Abstract

For any group G , $\pi_e(G)$ denotes the set of orders of its elements. If Ω is a non-empty subset of \mathbb{N} , $h(\Omega)$ stands for the number of isomorphism classes of finite groups G such that $\pi_e(G) = \Omega$. We put $h(G) = h(\pi_e(G))$. In this paper we show that $h(PGL(2, p^n)) = 1$ or ∞ , where $p = 2^\alpha 3^\beta + 1$ is a prime, $\alpha \geq 0, \beta \geq 0$ and $n \geq 1$. In particular, we show that $h(PGL(2, 7)) = h(PGL(2, 3^2)) = \infty$.

1 Introduction

The groups considered in this paper are finite and simple groups are non-Abelian. For a group G , we denote the set of orders of all elements in G by $\pi_e(G)$ which has been recently called the *spectrum* of G , and by $\pi(G)$ the set of all prime factors of $|G|$. Obviously $\pi_e(G)$ is a subset of the set \mathbb{N} of natural numbers, and it is *closed* and *partially ordered* by divisibility, hence, it is uniquely determined by $\mu(G)$, the subset of its maximal elements.

One of the most beautiful concepts in Finite Group Theory which has recently attracted many researchers is the problem of characterizing finite groups

2000 *Mathematics Subject Classification*: 20D05

Key words: Element order, Prime graph, Projective special linear group.

by element orders. Let Ω be a non-empty subset of \mathbb{N} . Now, we put forwards the following questions: *Is there any group G such that $\pi_e(G) = \Omega$? If the answer is affirmative then how many non-isomorphic groups exist with the above set of element orders ?* Certainly, if there exists such a group, Ω must contain 1 and furthermore Ω must be closed and partially ordered under the divisibility relation. These conditions are necessary but not sufficient, for example if $\Omega = \{1, 2, 3, 4, 5, 6, 7, 8, 9\}$, then there does not exist any group G with $\pi_e(G) = \Omega$. In fact, R. Brandl and W. J. Shi in [1] have classified all finite groups whose element orders are consecutive integers and in that paper they have shown that if $\pi_e(G) = \{1, 2, 3, \dots, n\}$, for some group G , then $n \leq 8$.

For a set Ω of natural numbers, define $h(\Omega)$ to be the number of isomorphism classes of finite groups G such that $\pi_e(G) = \Omega$, and put $h(G) = h(\pi_e(G))$. Evidently, $h(G) \geq 1$. Now we give a *New Classification* for groups using the h function. A group G is called *k-distinguishable* if $h(G) = k < \infty$; otherwise G is called *non-distinguishable*. Also a 1-distinguishable group is called a *characterizable* (or *recognizable*) group.

Let $q = p^n$, where p is a prime. The structure of $Aut(L_2(q))$ is well known, it is isomorphic to the semidirect product of $PGL(2, q)$ by a cyclic group of order n . On the other hand we know $\mu(L_2(q)) = \{\frac{q-1}{\epsilon}, p, \frac{q+1}{\epsilon}\}$, $\epsilon = (2, q-1)$, and $\mu(PGL(2, q)) = \{q-1, p, q+1\}$.

A finite group G is called *C_{p,p}-group* if p is a prime divisor of $|G|$ and the centralizer of any non-trivial p -element in G is a p -group. Evidently, the almost simple groups $PGL(2, q)$ where $q = p^n$, are *C_{p,p}-groups*. In [2], the authors have classified the finite simple *C_{p,p}-groups*, where p is prime and $p = 2^\alpha 3^\beta + 1$, $\alpha \geq 0, \beta \geq 0$ (see Lemma 8 and Table 1). Using these results, we prove the following theorem.

Theorem 1 *Let G be a finite group and $\pi_e(G) = \pi_e(PGL(2, p^n))$, where $p = 2^\alpha 3^\beta + 1$ ($\alpha \geq 0, \beta \geq 0$) is a prime and $n \in \mathbb{N}$. Then G has a normal 2-subgroup N such that $G/N \cong PSL(2, p^n)$. In particular, $h(PGL(2, p^n)) \in \{1, \infty\}$.*

Also, we prove that:

Theorem 2 *The almost simple group $PGL(2, 3^2)$ is non-distinguishable.*

For us it was interesting to face with some groups G such that $\mu(G)$ contain three consecutive natural numbers in the form $\{p-1, p, p+1\}$ where $p \geq 5$ is a prime. Such sets appear for almost simple groups $PGL(2, p)$, where $p \geq 5$ is a prime, in fact we proved in [10] that $h(PGL(2, p)) \in \{1, \infty\}$. For ∞ we have found an example. It has been proved in [1] that $PGL(2, 5) \cong S_5$ has ∞ for its h function. Here we also give another example of groups of type $PGL(2, p)$ with value ∞ for its h function.

Theorem 3 *There exists an extension G of a 7-group by $2.S_4$ such that $\mu(G) = \mu(PGL(2, 7)) = \{6, 7, 8\}$. In particular, the almost simple group $PGL(2, 7)$ is non-distinguishable.*

Notation. Our notation and terminology are standard (see [3]). If m and n are natural numbers and p is a prime, then we let $\pi(n)$ be the set of all primes dividing n , and $r_{[n]}$ the largest prime not exceeding n , the notation $p^m \parallel n$ means that $p^m | n$ and $p^{m+1} \nmid n$. The expression $G = K : C$ denotes the split extension of a normal subgroup K of G by a complement C .

2 Some Preliminary Results

First, we collect some results from Elementary Number Theory which will be useful tools for our further investigations in this paper. We start with a famous theorem due to Zsigmondy.

Zsigmondy's Theorem (see [15]). *Let a and n be integers greater than 1. Then there exists a "primitive prime divisor" of $a^n - 1$, that is a prime s dividing $a^n - 1$ and not dividing $a^i - 1$ for $1 \leq i \leq n - 1$, except if*

- (1) $a = 2$ and $n = 6$, or
- (2) a is a Mersenne prime and $n = 2$.

We denote by a_n one of these primitive prime divisors of $a^n - 1$. Evidently, if a_n is a primitive prime divisor of $a^n - 1$, then a has order n modulo a_n and so $a_n \equiv 1 \pmod{n}$. Thus $a_n \geq n + 1$.

The next elementary result will be needed later.

