# On the Geometry of Inhomogeneous Quantum Groups 

Paolo Aschieri<br>Scuola Normale Superiore<br>Piazza dei Cavalieri 7, 56100 Pisa, Italy<br>and<br>Theoretical Physics Group<br>Lawrence Berkeley Laboratory,<br>University of California<br>Berkeley, California 94720, USA

#### Abstract

We give a pedagogical introduction to the differential calculus on quantum groups by stressing at all stages the connection with the classical case. We further analize the relation between differential calculus and quantum Lie algebra of left (right) invariant vectorfields. Equivalent definitions of bicovariant differential calculus are studied and their geometrical interpretation is explained. From these data we construct and analize the space of vectorfields, and naturally introduce a contraction operator and a Lie derivative, their properties are discussed.

After a review of the geometry of the multiparametric deformation of the linear group $G L_{q, r}(N)$ and its real forms, we then construct the multiparametric linear inhomogeneous quantum group $I G L_{q, r}(N)$ as a projection from $G L_{q, r}(N+1)$, or equivalently, as a quotient of $G L_{q, r}(N+1)$ with respect to a suitable Hopf algebra ideal. The semidirect product structure of $I G L_{q, r}(N)$ given by the $G L_{q, r}(N)$ quantum subgroup times translations is analized. A bicovariant differential calculus on $I G L_{q, r}(N)$ is explicitly obtained as a projection from the one on $G L_{q, r}(N+1)$. The universal enveloping algebra of $I G L_{q, r}(N)$ and its $R$-matrix formulation are constructed along the same lines. This quotient procedure unifies in a single structure the quantum plane coordinates and the $q$-group matrix elements $T^{a}{ }_{b}$, and allows to deduce without effort the differential calculus on the $q$-plane $I G L_{q, r}(N) / G L_{q, r}(N)$. The general theory is illustrated on the example of $I G L_{q, r}(2)$.

We proceed similarly in the orthogonal and symplectic case. The inhomogeneous multiparametric $q$-groups of the $B_{n}, C_{n}, D_{n}$ series are found by means of a projection from $B_{n+1}, C_{n+1}, D_{n+1}$. A matrix formulation is given in terms of the $R$-matrix of $B_{n+1}, C_{n+1}, D_{n+1}$, and real forms are discussed: in particular we obtain the $q$ groups $I S O_{q, r}(n+1, n-1)$, including the quantum Poincaré group. The universal enveloping algebras of the multiparametric $B_{n+1}, C_{n+1}, D_{n+1} q$-groups are studied, they include as Hopf subalgebras the universal enveloping algebras of the inhomogeneous $B_{n}, C_{n}, D_{n}$. Bicovariant calculi on the minimal multiparametric deformations (twists) of these inhomogeneous groups are similarly found by means of a projection from the bicovariant calculus on $B_{n+1}, C_{n+1}, D_{n+1}$. In particular we obtain the bicovariant calculus on a dilatation-free minimal deformation of the Poincaré group $I S O_{q}(3,1)$. Then we construct differential calculi on multiparametric quantum orthogonal planes in any dimension $N$. These calculi are bicovariant under the action of the full inhomogeneous multiparametric quantum group $I S O_{q, r}(N)$, and do contain dilatations. We find a canonical group-geometric procedure to restrict these calculi on the $q$-plane and expressed them in terms of coordinates $x^{a}$, differentials $d x^{a}$ and partial derivatives $\partial_{a}$ without the need of dilatations, thus generalizing known results to the multiparametric case.Real forms are studied and in particular we obtain the quantum Minkowski space $I S O_{q, r}(3,1) / S O_{q, r}(3,1)$. The conjugated partial derivatives $\partial_{a}^{*}$ can be expressed as linear combinations of the $\partial_{a}$. This allows a deformation of the phase-space with hermitian operators $x^{a}$ and $p_{a}$.

## Acknowledgements

I am glad to thank Professor Leonardo Castellani for his guidance, for his support and encouragement I have always received, and for sharing the many moments of research. All this in a stimulating and friendly atmosphere.

I am grateful to Professor Corrado De Concini for his advice and for the many explanations that have enhanced my mathematical understanding of the subject. There are many colleagues I am indebted with, in particular Luigi Pilo and Peter Schupp.

About this year in Berkeley I would like to thank Professor Bruno Zumino for his advice, his support and the stimulating environment I experience. I also thank Professor Nicolai Reshetikhin for his suggestions. I am pleased to aknowledge the many fruitful discussions with Bogdan Morariu, Harold Steinacker and Gaetano Fiore.

This thesis has been possible also because of the support and affection of my parents. To them my gratitude.

This work in 1997 has been supported by an exchange fellowship Scuola Normale Superiore - University of California and by a research fellowship of Fondazione Angelo Della Riccia. It has been accomplished through the Director, Office of Energy Research, Office af High Energy and Nuclear Physics, Division of High Energy Physics of the U.S. Department of Energy under Contract DE-AC03-76SF00098 and by the National Science Foundation under grant PHY-95-14797.

## Introduction

Quantum Groups are particular deformations of Lie Groups. They are algebraic structures $G_{q}$ depending on one (or more) continuous parameter $q$. When $q=1$ we have a standard Lie group.

A method to modify a group could be to continuously deform the structure constants of the relative Lie algebra. This kind of deformations is uninteresting because it can be shown that for a semisimple Lie group, with a suitable redefinition of the generators it is always possible to recover the undeformed structure constants. At most, for special values of the deformation parameter, we get a contraction of the original group. (For example the Galilei group is a contraction of the Lorentz group, and the Poincaré group is a contraction of the de Sitter group).

Quantum deformations, on the contrary, allow to obtain new structures not isomorphic to the preceding ones. For example the quantum $S U(2)$ group is given by

$$
\begin{equation*}
\left[J^{+}, J^{-}\right]=\frac{q^{2 J^{0}}-q^{-2 J^{0}}}{q-q^{-1}} \quad, \quad\left[J^{0}, J^{ \pm}\right]= \pm J^{ \pm} \tag{0.0.1}
\end{equation*}
$$

Here we clearly see that the commutator depends continuously on $q$, moreover we loose the concept of structure constant (in sections 2.1 and 2.3 , we will see a generalization of this concept). We however still have a rich structure (Hopf algebra structure), as rich as the $S U(2)$ one [16], [17]. In the $q \rightarrow 1$ limit we recover the $S U(2)$ algebra $\left[J^{+}, J^{-}\right]=2 J^{0},\left[J^{0}, J^{ \pm}\right]= \pm J^{ \pm}$. Relations (0.0.1) define the universal enveloping algebra of $S U(2)$, i.e. the space given by all (formal) polynomials $\sum \lambda_{m n p}\left(J^{0}\right)^{m}\left(J^{+}\right)^{n}\left(J^{-}\right)^{p}$ where the ordering is always possible thanks to (0.0.1).

We know that a new physical theory can always be seen as a generalization of the previous existing one, in the sense that this is recovered as a limiting case in which some parameters of the new theory become negligible, e.g. special relativity where the Galilei symmetry group is replaced by the Lorentz one. Here the deformation parameter is $c$, and for $c \rightarrow \infty$ we recover Galiley relativity. The study of continuous deformation of Lie groups is therefore physically interesting, the symmetry group underlying many (particle) physics theories being Lie Groups.

The deformations we will deal with are in the context of noncommutative geometry. Both the group coordinates and the space coordinates on which the group
acts, consist of non-commuting elements. It is of interest to apply these rich mathematical structures to the study of spacetime physics at Planck scale. Indeed at this scale due to the gravitational forces, Gedanken experiments show that it is not possible to probe spacetime structuref, the description of spacetime as a smooth manifold becomes just a mathematical assumption. We can relax it and conceive a more general noncommutative structure. This is intresting because in a noncommutative spacetime uncertainty relations and discretization naturally arise. In this way one could incorporate the impossibility of an operational definition of spacetime structure beyond the Planck scale (due to gravity) in the noncommutative geometric structure of spacetime itself. A dynamic feature of spacetime would be incorporated at a kinematical level. This could be a fertile setting for the study of quantum gravity and field theory at Planck scale.

The easiest example of noncommuting space is given by the quantum plane, 48, 49, 50] where the coordinates $x$ and $y$ satisfy $x y=q y x$ where $q$ is a complex parameter. The $q$-plane and similar higher dimensional $q$-spaces admit a differential structure where the derivative operators are finite difference operators. This resembles lattice like structures. At the phase-space level the quantum plane relations imply expressions of the type $x \partial_{x}-q \partial_{x} x=1$ that lead to selfadjoint position and momentum operators with discrete heigenvalues: we obtain again a lattice structure [9]. In this context $q$ may play the role of short distance regularization parameter preserving the $q$-symmetries, see also (10. In the particular deformations where $q$ is a dimensionful parameter, one can also try to relate this parameter to the Planck length [11].

Notice that a minimal uncertainty relation in position measurement is also in agreement with string theory models [2]. Moreover, non-perturbative attempts to describe string theories have shown that a noncommutative structure of spacetime emerges [3], noncommutative geometry can be the correct geometrical framework for the description of such theories [4].

In our study of inhomogeneous $q$-groups we will consider examples of noncommuting quantum planes (in 2 and higher dimension) that have quantum symmetry groups. This is not the only approach to a possible model of noncommutative spacetime. For example one can consider a noncommutative Minkowski spacetime which is covariant under the classical Poincaré group, see [5], and [6] where also first attempts to construct quantum field theories on noncommutative spaces have shown that in some cases these theories are equivalent to a non local quantum field theory on ordinary space. We also mention a related approach [8] that, in the spirit

[^0]of [7], uses noncommutative geometric methods to study a Kaluza-Klein gravity theory with a discrete two point internal space.

In this thesis we generalize to Hopf algebras basic structures of differential geometry on commutative manifolds, we then examine examples of inhomogeneous quantum groups and consider their differential calculus.

