

Conjugacy classes of p -torsion in symplectic groups over S -integers

Cornelia Minette Busch*

September 2005

Abstract

For any odd prime p we consider representations of a group of order p in the symplectic group $\mathrm{Sp}(p-1, \mathbb{Z}[1/n])$ of $(p-1) \times (p-1)$ -matrices over the ring $\mathbb{Z}[1/n]$, $0 \neq n \in \mathbb{N}$. We construct a relation between the conjugacy classes of subgroups P of order p in the symplectic group and the ideal class group in the ring $\mathbb{Z}[1/n]$. This is used for the study of these classes. In particular we determine the centralizer $C(P)$ and $N(P)/C(P)$ where $N(P)$ denotes the normalizer.

Keywords: Representation theory, Cohomology theory

1 Introduction

We define the group of symplectic matrices $\mathrm{Sp}(2n, R)$ over a ring R to be the subgroup of matrices $M \in \mathrm{GL}(2n, R)$ that satisfy

$$M^T J M = J = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$$

where $1 \in \mathrm{M}(n, R)$ denotes the identity. Our motivation for studying subgroups of odd prime order p in the symplectic group $\mathrm{Sp}(p-1, \mathbb{Z}[1/n])$, $0 \neq n \in \mathbb{N}$, is given by the fact that the p -primary part of the Farrell cohomology of $\mathrm{Sp}(p-1, \mathbb{Z}[1/n])$ is determined by the Farrell cohomology of the normalizer of subgroups of order p in $\mathrm{Sp}(p-1, \mathbb{Z}[1/n])$ (see Brown [2]). First we consider the conjugacy classes of elements of order p in $\mathrm{Sp}(p-1, \mathbb{Z}[1/n])$ and get the following result.

*Research supported by a grant "Estancias de jóvenes doctores y tecnólogos extranjeros en España" (SB 2001 - 0138) from the Ministerio de Educación, Cultura y Deporte.

Theorem 3.14. *The number of conjugacy classes of matrices of order p in $\mathrm{Sp}(p-1, \mathbb{Z}[1/n])$, $0 \neq n \in \mathbb{Z}$, is*

$$|\mathcal{C}_0| 2^{\frac{p-1}{2} + \tau}$$

where \mathcal{C}_0 is the ideal class group of $\mathbb{Z}[1/n][\xi]$ and τ is the number of inert primes in $\mathbb{Z}[\xi + \xi^{-1}]$ that lie over primes in \mathbb{Z} that divide n .

In order to prove this theorem we establish a relation between some ideal classes in $\mathbb{Z}[1/n][\xi]$, ξ a primitive p th root of unity, and the conjugacy classes of matrices of order p . We define equivalence classes $[\mathfrak{a}, a]$ of pairs (\mathfrak{a}, a) where $\mathfrak{a} \subseteq \mathbb{Z}[1/n][\xi]$ is an ideal with $\mathfrak{a}\bar{\mathfrak{a}} = (a)$ and the equivalence relation is

$$(\mathfrak{a}, a) \sim (\mathfrak{b}, b) \Leftrightarrow \begin{aligned} &\exists \lambda, \mu \in \mathbb{Z}[1/n][\xi] \setminus \{0\} \\ &\lambda \mathfrak{a} = \mu \mathfrak{b}, \lambda \bar{\lambda} a = \mu \bar{\mu} b. \end{aligned}$$

We show that a bijection exists between the conjugacy classes of elements of order p in $\mathrm{Sp}(p-1, \mathbb{Z}[1/n])$ and the set of equivalence classes $[\mathfrak{a}, a]$. Sjerve and Yang (see [11]) construct an analogous bijection for $\mathrm{Sp}(p-1, \mathbb{Z})$. We use the bijection described above in order to study the subgroups of order p in $\mathrm{Sp}(p-1, \mathbb{Z}[1/n])$. We consider the case where $n \in \mathbb{Z}$ is such that $\mathbb{Z}[1/n][\xi]$ and $\mathbb{Z}[1/n][\xi + \xi^{-1}]$ are principal ideal domains because in this case the ideal class group of those rings is trivial. We get the following results.

Theorem 4.2. *Let $n \in \mathbb{Z}$ be such that $\mathbb{Z}[1/n][\xi]$ and $\mathbb{Z}[1/n][\xi + \xi^{-1}]$ are principal ideal domains. Then the centralizer $C(P)$ of a subgroup P of order p in $\mathrm{Sp}(p-1, \mathbb{Z}[1/n])$ is*

$$C(P) \cong \mathbb{Z}/2p\mathbb{Z} \times \mathbb{Z}^{\sigma^+}$$

where $\sigma^+ = \sigma$ if $p \nmid n$, $\sigma^+ = \sigma + 1$ if $p \mid n$ and σ is the number of primes in $\mathbb{Z}[\xi + \xi^{-1}]$ that split in $\mathbb{Z}[\xi]$ and lie over primes in \mathbb{Z} that divide n .

Theorem 4.1. *Let $n \in \mathbb{Z}$ be such that $\mathbb{Z}[1/n][\xi]$ and $\mathbb{Z}[1/n][\xi + \xi^{-1}]$ are principal ideal domains and moreover $p \mid n$. Let $N(P)$ denote the normalizer and $C(P)$ the centralizer of a subgroup P of order p in $\mathrm{Sp}(p-1, \mathbb{Z}[1/n])$. Then*

$$N(P)/C(P) \cong \mathbb{Z}/j\mathbb{Z}$$

where $j \mid p-1$, j odd. For each j with $j \mid p-1$, j odd, exists a subgroup of order p in $\mathrm{Sp}(p-1, \mathbb{Z}[1/n])$ with $N(P)/C(P) \cong \mathbb{Z}/j\mathbb{Z}$.

An application of these theorems is given in [5]; moreover they are a generalization of the results of Naffah [7] on the normalizer of $\mathrm{SL}(2, \mathbb{Z}[1/n])$.

Let $U((p-1)/2) \subset \mathrm{GL}((p-1)/2, \mathbb{C})$ be the group of unitary matrices. We consider the homomorphism

$$\begin{aligned} U\left(\frac{p-1}{2}\right) &\longrightarrow \mathrm{Sp}(p-1, \mathbb{R}) \\ X = A + iB &\longmapsto \begin{pmatrix} A & B \\ -B & A \end{pmatrix} \end{aligned}$$

where $A, B \in M(n, \mathbb{R})$. In [3] a condition is given for the matrix X such that the image of X is conjugate to a matrix of order p in $\mathrm{Sp}(p-1, \mathbb{Z})$. This is used in [4] to analyze the subgroups of order p in $\mathrm{Sp}(p-1, \mathbb{Z})$ by considering the corresponding subgroups in $\mathrm{U}((p-1)/2)$. Here we avoid the unitary group by taking an arithmetical approach.

2 A recall of algebraic number theory

For the convenience of the reader, we give a short introduction to algebraic number theory. More details and the proofs can be found in the books of Lang [6], Neukirch [8] and Washington [12].

Let p be an odd prime and let ξ be a primitive p th root of unity. Then $\mathbb{Z}[\xi]$ is the ring of integers of the cyclotomic field $\mathbb{Q}(\xi)$ and $\mathbb{Z}[\xi + \xi^{-1}]$ is the ring of integers of the maximal real subfield $\mathbb{Q}(\xi + \xi^{-1})$ of $\mathbb{Q}(\xi)$. For an integer $0 \neq n \in \mathbb{Z}$ we consider the ring $\mathbb{Z}[1/n]$ and the extensions $\mathbb{Z}[1/n][\xi]$ and $\mathbb{Z}[1/n][\xi + \xi^{-1}]$. It is well-known that $\mathbb{Z}[1/n][\xi]$ and $\mathbb{Z}[1/n][\xi + \xi^{-1}]$ are Dedekind rings. For $j = 1, \dots, p-1$ let the Galois automorphism $\gamma_j \in \mathrm{Gal}(\mathbb{Q}(\xi)/\mathbb{Q})$ be given by $\gamma_j(\xi) = \xi^j$. To simplify the notations, we define $x^{(j)} := \gamma_j(x)$ for any $x \in \mathbb{Q}(\xi)$ and $\gamma_j \in \mathrm{Gal}(\mathbb{Q}(\xi)/\mathbb{Q})$ as above. The Galois automorphism γ_j acts componentwise on a vector in $\mathbb{Q}(\xi)^k$.