Lemma 1 *Let p and q be two primes and m be a natural number, where p, q and m satisfying one of the following conditions. Then, for every $n \geq m$, there exists a primitive prime divisor $p_n > q$.*

- (1) $p = 7, \quad m = 5 \quad \text{and} \quad q = 13,$
- (2) $p = 13, \quad m = 5 \quad \text{and} \quad q = 19,$
- (3) $p = 17, \quad m = 4 \quad \text{and} \quad q = 19,$
- (4) $p = 19, \quad m = 7 \quad \text{and} \quad q = 37,$
- (5) $p = 37, \quad m = 7 \quad \text{and} \quad q = 109,$
- (6) $p = 73, \quad m = 5 \quad \text{and} \quad q = 127.$

PROOF. In all cases, if $n \leq q$, the result is straightforward. Therefore, we may assume that $n > q$. Since

$$\pi(q!) \subseteq \pi\left(p \prod_{i=1}^{q-1} (p^i - 1)\right) \subset \pi\left(p \prod_{i=1}^n (p^i - 1)\right),$$

by Zsigmondy's theorem we deduce that there exists a primitive prime divisor $p_n > q$, completing the proof. \square

Here, we list all primitive prime divisors p_n for $p = 7, 13, 17$ and $2 \leq n \leq 19$, in Table 1. Using Table 1, the reader can easily check the proof of Lemma 1 (1)-(3) for $n \leq q$.

Table 1 The primitive prime divisors p_n where $p \in \{7, 13, 17\}$ and $2 \leq n \leq 19$.

Lemma 2 Let p and q be two primes and m, n be natural numbers such that $p^m = q^n + 1$. Then one of the following holds:

- (1) $n = 1$, m is a prime number, $p = 2$ and $q = 2^m - 1$ is a Mersenne prime;
- (2) $m = 1$, n is a power of 2, $q = 2$ and $p = 2^n + 1$ is a Fermat prime;
- (3) $p = n = 3$ and $q = m = 2$.

PROOF. Well known exercise using the Zsigmondy's theorem. \square

The set $\pi_e(G)$ defines the *prime graph* $\Gamma(G)$ of G whose vertex-set is $\pi(G)$ and two primes p and q in $\pi(G)$ are adjacent (we write $p \sim q$) if and only if $pq \in \pi_e(G)$. The number of connected components of $\Gamma(G)$ is denoted by $t(G)$, and the connected components are denoted by $\pi_i = \pi_i(G)$, $i = 1, 2, \dots, t(G)$. If $2 \in \pi(G)$ we always assume $2 \in \pi_1$. Denote by $\mu_i(G)$ the set of all $n \in \mu(G)$ such that $\pi(n) \subseteq \pi_i$.

The Gruenberg-Kegel Theorem (see [14]). *If G is a finite group with disconnected graph $\Gamma(G)$ then one of the following holds:*

(1) $t(G) = 2$, G is Frobenius or 2-Frobenius.

(2) G is an extension of a $\pi_1(G)$ -group N by a group G_1 , where $S \leq G_1 \leq \text{Aut}(S)$, S is a non-Abelian simple group and G_1/S is a $\pi_1(G)$ -group. Moreover $t(S) \geq t(G)$ and for every i , $2 \leq i \leq t(G)$, there exists j , $2 \leq j \leq t(S)$ such that $\mu_j(S) = \mu_i(G)$.

Lemma 3 *Let S be a finite simple group with disconnected prime graph $\Gamma(S)$. Then $|\mu_i(S)| = 1$ for $2 \leq i \leq t(S)$. Let $n_i(S)$ be a unique element of $\mu_i(S)$ for $i \geq 2$. Then value for S , $\pi_1(S)$ and $n_i(S)$ for $2 \leq i \leq t(S)$ are the same as in Tables 1a – c of [7].*

PROOF. The simple groups S and the sets of $\pi_i(S)$ are described in [14] and [5]; the rest is proved in Lemma 4 of [6]. The values of the numbers $n_i(S)$, $i \geq 2$ are listed in Table 1a-c of [7]. \square

We also use the following lemma (see [9], Lemma 1).

Lemma 4 *If a group G contains a soluble minimal normal subgroup, then G is non-distinguishable. In particular, if G is a soluble group then G is non-distinguishable.*

The following result of V. D. Mazurov will be used several times.

Lemma 5 (see [8]) *Let G be a finite group, N a normal subgroup of G , and G/N a Frobenius group with Frobenius kernel F and cyclic complement C . If $(|F|, |N|) = 1$ and F is not contained in $NC_G(N)/N$, then $p|C| \in \pi_e(G)$ for some prime divisor p of $|N|$.*

The following lemma is taken from ([12], Theorem 2).

Lemma 6 *Let G be a finite group such that*

$$\mu(G) = \mu(\text{PGL}(2, 2^n)) = \{2^n - 1, 2, 2^n + 1\}.$$

Then, the following statements hold.

- (1) *If $n \geq 2$, then $G \cong \text{PGL}(2, 2^n)$.*
- (2) *If $n = 1$, then $G \cong S_3$ has ∞ for its h function.*

We are now ready to prove the following lemma.

Lemma 7 *Let G be a finite group such that*

$$\mu(G) = \mu(\text{PGL}(2, p^n)) = \{p^n - 1, p, p^n + 1\},$$

where p is an odd prime, $n \geq 2$. Then, the following statements hold.

(1) *If $(p, n) \neq (3, 2)$, then item (2) of the Gruenberg-Kegel theorem holds. Moreover, S is isomorphic to none of the following simple groups:*

- (a) *alternating groups on $n \geq 5$ letters,*
- (b) *sporadic simple groups,*
- (c) *$L_2(p^k)$ where $k \neq n$, or*
- (d) *$L_2(2p^m \pm 1)$, $m \geq 1$, where $2p^m \pm 1$ is a prime.*

(2) *If $(p, n) = (3, 2)$, then there exists a soluble group G such that $\mu(G) = \mu(\text{PGL}(2, 3^2))$.*

PROOF. (1) First of all, we show that G is insoluble. Assume the contrary. If $\pi(p^n - 1) = \{2\}$, then by Lemma 2 we obtain $(p, n) = (3, 2)$ which is a contradiction. Hence, there exists a prime $2 \neq r \in \pi(p^n - 1)$. On the other hand, we consider the primitive prime divisor $s = p_{2n}$. Now assume that H is a $\{p, r, s\}$ -Hall subgroup of G . Since G has no elements of order pr, ps and rs , it follows that H is a soluble group all of whose elements are of prime power orders. By ([4], Theorem 1), we must have $|\pi(H)| \leq 2$, which is a contradiction.