In the first chapters we introduce the concept of quantum group, and, stressing at all stages the connection with the classical case ( $q \rightarrow 1$ limit), we develop the differential calculus on quantum groups, first studied in the seminal paper by Woronowicz [21. We then examine in detail the quantum Lie algebra of left-invariant vectorfields (see Section 2.3). All the properties of the differential calculus can be derived from intuitive properties of the $q$-Lie algebra, in this way we emphasize the space of vectorfields that is more fundamental, for physical applications, than the space of 1forms. For example, this $q$-Lie algebras are a good starting point for the formulation of gauge theories based on deformed Lie groups [12]. Next, a Lie derivative and a contraction operator (inner derivative) are found and, for left-invariant vectorfields, we prove the Cartan identity $\ell_{\vec{t}}=i_{\vec{t}} d+d i_{\vec{t}}$ [27, 26, 34, 37]. These are basic tools in differential geometry, and are of interest in a geometric formulation of Einstein gravity. For example the invariance of Einstein action under diffeomorphisms can be expressed by $\ell_{\vec{t}} \int \mathcal{L} d^{4} x=0$, this relation leads to the covariant conservation of the matter energy-momentum tensor (if torsion vanishes). Also, in the soft group manifold approach to gravity theories [13], the Cartan-Maurer equation, the Lie derivative and the contraction operator for the $q$-Poincaré group are fundamental to formulate a geometric definition of curvature, covariant derivative and Lorentz gauge transformation. There the curved general relativity space time (with the Lorentz gauge group) is obtained as the coset space Poincaré/Lorentz where the rigid Poincaré group structure has been softened allowing for a curvature two form term in the Cartan-Maurer equations. For a first example of this construction in the case of a minimal $q$-deformation (twist) of the Poincaré group see 14.

The second part of this thesis deals with the specific study of deformations of the inhomogeneous general linear group $G L(N)$ and of the inhomogeneous orthogonal and symplectyc groups. Contrary to the case of semisimple Lie groups [where there is a canonical Poisson (symplectic) structure that can be quantized to give the quantum group] there is not a canonical deformation procedure for these groups; providing examples of inhomogeneous deformation is therefore per se interesting. The $G L(N)$ and $S L(N)$ cases are easier to consider than the orthogonal and symplectic ones and the basic structures of inhomogeneous quantum groups are first found in this cases and later shown for the $B_{n}, C_{n}, D_{n}$ series as well. There are many studies on inhomogeneous quantum groups [65, 57, 58, 59] and in particular on deformed Poincaré groups [66]. The analysis we present 60], [67] is based on a quotient procedure, we find deformations of the inhomogeneous version of the $A_{n}, B_{n}, C_{n}, D_{n}$ groups via a quotient from the $q$-deformed homoge-
neous $A_{n+1}, B_{n+1}, C_{n+1}, D_{n+1}$ groups. An $R$-matrix formulation is thus provided. The universal enveloping algebra of these groups is also studied as well as their semidirect product structure of their homogeneous subgroups times translations. Then we apply the general theory of the differential calculus on $q$-groups to these specific cases. Differential calculi on these inhomogeneous $q$-groups are found using again the quotient structure with respect to $A_{n+1}, B_{n+1}, C_{n+1}, D_{n+1}$.

In particular we obtain a deformation of the Poincaré group, of its $q$-Lie algebra and differential calculus. It turns out that the differential calculus on inhomogeneous orthogonal and symplectic quantum groups, contrary to the linear case, cannot be constructed for general values of the deformation parameters. It exists only for minimal deformations (twists), these are the same noncommutative deformations that do not require the presence of a dilatation in the fully $q$-deformed inhomogeneous structure. Our analysis includes the first example of bicovariant differential calculus on quantum Poincaré group with deformed Lorentz subgroup. For bicovariant calculi on other deformations of the Poincaré group see [70. The study of the differential calculi on orthogonal groups discussed in Chapter 4, leads to a good candidate for the differential calculus on the $q$-orthogonal planes and in particular on the $q$-Minkowski plane, with no restriction on the deformation parameters. Using the powerful result: $q$-Minkowski $=q$-Poincaré $/ q$-Lorentz, we derive canonically the $q$-Minkowski geometry from the $q$-Poincaré geometry [55]. In this way we rederive the known results of 48, 53, 54] using the broader setting of the differential calculus on quantum $I S O(N)$. A detailed analysis of the reality condition on the quantum Minkowski plane is possible since on the quantum $\operatorname{ISO}(3,1)$ differential calculus there is a canonical definition of $*$-conjugation. This operation is linear and one can canonically obtain real coordinates and momenta and a $q$ version of the Heisenberg $x, p$ commutation relations. An interesting issue, in the spirit of 99 is then the analysis of the representations in Hilbert space of this algebra in order to study the admissible (discrete) values of momentum and position of particle states.

## Chapter 1

## Quantum Groups

### 1.1 Hopf structures in ordinary Lie groups and Lie algebras

Let us begin by considering $\operatorname{Fun}(G)$, the set of differentiable functions from a Lie group $G$ into the complex numbers C. $\operatorname{Fun}(G)$ is an algebra with the usual pointwise sum and product $(f+h)(g)=f(g)+h(g),(f \cdot h)=f(g) h(g),(\lambda f)(g)=$ $\lambda f(g)$, for $f, h \in \operatorname{Fun}(G), g \in G, \lambda \in \mathbf{C}$. The unit of this algebra is $I$, defined by $I(g)=1, \forall g \in G$.

Using the group structure of $G$, we can introduce on $\operatorname{Fun}(G)$ three other linear mappings, the coproduct $\Delta$, the counit $\varepsilon$, and the coinverse (or antipode) $\kappa$ :

$$
\begin{align*}
\Delta(f)\left(g, g^{\prime}\right) & \equiv f\left(g g^{\prime}\right), \quad \Delta: \operatorname{Fun}(G) \rightarrow \operatorname{Fun}(G) \otimes \operatorname{Fun}(G)  \tag{1.1.1}\\
\varepsilon(f) & \equiv f\left(1_{G}\right), \quad \varepsilon: \operatorname{Fun}(G) \rightarrow \mathbf{C}  \tag{1.1.2}\\
(\kappa f)(g) & \equiv f\left(g^{-1}\right), \quad \kappa: \operatorname{Fun}(G) \rightarrow \operatorname{Fun}(G) \tag{1.1.3}
\end{align*}
$$

where $1_{G}$ is the unit of $G$. It is not difficult to verify the following properties of the co-structures:

$$
\begin{align*}
& (i d \otimes \Delta) \Delta=(\Delta \otimes i d) \Delta \quad(\text { coassociativity of } \Delta)  \tag{1.1.4}\\
& (i d \otimes \varepsilon) \Delta(a)=(\varepsilon \otimes i d) \Delta(a)=a  \tag{1.1.5}\\
& m(\kappa \otimes i d) \Delta(a)=m(i d \otimes \kappa) \Delta(a)=\varepsilon(a) I \tag{1.1.6}
\end{align*}
$$

and

$$
\begin{array}{ll}
\Delta(a b)=\Delta(a) \Delta(b), & \Delta(I)=I \otimes I \\
\varepsilon(a b)=\varepsilon(a) \varepsilon(b), & \varepsilon(I)=1 \\
\kappa(a b)=\kappa(b) \kappa(a), & \kappa(I)=I \tag{1.1.9}
\end{array}
$$

where $a, b \in A=\operatorname{Fun}(G)$ and $m$ is the multiplication map $m(a \otimes b) \equiv a b$. The product in $\Delta(a) \Delta(b)$ is the product in $A \otimes A:(a \otimes b)(c \otimes d)=a b \otimes c d$.

In general a coproduct can be expanded on $A \otimes A$ as:

$$
\begin{equation*}
\Delta(a)=\sum_{i} a_{1}^{i} \otimes a_{2}^{i} \equiv a_{1} \otimes a_{2}, \tag{1.1.10}
\end{equation*}
$$

where $a_{1}^{i}, a_{2}^{i} \in A$ and $a_{1} \otimes a_{2}$ is a shorthand notation we will often use in the sequel. For example for $A=\operatorname{Fun}(G)$ we have:

$$
\begin{equation*}
\Delta(f)\left(g, g^{\prime}\right)=\left(f_{1} \otimes f_{2}\right)\left(g, g^{\prime}\right)=f_{1}(g) f_{2}\left(g^{\prime}\right)=f\left(g g^{\prime}\right) \tag{1.1.11}
\end{equation*}
$$

Using (1.1.11), the proof of (1.1.4)-(1.1.6) is immediate. We will also use the following notation: $\Delta^{2}(a) \equiv(\Delta \otimes i d) \Delta(a)=(i d \otimes \Delta) \Delta(a)=a_{1} \otimes a_{2} \otimes a_{3}$, more in general $\Delta^{n}(a)=a_{1} \otimes a_{2} \otimes, \ldots a_{n+1}$.

An algebra $A$ endowed with the homomorphisms $\Delta: A \rightarrow A \otimes A$ and $\varepsilon: A \rightarrow \mathbf{C}$, and the antimorphism $\kappa: A \rightarrow A$ satisfying the properties (1.1.4)-(1.1.9) is a Hopf algebra. Thus $\operatorname{Fun}(G)$ is a Hopf algebra. $\square$ Note that the properties (1.1.4)-(1.1.9) imply the relations:

$$
\begin{align*}
& \Delta(\kappa(a))=\kappa\left(a_{2}\right) \otimes \kappa\left(a_{1}\right), \quad \kappa(a)_{1} \otimes \kappa(a)_{2}, \ldots \kappa(a)_{n}=\kappa\left(a_{n}\right) \otimes \kappa\left(a_{n-1}\right), \ldots \kappa\left(a_{1}\right)  \tag{1.1.12}\\
& \varepsilon(\kappa(a))=\varepsilon(a) . \tag{1.1.13}
\end{align*}
$$

Consider now the algebra $A$ of polynomials in the matrix elements $T^{a}{ }_{b}$ of the fundamental representation of $G$, i.e. the algebra $A$ generated by the $T^{a}{ }_{b}$.