Let A be a Dedekind ring and K the quotient field of A . Let L be a finite separable extension of K and B the integral closure of A in L . Let \mathfrak{a} be an additive subgroup of L . The complementary set \mathfrak{a}' of \mathfrak{a} is the set of $x \in L$ such that $\mathrm{tr}_{L/K}(x\mathfrak{a}) \subseteq A$. The different of the extension B/A is defined to be

$$D_{B/A} := B'_{L/K}^{-1}.$$

In $\mathbb{Z}[\xi]$ the different is generated by $D = p\xi^{(p+1)/2}/(\xi-1)$. It is a principal ideal. This is also true for $\mathbb{Z}[1/n][\xi]$ (see Lang [6] or Serre [9]).

Let \mathcal{O} be the ring of integers of a number field K . Let $G = \mathrm{Gal}(K/\mathbb{Q})$ be the Galois group of the extension and let \mathfrak{q} be a prime ideal of \mathcal{O} . The subgroup

$$G_{\mathfrak{q}} = \{\sigma \in G \mid \sigma\mathfrak{q} = \mathfrak{q}\}$$

is called the decomposition group of \mathfrak{q} over \mathbb{Q} . The fixed field

$$Z_{\mathfrak{q}} = \{x \in K \mid \sigma x = x \text{ for all } \sigma \in G_{\mathfrak{q}}\}$$

is called the decomposition field of \mathfrak{q} over \mathbb{Q} . The decomposition group of a prime ideal $\sigma\mathfrak{q}$ that is conjugate to \mathfrak{q} is the conjugate subgroup $G_{\sigma\mathfrak{q}} = \sigma G_{\mathfrak{q}} \sigma^{-1}$. Let $\mathfrak{q} \subset \mathcal{O}$ be a prime ideal in \mathcal{O} over the prime (q) in \mathbb{Z} . Let $\kappa(\mathfrak{q}) := \mathcal{O}/\mathfrak{q}$ and $\kappa(q) := \mathbb{Z}/q\mathbb{Z}$. The degree $f_{\mathfrak{q}}$ of the extension of fields $\kappa(\mathfrak{q})/\kappa(q)$ is called the residue class degree of \mathfrak{q} . We recall the following property. For any prime $q \neq p$ let $f_q \in \mathbb{N}$ be the smallest positive integer such that

$$q^{f_q} \equiv 1 \pmod{p}.$$

Then $(q) = (\mathfrak{q}_1 \cdots \mathfrak{q}_r)$ where $\mathfrak{q}_1, \dots, \mathfrak{q}_r$ are pairwise different prime ideals in $\mathbb{Q}(\xi)$ and all have residue class degree f_q (see Neukirch [8]).

Let p, q and ξ be as above. Let $\mathfrak{q}^+ \subseteq \mathbb{Z}[\xi + \xi^{-1}]$ be a prime ideal that lies over q . We consider the ideal $\mathfrak{q}^+ \mathbb{Z}[\xi] \subset \mathbb{Z}[\xi]$ generated by \mathfrak{q}^+ . Any prime $q \neq p$ is unramified and the prime p ramifies. Let $\sigma \in G := \text{Gal}(\mathbb{Q}(\xi)/\mathbb{Q})$ with $\sigma(x) = \bar{x}$. The Galois group G acts transitively on the set of prime ideals over q . It is known that $f_q = |G_{\mathfrak{q}}|$. We have the following three cases. The prime \mathfrak{q}^+ is inert: $\mathfrak{q}^+ \mathbb{Z}[\xi] = \mathfrak{q}$, a prime ideal in $\mathbb{Z}[\xi]$ that lies over q .

$$\begin{aligned} \mathfrak{q}^+ \mathbb{Z}[\xi] = \mathfrak{q} &\Leftrightarrow \mathfrak{q} = \bar{\mathfrak{q}} \\ &\Leftrightarrow \sigma \in G_{\mathfrak{q}}, \text{ i.e. } G_{\mathfrak{q}} \text{ contains an element of order 2,} \\ &\Leftrightarrow f_q \text{ is even.} \end{aligned}$$

Primes that split in $\mathbb{Z}[\xi]$: $\mathfrak{q}^+ \mathbb{Z}[\xi] = \mathfrak{q}\bar{\mathfrak{q}}$ where \mathfrak{q} is a prime ideal in $\mathbb{Z}[\xi]$ that lies over q .

$$\begin{aligned} \mathfrak{q}^+ \mathbb{Z}[\xi] = \mathfrak{q}\bar{\mathfrak{q}} &\Leftrightarrow \mathfrak{q} \neq \bar{\mathfrak{q}} \\ &\Leftrightarrow \sigma \notin G_{\mathfrak{q}}, \text{ i.e. } G_{\mathfrak{q}} \text{ does not contain an element of} \\ &\quad \text{order 2,} \\ &\Leftrightarrow f_q \text{ is odd.} \end{aligned}$$

The ramified case: $\mathfrak{p}^+ \mathbb{Z}[\xi] = \mathfrak{p}^2$ where $\mathfrak{p} := (1 - \xi)$ is the only prime ideal in $\mathbb{Z}[\xi]$ that lies over p . Moreover $\mathfrak{p}^+ \mathbb{Z}[\xi] := ((1 - \xi)(1 - \xi^{-1})) = \mathfrak{p}\bar{\mathfrak{p}}$ is the only prime ideal in $\mathbb{Z}[\xi + \xi^{-1}]$ that lies over p .

Let \mathcal{O}_K be a Dedekind ring and let S be a finite set of prime ideals $\mathfrak{q} \subseteq \mathcal{O}_K$. We define

$$\mathcal{O}_K^S := \left\{ \frac{f}{g} \mid f, g \in \mathcal{O}, g \not\equiv 0 \pmod{\mathfrak{q}} \text{ for } \mathfrak{q} \notin S \right\}.$$

Let K be the quotient field of \mathcal{O}_K . We call the group $(\mathcal{O}_K^S)^*$ the group of S -units of K . Let $\mathcal{C}(\mathcal{O}_K)$, resp. $\mathcal{C}(\mathcal{O}_K^S)$, denote the ideal class group of \mathcal{O}_K , resp. \mathcal{O}_K^S .

Proposition 2.1. *For the group $(\mathcal{O}_K^S)^*$ defined above we have an isomorphism*

$$(\mathcal{O}_K^S)^* \cong \mu(K) \times \mathbb{Z}^{|S|+r+s-1}$$

where $\mu(K)$ denotes the group of roots of unity of K , r denotes the number of real embeddings of K and s denotes the number of conjugate pairs of complex embeddings of K .

Proof. See Neukirch [8]. □

Therefore

$$\begin{aligned} (\mathcal{O}_K^S)^* &\cong \mu(K) \times \mathbb{Z}^{r+s-1} \times \mathbb{Z}^{|S|} \\ &\cong \mathcal{O}_K^* \times \mathbb{Z}^{|S|}. \end{aligned}$$

3 Matrices of order p

3.1 A relation between matrices and ideal classes

The results obtained in this section are based on the bijection given by Proposition 3.3. Sjerve and Yang prove in [11] the analogous statement of this proposition for the group $\mathrm{Sp}(p-1, \mathbb{Z})$. Since for our purpose it is important to understand the bijection and some proofs need a slightly different approach for the group $\mathrm{Sp}(p-1, \mathbb{Z}[1/n])$, we present in this subsection some of the proofs for the convenience of the reader.

