a_6^{a_4 a_3}\right)$  $\binom{a_4a_3}{6}$ <sup>e<sub>7</sub></sup>) and  $Q(s) = Pr(s = h)$  have the same variation distance from the uniform distribution.

<span id="page-32-0"></span>Thus we may conclude the following.

**Lemma 12** Suppose  $I = (i_1, \ldots, i_m)$  where  $i_1, \ldots, i_m \in \{1, \ldots, k\}$ . Suppose *I* has at least *j* distinct values where  $j \ge \log_2 n + 2\log_2(1/\epsilon) + \log_2(1/\delta)$  and  $j \leq k$ . Suppose  $\vec{\epsilon}$  is a vector determining  $\epsilon_{\ell}$  if  $i_{\ell} = i_{\ell'}$  for some  $\ell' < \ell$  or if  $\{i_1, \ldots, i_{\ell-1}\}\$  has at least j distinct values. Suppose the remaining j values from  $\epsilon_1, \ldots, \epsilon_m$  are i.i.d. uniform on  $\{0, 1\}$ . Then  $a_{i_1}^{\epsilon_1}$  $i_1^{i_1} \ldots a_{i_m}^{i_m}$  is  $(\epsilon, \delta)$ -good in variation distance.

We need to put together probabilities for the various possibilities for I and  $\vec{\epsilon}$ . The following exercise will be useful.

EXERCISE. Suppose  $P = p_1 P_1 + \ldots + p_\ell P_\ell$  where  $p_1, \ldots, p_\ell$  are positive numbers which sum to 1 and  $P_1, \ldots, P_\ell$  are probabilities on G. Show that

<span id="page-32-1"></span>
$$
||P - U|| \le \sum_{j=1}^{\ell} p_j ||P_j - U||.
$$

The following lemma comes from [\[15\]](#page-36-9).

**Lemma 13** Let  $c > 1$  be given. Suppose j is given such that  $j \leq k$ ,  $j \geq$  $\log_2 n + 2\log_2(1/\alpha) + \log_2(1/\beta)$ , and  $j \leq m$ . Suppose that the probability of getting at least j distinct values when choosing m i.i.d. random numbers which are uniform on  $\{1, \ldots, k\}$  is  $1 - p(j, k, m)$ . Then  $Pr(\Vert P_j^{*m} - U \Vert >$  $c\beta + \alpha + p(j,k,m) \leq 1/c$  where the probability is over a uniform choice of  $(a_1,\ldots,a_k)\in G^k$ .

**Proof:** Let I be an m-tuple  $(i_1, \ldots, i_m)$  of elements of  $\{1, \ldots, k\}$  and  $J = (a_1, \ldots, a_k)$  be a k-tuple of elements of G. Let  $\vec{\epsilon}$  be a vector with  $m - j$ elements of  $\{0, 1\}$ . Let  $S_1$  be the set of I such that I has fewer than j distinct values, and let  $S_2$  be the set of I such that I has at least j distinct values.

If  $I \in S_2$ , consider the probability distribution of  $a_{i_1}^{\epsilon_1}$  $\frac{\epsilon_1}{i_1} a_{i_2}^{\epsilon_2}$  $\epsilon_2^{\epsilon_2} \ldots a_{i_m}^{\epsilon_m}$  where  $\epsilon_\ell$ is determined by  $\vec{\epsilon}$  if  $i_{\ell} = i_{\ell'}$  for some  $\ell' < \ell$  or  $\{i_1, \ldots, i_{\ell-1}\}$  has at least j distinct values and where the remaining j values from  $\epsilon_1, \ldots, \epsilon_m$  are i.i.d.

uniform on  $\{0, 1\}$ . Let  $v(I, J, \vec{\epsilon})$  be the variation distance of this probability distribution from the uniform distribution. By the exercise

$$
||P_j^{*m} - U|| \le \sum_{I \in S_1} \frac{1}{k^m} 1 + \sum_{I \in S_2} \sum_{\vec{\epsilon}} \frac{1}{k^m} \frac{1}{2^{m-j}} v(I, J, \epsilon).
$$

Let

$$
G(I, J, \vec{\epsilon}) = \begin{cases} 1 & \text{if } v(I, J, \vec{\epsilon}) \le \alpha \\ 0 & \text{otherwise} \end{cases}
$$

For each  $I \in S_2$  and  $\vec{\epsilon}$ , the number of J with  $G(I, J, \vec{\epsilon}) = 0$  is no more than  $\beta$  times the total number of J since the family of probability distributions  $a_{i_1}^{\epsilon_1}$  $\frac{\epsilon_1}{i_1} a_{i_2}^{\epsilon_2}$  $\epsilon_2^{\epsilon_2} \ldots a_{i_m}^{\epsilon_m}$  (where j of the values  $\epsilon_1, \ldots, \epsilon_m$  are i.i.d. uniform on  $\{0, 1\}$ and the rest are determined by  $\vec{\epsilon}$  as previously described) is  $(\alpha, \beta)$ -good in variation distance by Lemma [12.](#page-32-0) For a given J, the number of  $I \in S_2$  and  $\vec{\epsilon}$ with  $G(I, J, \vec{\epsilon}) = 0$  may be more than  $c\beta$  times the total number of  $I \in S_2$ and  $\vec{\epsilon}$ . However, the number of such k-tuples J can be at most  $1/c$  times the total number of  $k$ -tuples  $J$ . For the other choices of  $J$ , we have

$$
||P_j^{*m} - U||
$$
  
\n
$$
\leq \sum_{I \in S_1} \frac{1}{k^m} 1 + \sum_{(I, \vec{\epsilon}): I \in S_2, G(I, J, \vec{\epsilon}) = 1} \frac{1}{k^m} 2^{m-j} \alpha + \sum_{(I, \vec{\epsilon}): I \in S_2, G(I, J, \vec{\epsilon}) = 0} \frac{1}{k^m} 2^{m-j} 1
$$
  