It is clear that $A \subset \operatorname{Fun}(G)$, since $T^{a}{ }_{b}(g)$ are functions on $G$. In fact $A$ is dense in $\operatorname{Fun}(G)$ [the reason is that the matrix elements of all finite irreducible dimensional representations of $G$ can be constructed out of appropriate products of $T^{a}{ }_{b}(g)$; these products span a dense subset in $\operatorname{Fun}(G)$ because the matrix elements of all irreducible representations of $G$ form a complete basis of $\operatorname{Fun}(G)$ ], therefore, a suitable completion $\hat{A}$ of $A$ is $\operatorname{Fun}(G): \hat{A}=\operatorname{Fun}(G)$. In the following we will drop the hat and we will not be concerned about these topological aspects. The group manifold $G$ can be completely characterized by $\operatorname{Fun}(G)$, the co-structures on Fun $(G)$ carrying the information about the group structure of $G$. Thus a classical Lie group can be "defined" as the algebra $A$ generated by the (commuting) matrix elements $T^{a}{ }_{b}$ of the fundamental representation of $G$, seen as functions on $G$. This definition admits noncommutative generalizations, i.e. the quantum groups discussed in the next section.

Using the elements $T^{a}{ }_{b}$ we can write an explicit formula for the expansion (1.1.10) or (1.1.11): indeed (1.1.1) becomes

$$
\begin{equation*}
\Delta\left(T^{a}{ }_{b}\right)\left(g, g^{\prime}\right)=T^{a}{ }_{b}\left(g g^{\prime}\right)=T^{a}{ }_{c}(g) T^{c}{ }_{b}\left(g^{\prime}\right), \tag{1.1.14}
\end{equation*}
$$

[^1]since $T$ is a matrix representation of $G$. Therefore:
\[

$$
\begin{equation*}
\Delta\left(T_{b}^{a}\right)=T_{c}^{a}{ }_{c} \otimes T_{b}^{c} . \tag{1.1.15}
\end{equation*}
$$

\]

Moreover, using (1.1.2) and (1.1.3), one finds:

$$
\begin{align*}
& \varepsilon\left(T^{a}{ }_{b}\right)=\delta_{b}^{a}  \tag{1.1.16}\\
& \kappa\left(T^{a}{ }_{b}\right)=\left(T^{-1}\right)^{a}{ }_{b} . \tag{1.1.17}
\end{align*}
$$

Thus the algebra $A=\operatorname{Fun}(G)$ of polynomials in the elements $T^{a}{ }_{b}$ is a Hopf algebra with co-structures defined by (1.1.15)-(1.1.17) and (1.1.7)-(1.1.9).

Another example of Hopf algebra is given by any ordinary Lie algebra $g$, or more precisely by the universal enveloping algebra $U(g)$ of a Lie algebra $g$, i.e. (by the Poincaré-Birkhoff-Witt theorem) the algebra, with unit $I$, of polynomials in the generators $\chi_{i}$ modulo the commutation relations

$$
\begin{equation*}
\left[\chi_{i}, \chi_{j}\right]=C_{i j}{ }^{k} \chi_{k} . \tag{1.1.18}
\end{equation*}
$$

Here we define the co-structures as:

$$
\begin{array}{ll}
\Delta^{\prime}\left(\chi_{i}\right)=\chi_{i} \otimes I+I \otimes \chi_{i} & \Delta^{\prime}(I)=I \otimes I \\
\varepsilon^{\prime}\left(\chi_{i}\right)=0 & \varepsilon^{\prime}(I)=1 \\
\kappa^{\prime}\left(\chi_{i}\right)=-\chi_{i} & \kappa^{\prime}(I)=I \tag{1.1.21}
\end{array}
$$

The reader can check that (1.1.4)-(1.1.6) are satisfied.

### 1.2 Quantum groups. The example of $G L_{q}(2)$

Quantum groups can be introduced as noncommutative deformations of the algebra $A=\operatorname{Fun}(G)$ of the previous section [more precisely as noncommutative Hopf algebras obtained by continuous deformations of the Hopf algebra $A=F u n(G)]$. The term quantum stems for the fact that they are obtained quantizing a Poisson (symplectic) structure of the algebra $\operatorname{Fun}(G)$ [16]. Here, following [19] (see also [20]), we will consider quantum groups defined as the associative algebras $A$ freely generated by non-commuting matrix entries $T^{a}{ }_{b}$ satisfying the relation

$$
\begin{equation*}
R^{a b}{ }_{e f} T^{e}{ }_{c} T^{f}{ }_{d}=T^{b}{ }_{f} T^{a}{ }_{e} R^{e f}{ }_{c d} \tag{1.2.1}
\end{equation*}
$$

and some other conditions depending on which classical group we are deforming (see later). The matrix $R$ controls the non-commutativity of the $T^{a}{ }_{b}$, and its elements depend continuously on a (in general complex) parameter $q$, or even a set of parameters. For $q \rightarrow 1$, the so-called "classical limit", we have

$$
\begin{equation*}
R_{c d}^{a b} \xrightarrow{q \rightarrow 1} \delta_{c}^{a} \delta_{d}^{b}, \tag{1.2.2}
\end{equation*}
$$

i.e. the matrix entries $T^{a}{ }_{b}$ commute for $q=1$, and one recovers the ordinary Fun $(G)$.

The associativity of $A$ leads to a consistency condition on the $R$ matrix, the quantum Yang-Baxter equation:

$$
\begin{equation*}
R_{a_{2} b_{2}}^{a_{1} b_{1}} R_{a_{3} c_{2}}^{a_{2} c_{1}} R_{b_{3} c_{3}}^{b_{2} c_{2}}=R_{b_{2} c_{2}}^{b_{1} c_{1}} R_{a_{2} c_{3}}^{a_{1} c_{2}} R_{a_{3} b_{3}}^{a_{2} b_{2}} . \tag{1.2.3}
\end{equation*}
$$

For simplicity we rewrite the "RTT" equation (1.2.1) and the quantum Yang-Baxter equation as

$$
\begin{align*}
R_{12} T_{1} T_{2} & =T_{2} T_{1} R_{12}  \tag{1.2.4}\\
R_{12} R_{13} R_{23} & =R_{23} R_{13} R_{12}, \tag{1.2.5}
\end{align*}
$$

where the subscripts 1,2 and 3 refer to different couples of indices. Thus $T_{1}$ indicates the matrix $T^{a}{ }_{b}, T_{1} T_{1}$ indicates $T^{a}{ }_{c} T^{c}{ }_{b}, R_{12} T_{2}$ indicates $R^{a b}{ }_{c d} T^{d}{ }_{e}$ and so on, repeated subscripts meaning matrix multiplication. The quantum Yang-Baxter equation ( $\mathbb{1 . 2 . 5 )}$ ) is a condition sufficient for the consistency of the RTT equation (1.2.4). Indeed the product of three distinct elements $T^{a}{ }_{b}, T^{c}{ }_{d}$ and $T^{e}{ }_{f}$, indicated by $T_{1} T_{2} T_{3}$, can be reordered as $T_{3} T_{2} T_{1}$ via two differents paths:

$$
T_{1} T_{2} T_{3} \searrow \begin{align*}
& T_{1} T_{3} T_{2} \rightarrow T_{3} T_{1} T_{2}  \tag{1.2.6}\\
& \searrow T_{2} T_{1} T_{3} \rightarrow T_{2} T_{3} T_{1}
\end{align*} \text { Ø } T_{3} T_{2} T_{1}
$$

by repeated use of the RTT equation. The relation (1.2.5) ensures that the two paths lead to the same result.

The algebra $A$ ("the quantum group") is a noncommutative Hopf algebra whose co-structures are the same of those defined for the commutative Hopf algebra $F u n(G)$ of the previous section, eqs. (1.1.15)-(1.1.17), (1.1.7)-(1.1.9).

Let us give the example of $S L_{q}(2) \equiv F u n_{q}(S L(2))$, the algebra freely generated by the elements $\alpha, \beta, \gamma$ and $\delta$ of the $2 \times 2$ matrix

$$
T^{a}{ }_{b}=\left(\begin{array}{cc}
\alpha & \beta  \tag{1.2.7}\\
\gamma & \delta
\end{array}\right)
$$

satisfying the commutations

$$
\begin{gather*}
\alpha \beta=q \beta \alpha, \quad \alpha \gamma=q \gamma \alpha, \quad \beta \delta=q \delta \beta, \quad \gamma \delta=q \delta \gamma \\
\beta \gamma=\gamma \beta, \quad \alpha \delta-\delta \alpha=\left(q-q^{-1}\right) \beta \gamma, \quad q \in \mathbf{C} \tag{1.2.8}
\end{gather*}
$$

and

$$
\begin{equation*}
\operatorname{det}_{q} T \equiv \alpha \delta-q \beta \gamma=I \tag{1.2.9}
\end{equation*}
$$

The commutations (1.2.8) can be obtained from (1.2.1) via the $R$ matrix

$$
R^{a b}{ }_{c d}=\left(\begin{array}{cccc}
q & 0 & 0 & 0  \tag{1.2.10}\\
0 & 1 & 0 & 0 \\
0 & q-q^{-1} & 1 & 0 \\
0 & 0 & 0 & q
\end{array}\right)
$$

where the rows and columns are numbered in the order 11, 12, $21,22$.
It is easy to verify that the "quantum determinant" defined in (1.2.9) commutes with $\alpha, \beta, \gamma$ and $\delta$, so that the requirement $\operatorname{det}_{q} T=I$ is consistent. The matrix inverse of $T^{a}{ }_{b}$ is

$$
\left(T^{-1}\right)^{a}{ }_{b}=\left(\operatorname{det}_{q} T\right)^{-1}\left(\begin{array}{cc}
\delta & -q^{-1} \beta  \tag{1.2.11}\\
-q \gamma & \alpha
\end{array}\right)
$$

The coproduct, counit and coinverse of $\alpha, \beta, \gamma$ and $\delta$ are determined via formulas (1.1.15)-(1.1.17) to be:

$$
\begin{array}{r}
\Delta(\alpha)=\alpha \otimes \alpha+\beta \otimes \gamma, \quad \Delta(\beta)=\alpha \otimes \beta+\beta \otimes \delta \\
\Delta(\gamma)=\gamma \otimes \alpha+\delta \otimes \gamma, \quad \Delta(\delta)=\gamma \otimes \beta+\delta \otimes \delta \\
\varepsilon(\alpha)=\varepsilon(\delta)=1, \quad \varepsilon(\beta)=\varepsilon(\gamma)=0 \\
\kappa(\alpha)=\delta, \quad \kappa(\beta)=-q^{-1} \beta, \quad \kappa(\gamma)=-q \gamma, \quad \kappa(\delta)=\alpha . \tag{1.2.14}
\end{array}
$$

Note 1.2.1 In general $\kappa^{2} \neq 1$, as can be seen from (1.2.14). The following useful relation holds (19):

$$
\begin{equation*}
\kappa^{2}\left(T^{a}{ }_{b}\right)=D^{a}{ }_{c} T^{c}{ }_{d}\left(D^{-1}\right)^{d}{ }_{b}=d^{a} d_{b}^{-1} T^{a}{ }_{b}, \tag{1.2.15}
\end{equation*}
$$

where $D$ is a diagonal matrix, $D^{a}{ }_{b}=d^{a} \delta_{b}^{a}$, given by $d^{a}=q^{2 a-1}$ for the $q$-groups $A_{n-1}$ and $G L_{q}(n)$.