Definition. Let I be the set of pairs (\mathfrak{a}, a) where $\mathfrak{a} \subseteq \mathbb{Z}[1/n][\xi]$ is a $\mathbb{Z}[1/n][\xi]$ -ideal and $0 \neq a \in \mathbb{Z}[1/n][\xi]$ is such that $\mathfrak{a}\bar{\mathfrak{a}} = (a) \subseteq \mathbb{Z}[1/n][\xi]$. Here $\bar{\mathfrak{a}}$ denotes the ideal generated by the complex conjugate of the elements of \mathfrak{a} . We define an equivalence relation on I .

$$(\mathfrak{a}, a) \sim (\mathfrak{b}, b) \Leftrightarrow \begin{aligned} &\exists \lambda, \mu \in \mathbb{Z}[1/n][\xi], \lambda, \mu \neq 0 \\ &\lambda \mathfrak{a} = \mu \mathfrak{b}, \lambda \bar{\lambda} a = \mu \bar{\mu} b. \end{aligned}$$

Let $[\mathfrak{a}, a]$ denote the equivalence class of the pair (\mathfrak{a}, a) and let \mathcal{I} be the set of equivalence classes $[\mathfrak{a}, a]$.

Lemma 3.1. *Let (\mathfrak{a}, a) be a pair consisting of a $\mathbb{Z}[1/n][\xi]$ -ideal $\mathfrak{a} \subseteq \mathbb{Z}[1/n][\xi]$ and $0 \neq a \in \mathbb{Z}[1/n][\xi]$. Then $(\mathfrak{a}, a) \in I$ if and only if a $\mathbb{Z}[1/n]$ -basis $\alpha_1, \dots, \alpha_{p-1}$ of \mathfrak{a} exists such that*

$$\alpha^T J \bar{\alpha}^{(i)} = \delta_{1i} a D$$

where $D = p\xi^{(p+1)/2}/(\xi-1)$ and $\alpha = (\alpha_1, \dots, \alpha_{p-1})^T$.

Proof. The proof is analogous to the proof of Lemma 2.3 in [11]. \square

Lemma 3.2. *Let M, N be two $(p-1) \times (p-1)$ -matrices over $\mathbb{Z}[1/n]$ and let*

$$\alpha = (\alpha_1, \dots, \alpha_{p-1})^T \in \mathbb{Z}[1/n][\xi]^{p-1}$$

where $\alpha_1, \dots, \alpha_{p-1}$ are $\mathbb{Z}[1/n]$ -linear independent. If for $i = 1, \dots, p-1$

$$\alpha^T M \bar{\alpha}^{(i)} = \alpha^T N \bar{\alpha}^{(i)}$$

then we have $M = N$.

Proof. It suffices to prove the case $N = 0$ because

$$\alpha^T M \bar{\alpha}^{(i)} = \alpha^T N \bar{\alpha}^{(i)} \Leftrightarrow \alpha^T (M - N) \bar{\alpha}^{(i)} = 0 = \alpha^T 0 \bar{\alpha}^{(i)}.$$

Let $a_i = \alpha^T M \bar{\alpha}^{(i)}$, then $a_i^{(k)} = \alpha^{(k)T} M (\bar{\alpha}^{(i)})^{(k)}$. For all k, l with $1 \leq k, l \leq p-1$ let i be such that $1 \leq i \leq p-1$ and $ki \equiv l \pmod{p}$. Then $(\bar{\alpha}^{(i)})^{(k)} = \bar{\alpha}^{(l)}$

and therefore $\alpha^{(k)\text{T}} M \bar{\alpha}^{(l)} = 0$ for $k, l = 1, \dots, p-1$. This implies $A^{\text{T}} M B = 0$ where

$$A := (\alpha_i^{(j)}) \text{ and } B := (\bar{\alpha}_i^{(j)})$$

are $(p-1) \times (p-1)$ -matrices. Since $\alpha_1, \dots, \alpha_{p-1}$ are $\mathbb{Z}[1/n]$ -linear independent we have $\det A \neq 0$ and $\det B \neq 0$. But this yields $M = 0$. \square

Proposition 3.3. *A bijection ψ exists between the set of conjugacy classes of elements of order p in $\text{Sp}(p-1, \mathbb{Z}[1/n])$ and the set of equivalence classes of pairs $[\mathfrak{a}, a] \in \mathcal{I}$.*

In order to prove this proposition, we first construct the bijection and then we show that the mapping we constructed is a bijection (Lemma 3.5, Lemma 3.6).

Let $Y \in \text{Sp}(p-1, \mathbb{Z}[1/n])$ be of order p . The eigenvalues of Y are the primitive p th roots of unity. An eigenvector

$$\alpha = (\alpha_1, \dots, \alpha_{p-1})^{\text{T}} \in (\mathbb{Z}[1/n])^{p-1}$$

exists for the eigenvalue $\xi = e^{i2\pi/p}$, i.e. $Y\alpha = \xi\alpha$. The $\alpha_1, \dots, \alpha_{p-1}$ are $\mathbb{Z}[1/n]$ -linear independent. Let \mathfrak{a} be the $\mathbb{Z}[1/n]$ -module generated by $\alpha_1, \dots, \alpha_{p-1}$. Let $a = D^{-1}\alpha^{\text{T}} J \bar{\alpha}$. Then $\mathfrak{a} \subseteq \mathbb{Z}[1/n][\xi]$ is a $\mathbb{Z}[1/n][\xi]$ -ideal and $a = \bar{a}$.

Lemma 3.4. *The pair (\mathfrak{a}, a) we construct above is an element of \mathcal{I} .*

Proof. Because of Lemma 3.1 it suffices to show that $\alpha^{\text{T}} J \bar{\alpha}^{(i)} = 0$ for $i = 2, \dots, p-1$. Since $Y\alpha = \xi\alpha$ we have

$$Y\alpha^{(i)} = \xi^i \alpha^{(i)} \text{ and } Y\bar{\alpha}^{(i)} = \frac{1}{\xi^i} \bar{\alpha}^{(i)},$$

$2 \leq i \leq p-1$. Therefore

$$\alpha^{\text{T}} J \bar{\alpha}^{(i)} = \frac{\xi^i}{\xi} \alpha^{\text{T}} Y^{\text{T}} J Y \bar{\alpha}^{(i)} = \frac{\xi^i}{\xi} \alpha^{\text{T}} J \bar{\alpha}^{(i)}$$

where the last equation follows from the fact that $Y \in \text{Sp}(p-1, \mathbb{Z}[1/n])$. Since $\xi \neq \xi^i$ we get $\alpha^{\text{T}} J \bar{\alpha}^{(i)} = 0$. \square

Let $Y, \tilde{Y} \in \text{Sp}(p-1, \mathbb{Z}[1/n])$ be matrices of odd prime order p . Let $\alpha \in (\mathbb{Z}[1/n][\xi])^{p-1}$, resp. $\beta \in (\mathbb{Z}[1/n][\xi])^{p-1}$ be an eigenvector of Y , resp. \tilde{Y} , to the eigenvalue ξ , i.e. $Y\alpha = \xi\alpha$ and $\tilde{Y}\beta = \xi\beta$. Let $\alpha = (\alpha_1, \dots, \alpha_{p-1})^{\text{T}}$, $\beta = (\beta_1, \dots, \beta_{p-1})^{\text{T}}$. Let $\mathfrak{a} \subseteq \mathbb{Z}[1/n][\xi]$, resp. $\mathfrak{b} \subseteq \mathbb{Z}[1/n][\xi]$, be the ideal with $\mathbb{Z}[1/n]$ -basis $\alpha_1, \dots, \alpha_{p-1}$, resp. $\beta_1, \dots, \beta_{p-1}$. We define $a = D^{-1}\alpha^{\text{T}} J \bar{\alpha}$ and $b = D^{-1}\beta^{\text{T}} J \bar{\beta}$. We show the injectivity of ψ .

Lemma 3.5. *Let $Y, \tilde{Y} \in \text{Sp}(p-1, \mathbb{Z}[1/n])$ be matrices of odd prime order p . Then Y and \tilde{Y} are conjugate if and only if $[\mathfrak{a}, a] = [\mathfrak{b}, b]$.*

Proof. Let Y and \tilde{Y} be conjugate. Then $Q \in \mathrm{Sp}(p-1, \mathbb{Z}[1/n])$ exists such that $\tilde{Y} = Q^{-1}YQ$. Then $Q\tilde{Y} = YQ$ and for the eigenvector β to the eigenvalue ξ of \tilde{Y} we get

$$YQ\beta = Q\tilde{Y}\beta = \xi Q\beta$$

and therefore $Q\beta$ is an eigenvector of Y . But α is also an eigenvector to the eigenvalue ξ of Y . So $\lambda, \mu \in \mathbb{Z}[1/n][\xi]$, $\lambda, \mu \neq 0$, exist such that

$$\lambda\alpha = \mu Q\beta = Q\mu\beta.$$

Then $\lambda\mathbf{a} = \mu\mathbf{b}$ and for $a = D^{-1}\alpha^T J\bar{\alpha}$, $b = D^{-1}\beta^T J\bar{\beta}$ we get $\lambda\bar{\lambda}a = \mu\bar{\mu}b$. This shows that $[\mathbf{a}, a] = [\mathbf{b}, b]$.