Since $t(G) = 2$, G satisfies the conditions of the Gruenberg-Kegel theorem. Now we show that G is neither Frobenius nor 2-Frobenius. Evidently, G can not be a 2-Frobenius group, because G is insoluble. Suppose $G = KC$ is a Frobenius group with kernel K and complement C . Clearly C is insoluble, $\pi(C) = \pi_1(G) = \pi(p^{2n} - 1)$, $\pi(K) = \pi_2(G) = \{p\}$ and by ([11], Theorem 18.6) C has a normal subgroup C_0 of index ≤ 2 such that $C_0 \cong SL(2, 5) \times Z$, where every Sylow subgroup of Z is cyclic and $\pi(Z) \cap \pi(30) = \emptyset$. Therefore $\Gamma(C)$ can be obtained from the complete graph on $\pi(C)$ by deleting the edge $\{3, 5\}$. On the other hand, if there exist primes $2 \neq r \in \pi(p^n - 1)$ and $2 \neq s \in \pi(p^n + 1)$, then since $rs \notin \pi_e(G)$ it follows that $rs \notin \pi_e(C)$. Hence, we must have $Z = 1$ and $\pi(p^{2n} - 1) = \pi(SL_2(5)) = \{2, 3, 5\}$ and since $\{2, 3, 5\} \subset \pi(p^4 - 1)$, by Zsigmondy's theorem we obtain that $n = 2$. Now, it is easy to see that $\pi(p^2 - 1) = \{2, 3\}$ and $\pi(p^2 + 1) = \{2, 5\}$. From $\pi(p^2 - 1) = \{2, 3\}$, we infer that p is a Mersenne prime or a Fermat prime. In the first case we obtain $p = 7$, and in the latter case $p = 17$. If $p = 17$, then $29 \in \pi(p^2 + 1)$, a contradiction. If $p = 7$, then C contains an element of order 16, which is a contradiction.

Therefore, by the Gruenberg-Kegel theorem, G is an extension of a $\pi_1(G)$ -group N by a group G_1 , where $S \leq G_1 \leq Aut(S)$, S is a non-Abelian simple group and G_1/S is a $\pi_1(G)$ -group. Now, we show that S is not isomorphic to an alternating group, a sporadic simple group, a linear group $L_2(p^k)$ where $k \neq n$ or $L_2(2p^m \pm 1)$, $m \geq 1$, where $2p^m \pm 1$ is a prime.

Before beginning we recall that in the prime graph of G the connected component $\pi_1(G)$ consists of the primes in $\pi(p^n - 1)$ which form a complete subsection and also the primes in $\pi(p^n + 1)$ which forms another complete subsection. Moreover, every odd vertex in $\pi(p^n - 1)$ is not joined to any odd vertex in $\pi(p^n + 1)$.

(a) Assume that $S \cong A_m$, $m \geq 5$. By Lemma 3, $m = p, p + 1, p + 2$. Suppose $S \cong A_p$, $p \geq 5$. We have that in the prime graph $\Gamma(A_p)$ the vertex 3 is joined to $2, 5, 7, \dots, r_{[p-3]}$. If 3 divides $p - 1$, then by the remark mentioned in the previous paragraph, we conclude that $2, 3, 5, \dots, r_{[p-3]}$ belong to $\pi(p^n - 1)$. Now, if there exists a prime $s \in \pi(p^n + 1) \setminus \pi(A_p)$ then $s \in \pi(N)$, because $A_p \cong S \leq G/N \leq Aut(S) \cong S_p$. On the other hand, $A_4 = 2^2 : 3 \leq A_p$ and by lemma 5 it follows that $s \sim 3$ which is a contradiction. Hence, $\pi(p^n + 1) \subseteq \pi(A_p)$. As $(p^n - 1, p^n + 1) = 2$ and $2, 3, 5, 7, \dots, r_{[p-3]} \in \pi(p^n - 1)$, the only possible cases are: $\pi(p^n + 1) = \{2\}$ or $\pi(p^n + 1) = \{2, p - 2\}$ in which in the latter case $p - 2$ is a prime. Evidently, the first case will never occur. So, we consider the case $\pi(p^n + 1) = \{2, p - 2\}$, i.e., $p^n + 1 = 2^l(p - 2)^k$. Now, if $k > 1$ then since $(p - 2)^k \in \pi_e(G)$ and $(p - 2)^k \notin \pi_e(Aut(S)) = \pi_e(S_p)$ we obtain $(p - 2) \in \pi(N)$ and again since A_p contains a Frobenius subgroup of shape $2^2 : 3$ by Lemma 5,

we get $p - 2 \sim 3$ which is a contradiction. Finally, we have $k = 1$ and $l > 1$. Moreover $2 \parallel p^n - 1$ which implies that n must be odd. But in this case we have $p^n + 1 = (p + 1)(p^{n-1} - p^{n-2} + \cdots - p + 1) = 2^l(p - 2)$ for which it follows that $p^{n-1} - p^{n-2} + \cdots - p + 1 = p - 2$, giving no solution for $p \geq 5$. This final contradiction shows that $S \not\cong A_p$. The case when 3 divides $p + 1$, is similar. The other cases are settled similarly.

(b) Suppose S is isomorphic to one of the sporadic simple groups, for instance $S \cong J_2$. Since $p \in \pi_2(G)$, by Lemma 3 it follows that $p = 7$. If $n \geq 5$, then we choose the primitive prime divisors $7_n, 7_{2n}$ in $\pi(G)$. Evidently, $7_{2n} \in \pi(p^n + 1)$, and so G does not contain an element of order $7_n \cdot 7_{2n}$. On the other hand since $\pi(\text{Aut}(S)) = \{2, 3, 5, 7\} \subset \pi(7 \prod_{i=1}^4 (7^i - 1))$, it follows that $7_n, 7_{2n} \notin \pi(\text{Aut}(S))$. Therefore $7_n, 7_{2n} \in \pi(N)$, and since N is nilpotent we obtain that $7_n \cdot 7_{2n} \in \pi_e(N)$, which is a contradiction. Thus $n \leq 4$. If $n = 4$, then $\mu(G) = \{2^5 \cdot 3 \cdot 5^2, 7, 2, 1201\}$. Because, there does not exist any element of order 1201 in $\text{Aut}(S)$, 1201 divides the order of N . Without loss of generality we may assume that $N \neq 1$ is an elementary Abelian 1201-group. Now since S contains the Frobenius group $A_4 = 2^2 : 3$, from Lemma 5 we infer that G contains an element of order 1201.3, which is a contradiction. If $n = 2$ or 3, then $5 \in \pi(S) \setminus \pi(G)$, which is impossible.

The other sporadic simple groups are examined similarly.

(c) Assume that $S \cong L_2(p^k)$, where $k \neq n$. In this case we must have $k < n$, since otherwise by Zsigmondy's Theorem we get $p_{2k} \in \pi(S) \setminus \pi(G)$, which is a contradiction. Now, we choose the primitive prime divisors p_n and p_{2n} in $\pi(G)$. Since $p_{2n} \in \pi(p^n + 1)$, G does not contain an element of order $p_n \cdot p_{2n}$. On the other hand, since $p_n > n > k$ we have $p_n, p_{2n} \notin \pi(\text{Aut}(S)) = \pi(\text{PGL}(2, p^k) \rtimes Z_k)$, and so $p_n, p_{2n} \in \pi(N)$. Now, since N is nilpotent we obtain that $p_n \cdot p_{2n} \in \pi_e(N) \subset \pi_e(G)$, which is a contradiction.