\n
$$
\leq p(j, k, m) + \alpha + c\beta.
$$

The proof of the lemma is complete.  $\Box$ 

Using Lemma [13](#page-32-1) to prove Theorems [12](#page-29-0) and [13](#page-29-1) involves finding a bound on  $p(j, k, n)$  and choosing c appropriately. The technique to find the bound involves the time it takes to choose  $j$  out of  $k$  objects in the coupon collector's problem. More details may be found in Pak [\[18\]](#page-36-8) and in Hildebrand [\[15\]](#page-36-9); these sources refer to p. 225 of Feller [\[8\]](#page-35-0).

By using comparison theorems (Theorem 3 and Proposition 7 of Hildebrand [\[16\]](#page-36-10)), one can extend Theorems [12](#page-29-0) and [13](#page-29-1) to deal with the cases where

$$
P_J(s) = \frac{1-a}{k} |\{i : a_i = s\}| + a\delta_{\{s=e\}}
$$

if a is a constant in the interval  $(0, 1)$  and k is as in those theorems. The constant multiple in the expression for  $m$  may depend on  $a$ .

PROBLEM FOR FURTHER STUDY. Can these theorems be extended to the case where  $a = 0$  for these values of k?

Hildebrand in [\[15\]](#page-36-9) and [\[16\]](#page-36-10) also considers some random symmetric lazy random walks and again extends results of Pak [\[18\]](#page-36-8). One of these results from [\[15\]](#page-36-9) is the following.

**Theorem 14** Suppose  $X_m = a_{i_1}^{\epsilon_1}$  $\epsilon_1^{\epsilon_1} \ldots \epsilon_m^{\epsilon_m}$  where  $\epsilon_1, \ldots, \epsilon_m$  are *i.i.d.* with  $P(\epsilon_i = 1) = P(\epsilon_i = -1) = 1/4$  and  $P(\epsilon_i = 0) = 1/2$ . Suppose  $i_1, \ldots, i_m$ are i.i.d. uniform on  $\{1, \ldots, k\}$  where k is as in Theorem [13.](#page-29-1) Given  $J \in G^k$ , let  $Q_{sym}$  be the probability of  $X_1$ . If  $m = m(n) > (1 + \epsilon)(\log_2 n) \log(\log_2 n)$ , then  $E(||Q_{sym}^{*m} - U||) \rightarrow 0$  as  $n \rightarrow \infty$  where the expectation is over a uniform choice of  $J = (a_1, \ldots, a_k)$  from  $G^k$ .

#### 4.6 Some random random walks on  $\mathbb{Z}_2^d$ 2

Greenhalgh [\[12\]](#page-35-13) uses some fairly elementary arguments to examine random random walks on  $\mathbb{Z}_2^d$ , and Wilson [\[26\]](#page-36-11) uses a binary entropy function argument to examine these random random walks. The main result of [\[26\]](#page-36-11) is the following theorem, which we state but do not prove.

**Theorem 15** Suppose  $k > d$ . There exists a function  $T(d, k)$  such that the following holds. Let  $\epsilon > 0$  be given. For any choice of  $a_1, \ldots, a_k$  (each from  $(\mathbb{Z}_2^d)$ , if  $m \leq (1-\epsilon)T(d,k)$ , then  $||P_{a_1,...,a_k} - U|| > 1-\epsilon$ . For almost all choices of  $a_1, \ldots, a_k$ , if  $m \geq (1+\epsilon)T(d, k)$ , then  $||P_{a_1, \ldots, a_k} - U|| < \epsilon$  provided that the Markov chain is ergodic.

Note that "for almost all choices" a property holds means here that with probability approaching 1 as  $d \to \infty$ , the property holds. Also note that here  $P_{a_1,...,a_k}(s) = |\{i : a_i = s\}|/k.$ 

Some properties of  $T(d, k)$  are described in [\[26\]](#page-36-11) and are also mentioned on p. 321 of Saloff-Coste [\[22\]](#page-36-3).

Wilson [\[26\]](#page-36-11) noted that the upper bound remains valid for any finite abelian group G provided that d is replaced by  $log_2 |G|$ .

PROBLEM FOR FURTHER STUDY. Does the expression for the upper bound remain valid for any finite group  $G$  provided that  $d$  is replaced by  $\log_2|G|$ ?

PROBLEM FOR FURTHER STUDY. Relatively little is known about random random walks on specific families of finite non-abelian groups if  $k < \log_2|G|$ . Indeed, Saloff-Coste [\[22\]](#page-36-3) (p. 324) cites a wide-open problem involving the alternating group with  $k = 2$ .