In order to show the other direction we assume that $\lambda, \mu \in \mathbb{Z}[1/n][\xi]$, $\lambda, \mu \neq 0$, exist such that $\lambda\mathbf{a} = \mu\mathbf{b}$ and $\lambda\bar{\lambda}a = \mu\bar{\mu}b$. Then a matrix $Q \in \mathrm{GL}(p-1, \mathbb{Z}[1/n])$ exists such that $\lambda\alpha = \mu Q\beta$. We have

$$\mu Q\tilde{Y}\beta = \mu Q\xi\beta = \xi\mu Q\beta = \xi\lambda\alpha = \lambda Y\alpha = \mu YQ\beta$$

and therefore

$$Q\tilde{Y}\beta = YQ\beta.$$

Since $\beta_1, \dots, \beta_{p-1}$ are $\mathbb{Z}[1/n]$ -linear independent, we have $Q\tilde{Y} = YQ$ and herewith

$$\tilde{Y} = Q^{-1}YQ.$$

It remains to show that $Q \in \mathrm{Sp}(p-1, \mathbb{Z}[1/n])$. For $i = 2, \dots, p-1$ we have

$$\beta^T Q^T J Q \bar{\beta}^{(i)} = \frac{\lambda\bar{\lambda}^{(i)}}{\mu\bar{\mu}^{(i)}} \alpha^T J \bar{\alpha}^{(i)} = 0 = \beta^T J \bar{\beta}^{(i)}$$

and for $i = 1$ we have

$$\beta^T Q^T J Q \bar{\beta} = \frac{\lambda\bar{\lambda}}{\mu\bar{\mu}} \alpha^T J \bar{\alpha} = \frac{b}{a} \alpha^T J \bar{\alpha} = \beta^T J \bar{\beta}$$

because $\lambda\bar{\lambda}a = \mu\bar{\mu}b$ implies that $\frac{\lambda\bar{\lambda}}{\mu\bar{\mu}} = \frac{b}{a}$. Now it follows from Lemma 3.2 that $Q^T J Q = J$ and this means that $Q \in \mathrm{Sp}(p-1, \mathbb{Z}[1/n])$. \square

Lemma 3.6. *The mapping ψ is surjective.*

Proof. Let (\mathbf{a}, a) and $\alpha = (\alpha_1, \dots, \alpha_{p-1})^T$ be like in Lemma 3.1. Then $\xi\alpha_1, \dots, \xi\alpha_{p-1}$ is a new basis of \mathbf{a} . Therefore $X \in \mathrm{GL}(p-1, \mathbb{Z}[1/n])$ exists with $X\alpha = \xi\alpha$. It is evident that the order of X is p . We show that $X \in \mathrm{Sp}(p-1, \mathbb{Z}[1/n])$. We have

$$\alpha^T X^T J X \bar{\alpha}^{(i)} = \frac{\xi}{\xi^i} \alpha^T J \bar{\alpha}^{(i)} = \delta_{1i} \alpha^T J \bar{\alpha}$$

hence

$$\alpha^T X^T J X \bar{\alpha}^{(i)} = \alpha^T J \bar{\alpha}^{(i)}.$$

The last equation and Lemma 3.2 imply that $X^T J X = J$ and therefore $X \in \mathrm{Sp}(p-1, \mathbb{Z}[1/n])$. \square

Let \mathcal{I} be the set of equivalence classes of pairs $(\mathbf{a}, a) \in I$ defined above. We define a multiplication on \mathcal{I} by

$$[\mathbf{a}, a] \cdot [\mathbf{b}, b] = [\mathbf{ab}, ab].$$

The unit is $[\mathbb{Z}[1/n][\xi], 1]$ and the inverse of $[\mathbf{a}, a]$ is $[\bar{\mathbf{a}}, a]$ since

$$[\mathbf{a}, a] \cdot [\bar{\mathbf{a}}, a] = [(a), a^2] = [\mathbb{Z}[1/n][\xi], 1].$$

Lemma 3.7. *Let $(\mathbf{a}, a) \in I$, $\lambda \in \mathbb{Z}[1/n][\xi]$, $\lambda \neq 0$. Then*

- i) $(\lambda \mathbf{a}, \lambda \bar{\lambda} a) \in I$,
- ii) $(\mathbf{a}, \lambda a) \in I$ if and only if $\lambda \in \mathbb{Z}[1/n][\xi + \xi^{-1}]^*$.

Proof. Trivial. \square

Let

$$N : \mathbb{Q}(\xi) \longrightarrow \mathbb{Q}(\xi + \xi^{-1})$$

be the norm mapping, i.e. $N(x) = x\bar{x}$ for $x \in \mathbb{Q}(\xi)$. Then

$$N(\mathbb{Z}[1/n][\xi]^*) \subsetneq \mathbb{Z}[1/n][\xi + \xi^{-1}]^*.$$

Lemma 3.8. *Let $(\mathbf{a}, a), (\mathbf{b}, b) \in I$. Then $[\mathbf{a}, a] = [\mathbf{b}, b]$ if and only if*

$$\frac{a}{b} \in N(\mathbb{Z}[1/n][\xi]^*).$$

Proof. Suppose that $[\mathbf{a}, a] = [\mathbf{b}, b]$. Then $\lambda, \mu \in \mathbb{Z}[1/n][\xi]$, $\lambda, \mu \neq 0$, exist such that $\lambda \mathbf{a} = \mu \mathbf{b}$ and $\lambda \bar{\lambda} a = \mu \bar{\mu} b$. Let $u = \mu/\lambda$, then $u \in \mathbb{Z}[1/n][\xi]^*$ (since $\mathbf{a} = (\mu/\lambda) \mathbf{b}$) and $a/b = \mu \bar{\mu} / \lambda \bar{\lambda} = u \bar{u}$. This shows that $a/b \in N(\mathbb{Z}[1/n][\xi]^*)$. Now let $a/b = u \bar{u}$ for some $u \in \mathbb{Z}[1/n][\xi]^*$. Then $[\mathbf{a}, a] = [\mathbf{a}, u \bar{u} b] = [u \mathbf{a}, u \bar{u} b] = [\mathbf{b}, b]$. \square

Lemma 3.9. *Let $(\mathbf{a}, a), (\mathbf{b}, b) \in I$ and $\lambda \mathbf{a} = \mu \mathbf{b}$ for some $\lambda, \mu \in \mathbb{Z}[1/n][\xi]$, $\lambda, \mu \neq 0$. Then $u \in \mathbb{Z}[1/n][\xi + \xi^{-1}]^*$ exists such that $[\mathbf{a}, a] = [\mathbf{b}, ub]$.*

Proof. If $\lambda \mathbf{a} = \mu \mathbf{b}$, then $\bar{\lambda} \bar{\mathbf{a}} = \bar{\mu} \bar{\mathbf{b}}$ and herewith

$$(\lambda \bar{\lambda} a) = \lambda \bar{\lambda} \bar{\mathbf{a}} = \mu \bar{\mu} \bar{\mathbf{b}} = (\mu \bar{\mu} b).$$

But then a unit $u \in \mathbb{Z}[1/n][\xi + \xi^{-1}]^*$ exists with $\lambda \bar{\lambda} a = \mu \bar{\mu} ub$. Herewith

$$[\mathbf{a}, a] = [\lambda \mathbf{a}, \lambda \bar{\lambda} a] = [\mu \mathbf{b}, \mu \bar{\mu} ub] = [\mathbf{b}, ub].$$

\square

Proposition 3.10. *Let \mathcal{C}_0 be the ideal class group of $\mathbb{Z}[1/n][\xi]$. Then the sequence*

$$1 \longrightarrow \mathbb{Z}[1/n][\xi + \xi^{-1}]^*/N(\mathbb{Z}[1/n][\xi]^*) \xrightarrow{\delta} \mathcal{I} \xrightarrow{\eta} \mathcal{C}_0 \longrightarrow 1$$

where $\delta([u]) = [\mathbb{Z}[1/n][\xi], u]$, $\eta([\mathbf{a}, a]) = [\mathbf{a}]$, is a short exact sequence.