(d) Suppose that $S \cong L_2(2p^m \pm 1)$, $m \geq 1$, where $2p^m \pm 1$ is a prime. By the structure of $\mu(G)$, we see that $p \in \pi_e(G)$ and $p^2 \notin \pi_e(G)$. So, if $S \cong L_2(2p^m \pm 1)$, where $2p^m \pm 1$ is a prime and $m \geq 1$, then we deduce $m = 1$, because in this case $p^m \in \pi_e(L_2(2p^m \pm 1)) = \pi_e(S) \subseteq \pi_e(G)$. On the other hand, we know $|\text{Aut}(S)| = 2^2 p(p \pm 1)(2p \pm 1)$, where $2p \pm 1$ is a prime, and so $\pi(\text{Aut}(S)) = \{p, 2p \pm 1\} \cup \pi(p \pm 1)$. If $n = 2$, then $(2p \pm 1, |G|) = 1$, which is a contradiction. Therefore $n \geq 3$. Now, we consider the primitive prime divisors p_n and p_{2n} . Since $(p_n, p_{2n}) = (p_n, p \pm 1) = (p_{2n}, p \pm 1) = 1$, it follows that $p_n \notin \pi(\text{Aut}(S))$ or $p_{2n} \notin \pi(\text{Aut}(S))$, thus we may assume N is a p_n -subgroup or a p_{2n} -subgroup. First, we assume that $2p + 1$ is a prime. Let P be a Sylow $(2p + 1)$ -subgroup of S , then $N_S(P)$, the normalizer of P in S , is a Frobenius group of order $(2p + 1)p$, with cyclic complement of order p . Now, by Lemma 5, we deduce that $p_n \sim p$ or $p_{2n} \sim p$, which is a contradiction. Next, we assume that $2p - 1$ is a prime. In this case, if there exists a prime $s \in \pi(p^n + 1) \setminus \pi(\text{Aut}(S))$ then $s \in \pi(N)$, because $G/N \leq \text{Aut}(S)$. Moreover, if Q is a Sylow $(2p - 1)$ -subgroup of S , then $N_S(Q)$ is a Frobenius group of order $(2p - 1)(p - 1)$, with cyclic complement of order $p - 1$. Now, as previous case we get $s \cdot (p - 1) \in \pi_e(G)$, which is a contradiction. Hence, $\pi(p^n + 1) \subseteq \pi(\text{Aut}(S))$. As $(p^n - 1, p^n + 1) = 2$, the only possible case

is $\pi(p^n + 1) = \{2, 2p - 1\}$, i.e., $p^n + 1 = 2^l(2p - 1)^k$ for some l and k in \mathbb{N} . Now, if $k > 1$ then since $(2p - 1)^k \in \pi_e(G)$ and $(2p - 1)^k \notin \pi_e(\text{Aut}(S))$ we obtain $(2p - 1) \in \pi(N)$. On the other hand, it is easy to see that $p_n \in \pi(G) \setminus \pi(\text{Aut}(S))$, and so $p_n \in \pi(N)$. Since N is nilpotent, we deduce that $p_n \sim (2p - 1)$, which is a contradiction. Finally, we have $k = 1$ and since $(p, n) \neq (3, 2)$, we obtain that $l > 1$. Moreover $2 \parallel p^n - 1$ which implies that n must be odd. But in this case we have $p^n + 1 = (p + 1)(p^{n-1} - p^{n-2} + \dots - p + 1) = 2^l(2p - 1)$ for which it follows that $p^{n-1} - p^{n-2} + \dots - p + 1 = 2p - 1$, giving no solution for $p \geq 3$. This final contradiction shows that $S \not\cong L_2(2p^m \pm 1)$.

(2) Consider the group $H = \langle a, b \mid a^8 = b^5 = 1, ba = ab^2 \rangle \cong Z_5 : Z_8$. For this group we have $\mu(H) = \{8, 10\}$. Now, we assume that G is an extension of elementary Abelian 3-group K of order 3^{40l} by H , and the generators a, b of H act on K cyclically. Then G is a soluble group and $\pi_e(G) = \pi_e(\text{PGL}(2, 3^2)) = \{1, 2, 3, 4, 5, 8, 10\}$. \square

The following lemma gives a classification of simple $C_{p,p}$ -groups, where p is a prime of form $p = 2^\alpha 3^\beta + 1$, $\alpha \geq 0, \beta \geq 0$.

Lemma 8 (see [2]) *Let p be a prime and $p = 2^\alpha 3^\beta + 1$, $\alpha \geq 0, \beta \geq 0$. Then any finite simple $C_{p,p}$ -group is given by Table 2.*

The next lemma gives the maximal odd factors set $\psi(F_4(q))$ of $\mu(F_4(q))$, $q = 2^e$.

Lemma 9 *Let $S \cong F_4(q)$, where $q = 2^e$, $e \geq 1$. Then $\psi(S) = \{q^4 - 1, q^4 + 1, q^4 - q^2 + 1, (q - 1)(q^3 + 1), (q + 1)(q^3 - 1)\}$.*

PROOF. The $2'$ -elements of S is contained in the maximal tori of S . From [13] we see that $\mu(F_4(q))$ contains 25 maximal tori $H(1), H(2), \dots, H(25)$. Since $(q - 1, q^3 + 1) = 1, (q + 1, q^3 - 1) = 1, H(13)$ and $H(15)$ are all cyclic. The conclusion holds. \square

3 Main Results

In this section we prove the statement of Theorems 1, 2 and 3.

PROOF OF THEOREM 1. Let G be a finite group and

$$\mu(G) = \mu(\text{PGL}(2, p^n)) = \{p^n - 1, p, p^n + 1\},$$

where $p = 2^\alpha 3^\beta + 1$ is a prime, and n is a natural numbers. If $\alpha = \beta = 0$, then $p = 2$ and the result is correct by Lemma 6. Also for $n = 1$, the result holds by [10], and so from now on we assume that p is an odd prime and $n \geq 2$. Then $t(G) = 2$, in fact we have

$$\pi_1(G) = \pi(p^{2n} - 1) \quad \text{and} \quad \pi_2(G) = \{p\}.$$

Lemma 7(1) shows that G is an extension of a $\pi_1(G)$ -group N by a group G_1 , where $S \leq G_1 \leq \text{Aut}(S)$, S is a non-Abelian simple group of Lie type (except $L_2(p^k)$, $k \neq n$ and $L_2(2p^m \pm 1)$ where $m \geq 1$ and $2p^m \pm 1$ is a prime) and G_1/S is a $\pi_1(G)$ -group. Moreover there exists $2 \leq j \leq t(S)$, such that $\mu_j(S) = \{p\}$, in fact S is a simple $C_{p,p}$ -group. Using the results summarized in Table 2, we will show that S is isomorphic to $L_2(p^n)$.