Note 1.2.2 The commutations (1.2.8) are compatible with the coproduct $\Delta$, in the sense that $\Delta(\alpha \beta)=q \Delta(\beta \alpha)$ and so on. In general we must have

$$
\begin{equation*}
\Delta\left(R_{12} T_{1} T_{2}\right)=\Delta\left(T_{2} T_{1} R_{12}\right) \tag{1.2.16}
\end{equation*}
$$

which is easily verified using $\Delta\left(R_{12} T_{1} T_{2}\right)=R_{12} \Delta\left(T_{1}\right) \Delta\left(T_{2}\right)$ and $\Delta\left(T_{1}\right)=T_{1} \otimes T_{1}$. This is equivalent to proving that the matrix elements of the matrix product $T_{1} T_{1}^{\prime}$, where $T^{\prime}$ is a matrix [satisfying (1.2.1)] whose elements commute with those of $T^{a}{ }_{b}$, still obey the commutations (1.2.4).

Note 1.2.3 $\Delta\left(\operatorname{det}_{q} T\right)=\operatorname{det}_{q} T \otimes \operatorname{det}_{q} T$ so that the coproduct property $\Delta(I)=I \otimes I$ is compatible with $\operatorname{det}_{q} T=I$.

Note 1.2.4 The condition ( $\boxed{\boxed{2} .2 .9)}$ can be relaxed. Then we have to include the central element $\zeta=\left(\operatorname{det}_{q} T\right)^{-1}$ in $A$, so as to be able to define the inverse of the
$q$-matrix $T^{a}{ }_{b}$ as in (1.2.11), and the coinverse of the element $T^{a}{ }_{b}$ as in (1.1.17). The $q$-group is then $G L_{q}(2)$. The reader can deduce the co-structures on $\zeta: \Delta(\zeta)=$ $\zeta \otimes \zeta, \varepsilon(\zeta)=1, \kappa(\zeta)=\operatorname{det}_{q} T$.

Note 1.2.5 More generally, the quantum determinant of $n \times n q$-matrices is defined by $\operatorname{det}_{q} T=\sum_{\sigma}(-q)^{l(\sigma)} T^{1}{ }_{\sigma(1)} \cdots T^{n}{ }_{\sigma(n)}$, where $l(\sigma)$ is the minimal number of inversions in the permutation $\sigma$. Then $\operatorname{det}_{q} T=1$ restricts $G L_{q}(n)$ to $S L_{q}(n)$.

Note 1.2.6 The explicit expression of the $R$-matrices for the A,B,C,D $q$-groups will be given later. Here we recall the important relations 19 for the $\hat{R}$ matrix defined by $\hat{R}^{a b}{ }_{c d} \equiv R^{b a}{ }_{c d}$, whose $q=1$ limit is the permutation operator $\delta_{d}^{a} \delta_{c}^{b}$ :

$$
\begin{gather*}
\hat{R}^{2}=\left(q-q^{-1}\right) \hat{R}+I, \text { for } A_{n-1} \quad \text { (Hecke condition) }  \tag{1.2.17}\\
(\hat{R}-q I)\left(\hat{R}+q^{-1} I\right)\left(\hat{R}-q^{1-N} I\right)=0,  \tag{1.2.18}\\
\text { for } B_{n}, C_{n}, D_{n}
\end{gather*}
$$

with $N=2 n+1$ for the series $B_{n}$ and $N=2 n$ for $C_{n}$ and $D_{n}$. Moreover for all $A, B, C, D q$-groups the $R$ matrix is lower triangular $\left(R^{a b}{ }_{c d}=0\right.$ if $[a=c$ and $b<d]$ or $a<c$ ) and satisfies:

$$
\begin{gather*}
\left(R^{-1}\right)^{a b}{ }_{c d}(q)=R^{a b}{ }_{c d}\left(q^{-1}\right)  \tag{1.2.19}\\
R^{a b}{ }_{c d}=R^{d c}{ }_{b a} . \tag{1.2.20}
\end{gather*}
$$

### 1.3 Duality and *-Structure

## Duality

Consider a finite dimensional Hopf algebra $A$, the vector space $A^{\prime}$ dual to $A$ is also a Hopf algebra with the following product, unit and costructures [we use the notation $\psi(a)=\langle\psi, a\rangle$ in order to stress the duality between $A^{\prime}$ and $\left.A\right]: \forall \psi, \phi \in A^{\prime}$, $\forall a, b \in A$

$$
\begin{gather*}
\langle\psi \phi, a\rangle=\langle\psi \otimes \phi, \Delta a\rangle, \quad\langle I, a\rangle=\varepsilon(a)  \tag{1.3.1}\\
\left\langle\Delta^{\prime}(\psi), a \otimes b\right\rangle=\langle\psi, a b\rangle, \quad \varepsilon^{\prime}(\psi)=\langle\psi, I\rangle  \tag{1.3.2}\\
\left\langle\kappa^{\prime}(\psi), a\right\rangle=\langle\psi, \kappa(a)\rangle \tag{1.3.3}
\end{gather*}
$$

where $\langle\psi \otimes \phi, a \otimes b\rangle \equiv\langle\psi, a\rangle\langle\phi, b\rangle$. Obviously $\left(A^{\prime}\right)^{\prime}=A$ and $A$ and $A^{\prime}$ are dual Hopf algebras.

In the infinite dimensional case the definition of duality between Hopf algebras is more delicate because the coproduct on $A^{\prime}$ might not take values in the subspace $A^{\prime} \otimes A^{\prime}$ of $(A \otimes A)^{\prime}$ and therefore is ill defined. However, the space $A^{0}$ spanned by the matrix elements of all finite-dimensional representations of $A$ is a subalgebra of $A^{\prime}$ and obviously $\Delta^{\prime}\left(A^{0}\right) \subset A^{0} \otimes A^{0}, \kappa\left(A^{0}\right) \subset A^{0}\left[\right.$ indeed $\Delta^{\prime}\left(M^{i}{ }_{j}\right)=\sum_{k=1}^{\operatorname{dim}(M)} M^{i}{ }_{k} \otimes$ $\left.M^{k}{ }_{j}, \kappa\left(M^{i}{ }_{j}\right)=\left(M^{-1}\right)^{i}{ }_{j}\right]$. Then $A^{0}$ is a Hopf algebra: the Hopf dual of $A$. In general $\left(A^{0}\right)^{0} \neq A$, for example if $g$ is semisimple $U(g)^{0}=\operatorname{Fun}(G)$ while the vector space
underlying $\operatorname{Fun}(G)^{0}$ is $U(g) \otimes \mathbf{C}(G)$ where $\mathbf{C}(G)$ is the vector space on $\mathbf{C}$ freely generated by the elments of $G$ [85]. Later on we will consider the quantum groups of the series $A_{n}, B_{n}, C_{n}, D_{n}$ and their quantized universal enveloping algebras (as the algebras of regualr functionals on the deformed $A_{n}, B_{n}, C_{n}, D_{n}$ [19]); disregarding the topological aspects we will call these algebras dually paired or dual, the quantum group $S L_{q}(N)$ can indeed be considered as the Hopf dual of the deformed universal enveloping algebra of the $A_{n}$ series.

For generic Hopf algebras we will use the notion of non-degenerate pairing: two Hopf algebras $A$ and $U$ are paired if there exists a bilinear map $\langle\rangle:, U \otimes A \rightarrow \mathbf{C}$ satisfying (1.3.1) and (1.3.2), the pairing is non-degenerate if we also have

$$
\begin{equation*}
\forall \psi \in U\langle\psi, a\rangle=0 \Rightarrow a=0 \tag{1.3.4}
\end{equation*}
$$

and

$$
\begin{equation*}
\forall a \in A \quad\langle\psi, a\rangle=0 \Rightarrow \psi=0 \tag{1.3.5}
\end{equation*}
$$

Condition (1.3.4) states that $U$ separates the points (elements) of $A$ and viceversa for (1.3.5). If $U$ and $A$ are finite dimensional then (1.3.4) and (1.3.5) are equivalent to $A^{\prime}=U$; indeed (1.3.4) induces the injection $a \rightarrow\langle, a\rangle$ of $A$ in $U^{\prime}$, similarly, by (1.3.5) $U \subseteq A^{\prime}$ and therefore $A^{\prime}=U$.