Proof. Lemma 3.8 implies that δ is injective and η is well-defined and surjective. Moreover

$$\eta(\delta([u])) = \eta([\mathbb{Z}[1/n][\xi], u]) = [\mathbb{Z}[1/n][\xi]]$$

and Lemma 3.9 implies that the kernel of η is equal to the image of δ . \square

Corollary 3.11. *The number of conjugacy classes of matrices of order p in $\mathrm{Sp}(p-1, \mathbb{Z}[1/n])$ is equal to*

$$|\mathcal{C}_0| \cdot [\mathbb{Z}[1/n][\xi + \xi^{-1}]^* : N(\mathbb{Z}[1/n][\xi]^*)].$$

Proof. This corollary is a direct consequence of Proposition 3.10 because the number of conjugacy classes of matrices of order p in $\mathrm{Sp}(p-1, \mathbb{Z}[1/n])$ is equal to the cardinality of \mathcal{I} . \square

If $\mathbb{Z}[1/n][\xi]$ is a principal ideal domain the cardinality of \mathcal{C}_0 is 1 and the number of conjugacy classes of matrices of order p in $\mathrm{Sp}(p-1, \mathbb{Z}[1/n])$ is given only by the index defined above. In fact we can choose $n \in \mathbb{Z}$ such that $\mathbb{Z}[1/n][\xi]$ is a principal ideal domain. Indeed let $\mathbf{a}_1, \dots, \mathbf{a}_h$ be representatives of the ideal classes of $\mathbb{Q}(\xi)$. For $j = 1, \dots, h$ choose $n_j \in \mathbf{a}_j$ with $n_j \in \mathbb{Z}[1/n][\xi]$. It is possible to choose the n_j such that $n_j \in \mathbb{Z}$. Then $n = \prod_{j=1}^h n_j \in \mathbf{a}_k$ for any k with $1 \leq k \leq h$. For more details see Lang [6] and Neukirch [8].

3.2 The number of conjugacy classes

Let $N : \mathbb{Q}(\xi) \longrightarrow \mathbb{Q}(\xi + \xi^{-1})$ be the norm mapping defined above. Let $n \in \mathbb{Z}$ and ξ a primitive p th root of unity. This is the aim of this section is to compute the number of conjugacy classes of elements of order p in $\mathrm{Sp}(p-1, \mathbb{Z}[1/n])$. Therefore we use Corollary 3.11.

Kummer proved that $\mathbb{Z}[1/n][\xi]^* = \mathbb{Z}[1/n][\xi + \xi^{-1}]^* \times \langle -\xi \rangle$ where $\langle -\xi \rangle$ is the group of roots of unity in $\mathbb{Q}(\xi)$. This implies that

$$[\mathbb{Z}[\xi + \xi^{-1}]^* : N(\mathbb{Z}[\xi]^*)] = [\mathbb{Z}[\xi + \xi^{-1}]^* : (\mathbb{Z}[\xi + \xi^{-1}]^*)^2].$$

Moreover $\mathbb{Z}[\xi + \xi^{-1}]^* \cong \mathbb{Z}^{(p-3)/2} \times \mathbb{Z}/2\mathbb{Z}$ because of the Dirichlet unit theorem. Therefore

$$[\mathbb{Z}[\xi + \xi^{-1}]^* : N(\mathbb{Z}[\xi]^*)] = 2^{\frac{p-1}{2}}.$$

Since the prime above p in $\mathbb{Z}[\xi]$ is principal, generated by $1-\xi$, and the prime above p in $\mathbb{Z}[\xi + \xi^{-1}]$ is principal, generated by $N(1-\xi) = (1-\xi)(1-\xi^{-1})$, we get

$$[\mathbb{Z}[1/p][\xi + \xi^{-1}]^* : N(\mathbb{Z}[1/p][\xi]^*)] = 2^{\frac{p-1}{2}}.$$

Proposition 3.12. *Let p be an odd prime and let ξ be a primitive p th root of unity. Let S^+ be a finite set of prime ideals in $\mathbb{Z}[\xi + \xi^{-1}]$, and let S be the set of the prime ideals in $\mathbb{Z}[\xi]$ that lie over those in S^+ . Then*

$$[(\mathbb{Z}[\xi + \xi^{-1}]^{S^+})^* : N((\mathbb{Z}[\xi]^S)^*)] = 2^{\frac{p-1}{2} + \tau}$$

where τ is the number of inert primes in S^+ .

Proof. Let $S := \{\mathfrak{q}_1, \dots, \mathfrak{q}_k\}$ be a set of prime ideals in $\mathbb{Z}[\xi]$. Then the isomorphism given by the generalization of the Dirichlet unit theorem implies that for each prime ideal $\mathfrak{q}_j \in S$, $j = 1, \dots, k$, $g_j \in \mathfrak{q}_j$ exists such that each unit $u \in (\mathbb{Z}[\xi]^S)^*$ can be written

$$u = u' g_1^{n_1} \cdots g_k^{n_k}$$

where $u' \in \mathbb{Z}[\xi]^*$, $n_j \in \mathbb{Z}$, $j = 1, \dots, k$. We compute the index we want to know by induction on the number of primes in S^+ . Let T^+ be a finite set of prime ideals in $\mathbb{Z}[\xi + \xi^{-1}]$. Let T be the set of those prime ideals in $\mathbb{Z}[\xi]$ that lie over the prime ideals in T^+ . Define $S^+ := T^+ \cup \{\mathfrak{q}^+\}$ where $\mathfrak{q}^+ \subset \mathbb{Z}[\xi + \xi^{-1}]$, $\mathfrak{q}^+ \notin T^+$, is a prime ideal. Let S be the set of the prime ideals in $\mathbb{Z}[\xi]$ that lie over the prime ideals in S^+ . We have the following possibilities.

- i) The prime \mathfrak{q}^+ is inert. Then $S = T \cup \{\mathfrak{q}\}$ where \mathfrak{q} is the prime that lies over \mathfrak{q}^+ .
- ii) The prime \mathfrak{q}^+ splits in $\mathbb{Z}[\xi]$. Then $S = T \cup \{\mathfrak{q}, \bar{\mathfrak{q}}\}$ where $\mathfrak{q}, \bar{\mathfrak{q}}$ are the primes that lie over \mathfrak{q}^+ .
- iii) The prime \mathfrak{q}^+ lies over p . Then $S = T \cup \{\mathfrak{p}\}$ where $\mathfrak{p} = (1-\xi)$, the prime over p .