Table 2 Simple $C_{p,p}$ -groups, $p = 2^\alpha 3^\beta + 1$, $\alpha \geq 0, \beta \geq 0$.

p	simple $C_{p,p}$ -groups
2	$A_5, A_6, L_2(q)$ where q is a Fermat prime, a Mersenne prime or $q = 2^m$, $m \geq 3$, $L_3(2^2)$, $Sz(2^{2m+1})$, $m \geq 1$.
3	$A_5, A_6, L_2(q)$, $q = 2^3, 3^m$ or $2 \cdot 3^m \pm 1$, which is a prime, $m \geq 1$, $L_3(2^2)$
5	$A_5, A_6, A_7, M_{11}, M_{22}, L_2(q)$, $q = 7^2, 5^m$ or $2 \cdot 5^m \pm 1$, which is a prime, $m \geq 1$, $L_3(2^2)$, $S_4(q)$, $q = 3, 7$, $U_4(3)$, $Sz(q)$, $q = 2^3, 2^5$.
7	$A_7, A_8, A_9, M_{22}, J_1, J_2, HS, L_2(q)$, $q = 2^3, 7^m$ or $2 \cdot 7^m - 1$, which is a prime, $m \geq 1$, $L_3(2^2)$, $S_6(2)$, $O_8^+(2)$, $G_2(q)$, $q = 3, 19$, $U_3(q)$, $q = 3, 5, 19$, $U_4(3)$, $U_6(2)$, $Sz(2^3)$.

17	$A_{17}, A_{18}, A_{19}, J_3, He, Fi_{23}, Fi'_{24}, L_2(q)$, $q = 2^4, 17^m$ or $2 \cdot 17^m \pm 1$, which is a prime, $m \geq 1$, $S_4(4)$, $S_8(2)$, $F_4(2)$, $O_8^-(2)$, $O_{10}^-(2)$, ${}^2E_6(2)$.
19	$A_{19}, A_{20}, A_{21}, J_1, J_3, O'N, Th, HN, L_2(q)$, $q = 19^m$ or $2 \cdot 19^m - 1$, which is a prime, $m \geq 1$, $L_3(7)$, $U_3(2^3)$, $R(3^3)$, ${}^2E_6(2)$.
37	$A_{37}, A_{38}, A_{39}, J_4, Ly, L_2(q)$, $q = 37^m$ or $2 \cdot 37^m - 1$, which is a prime, $m \geq 1$, $U_3(11)$, $R(3^3)$, ${}^2F_4(2^3)$.
73	$A_{73}, A_{74}, A_{75}, L_2(q)$, $q = 73^m$ or $2 \cdot 73^m - 1$, which is a prime, $m \geq 1$, $L_3(2^3)$, $S_6(2^3)$, $G_2(q)$, $q = 2^3, 3^2$, $F_4(3)$, $E_6(2)$, $E_7(2)$, $U_3(3^2)$, ${}^3D_4(3)$.
109	$A_{109}, A_{110}, A_{111}, L_2(q)$, $q = 109^m$ or $2 \cdot 109^m - 1$, which is a prime, $m \geq 1$, ${}^2F_4(2^3)$.
$p = 2^m + 1$, $m = 2^s$	$A_p, A_{p+1}, A_{p+2}, L_2(q)$, $q = 2^m, p^k$, $2p^k \pm 1$, which is a prime, $k \geq 1$, $S_a(2^b)$, $a = 2^{c+1}$ and $b = 2^d$, $c \geq 1$, $c + d = s$, $F_4(2^e)$, $e \geq 1$, $4e = 2^s$, $O_{2(m+1)}^-(2)$, $s \geq 2$, $O_a^-(2^b)$, $a = 2^{c+1}$ and $b = 2^d$, $c \geq 2$, $c + d = s$.
Other	$A_p, A_{p+1}, A_{p+2}, L_2(q)$, $q = p^m$ or $2p^m - 1$, which is a prime, $m \geq 1$.

Step 1 $S \cong L_2(q)$, $q = p^n$, $n \geq 2$.

In the following case by case analysis we assume that $S \not\cong L_2(p^n)$ and try to obtain a contradiction. Moreover, as S is always a $C_{p,p}$ -group for some appropriate prime p , we make use of the results summarized in Table 2 and Lemma 7 and omit the details of the argument.

Case 1 $q = 3^n$, $n \geq 2$.

In this case S can only be isomorphic to one of the following simple groups: $L_2(2^3)$, $L_3(2^2)$. Since G does not contain an element of order 9, S can not be isomorphic to $L_2(2^3)$. If $S \cong L_3(2^2)$, then since $7 \in \pi(S)$ we obtain that $n \geq 6$. Assume first that $n = 6$. In this case we have $\pi(G) = \{2, 3, 5, 7, 13, 73\}$. Evidently $13, 73 \notin \pi(\text{Aut}(S))$ and $13 \approx 73$. Hence $\{13, 73\} \subseteq \pi(N)$, and since N is nilpotent we get $13 \cdot 73 \in \pi_e(N)$, which is a contradiction. Next we suppose that $n \geq 7$. Now we choose the primitive prime divisors 3_n and 3_{2n} in $\pi(G)$. Evidently $3_{2n} \in \pi(3^n + 1)$, and so $3_n \approx 3_{2n}$. Moreover, since $\{2, 3, 5, 7, 11, 13\} = \pi(3 \prod_{i=1}^6 (3^i - 1))$, $3_n, 3_{2n} \notin \pi(\text{Aut}(S))$, and hence $3_n, 3_{2n} \in \pi(N)$. Again since N is nilpotent, N contains an element of order $3_n \cdot 3_{2n}$, which is of course impossible.

Case 2 $q = 5^n$, $n \geq 2$.

In this case we see that S can only be isomorphic to one of the following simple groups: $L_2(7^2)$, $L_3(2^2)$, $S_4(3)$, $S_4(7)$, $U_4(3)$, $Sz(2^3)$ or $Sz(2^5)$. Since G has no element of order 25, S can not be isomorphic to $L_2(7^2)$ or $Sz(2^5)$. If S is isomorphic to one of the simple groups: $L_3(2^2)$, $S_4(7)$, $U_4(3)$, or $Sz(2^3)$, then $7 \in \pi(S)$ and so we must have $n \geq 6$. Also note that

$$\pi(S) \subset \{2, 3, 5, 7, 11, 13\} \subset \pi(5 \prod_{i=1}^6 (5^i - 1)).$$

If $n = 6$, then $31, 601 \in \pi(G) \setminus \pi(\text{Aut}(S))$ and thus $31, 601 \in \pi(N)$. Therefore N contains an element of order $31 \cdot 601$, which is a contradiction as $31 \cdot 601 \notin \pi_e(G)$. For case $n \geq 7$, since by Zsigmondy's Theorem $5_n, 5_{2n} > 13$, a similar argument with the primitive prime divisors $5_n, 5_{2n} \in \pi(G)$ also leads to a contradiction. Similarly, S can not be isomorphic to $S_4(3)$.

Case 3 $q = 7^n$, $n \geq 2$.