It is easy to prove that the Hopf algebras $\operatorname{Fun}(G)$ and $U(g)$ described in Section 1.1 are paired when $g$ is the Lie algebra of $G$. Indeed we realize $g$ as left invariant vectorfields $t$ on the group manifold and $U(g)$ as the algebra generated by composition of the operators $t$. Then the pairing is defined by

$$
\forall t \in g, \forall f \in \operatorname{Fun}(G), \quad\langle t, f\rangle=\left.t(f)\right|_{1_{G}}
$$

where $1_{G}$ is the unit of $G$. Notice that $t$ is left invariant if $T L_{g}\left(\left.t\right|_{1_{G}}\right)=\left.t\right|_{g}$, where $T L_{g}$ is the tangent map induced by the left multiplication of the group on itself: $L_{g} g^{\prime}=g g^{\prime}$. We then have

$$
\begin{equation*}
\left.t(f)\right|_{g}=\left(\left.T L_{g} t\right|_{1_{G}}\right)(f)=\left.t[f(g \tilde{g})]\right|_{\tilde{g}_{\tilde{G}}}=\left.t\left[f_{1}(g) f_{2}(\tilde{g})\right]\right|_{\tilde{g}=1_{G}}=\left.f_{1}(g) t\left(f_{2}\right)\right|_{1_{G}} \tag{1.3.6}
\end{equation*}
$$

and therefore

$$
\langle\tilde{t} \circ t, f\rangle=\left.\tilde{t}(t(f))\right|_{1_{G}}=\left.\left.\tilde{t} f_{1}\right|_{1_{G}} t f_{2}\right|_{1_{G}}=\langle\tilde{t} \otimes t, \Delta f\rangle
$$

and, in agreement with (1.1.19) and (1.1.21):

$$
\begin{gathered}
\langle t, f h\rangle=\left.\left.t(f)\right|_{1_{G}} h\right|_{1_{G}}+\left.\left.f\right|_{1_{G}} t(h)\right|_{1_{G}}=\left\langle\Delta^{\prime}(t), f \otimes h\right\rangle \\
\langle t, \kappa(f)\rangle=\left.t\left[f\left(g^{-1}\right)\right]\right|_{g=1_{G}}=-\left.t[f(g)]\right|_{g=1_{G}}=\left\langle\kappa^{\prime}(t), f\right\rangle
\end{gathered}
$$

## *-Structure

The Hopf algebra $S L_{q}(2)$ we have considered in the previous section can be interpreted as the deformation of the algebra of functions on a group manifold only introducing a $*$-structure on $S L_{q}(2)$ (the analogue of complex conjugation). This procedure leads to the quantum groups $S L_{q}(2, \mathbf{R})=F u n_{q}(S L(2, \mathbf{R}))$ and $S U_{q}(2)=\operatorname{Fun}_{q}(S U(2))$. We need a $*$-structure because the algebra of regular functions on $S U(2)$ is isomorphic to the algebra of regular functions on $S L(2, \mathbf{R})$ and to the algebra of analytic functions on the complex manifold $S L(2, \mathbf{C})$; indeed any $f \in \operatorname{Fun}(S U(2))$ can be analytically continued in a unique function $\hat{f} \in \operatorname{Fun}(S L(2, \mathbf{C}))$, then the restriction of $\hat{f}$ to the $S L(2, \mathbf{R})$ sub-manifold of $S L(2, \mathbf{C})$ belongs to $\operatorname{Fun}(S L(2, \mathbf{R}))$. Therefore, without a $*$-structure we cannot understand if the polynomials in the symbols $T^{i}{ }_{j}$ with the relation $\operatorname{det} T=1$ generate functions on $S U(2)$ or on $S L(2, \mathbf{R})$ or analytic functions on $S L(2, \mathbf{C})$.

In general a $*$-algebra over the complex numbers is an algebra with an antilinear map $*: A \rightarrow A$ that is involutive, $*^{2}=i d$ and anti-multiplicative, $(a b)^{*}=$ $b^{*} a^{*} \forall a, b \in A$. A Hopf $*$-algebra $A$ is a Hopf algebra $A$ over $\mathbf{C}$ equipped with a *-algebra structure which is compatible with the costructures of $A$ :

$$
\begin{equation*}
\Delta\left(a^{*}\right)=a_{1}^{*} \otimes a_{2}^{*} ; \quad \varepsilon\left(a^{*}\right)=\varepsilon(a) \tag{1.3.7}
\end{equation*}
$$

These two conditions imply, forall $a \in A$

$$
\begin{equation*}
[\kappa(a)]^{*}=\kappa^{-1}\left(a^{*}\right) ; \tag{1.3.8}
\end{equation*}
$$

indeed the operator $* \circ \kappa^{-1} \circ *$ satisfies all the properties of the antipode and since (as the inverse of an element in a group) the antipode is unique, we have (1.3.8).

Let us clarify the interrelation between real forms of groups and $*$-structures on Hopf algebras.

Let $A=\mathcal{F}\left(G_{\mathbf{C}}\right)$ be the algebra of analytic functions on a complex group $G_{\mathbf{C}}$. A $*$-structure on $A$ determines the following real form $G_{\mathbf{R}}$ of $G_{\mathbf{C}}: G_{\mathbf{R}}=\{g \in$ $\left.G / f^{*}(g)=\overline{f(g)}\right\}$; viceversa $G_{\mathbf{R}}$ induces on $\operatorname{Fun}\left(G_{\mathbf{R}}\right)=\mathcal{F}\left(G_{\mathbf{C}}\right)$ the following *structure: $f^{*}=h \Leftrightarrow \overline{f(g)}=h(g) \forall g \in G_{\mathbf{R}}$. Moreover a real form of $G_{\mathbf{C}}$ determines a real form $g_{\mathbf{R}}$ of its Lie algebra, i.e. $g=g_{\mathbf{R}} \oplus \sqrt{-1} g_{\mathbf{R}}$. The $*$-operation that acts as minus the identity on $g_{\mathbf{R}}$ satisfies $\left[\chi, \chi^{\prime}\right]^{*}=\left[\chi^{\prime *}, \chi^{*}\right] \quad \forall \chi, \chi^{\prime} \in g_{\mathbf{R}}$ and is uniquely extended as an anti-linear, anti-multiplicative and involutive map on the Hopf algebra $U(g)$, the universal enveloping algebra of $g$. We have seen that a $*_{-}$ structure on $A=\mathcal{F}\left(G_{\mathbf{C}}\right)=F u n(G)$ determines a $*$-structure on $U(g)$, the viceversa is also obviously true. The explicit relation is $\forall \psi \in U(g), \forall a \in \operatorname{Fun}(G)$,

$$
\begin{equation*}
\left\langle\psi^{*}, a\right\rangle=\overline{\left\langle\psi,[\kappa(a)]^{*}\right\rangle} \quad \text { i.e. } \quad\left\langle\psi, a^{*}\right\rangle=\overline{\left\langle\left[\kappa^{\prime}(\psi)\right]^{*}, a\right\rangle} \tag{1.3.9}
\end{equation*}
$$

where we have used the pairing $\langle$,$\rangle between the two Hopf algebras Fun (G)$ and $U(g)$, and - denotes complex conjugation.

More in general two Hopf $*$-algebras $A$ and $U$ are paired if, in addition to (1.3.1) and (1.3.2), relation (1.3.9) holds $\forall \psi \in U$ and $\forall a \in A$.

In a functional-analytic context, the *-operation becomes the hermitian conjugation. For example, Hopf $*$-algebras that are deformations of compact matrix groups can be canonically realized (using the Gelfand-Naimark-Segal (GNS) construction, since they are dense in a $C^{*}$-algebra and since they have a Haar measure) as bounded operators on a Hilbert space. Then the $*$-operation is realized as the usual adjoint map ${ }^{\dagger}$ on operators in Hilbert space.

We end this section listing the $*$-structures that define $S U_{q}(2)$ and $S L_{q}(2, R)$; these $*$-involutions are well defined because they are compatible with the $R T T$ relations ( $R T_{1} T_{2}=T_{2} T_{1} R \Leftrightarrow \bar{R} T_{2}^{*} T_{1}^{*}=T_{1}^{*} T_{2}^{*} \bar{R}$ ) and with the determinat condition.
i) $T^{*}=T^{-1^{t}} \Rightarrow \alpha^{*}=\delta, \beta^{*}=-q \gamma, \gamma^{*}=-q^{-1} \beta, \delta^{*}=\alpha$, where $q$ is a real number. Gives the Hopf $*$-algebra $S U_{q}(2)$.
ii) $T^{*}=T \Rightarrow \alpha^{*}=\alpha, \beta^{*}=\beta, \gamma^{*}=\gamma, \delta^{*}=\delta,|q|=1$. Gives the Hopf $*$-algebra $S L_{q}(2, \mathbf{R})$.

## Chapter 2

## Differential Geometry on Quantum Groups

In this chapter we study basic notions of differential geometry on a Hopf algebra. We first give an introductory review of the $q$-differential calculus studied by [21]. In the first section, following [21], [27, we define the conditions an exterior differential $d$ has to satisfy and we explain them as natural generalizations of the conditions on a classical Lie group. The space of 1 -forms and then that of $n$-forms is fully characterized. Then we introduce the left invariant vectorfields and deduce their $q$ Lie algebra properties from the properties of the exterior differential $d$. The theory is exemplified on the quantum group $G L_{q}(N)$ in Section 2.2. In Section 2.3 we reconsider the basic postulates of a differential calculus and describe equivalent ones. This section is complementary to Section 2.1 because emphasizes the space of vectorfields rather than the space of one forms and the exterior differential. We start from a $q$-Lie algebra that closes under a quadratic $q$-Lie bracket and then we derive the properties of the exterior differential.

The last section of this chapter is a deeper study of the geometric structures on Hopf algebras. We analize the duality between the space of vectorfields and the space of 1-forms (tangent and the cotangent bundle) and generalize the construction to tensorfields. An inner derivative or contraction operator naturally arises from the above duality. We then introduce a Lie derivative and analize its properties. Finally we show how these operators and the exterior differential form a graded quantum Lie algebra of differantial operators.

### 2.1 Bicovariant differential calculus

In this section we review the bicovariant differential calculus on $q$-groups as developed by Woronowicz [21]. The $q \rightarrow 1$ limit will constantly appear in our discussion, so as to make clear which classical structure is being $q$-generalized.

The calculus can be developed on a generic Hopf algebra $A$ with invertible
antipode. Since we will constantly compare the construction with the classical one on Lie groups, we will think of $A$ as the algebra of the preceding section, i.e. the algebra freely generated by the matrix entries $T^{a}{ }_{b}$, modulo the relations (1.2.1) and possibly some reality or orthogonality conditions. However, as said, the construction can be applied to more general cases, for example it gives differential calculi on finite groups, where one cannot apply the usual techniques of differential geometry.