We have

$$(\mathbb{Z}[\xi + \xi^{-1}]^{S^+})^* \cong (\mathbb{Z}[\xi + \xi^{-1}]^{T^+})^* \times \mathbb{Z}.$$

If the prime \mathfrak{q}^+ is inert or if it lies over p , cases i) and iii) above, then

$$\begin{aligned} (\mathbb{Z}[\xi]^S)^* &\cong \mathbb{Z}[\xi]^* \times \mathbb{Z}^{|S|} \cong \mathbb{Z}[\xi]^* \times \mathbb{Z}^{|T|} \times \mathbb{Z} \\ &\cong (\mathbb{Z}[\xi]^T)^* \times \mathbb{Z} \end{aligned}$$

and if the prime \mathfrak{q}^+ splits in $\mathbb{Z}[\xi]$, case ii) above, then

$$(\mathbb{Z}[\xi]^S)^* \cong (\mathbb{Z}[\xi]^T)^* \times \mathbb{Z}^2.$$

We give a formula for the index

$$[(\mathbb{Z}[\xi + \xi^{-1}]^{S^+})^* : N((\mathbb{Z}[\xi]^S)^*)]$$

in relation to the index

$$[(\mathbb{Z}[\xi + \xi^{-1}]^{T^+})^* : N((\mathbb{Z}[\xi]^T)^*)].$$

If the prime \mathfrak{q}^+ is inert, then

$$[(\mathbb{Z}[\xi + \xi^{-1}]^{S^+})^* : N((\mathbb{Z}[\xi]^S)^*)] = 2[(\mathbb{Z}[\xi + \xi^{-1}]^{T^+})^* : N((\mathbb{Z}[\xi]^T)^*)].$$

If the prime \mathfrak{q}^+ splits in $\mathbb{Z}[\xi]$ or if it lies over p , then

$$[(\mathbb{Z}[\xi + \xi^{-1}]^{S^+})^* : N((\mathbb{Z}[\xi]^S)^*)] = [(\mathbb{Z}[\xi + \xi^{-1}]^{T^+})^* : N((\mathbb{Z}[\xi]^T)^*)].$$

This shows that if we add an inert prime to the set S the index is multiplied by 2, and if we add primes that split or the prime over p , then the index does not change. \square

Theorem 3.13. *Let $n \in \mathbb{Z}$. Then*

$$[\mathbb{Z}[1/n][\xi + \xi^{-1}]^* : N(\mathbb{Z}[1/n][\xi]^*)] = 2^{\frac{p-1}{2} + \tau}$$

where τ is the number of inert primes in $\mathbb{Z}[\xi + \xi^{-1}]$ that lie over primes in \mathbb{Z} that divide n .

Proof. Let $n \in \mathbb{Z}$ and let S^+ , resp. S , be the prime ideals in $\mathbb{Z}[\xi + \xi^{-1}]$, resp. $\mathbb{Z}[\xi]$, over the primes in \mathbb{Z} that divide n . Then the assumption follows directly from Proposition 3.12. \square

Theorem 3.14. *The number of conjugacy classes of matrices of order p in $\mathrm{Sp}(p-1, \mathbb{Z}[1/n])$, $0 \neq n \in \mathbb{Z}$, is*

$$|\mathcal{C}_0| 2^{\frac{p-1}{2} + \tau}$$

where \mathcal{C}_0 is the ideal class group of $\mathbb{Z}[1/n][\xi]$ and τ is the number of inert primes in $\mathbb{Z}[\xi + \xi^{-1}]$ that lie over primes in \mathbb{Z} that divide n .

Proof. This follows directly from Corollary 3.11 and Theorem 3.13. \square

4 Subgroups of order p

4.1 The quotient of the normalizer by the centralizer of subgroups of order p

The aim is to study the centralizers and normalizers of conjugacy classes of subgroups of order p in $\mathrm{Sp}(p-1, \mathbb{Z}[1/n])$. We use the bijection between

the set \mathcal{I} of equivalence classes $[\mathfrak{a}, a]$ and the conjugacy classes of matrices of order p . Each conjugacy class of matrices generates a conjugacy class of subgroups of order p in $\mathrm{Sp}(p-1, \mathbb{Z}[1/n])$. We determine the equivalence classes $[\mathfrak{a}, a]$ that correspond to the conjugacy classes of the elements of a subgroup.

Let $Y \in \mathrm{Sp}(p-1, \mathbb{Z}[1/n])$ be of odd prime order p . We have seen that the conjugacy class of Y corresponds to an equivalence class $[\mathfrak{a}, a]$. Let

$$\alpha = (\alpha_1, \dots, \alpha_{p-1})^T \in (\mathbb{Z}[1/n][\xi])^{p-1}$$

be an eigenvector of Y to the eigenvalue $\xi = e^{i2\pi/p}$. It is obvious that $Y^l = \xi^l \alpha$. Let $\gamma_k \in \mathrm{Gal}(\mathbb{Q}[\xi]/\mathbb{Q})$ be such that $\gamma_k(\xi) = \xi^k$. Then $\gamma_k(\xi^l) = \xi^{kl}$. If $kl \equiv 1 \pmod{p}$, then $\gamma_k(\xi^l) = \xi$ and moreover

$$Y^l \gamma_k(\alpha) = \gamma_k(Y^l \alpha) = \gamma_k(\xi^l \alpha) = \gamma_k(\xi^l) \gamma_k(\alpha) = \xi^{kl} \gamma_k(\alpha) = \xi \gamma_k(\alpha).$$

So $\gamma_k(\alpha)$ is the eigenvector of Y^l to the eigenvalue ξ . Let \mathfrak{b} be the ideal given by the $\mathbb{Z}[1/n]$ -basis $\gamma_k(\alpha_1), \dots, \gamma_k(\alpha_{p-1})$. Moreover let

$$b = D^{-1}(\gamma_k(\alpha))^T J \gamma_k(\bar{\alpha}) = D^{-1} \gamma_k(\alpha^T J \bar{\alpha}).$$

So the conjugacy class of Y^l corresponds to the equivalence class $[\mathfrak{b}, b]$ with

$$\begin{aligned} \mathfrak{b} &= \gamma_k(\mathfrak{a}) \\ b &= D^{-1} \gamma_k(Da) = D^{-1} \gamma_k(D) \gamma_k(a). \end{aligned}$$

Let S be a multiplicative set such that $S^{-1}\mathbb{Z} = \mathbb{Z}[1/n]$. Then $S^{-1}\mathbb{Z}[\xi] = \mathbb{Z}[1/n][\xi]$ and the different in $\mathbb{Z}[\xi]$ and in $\mathbb{Z}[1/n][\xi]$ are both principal ideals generated by $D = p\xi^{(p+1)/2}/(\xi-1)$. If $p \mid n$, then D is a unit in $\mathbb{Z}[1/n][\xi]$ since $(\xi-1)$ is a prime that divides p . If $u, v \in \mathbb{Z}[1/n][\xi]^*$ are units with $u = \bar{u}$, $v = -\bar{v}$, then $Du = -\overline{D}u$ and $Dv = \overline{D}v$. This shows that the multiplication with D defines an isomorphism on $\mathbb{Z}[1/n][\xi]^*$ that yields a bijection between the real and the purely imaginary units.

Theorem 4.1. *Let $n \in \mathbb{Z}$ be such that $\mathbb{Z}[1/n][\xi]$ and $\mathbb{Z}[1/n][\xi + \xi^{-1}]$ are principal ideal domains and moreover $p \mid n$. Let $N(P)$ denote the normalizer and $C(P)$ the centralizer of a subgroup P of order p in $\mathrm{Sp}(p-1, \mathbb{Z}[1/n])$. Then*

$$N(P)/C(P) \cong \mathbb{Z}/j\mathbb{Z}$$

where $j \mid p-1$, j odd. For each j with $j \mid p-1$, j odd, exists a subgroup of order p in $\mathrm{Sp}(p-1, \mathbb{Z}[1/n])$ with $N(P)/C(P) \cong \mathbb{Z}/j\mathbb{Z}$.

Proof. Let n be such that $\mathbb{Z}[1/n][\xi]$ is a principal ideal domain. Then the ideal \mathfrak{a} in the pair $[\mathfrak{a}, a]$ is a principal ideal. If $\mathfrak{a} = (x)$, then $(x)\overline{(x)} = (x\bar{x}) = (a)$, i.e. a unit u exists such that $a = ux\bar{x}$. Then

$$[\mathfrak{a}, a] = [(x), a] = [\mathbb{Z}[1/n][\xi], u].$$

The conjugacy class of $Y \in \mathrm{Sp}(p-1, \mathbb{Z}[1/n])$ corresponds to $[\mathbb{Z}[1/n][\xi], u]$. For $1 < l < p-1$ we have seen that the conjugacy class of Y^l corresponds to $[\mathbb{Z}[1/n][\xi], D^{-1}\gamma_k(Du)]$ where $\gamma_k \in \mathrm{Gal}(\mathbb{Q}[\xi]/\mathbb{Q})$ is defined such that $\gamma_k(\xi^l) = \xi$. The matrices Y and Y^l are conjugate if and only if

$$[\mathbb{Z}[1/n][\xi], u] = [\mathbb{Z}[1/n][\xi], D^{-1}\gamma_k(Du)].$$

Lemma 3.8 shows that this equation is satisfied if and only if $\omega \in \mathbb{Z}[1/n][\xi]^*$ exists such that