In this case the possibilities for S are: $L_2(2^3)$, $L_3(2^2)$, $S_6(2)$, $O_8^+(2)$, $G_2(3)$, $G_2(19)$, $U_3(3)$, $U_3(5)$, $U_3(19)$, $U_4(3)$, $U_6(2)$ or $Sz(2^3)$. First of all, since G has no element of order 49, $S \not\cong G_2(19)$ or $U_3(19)$. Next, we note that $\pi(S) \subset \pi(13!)$ and by Lemma 1 we see that for every $n \geq 5$ there exists a primitive prime divisor $7_n \geq 13$. Therefore for $n \geq 5$, as previous cases a similar argument with the primitive prime divisors 7_n and 7_{2n} , leads to a contradiction.

If $n = 4$, then $\mu(G) = \{2^5 \cdot 3 \cdot 5^2, 7, 2 \cdot 1201\}$. In this case S can only be $L_2(2^3)$, $L_3(2^2)$, $S_6(2)$, $O_8^+(2)$, $U_3(3)$, $U_3(5)$, or $U_4(3)$ by checking their prime divisors

sets. On the other hand, since the simple groups $L_2(2^3)$, $S_6(2)$, $O_8^+(2)$ and $U_4(3)$ contain an element of order 9 and $9 \notin \pi_e(G)$, S can only be $L_3(2^2)$, $U_3(3)$ or $U_3(5)$. Moreover, since there does not exist any element of order 1201 in $Aut(S)$, 1201 divides the order of N . Without loss of generality we may assume that $N \neq 1$ is an elementary Abelian 1201-group. Because $A_4 = 2^2 : 3 < A_6 < L_3(2^2)$, $7 : 3 < L_2(7) < U_3(3)$ and $A_4 = 2^2 : 3 < A_7 < U_3(5)$, in all cases S contains a Frobenius group of shape $2^2 : 3$ or $7 : 3$, and so G contains an element of order 1201.3 by Lemma 5, which is a contradiction.

If $n = 3$, then $\mu(G) = \{2 \cdot 3^2 \cdot 19, 7, 2^3 \cdot 43\}$. In this case, S can only be $L_2(2^3)$ by checking their element orders sets. As $43 \notin \pi(Aut(S))$ we have $43 \in \pi(N)$. Now, we may assume that $N \neq 1$ is an elementary Abelian 43-group. Since $2^3 : 7 < L_2(2^3)$ we get $43 \cdot 7 \in \pi_e(G)$ by Lemma 5, which is a contradiction.

If $n = 2$, then $\mu(G) = \{2^4 \cdot 3, 7, 2 \cdot 5^2\}$. In this case, by checking element orders S can only be $L_3(2^2)$, $U_3(3)$ or $U_3(5)$. If $S \cong L_3(2^2)$ or $U_3(5)$, then 5 divides the order of N since $25 \notin \pi_e(Aut(S))$. Without loss of generality we may assume that $N \neq 1$ is an elementary Abelian 5-group. Since S contains a Frobenius subgroup of shape $2^2 : 3$ (in fact we have $A_4 = 2^2 : 3 \leq A_6 \leq L_3(4)$ and $A_4 = 2^2 : 3 \leq A_7 \leq U_3(5)$), we get $5 \cdot 3 \in \pi_e(G)$ by Lemma 5, a contradiction. If $S \cong U_3(3)$, then $5 \in \pi(N)$, because $5 \notin \pi(Aut(S))$. Again, since $7 : 3 \leq L_2(7) \leq U_3(3)$ we get $5 \cdot 3 \in \pi_e(G)$ by Lemma 5, a contradiction.

Case 4 $q = 13^n$, $n \geq 2$.

In this case S can only be isomorphic to one of the following simple groups: $L_2(3^3)$, $L_2(5^2)$, $L_3(3)$, $L_4(3)$, $O_7(3)$, $S_4(5)$, $S_6(3)$, $O_8^+(3)$, $G_2(2^2)$, $G_2(3)$, $F_4(2)$, $U_3(2^2)$, $U_3(23)$, $Sz(2^3)$, ${}^3D_4(2)$, ${}^2E_6(2)$ or ${}^2F_4(2)'$. Since $13^2 \notin \pi_e(G)$, and $U_3(23)$ contains an element of order 13^2 , $S \not\cong U_3(23)$. Moreover, we have $\pi(S) \subseteq \pi(19!)$. Now since, by Lemma 1, for every $n \geq 5$, there exists a primitive prime divisor $13_n > 19$. we can consider the primitive prime divisors 13_n and 13_{2n} , and we get a contradiction as before cases. Henceforth, we may assume that $n \leq 4$.

If $n = 4$, then $\mu(G) = \{2^4 \cdot 3 \cdot 5 \cdot 7 \cdot 17, 13, 2 \cdot 14281\}$. In this case, by comparing element orders, we conclude that S can only be $L_2(3^3)$, $L_2(5^2)$, $L_3(3)$, $L_4(3)$, $O_7(3)$, $S_4(5)$, $O_8^+(3)$, $G_2(2^2)$, $G_2(3)$, $F_4(2)$, $U_3(2^2)$, $Sz(2^3)$, ${}^3D_4(2)$, or ${}^2F_4(2)'$. In all above cases, except $S \cong F_4(2)$, since $17, 14281 \notin \pi(Aut(S))$, we have $17, 14281 \in \pi(N)$, and so $17 \cdot 14281 \in \pi_e(N)$, which is a contradiction. If $S \cong F_4(2)$, then 14281 divides the order of N , and since S contains a Frobenius group $2^2 : 3$ (note that $2^2 : 3 = A_4 < S_{10} < S_8(2) < F_4(2)$), G must contain an element of order 14281.3, by Lemma 5, which is not possible. If $n = 3$, then $\mu(G) = \{2^2 \cdot 3^2 \cdot 61, 13, 2 \cdot 7 \cdot 157\}$. In this case we have $61, 157 \notin \pi(Aut(S))$ and so $61, 157 \in \pi(N)$, hence we get $61 \cdot 157 \in \pi_e(N) \subset \pi_e(G)$, which is impossible.

Case 5 $q = 17^n$, $n \geq 2$.

In this case S can only be isomorphic to one of the following simple groups: $L_2(2^4)$, $S_4(4)$, $S_8(2)$, $F_4(2)$, $O_8^-(2)$, $O_{10}^-(2)$ or ${}^2E_6(2)$. First of all, since $5 \in \pi(S)$, we deduce $n \geq 4$. Moreover, we have $\pi(S) \subseteq \pi(19!)$. From Lemma 1, for

every $n \geq 4$, there exists a primitive prime divisor $17_n > 19$. Now, for the primitive prime divisors 17_n and 17_{2n} , a similar argument as before leads to a contradiction.

Case 6 $q = 19^n$, $n \geq 2$.