A first-order differential calculus on $A$ is defined by
i) a linear map $d: A \rightarrow \Gamma$, satisfying the Leibniz rule

$$
\begin{equation*}
d(a b)=(d a) b+a(d b), \quad \forall a, b \in A \tag{2.1.1}
\end{equation*}
$$

$\Gamma$ is an appropriate bimodule on $A$, which essentially means that its elements can be multiplied on the left and on the right by elements of $A$. [More precisely $A$ is a left-module if $\forall a, b \in A \forall \rho, \rho^{\prime} \in \Gamma$ we have: $a\left(\rho+\rho^{\prime}\right)=a \rho+a \rho^{\prime},(a+b) \rho=a \rho+b \rho$, $a(b \rho)=(a b) \rho, I \rho=\rho$. Similarly one defines a right-module. A left- and rightmodule is a bimodule if we also have $a(\rho b)=(a \rho) b]$. The space $\Gamma q$-generalizes the space of 1-forms on a Lie group.
ii) the possibility of expressing any $\rho \in \Gamma$ as

$$
\begin{equation*}
\rho=\sum_{k} a_{k} d b_{k} \tag{2.1.2}
\end{equation*}
$$

for some $a_{k}, b_{k}$ belonging to $A$.

## Bicovariance

The first-order differential calculus $(\Gamma, d)$ is said to be bicovariant if it is both left- and right-covariant, i.e. if we can consistently define a left and right action of the $q$-group on $\Gamma$ as follows

$$
\begin{array}{lll}
\Delta_{\Gamma}(a d b)=\Delta(a)(i d \otimes d) \Delta(b), & \Delta_{\Gamma}: \Gamma \rightarrow A \otimes \Gamma & \text { (left covariance) (2.1.3) } \\
\Gamma \Delta(a d b)=\Delta(a)(d \otimes i d) \Delta(b), & { }_{\Gamma} \Delta: \Gamma \rightarrow \Gamma \otimes A &  \tag{2.1.4}\\
\left.{ }^{2} \Delta i g h t ~ c o v a r i a n c e\right)(2.1 .4)
\end{array}
$$

How can we understand these left and right actions on $\Gamma$ in the $q \rightarrow 1$ limit? The first observation is that the coproduct $\Delta$ on $A$ is directly related, for $q=1$, to the pullback induced by left multiplication of the group on itself

$$
\begin{equation*}
L_{x} y \equiv x y, \quad \forall x, y \in G \tag{2.1.5}
\end{equation*}
$$

This induces the left action (pullback) $L_{x}^{*}$ on the functions on $G$ :

$$
\begin{equation*}
\left.L_{x}^{*} f(y) \equiv f(x y)\right|_{y}, \quad L_{x}^{*}: \operatorname{Fun}(G) \rightarrow \operatorname{Fun}(G) \tag{2.1.6}
\end{equation*}
$$

where $\left.f(x y)\right|_{y}$ means $f(x y)$ seen as a function of $y$. Let us introduce the mapping $L^{*}$ defined by

$$
\begin{gather*}
\left(L^{*} f\right)(x, y) \equiv\left(L_{x}^{*} f\right)(y)=\left.f(x y)\right|_{y} \\
L^{*}: \operatorname{Fun}(G) \rightarrow \operatorname{Fun}(G \times G) \approx \operatorname{Fun}(G) \otimes \operatorname{Fun}(G) . \tag{2.1.7}
\end{gather*}
$$

The coproduct $\Delta$ on $A$, when $q=1$, reduces to the mapping $L^{*}$. Indeed, considering $T^{a}{ }_{b}(y)$ as a function on $G$, we have:

$$
\begin{equation*}
L^{*}\left(T^{a}{ }_{b}\right)(x, y)=L_{x}^{*} T^{a}{ }_{b}(y)=T_{b}^{a}(x y)=T^{a}{ }_{c}(x) T_{b}^{c}(y), \tag{2.1.8}
\end{equation*}
$$

since $T^{a}{ }_{b}$ is a representation of $G$. Therefore

$$
\begin{equation*}
L^{*}\left(T^{a}{ }_{b}\right)=T^{a}{ }_{c} \otimes T_{b}^{c} \tag{2.1.9}
\end{equation*}
$$

and $L^{*}$ is seen to coincide with $\Delta$, cf. (1.1.15).
The pullback $L_{x}^{*}$ can also be defined on 1-forms $\rho$ as

$$
\begin{equation*}
\left.\left(L_{x}^{*} \rho\right)(y) \equiv \rho(x y)\right|_{y} \tag{2.1.10}
\end{equation*}
$$

and here too we can define $L^{*}$ as

$$
\begin{equation*}
\left(L^{*} \rho\right)(x, y) \equiv\left(L_{x}^{*} \rho\right)(y)=\left.\rho(x y)\right|_{y} . \tag{2.1.11}
\end{equation*}
$$

In the $q=1$ case we are now discussing, the left action $\Delta_{\Gamma}$ coincides with this mapping $L^{*}$ for 1 -forms. Indeed for $q=1$

$$
\begin{align*}
& \Delta_{\Gamma}(a d b)(x, y)=[\Delta(a)(i d \otimes d) \Delta(b)](x, y)=\left[\left(a_{1} \otimes a_{2}\right)(i d \otimes d)\left(b_{1} \otimes b_{2}\right)\right](x, y) \\
& \quad=\left[a_{1} b_{1} \otimes a_{2} d b_{2}\right](x, y)=a_{1}(x) b_{1}(x) a_{2}(y) d b_{2}(y)=a_{1}(x) a_{2}(y) d_{y}\left[b_{1}(x) b_{2}(y)\right] \\
& \quad=L^{*}(a)(x, y) d_{y}\left[L^{*}(b)(x, y)\right]=\left.a(x y) d b(x y)\right|_{y} \tag{2.1.12}
\end{align*}
$$

On the other hand:

$$
\begin{equation*}
L^{*}(a d b)(x, y)=\left.a(x y) d b(x y)\right|_{y} \tag{2.1.13}
\end{equation*}
$$

so that $\Delta_{\Gamma} \rightarrow L^{*}$ when $q \rightarrow 1$. In the last equation we have used the well-known property $L_{x}^{*}(a d b)=L_{x}^{*}(a) L_{x}^{*}(d b)=L_{x}^{*}(a) d L_{x}^{*}(b)$ of the classical pullback. A similar discussion holds for ${ }_{\Gamma} \Delta$, and we have ${ }_{\Gamma} \Delta \rightarrow R^{*}$ when $q \rightarrow 1$, where $R^{*}$ is defined via the pullback $R_{x}^{*}$ on functions ( 0 -forms) or on 1 -forms induced by the right multiplication:

$$
\begin{gather*}
R_{x} y=y x, \quad \forall x, y \in G  \tag{2.1.14}\\
\left(R_{x}^{*} \rho\right)(y)=\left.\rho(y x)\right|_{y}  \tag{2.1.15}\\
\left(R^{*} \rho\right)(y, x) \equiv\left(R_{x}^{*} \rho\right)(y) . \tag{2.1.16}
\end{gather*}
$$

These observations explain why $\Delta_{\Gamma}$ and ${ }_{\Gamma} \Delta$ are called left and right actions of the quantum group on $\Gamma$ when $q \neq 1$.

From the definitions (2.1.3) and (2.1.4) one deduces the following properties (21):

$$
\begin{gather*}
(\varepsilon \otimes i d) \Delta_{\Gamma}(\rho)=\rho, \quad(i d \otimes \varepsilon)_{\Gamma} \Delta(\rho)=\rho  \tag{2.1.17}\\
(\Delta \otimes i d) \Delta_{\Gamma}=\left(i d \otimes \Delta_{\Gamma}\right) \Delta_{\Gamma}, \quad(i d \otimes \Delta)_{\Gamma} \Delta=\left({ }_{\Gamma} \Delta \otimes i d\right)_{\Gamma} \Delta  \tag{2.1.18}\\
\left(i d \otimes_{\Gamma} \Delta\right) \Delta_{\Gamma}=\left(\Delta_{\Gamma} \otimes i d\right)_{\Gamma} \Delta, \tag{2.1.19}
\end{gather*}
$$

this last condition is the $q$-analogue of the fact that left and right actions commute for $q=1\left(L_{x}^{*} R_{y}^{*}=R_{y}^{*} L_{x}^{*}\right)$.

## Left- and right-invariant $\omega$

An element $\omega$ of $\Gamma$ is said to be left-invariant if

$$
\begin{equation*}
\Delta_{\Gamma}(\omega)=I \otimes \omega \tag{2.1.20}
\end{equation*}
$$

and right-invariant if

$$
\begin{equation*}
{ }_{\Gamma} \Delta(\omega)=\omega \otimes I . \tag{2.1.21}
\end{equation*}
$$

This terminology is easily understood: in the classical limit,

$$
\begin{align*}
L^{*} \omega & =I \otimes \omega  \tag{2.1.22}\\
R^{*} \omega & =\omega \otimes I \tag{2.1.23}
\end{align*}
$$

indeed define respectively left- and right-invariant 1-forms.
Proof: the classical definition of left-invariance is

$$
\begin{equation*}
\left(L_{x}^{*} \omega\right)(y)=\omega(y) \tag{2.1.24}
\end{equation*}
$$

or, in terms of $L^{*}$,

$$
\begin{equation*}
\left(L^{*} \omega\right)(x, y)=L_{x}^{*} \omega(y)=\omega(y) . \tag{2.1.25}
\end{equation*}
$$

But

$$
\begin{equation*}
(I \otimes \omega)(x, y)=I(x) \omega(y)=\omega(y) \tag{2.1.26}
\end{equation*}
$$

so that

$$
\begin{equation*}
L^{*} \omega=I \otimes \omega \tag{2.1.27}
\end{equation*}
$$

for left-invariant $\omega$. A similar argument holds for right-invariant $\omega$.