$$D^{-1}\gamma_k(Du) = u\omega\bar{\omega}. \quad (1)$$

We know that $u \in \mathbb{Z}[1/n][\xi + \xi^{-1}]^*$ and this implies that Du is purely imaginary. First we check if $u \in \mathbb{Z}[1/n][\xi + \xi^{-1}]^*$ exists such that a special case of (1) holds, namely the case with $\omega = 1$, i.e. we try to find γ_k and u such that $\gamma_k(Du) = Du$. The automorphism $\gamma_{p-1}(= \gamma_{-1})$ has order 2, i.e. γ_{p-1} yields the complex conjugation. Since u is real and therefore Du purely imaginary, we get $\gamma_{p-1}(Du) = -Du$. This proves that neither $\gamma_k(Du) = Du$ nor (1) can be satisfied if $k = p-1$ (the image of $\omega\bar{\omega}$ under any embedding of $\mathbb{Z}[1/n][\xi]$ in \mathbb{C} is a positive real number). Any automorphism $\gamma_k \in \mathrm{Gal}(\mathbb{Q}[\xi]/\mathbb{Q})$ generates a subgroup $\langle \gamma_k \rangle \subseteq \mathrm{Gal}(\mathbb{Q}[\xi]/\mathbb{Q})$ and the order of this subgroup divides $p-1$, the order of $\mathrm{Gal}(\mathbb{Q}[\xi]/\mathbb{Q})$. Let $j = |\langle \gamma_k \rangle|$ denote the order of γ_k . If j is even the order of $\gamma_k^{j/2}$ is 2 and on the other hand $\gamma_k^r(Du) = Du$ for any $1 < r < j$. This yields a contradiction and therefore $\gamma_k(Du) = Du$ cannot be satisfied if the order of γ_k is even. This implies that if γ_k and u exist with $\gamma_k(Du) = Du$, then the order of γ_k is odd.

The main theorem of Galois theory says that a subfield $\mathbb{Q} \subseteq K \subseteq \mathbb{Q}(\xi)$ corresponds to the subgroup $\langle \gamma_k \rangle \subseteq \mathrm{Gal}(\mathbb{Q}[\xi]/\mathbb{Q})$ and that

$$K = \{x \in \mathbb{Q}(\xi) \mid \forall \gamma_{k^r} \in \langle \gamma_k \rangle, \gamma_{k^r}(x) = x\}.$$

Let $n \in \mathbb{Z}$ with $p \mid n$. We have seen that in this case $D = p\xi^{(p+1)/2}/(\xi-1)$ is a unit in $\mathbb{Z}[1/n][\xi]$. We also know that $D = -\bar{D}$. Let $\gamma_k \in \mathrm{Gal}(\mathbb{Q}[\xi]/\mathbb{Q})$ be of odd order j . Since complex conjugation commutes with the Galois automorphisms, we get for any r , $1 \leq r \leq j$, $\gamma_{k^r}(D) = -\overline{\gamma_{k^r}(\bar{D})}$. Since j is odd,

$$\prod_{r=1}^j \gamma_{k^r}(D) = (-1)^j \prod_{r=1}^j \gamma_{k^r}(\bar{D}) = - \prod_{r=1}^j \gamma_{k^r}(\bar{D}).$$

Moreover this product is invariant under γ_k since

$$\gamma_k \left(\prod_{r=1}^j \gamma_{k^r}(D) \right) = \prod_{r=1}^j \gamma_k(\gamma_{k^r}(D)) = \prod_{r=1}^j \gamma_{k^r}(D).$$

Now consider the composition $\gamma_k \circ \gamma_{p-1} = \gamma_{-k}$ where the order of γ_k is odd. The order of γ_{-k} is even and $\langle \gamma_k \rangle$ is a subgroup of $\langle \gamma_{-k} \rangle$. Let L denote the

subfield $\mathbb{Q} \subseteq L \subseteq K \subseteq \mathbb{Q}(\xi)$ corresponding to $\langle \gamma_{-k} \rangle$. Sinnott constructs in [10] cyclotomic units in any subfield L of $\mathbb{Q}(\xi_m)$ where ξ_m is a m th root of unity. This means that units exist in L , that are contained in no subfield of L . Let $v \in L$ be such a unit ($v \in \mathbb{Z}[\xi]$). Then $\gamma_{p-1}(v) = v$, $\gamma_k(v) = v$ since $\langle \gamma_{-k} \rangle$ fixes the elements of L . Let $w := \prod_{r=1}^{j-1} \gamma_{k^r}(D) \in \mathbb{Z}[1/n][\xi]$. Then

$$w = \prod_{r=1}^{j-1} \gamma_{k^r}(D) = (-1)^{j-1} \prod_{r=1}^{j-1} \overline{\gamma_{k^r}(D)} = \bar{w}$$

since j is odd. Moreover $Dw = \prod_{r=1}^j \gamma_{k^r}(D)$ and therefore $\gamma_k(Dw) = Dw$. We have $Dw = -\bar{Dw}$ since $w = \bar{w}$. Now $wv = \bar{w}\bar{v}$ is a unit. Let $u = wv$, then the construction implies that

$$\gamma_k(Du) = \gamma_k(Dwv) = Dwv = Du.$$

So for any $\gamma_k \in \text{Gal}(\mathbb{Q}(\xi)/\mathbb{Q})$ of odd order, we found $u \in \mathbb{Z}[1/n][\xi + \xi^{-1}]^*$ with $\gamma_k(Du) = Du$ and such that

$$[\mathbb{Z}[1/n][\xi], u] = [\mathbb{Z}[1/n][\xi], D^{-1}\gamma_k(Du)].$$

If $Y \in \text{Sp}(p-1, \mathbb{Z}[1/n])$ is in the corresponding equivalence class then this is also true for Y^l with l such that $\gamma_k(\xi^l) = \xi$. If Y is conjugate to Y^l with $\gamma_k(\xi^l) = \xi$, then Y is also conjugate to Y^{l^r} where $1 \leq r \leq j$ and j is the order of γ_k . Indeed $\gamma_{k^r}(\xi^{l^r}) = \xi$ for $1 \leq r \leq j$ and therefore $l^j \equiv 1 \pmod{p}$ (since $\gamma_{k^j} = \text{id}$) and $Y^{l^j} = Y$ because the order of Y is p . The l^r form a cyclic subgroup of $\mathbb{Z}/p\mathbb{Z}$.

Let $k, l \in \mathbb{Z}$ be as above, i.e. $\gamma_k(\xi^l) = \xi$. Let $\gamma_l \in \text{Gal}(\mathbb{Q}(\xi)/\mathbb{Q})$ with $\gamma_l(\xi) = \xi^l$. Then $\gamma_l = \gamma_k^{-1}$ and if j is the order of γ_k , then j is also the order of γ_l . Therefore $l^j \equiv 1 \pmod{p}$. This means that $Y^{l^j} = Y$ and the Y^{l^r} , $1 \leq r \leq j$ are conjugate to Y . We know that j is odd and $j \mid p-1$.

If j elements are conjugate in the subgroup generated by the matrix $Y \in \text{Sp}(p-1, \mathbb{Z}[1/n])$, and if j is maximal with this property, then we have for this subgroup $N(P)/C(P) \cong \mathbb{Z}/j\mathbb{Z}$ since $\langle \gamma_k \rangle \cong \mathbb{Z}/j\mathbb{Z}$. Since we showed that for any odd divisor $j \mid p-1$ a matrix $Y \in \text{Sp}(p-1, \mathbb{Z}[1/n])$ exists for which j powers are conjugate, we showed that for any $j \mid p-1$, j odd, a subgroup of order p exists in $\text{Sp}(p-1, \mathbb{Z}[1/n])$, for which $N(P)/C(P) \cong \mathbb{Z}/j\mathbb{Z}$. \square

4.2 The centralizer of subgroups of order p

Theorem 4.2. *Let $n \in \mathbb{Z}$ be such that $\mathbb{Z}[1/n][\xi]$ and $\mathbb{Z}[1/n][\xi + \xi^{-1}]$ are principal ideal domains. Then the centralizer $C(P)$ of a subgroup P of order p in $\text{Sp}(p-1, \mathbb{Z}[1/n])$ is*

$$C(P) \cong \mathbb{Z}/2p\mathbb{Z} \times \mathbb{Z}^{\sigma^+}$$

where $\sigma^+ = \sigma$ if $p \nmid n$, $\sigma^+ = \sigma + 1$ if $p \mid n$ and σ is the number of primes in $\mathbb{Z}[\xi + \xi^{-1}]$ that split in $\mathbb{Z}[\xi]$ and lie over primes in \mathbb{Z} that divide n .