In this case S can only be isomorphic to one of the following simple groups: $L_3(7)$, $U_3(2^3)$, $R(3^3)$ or ${}^2E_6(2)$. Evidently $\pi(S) \subseteq \pi(37!)$. Since $7 \in \pi(S)$, $3|n$. If $n > 7$, then by Lemma 1 there exists a primitive prime divisor $19_n > 37$. Now we consider the primes 19_n and 19_{2n} , and we get a contradiction as previous cases. If $n = 6$, then we have

$$\mu(G) = \{2^3 \cdot 3^3 \cdot 5 \cdot 7 \cdot 127, 19, 2 \cdot 13^2 \cdot 181 \cdot 769\}.$$

In this case we consider the primes $127, 769 \in \pi(G)$, and we obtain a contradiction as before. If $n = 3$, then $\mu(G) = \{2 \cdot 3^3 \cdot 127, 19, 2^2 \cdot 5 \cdot 7^3\}$. In this case S can be only $L_3(7)$ or $U_3(2^3)$, and since $5, 127 \notin \pi(\text{Aut}(S))$, we get a contradiction.

Case 7 $q = 37^n$, $n \geq 2$.

In this case S can only be isomorphic to one of the following simple groups: $U_3(11)$, $R(3^3)$ or ${}^2F_4(2^3)$. Evidently, $\pi(S) \subseteq \{2, 3, 5, 7, 11, 13, 19, 37, 73, 109\}$. If $n \geq 7$, then by Lemma 1 there exists a primitive prime divisors $37_n > 109$, and hence we consider the primes $37_n, 37_{2n} \in \pi(G)$, and we get a contradiction as before. Therefore we may assume that $n \leq 6$. Since

$$\begin{aligned} \pi(G) &= \{2, 3, 5, 7, 13, 19, 31, 37, 43, 67, 137, 144061\}, & n = 6, \\ \pi(G) &= \{2, 3, 11, 19, 37, 41, 4271, 1824841\}, & n = 5, \\ \pi(G) &= \{2, 3, 5, 19, 37, 89, 137, 10529\}, & n = 4, \\ \pi(G) &= \{2, 3, 7, 19, 31, 37, 43, 67\}, & n = 3, \\ \pi(G) &= \{2, 3, 5, 19, 37, 137\}, & n = 2, \end{aligned}$$

it is easy to see that $109 \notin \pi(G)$, and so $S \not\cong {}^2F_4(2^3)$. Moreover, since $55 \in \pi_e(U_3(11)) \setminus \pi_e(G)$, $S \not\cong U_3(11)$. Finally, if $S \cong R(3^3)$, since $13 \in \pi(R(3^3))$, we must have $n = 6$. Yet, in this case, we can choose the primes $67, 144061 \in \pi(G) \setminus \pi(\text{Aut}(S))$, and we get a contradiction as before (note that $67 \cdot 144061 \notin \pi_e(G)$).

Case 8 $q = 73^n$, $n \geq 2$.

In this case S can only be $L_2(73^n)$, $L_3(2^3)$, $S_6(2^3)$, $G_2(2^3)$, $G_2(3^2)$, $F_4(3)$, $E_6(2)$, $E_7(2)$, $U_3(3^2)$ or ${}^3D_4(3)$. We assume that $S \not\cong L_2(73^n)$. It is not difficult to see that $\pi(S) \subseteq \pi(19!) \cup \{31, 41, 43, 73, 127\}$. Let $n \geq 5$. Then by Lemma 1(6), $73_n, 73_{2n} > 127$. Evidently $73_n \cdot 73_{2n} \notin \pi_e(G)$, as $73_{2n} \in \pi(73^n + 1)$. On the other hand, since $73_n, 73_{2n} \notin \pi(\text{Aut}(S))$, $73_n, 73_{2n} \in \pi(N)$ which implies that $73_n, 73_{2n} \in \pi_e(N) \subseteq \pi_e(G)$, a contradiction. Hence $n \leq 4$. Because

$$\begin{aligned} \pi_e(G) &= \{2^5 \cdot 3^2 \cdot 5 \cdot 13 \cdot 37 \cdot 41, 73, 2 \cdot 14199121\}, & n = 4, \\ \pi_e(G) &= \{2^3 \cdot 3^3 \cdot 1801, 73, 2 \cdot 7 \cdot 37 \cdot 751\}, & n = 3, \\ \pi_e(G) &= \{2^4 \cdot 3^2 \cdot 37, 73, 2 \cdot 5 \cdot 13 \cdot 41\}, & n = 2, \end{aligned}$$

by checking the sets of element orders for each simple group, the only possibility

for S is $U_3(3^2)$, when $n = 4$. In this case, we consider the primes 41 and 14199121 in $\pi(G)$. Since $41 \in \pi(73^4 - 1)$ and $14199121 \in \pi(73^4 + 1)$, $41 \approx 14199121$ and also $41, 14199121 \notin \pi(\text{Aut}(S))$, which implies that $41, 14199121 \in \pi(N)$. Now by the nilpotency of N , we obtain that $41, 14199121 \in \pi_e(N) \subset \pi_e(G)$, which is a contradiction.

Case 9 $q = 109^n$, $n \geq 2$.

The proof of this case follows immediately from Lemmas 7(1) and 8.

Case 10 $q = (2^m + 1)^n$, where $2^m + 1$ is a prime and $n \geq 2$.

In this case S can only be isomorphic to: $L_2(2^m)$, $S_a(2^b)$, $a = 2^{c+1}$, $c \geq 1$, and $b = 2^d$, $c + d = s$, $F_4(2^e)$, $e \geq 1$, $4e = 2^s$, $O_{2(m+1)}^-(2)$, $s > 1$, or $O_a^-(2^b)$, $a = 2^{c+1}$, $c \geq 2$, and $b = 2^d$, $c + d = s$.

If $S \cong L_2(2^m)$, then $\mu(\text{Aut}(S)) = \{m, 2^m - 1, 2^m + 1\} = \{m, p - 2, p\}$. First, assume that n is odd. In this case we have $(p - 2, p^n - 1) = 1$, in fact if $(p - 2, p^n - 1) = d$ then d divides $2^n - 1$, and so $d \mid (p - 2, 2^n - 1) = (2^m - 1, 2^n - 1) = 2^{(m,n)} - 1 = 1$. Now since $\pi(S) \subseteq \pi(G)$, it follows that $\pi(p - 2) \subset \pi(p^n + 1)$. Moreover, it is easy to see that $2^{m-1} + 1$ divides $p^n + 1$ and $(p - 2, 2^{m-1} + 1) = 3$. Now we consider the primitive prime divisors

$$r := p_n \in \pi(p^n - 1) \quad \text{and} \quad s := 2_{2(m-1)} \in \pi(2^{m-1} + 1).$$