## Consequences

For any bicovariant first-order calculus one can prove the following [21] [statements i), ii), iii) and formulae (2.1.85) and (2.1.115)-(2.1.117) holds also for a calculus that is only left covariant)]:
i) Any $\rho \in \Gamma$ can be uniquely written in the form:

$$
\begin{gather*}
\rho=a_{i} \omega^{i}  \tag{2.1.28}\\
\rho=\omega^{i} b_{i} \tag{2.1.29}
\end{gather*}
$$

with $a_{i}, b_{i} \in A$, and $\omega^{i}$ a basis of ${ }_{\text {inv }} \Gamma$, the linear subspace of all left-invariant elements of $\Gamma$. Thus, as in the classical case, the whole of $\Gamma$ is generated by a basis of left invariant $\omega^{i}$. An analogous theorem holds with a basis of right invariant elements $\eta^{i} \in_{\text {inv }} \Gamma$. Note that in the quantum case we have $a \omega^{i} \neq \omega^{i} a$, the bimodule structure of $\Gamma$ being non-trivial for $q \neq 1$. [This is a consequence of associativity: $\forall \rho \in \Gamma, \forall a, a^{\prime} \in A, \rho a=a \rho \Rightarrow\left(a a^{\prime}\right) \rho=\rho\left(a a^{\prime}\right)=(\rho a) a^{\prime}=a^{\prime}(\rho a)=a^{\prime} a \rho \Rightarrow$ $\left.a a^{\prime}=a^{\prime} a\right]$
ii) There exist linear functionals $f^{i}{ }_{j}$ on $A$ such that, for any $a, b \in A$ :

$$
\begin{align*}
& \omega^{i} b=\left(f_{j}^{i} * b\right) \omega^{j} \equiv\left(i d \otimes f_{j}^{i}\right) \Delta(b) \omega^{j}  \tag{2.1.30}\\
& a \omega^{i}=\omega^{j}\left[\left(f_{j}^{i} \circ \kappa^{-1}\right) * a\right] \tag{2.1.31}
\end{align*}
$$

Once we have the functionals $f^{i}{ }_{j}$, we know how to commute elements of $A$ through elements of $\Gamma$. The $f^{i}{ }_{j}$ are uniquely determined by (2.1.30) and for consistency must satisfy the conditions:

$$
\begin{align*}
& f^{i}(a b)=f^{i}{ }_{k}(a) f^{k}{ }_{j}(b)  \tag{2.1.32}\\
& f^{i}{ }_{j}(I)=\delta_{j}^{i}  \tag{2.1.33}\\
& \left(f^{k}{ }_{j} \circ \kappa\right) f^{j}{ }_{i}=\delta_{i}^{k} \varepsilon ; \quad f^{k}{ }_{j}\left(f^{j}{ }_{i} \circ \kappa\right)=\delta_{i}^{k} \varepsilon, \tag{2.1.34}
\end{align*}
$$

so that their coproduct, counit and coinverse are given by:

$$
\begin{align*}
& \Delta^{\prime}\left(f^{i}{ }_{j}\right)=f^{i}{ }_{k} \otimes f^{k}{ }_{j}  \tag{2.1.35}\\
& \varepsilon^{\prime}\left(f^{i}{ }_{j}\right)=\delta_{j}^{i}  \tag{2.1.36}\\
& \kappa^{\prime}\left(f^{k}{ }_{j}\right) f^{j}{ }_{i}=\delta_{i}^{k} \varepsilon=f^{k}{ }_{j} \kappa^{\prime}\left(f^{j}{ }_{i}\right) \tag{2.1.37}
\end{align*}
$$

cf. (1.3.1)-(1.3.3). Note that in the $q=1$ limit $f^{i}{ }_{j} \rightarrow \delta_{j}^{i} \varepsilon$, i.e. $f_{j}^{i}$ becomes proportional to the identity functional $\varepsilon(a)=a\left(1_{G}\right)$, and formulas (2.1.30), (2.1.31) become trivial, e.g. $\omega^{i} b=b \omega^{i}$ [use $\varepsilon * a=a$ from (1.1.5)].
iii) There exists an adjoint representation $M_{j}{ }^{i}$ of the quantum group, defined by the right action on the (left invariant) $\omega^{i}$ :

$$
\begin{equation*}
\Gamma \Delta\left(\omega^{i}\right)=\omega^{j} \otimes M_{j}^{i}, \quad M_{j}^{i} \in A . \tag{2.1.38}
\end{equation*}
$$

It is easy to show that ${ }_{\Gamma} \Delta\left(\omega^{i}\right)$ belongs to ${ }_{\text {inv }} \Gamma \otimes A$, which proves the existence of $M_{j}{ }^{i}$. In the classical case, $M_{j}{ }^{i}$ is indeed the adjoint representation of the group. We recall that in this limit the left invariant 1-form $\omega^{i}$ can be constructed as

$$
\begin{equation*}
\omega^{i}(y) T_{i}=\left(y^{-1} d y\right)^{i} T_{i}, \quad y \in G \tag{2.1.39}
\end{equation*}
$$

Under right multiplication by a (constant) element $x \in G: y \rightarrow y x$ we have, 囚

$$
\begin{align*}
& \omega^{i}(y x) T_{i}=\left[x^{-1} y^{-1} d(y x)\right]^{i} T_{i}=\left[x^{-1}\left(y^{-1} d y\right) x\right]^{i} T_{i}  \tag{2.1.40}\\
& \quad=\left[x^{-1} T_{j} x\right]^{i}\left(y^{-1} d y\right)^{j} T_{i}=M_{j}{ }^{i}(x) \omega^{j}(y) T_{i}, \tag{2.1.41}
\end{align*}
$$

so that

$$
\begin{equation*}
\omega^{i}(y x)=\omega^{j}(y) M_{j}^{i}(x) \tag{2.1.42}
\end{equation*}
$$

or

$$
\begin{equation*}
R^{*} \omega^{i}(y, x)=\omega^{j} \otimes M_{j}^{i}(y, x) \tag{2.1.43}
\end{equation*}
$$

which reproduces (2.1.38) for $q=1$.
The co-structures on the $M_{j}{ }^{i}$ can be deduced [21]:

$$
\begin{align*}
& \Delta\left(M_{j}{ }^{i}\right)=M_{j}^{l} \otimes M_{l}^{i}  \tag{2.1.44}\\
& \varepsilon\left(M_{j}{ }^{i}\right)=\delta_{j}^{i}  \tag{2.1.45}\\
& \kappa\left(M_{i}^{l}\right) M_{l}^{j}=\delta_{i}^{j}=M_{i}^{l} \kappa\left(M_{l}^{j}\right) . \tag{2.1.46}
\end{align*}
$$

For example, in order to find the coproduct (2.1.44) it is sufficient to apply (id $\otimes \Delta)$ to both members of (2.1.38) and use the second of eqs.(2.1.18).

The elements $M_{j}{ }^{i}$ can be used to build a right-invariant basis of $\Gamma$. Indeed the $\eta^{i}$ defined by

$$
\begin{equation*}
\eta^{i} \equiv \kappa^{-1}\left(M_{j}{ }^{i}\right) \omega^{j} \tag{2.1.47}
\end{equation*}
$$

are right invariant $\left[\right.$ use $\left.\kappa^{-1}\left(a_{2}\right) a_{1}=\varepsilon(a)\right]$ :

$$
\begin{aligned}
& \Gamma \Delta\left(\eta^{i}\right)=\Delta\left[\kappa^{-1}\left(M_{j}{ }^{i}\right)\right]_{\Gamma} \Delta\left(\omega^{j}\right)= \\
& \quad\left[\kappa^{-1}\left(M_{s}{ }^{i}\right) \otimes \kappa^{-1}\left(M_{j}{ }^{s}\right)\right]\left[\omega^{k} \otimes M_{k}{ }^{j}\right]=\kappa^{-1}\left(M_{s}{ }^{i}\right) \omega^{k} \otimes \delta_{k}^{s} I=\eta^{i} \otimes I(2.1 .48)
\end{aligned}
$$

moreover every element of $\Gamma$ can be written as $\rho=a_{i} \eta^{i}$ or $\rho=\eta^{i} b_{i}$ where $a_{i}$ and $b_{i}$ are uniquely determined.
It can be shown that the functionals $f^{i}{ }_{j}$ previously defined satisfy:

$$
\begin{align*}
\eta^{i} b & =\left(b * f_{j}^{i}\right) \eta^{j}  \tag{2.1.49}\\
a \eta^{i} & =\eta^{j}\left[a *\left(f_{j}^{i} \circ \kappa\right)\right], \tag{2.1.50}
\end{align*}
$$

where $a * f \equiv(f \otimes i d) \Delta(a), f \in A^{\prime}$.
From (2.1.30), using (2.1.47) i.e. $\omega^{i}=M_{l}{ }^{i} \eta^{l}$ and from (2.1.49) one immediately prove the relation

$$
\begin{equation*}
M_{i}^{j}\left(a * f_{k}^{i}\right)=\left(f_{i}^{j} * a\right) M_{k}^{i}, \tag{2.1.51}
\end{equation*}
$$

with $a * f_{j}^{i} \equiv\left(f^{i}{ }_{k} \otimes i d\right) \Delta(a)$.