Proof. Let $Y \in \mathrm{Sp}(p-1, \mathbb{Z}[1/n])$ be of order p and let $[a, a]$ be the equivalence class corresponding to the conjugacy class of Y . Let P be the subgroup generated by Y . Let $Z \in \mathrm{Sp}(p-1, \mathbb{Z}[1/n])$ be an element of the centralizer of Y , i.e. $Z^{-1}YZ = Y$ or $YZ = ZY$. Then Z is an element of the centralizer of P . If α is an eigenvector of Y to the eigenvalue ξ , then so is $Z\alpha$:

$$\xi Z\alpha = Z\xi\alpha = ZY\alpha = YZ\alpha.$$

But this means that $Z\alpha = w\alpha$ for some $w \in \mathbb{Z}[1/n][[\xi]]$ and w is a unit since Z is invertible. Therefore

$$\begin{aligned} (Z\alpha)^T J \overline{Z\alpha}^{(i)} &= \alpha^T Z^T J Z \overline{\alpha}^{(i)} = w\alpha^T J \overline{w}^{(i)} \overline{\alpha}^{(i)} \\ &= w \overline{w}^{(i)} \alpha^T J \overline{\alpha}^{(i)} = \delta_{1i} a w \overline{w}^{(i)} D \end{aligned}$$

and, since $\delta_{1i} = 0$ for $i \neq 1$, we get

$$(Z\alpha)^T J \overline{Z\alpha} = a w \overline{w} D.$$

But $Z \in \mathrm{Sp}(p-1, \mathbb{Z}[1/n])$ and therefore

$$(Z\alpha)^T J \overline{Z\alpha} = \alpha^T Z^T J Z \overline{\alpha} = \alpha^T J \overline{\alpha} = a D.$$

This implies that $w \overline{w} = 1$. In order to determine the centralizer $C(P)$ of a subgroup $P \subseteq \mathrm{Sp}(p-1, \mathbb{Z}[1/n])$ of order p , we have to find the units $w \in \mathbb{Z}[1/n][[\xi]]^*$ that satisfy $w \overline{w} = 1$. This corresponds to the kernel of the norm mapping

$$\begin{aligned} N : \mathbb{Z}[1/n][[\xi]]^* &\longrightarrow \mathbb{Z}[1/n][[\xi + \xi^{-1}]]^* \\ x &\longmapsto x \overline{x}. \end{aligned}$$

Brown [1] and Sjerve and Yang [11] showed that the kernel of the norm mapping

$$\begin{aligned} N' : \mathbb{Z}[[\xi]]^* &\longrightarrow \mathbb{Z}[[\xi + \xi^{-1}]]^* \\ x &\longmapsto x \overline{x} \end{aligned}$$

is the set of roots of unity

$$\ker(N') = \{\pm \xi^r \mid \xi^p = 1, 1 \leq r \leq p\}.$$

It is obvious that $\ker(N') \subseteq \ker(N)$. The prime ideals that lie over the primes in \mathbb{Z} and divide n yield units in $\mathbb{Z}[1/n][[\xi]]^* \setminus \mathbb{Z}[[\xi]]^*$. Let $\mathfrak{q}^+ \subseteq \mathbb{Z}[[\xi + \xi^{-1}]]^*$ be a prime over a prime $q \mid n$ and let $\mathfrak{q} \subseteq \mathbb{Z}[[\xi]]^*$ be a prime over \mathfrak{q}^+ . If \mathfrak{q}^+ is inert, then $\mathfrak{q} = \overline{\mathfrak{q}}$ and if \mathfrak{q}^+ splits, then $\mathfrak{q}^+ \mathbb{Z}[[\xi]] = \mathfrak{q} \overline{\mathfrak{q}}$. A generalization for S -units of the Dirichlet unit theorem says that for each prime \mathfrak{q}_j , $j = 1, \dots, k$, over n a $g_j \in \mathfrak{q}_j$ exists such that any unit $u \in (\mathbb{Z}[1/n][[\xi]])^*$ can be written as

$$u = u' g_1^{n_1} \dots g_k^{n_k}$$

where $u' \in \mathbb{Z}[\xi]^*$, $n_j \in \mathbb{Z}$, $j = 1, \dots, k$. So the group of units $\mathbb{Z}[1/n][\xi + \xi^{-1}]^*$ is generated by $\mathbb{Z}[\xi + \xi^{-1}]^*$, the inert primes over n , the primes over n that split and, if $p \mid n$, the prime over p . The inert primes yield nontrivial elements in $\mathbb{Z}[1/n][\xi + \xi^{-1}]^*/N(\mathbb{Z}[1/n][\xi]^*)$ since for those holds $w\bar{w} = w^2 \neq 1$ for $w \neq \pm 1$. The centralizer $C(P)$ is a finitely generated group whose torsion subgroup is isomorphic to the group of roots of unity in $\mathbb{Q}(\xi)$ and whose rank is equal to σ if $p \nmid n$ and to $\sigma + 1$ if $p \mid n$ where

$$\sigma^+ = \text{rank}(\mathbb{Z}[1/n][\xi]^*) - \text{rank}(\mathbb{Z}[1/n][\xi + \xi^{-1}]^*).$$

This difference is equal to the number of primes in $\mathbb{Z}[\xi + \xi^{-1}]$ that split or ramify in $\mathbb{Z}[\xi]$ and lie over primes in \mathbb{Z} that divide n . This follows directly from a generalization of the Dirichlet unit theorem and proves our theorem. \square

4.3 The action of the normalizer on the centralizer of subgroups of order p

Theorem 4.3. *Let $N(P)$ be the normalizer and $C(P)$ the centralizer of a subgroup P of order p in $\text{Sp}(p-1, \mathbb{Z}[1/n])$. Let p be an odd prime, ξ a primitive p th root of unity, $n \in \mathbb{Z}$ such that $\mathbb{Z}[1/n][\xi]$ and $\mathbb{Z}[1/n][\xi + \xi^{-1}]$ are principal ideal domains and moreover $p \mid n$. Then the action of $N(P)/C(P)$ on $C(P)$ is given by the action of the Galois group $\text{Gal}(\mathbb{Q}(\xi)/\mathbb{Q})$ on the group of units $\mathbb{Z}[1/n][\xi]^*$. Moreover $N(P)/C(P)$ acts faithfully on $C(P)$.*

Proof. We have seen in the proof of Theorem 4.2 that the centralizer of a subgroup of order p in $\text{Sp}(p-1, \mathbb{Z}[1/n])$ is given by the kernel of the norm mapping $\mathbb{Z}[1/n][\xi]^* \rightarrow \mathbb{Z}[1/n][\xi + \xi^{-1}]^*$, $x \mapsto x\bar{x}$. Herewith the centralizer is isomorphic to a subgroup of the group of units $\mathbb{Z}[1/n][\xi]^*$. In the proof of Theorem 4.1 we identify the quotient $N(P)/C(P)$ with a subgroup of the Galois group $\text{Gal}(\mathbb{Q}(\xi)/\mathbb{Q})$. Herewith the action of the quotient $N(P)/C(P)$ on the centralizer $C(P)$ is given by the action of the subgroup of $\text{Gal}(\mathbb{Q}(\xi)/\mathbb{Q})$ corresponding to $N(P)/C(P)$ on the kernel of the norm mapping $\mathbb{Z}[1/n][\xi]^* \rightarrow \mathbb{Z}[1/n][\xi + \xi^{-1}]^*$. Since it is nontrivial, the action of $N(P)/C(P)$ on $C(P)$ is faithful. \square