Evidently $r, s \notin \pi(\text{Aut}(S))$, and so $r, s \in \pi(N)$. From the nilpotency of N it follows that $r \sim s$, which is a contradiction. Next, we suppose that n is even. In this case we have $2^{m-1} + 1$ divides $p^n - 1$ and $(2^{m-1} + 1, p - 2) = 1$. Now, if $\pi(p - 2) \subset \pi(p^n - 1)$ then $(p - 2, p^n + 1) = 1$ and again we consider the following primitive prime divisors

$$r := p_{2n} \in \pi(p^n + 1) \quad \text{and} \quad s := 2_{m-1} \in \pi(2^{m-1} - 1),$$

and we get $r \sim s$, as before. But this a contradiction. Therefore we must have $\pi(p - 2) \subseteq \pi(p^n + 1)$. Let $r \in \pi(2^{m-1} + 1) \subseteq \pi(p^n - 1)$. Clearly $r \notin \pi(\text{Aut}(S))$, hence $r \in \pi(N)$. Now since $2^m : 2^m - 1 \leq L_2(2^m)$, by Lemma 5 we deduce that $r(2^m - 1) \in \pi_e(G)$, which is a contradiction.

If $S \cong F_4(2^e)$, then the maximal odd factors set $\psi(\text{Aut}(S))$ of $\mu(\text{Aut}(S))$ is equal to the same set of $\mu(S)$ since $|\text{Out}(S)| = 2^{e+1}$. From Lemma 9 we have

$$\psi(\text{Aut}(S)) = \{q'^4 - 1, q'^4 + 1, q'^4 - q'^2 + 1, (q' - 1)(q'^3 + 1), (q' + 1)(q'^3 - 1)\},$$

where $q' = 2^e$, $e \geq 1$.

In this case $q'^4 + 1 = p$, $q'^4 - 1 = p - 2$. Since G is an extension of a $\pi_1(G)$ -group N by a group G_1 , where $S \leq G_1 \leq \text{Aut}(S)$, and $\mu(G) = \{p^n - 1, p, p^n + 1\}$, we may get a contradiction dividing the two cases. If $n \geq 4$, then the odd number $\frac{1}{2}(p^n + 1)$ and the odd factor of $p^n - 1$ are all greater than any number in $\psi(\text{Aut}(S))$. Hence we have r, s such that

$$r \in \pi(p^n + 1) \quad \text{and} \quad s \in \pi(p^n - 1),$$

and $r, s \notin \pi(\text{Aut}(S))$, so $r, s \in \pi(N)$. From the nilpotency of N it follows that $r \sim s$, which is a contradiction. If $n = 2$, then we may infer that $(p-2, p^2+1) = 5$ and $(p-2, p^2-1) = 3$. It is impossible. Also we may get a similar contradiction if $n = 3$.

If $S \cong S_a(2^b)$, then the maximal odd factors set $\psi(\text{Aut}(S))$ of $\mu(\text{Aut}(S))$ is equal to the same set of $\mu(S)$ since $|\text{Out}(S)| = b = 2^d$. From [5], §3(3) we have

$$\{q'^{\frac{1}{2}(a)} - 1, q'^{\frac{1}{2}(a)} + 1\} \subseteq \psi(\text{Aut}(S)),$$

where $q' = 2^b, b \geq 1$. In this case $q'^{\frac{1}{2}(a)} + 1 = p$, and $q'^{\frac{1}{2}(a)} - 1 = p - 2$, since the other numbers are not primes in $\psi(\text{Aut}(S))$. The rest of proof is similar to the case of $S \cong F_4(2^e)$ by comparing the two sets of $\psi(\text{Aut}(S))$ and $\mu(G)$.

If $S \cong O_{2(m+1)}^-(2), m = 2^s, s > 1$, then the maximal odd factors set $\psi(\text{Aut}(S))$ of $\mu(\text{Aut}(S))$ is equal to the same set of $\mu(S)$ since $|\text{Out}(S)| = 2$. From [5], §3(5) we have

$$\{q'^{m+1} + 1, q'^m + 1, q'^m - 1\} \subseteq \psi(\text{Aut}(S)),$$

where $q' = 2$. In this case $q'^m + 1 = p$, and $q'^m - 1 = p - 2$. The rest of proof is similar to the above cases.

If $S \cong O_a^-(2^b), a = 2^{c+1}, c \geq 2$, and $b = 2^d, c + d = s$, the proof is similar.

Case 11 $q = 97^n$ or $q = p^n$, where $p = 2^\alpha 3^\beta + 1 > 109$ is a prime, $\beta \neq 0$ and $n \geq 2$.

In this case S is a simple $C_{p,p}$ -group, and from Table 1 and Lemma 7, we obtain that $S \cong L_2(q)$.

Step 2 N is a 2-group.

Let P/N be a Sylow p -subgroup of S and X/N be the normalizer in S of P/N . Then X/N is a Frobenius group of order $q(q-1)/2$, with cyclic complement of order $(q-1)/2$. Now, by lemma 5, we deduce that N is a 2-group.

Step 3 $h(G) \in \{1, \infty\}$.

First suppose that $N = 1$. In this case, we have $S = L_2(q), q = p^n, S \leq G \leq \text{Aut}(S)$. Denote the factor group G/S by M . Obviously, $M \leq \text{Out}(S)$. Therefore, every element of M is a product of a field automorphism f , whose order is a divisor of n , and diagonal automorphism d of order dividing 2. Let $f \neq 1$ and r be a prime dividing the order of f . Without loss of generality, we may assume that $o(f) = r$. Evidently, r divides n , and we put $\bar{q} = p^{n/r}$. Denote by φ an automorphism of the field \mathbb{F}_q inducing f . Since φ fixes a subfield $\mathbb{F}_{\bar{q}}$ of \mathbb{F}_q , f centralizes a subgroup \bar{S} of S isomorphic to $L_2(\bar{q})$. But then G can not be a $C_{p,p}$ -group, which is a contradiction. Thus $f = 1$. Hence, we have $M \leq \langle d \rangle$ and so $|G/S| \leq 2$. Therefore $G \cong S$ or $G \cong PGL(2, q)$. From $q+1 \in \pi_e(PGL(2, q)) \setminus \pi_e(S)$, we have $G \cong PGL(2, q)$. Thus, in this case $h(G) = 1$. Next, suppose that $N \neq 1$. Now, by Lemma 4, we get $h(G) = \infty$. The proof of Theorem 1 is complete. \square

PROOF OF THEOREM 2. Proof follows immediately from Lemma 7(2) and Lemma 4. \square

PROOF OF THEOREM 3. Let H be an extension of a group of order 2 by S_4 such that a Sylow 2-subgroup of H is a quaternion group. Then $\mu(H) = \{6, 8\}$. By Lemma 8 in [7], there exists an extension G of an elementary Abelian 7-group by H , which is a Frobenius group. It follows that $\mu(G) = \{6, 7, 8\}$, and then Theorem 1 follows from Lemma 4. \square