[^2]Note 2.1.1 Given a first order differential calculus, the space $\Gamma$ is a bicovariant bimodule i.e. $\Gamma$ is a bimodule with left and right actions $\Delta_{\Gamma}$ and ${ }_{\Gamma} \Delta$ that satisfy (2.1.17), (2.1.18), (2.1.19) and that are compatible with the bimodule structure:

$$
\begin{equation*}
\Delta_{\Gamma}(a \rho b)=\Delta(a) \Delta_{\Gamma}(\rho) \Delta(b) \quad ; \quad{ }_{\Gamma} \Delta(a \rho b)=\Delta(a)_{\Gamma} \Delta(\rho) \Delta(b) . \tag{2.1.52}
\end{equation*}
$$

Points i), ii), iii), and iv) below, hold not only for a first order differential calculus but also for a generic bicovariant bimodule (where $\Delta_{\Gamma}$ and ${ }_{\Gamma} \Delta$ are not defined via $d$ ). Any bicovariant bimodule is uniquely characterized by the functionals $f^{i}{ }_{j}$ and the elements $M_{i}{ }^{j}$ satisfying (2.1.32), (2.1.33), (2.1.44), (2.1.45) and the fundamental condition (2.1.51). Indeed, cf. Theorem 2.4.3, $\Delta_{\Gamma}$ is well defined via (2.1.20) while ${ }_{\Gamma} \Delta$, defined by (2.1.38), is compatible with the right product in $\Gamma$ :

$$
\begin{equation*}
{ }_{\Gamma} \Delta\left(\omega^{i} a\right)={ }_{\Gamma} \Delta\left(\omega^{i}\right) \Delta(a) \tag{2.1.53}
\end{equation*}
$$

if and only if (2.1.51) holds. Proof. The projection $P: \Gamma \rightarrow{ }_{\mathrm{inv}} \Gamma$ defined by $\forall \rho \in \Gamma, P(\rho)=m(\kappa \otimes i d) \Delta_{\Gamma}(\rho)$ [where $m$ is the multiplication in the bimodule $\Gamma$ ] maps $a \omega^{i}$ in $P\left(a \omega^{i}\right)=\varepsilon(a) \omega^{i}$ and $\omega^{i} a$ in $P\left(\omega^{i} a\right)=f^{i}{ }_{j}(a) \omega^{j}$ and is an epimorphism between the two bimodules $\Gamma$ and inv $\Gamma$. We then have:

$$
\begin{aligned}
(P \otimes i d)_{\Gamma} \Delta\left(\omega^{i} a\right) & =(P \otimes i d)_{\Gamma} \Delta\left[\left(f_{j}^{i} * a\right) \omega^{j}\right]=\omega^{k} \otimes\left(f_{j}^{i} * a\right) M_{k}{ }^{j} ; \\
(P \otimes i d)_{\Gamma} \Delta\left(\omega^{i} a\right) & =(P \otimes i d)\left(\omega^{k} a_{1} \otimes M_{k}{ }^{j} a_{2}\right)=(P \otimes i d)\left[\left(f^{i}{ }_{k} * a_{1}\right) \omega^{k} \otimes M_{k}{ }^{j} a_{2}\right] \\
& =\omega^{k} \otimes M_{k}{ }^{j}\left(a * f^{i}{ }_{k}\right) .
\end{aligned}
$$

This proves the implication $(2.1 .53) \Rightarrow(2.1 .51)$; the viceversa is also true since $\left(a_{1} \otimes i d\right)(P \otimes i d)_{\Gamma} \Delta\left(\omega^{i} a_{2}\right)={ }_{\Gamma} \Delta\left(\omega^{i} a\right)$.
iv) An exterior product, compatible with the left and right actions of the $q$ group, can be defined by a bimodule automorphism $\Lambda$ in $\Gamma \otimes \Gamma$ that generalizes the ordinary permutation operator:

$$
\begin{equation*}
\Lambda\left(\omega^{i} \otimes \eta^{j}\right)=\eta^{j} \otimes \omega^{i} \tag{2.1.54}
\end{equation*}
$$

where $\omega^{i}$ and $\eta^{j}$ are respectively left and right invariant elements of $\Gamma$. Bimodule automorphism means that

$$
\begin{align*}
& \Lambda(a \tau)=a \Lambda(\tau)  \tag{2.1.55}\\
& \Lambda(\tau b)=\Lambda(\tau) b \tag{2.1.56}
\end{align*}
$$

for any $\tau \in \Gamma \otimes \Gamma$ and $a, b \in A$. The tensor product between elements $\rho, \rho^{\prime} \in \Gamma$ is defined to have the properties $\rho a \otimes \rho^{\prime}=\rho \otimes a \rho^{\prime}, a\left(\rho \otimes \rho^{\prime}\right)=(a \rho) \otimes \rho^{\prime}$ and $\left(\rho \otimes \rho^{\prime}\right) a=\rho \otimes\left(\rho^{\prime} a\right)$. Left and right actions on $\Gamma \otimes \Gamma$ are defined by:

$$
\begin{align*}
& \Delta_{\Gamma}\left(\rho \otimes \rho^{\prime}\right) \equiv \rho_{1} \rho_{1}^{\prime} \otimes \rho_{2} \otimes \rho_{2}^{\prime}, \quad \Delta_{\Gamma}: \Gamma \otimes \Gamma \rightarrow A \otimes \Gamma \otimes \Gamma  \tag{2.1.57}\\
& \Gamma \Delta\left(\rho \otimes \rho^{\prime}\right) \equiv \rho_{1} \otimes \rho_{1}^{\prime} \otimes \rho_{2} \rho_{2}^{\prime}, \quad{ }_{\Gamma} \Delta: \Gamma \otimes \Gamma \rightarrow \Gamma \otimes \Gamma \otimes A \tag{2.1.58}
\end{align*}
$$

where as usual $\rho_{1}, \rho_{2}$, etc., are defined by

$$
\begin{align*}
\Delta_{\Gamma}(\rho)=\rho_{1} \otimes \rho_{2}, & \rho_{1} \in A, \rho_{2} \in \Gamma  \tag{2.1.59}\\
{ }_{\Gamma} \Delta(\rho)=\rho_{1} \otimes \rho_{2}, & \rho_{1} \in \Gamma, \rho_{2} \in A \tag{2.1.60}
\end{align*}
$$

More generally, we can define the action of $\Delta_{\Gamma}$ on $\Gamma^{\otimes n} \equiv \underbrace{\Gamma \otimes \Gamma \otimes \cdots \otimes \Gamma}_{n \text {-times }}$ as

$$
\begin{gather*}
\Delta_{\Gamma}\left(\rho \otimes \rho^{\prime} \otimes \cdots \otimes \rho^{\prime \prime}\right) \equiv \rho_{1} \rho_{1}^{\prime} \cdots \rho_{1}^{\prime \prime} \otimes \rho_{2} \otimes \rho_{2}^{\prime} \otimes \cdots \otimes \rho_{2}^{\prime \prime} \\
\Delta_{\Gamma}: \Gamma^{\otimes n} \rightarrow A \otimes \Gamma^{\otimes n}  \tag{2.1.61}\\
{ }_{\Gamma} \Delta\left(\rho \otimes \rho^{\prime} \otimes \cdots \otimes \rho^{\prime \prime}\right) \equiv \rho_{1} \otimes \rho_{1}^{\prime} \cdots \otimes \rho_{1}^{\prime \prime} \otimes \rho_{2} \rho_{2}^{\prime} \cdots \rho_{2}^{\prime \prime} \\
\Gamma \Delta: \Gamma^{\otimes n} \rightarrow \Gamma^{\otimes n} \otimes A \tag{2.1.62}
\end{gather*}
$$

Left invariance on $\Gamma \otimes \Gamma$ is naturally defined as $\Delta_{\Gamma}\left(\rho \otimes \rho^{\prime}\right)=I \otimes \rho \otimes \rho^{\prime}$ (similar definition for right-invariance), so that, for example, $\omega^{i} \otimes \omega^{j}$ is left invariant, and is in fact a left invariant basis for $\Gamma \otimes \Gamma$.

- In general $\Lambda^{2} \neq 1$, since $\Lambda\left(\eta^{j} \otimes \omega^{i}\right)$ is not necessarily equal to $\omega^{i} \otimes \eta^{j}$. By linearity, $\Lambda$ can be extended to the whole of $\Gamma \otimes \Gamma$.
- $\Lambda$ is invertible and commutes with the left and right action of the $q$-group, i.e. $\Delta_{\Gamma} \Lambda\left(\rho \otimes \rho^{\prime}\right)=(i d \otimes \Lambda) \Delta_{\Gamma}\left(\rho \otimes \rho^{\prime}\right)=\rho_{1} \rho_{1}^{\prime} \otimes \Lambda\left(\rho_{2} \otimes \rho_{2}^{\prime}\right)$, and similar for ${ }_{\Gamma} \Delta$. Then we see that $\Lambda\left(\omega^{i} \otimes \omega^{j}\right)$ is left invariant, and therefore can be expanded on the left invariant basis $\omega^{k} \otimes \omega^{l}$ :

$$
\begin{equation*}
\Lambda\left(\omega^{i} \otimes \omega^{j}\right)=\Lambda_{k l}^{i j} \omega^{k} \otimes \omega^{l} \tag{2.1.63}
\end{equation*}
$$

- From the definition (2.1.54) one can prove that [21]:

$$
\begin{equation*}
\Lambda^{i j}{ }_{k l}=f^{i}{ }_{l}\left(M_{k}{ }^{j}\right) ; \tag{2.1.64}
\end{equation*}
$$

thus the functionals $f^{i}{ }_{l}$ and the elements $M_{k}{ }^{j} \in A$ characterizing the bimodule $\Gamma$ are dual in the sense of eq. (2.1.64) and determine the exterior product:

$$
\begin{align*}
& \rho \wedge \rho^{\prime} \equiv W\left(\rho \otimes \rho^{\prime}\right) \equiv \rho \otimes \rho^{\prime}-\Lambda\left(\rho \otimes \rho^{\prime}\right)  \tag{2.1.65}\\
& \omega^{i} \wedge \omega^{j} \equiv W_{k l}^{i j} \omega^{k} \otimes \omega^{l} \equiv \omega^{i} \otimes \omega^{j}-\Lambda^{i j}{ }_{k l} \omega^{k} \otimes \omega^{l} \tag{2.1.66}
\end{align*}
$$

Notice that, given the tensor $\Lambda^{i j}{ }_{k l}$, we can compute the exterior product of any $\rho, \rho^{\prime} \in \Gamma$, since any $\rho \in \Gamma$ is expressible in terms of $\omega^{i}$ [cf. (2.1.28), (2.1.29)]. The classical limit of $\Lambda^{i j}{ }_{k l}$ is

$$
\begin{equation*}
\Lambda_{k l}^{i j} \xrightarrow{q \rightarrow 1} \delta_{l}^{i} \delta_{k}^{j} \tag{2.1.67}
\end{equation*}
$$

since $f^{i}{ }_{j} \xrightarrow{q \rightarrow 1} \delta_{l}^{i} \varepsilon$ and $\varepsilon\left(M_{j}{ }^{k}\right)=\delta_{k}^{j}$. Thus in the $q=1$ limit the product defined in (2.1.66) coincides with the usual exterior product.

From the property (2.1.55) and (2.1.56) applied to the case $\tau=\omega^{i} \otimes \omega^{j}$, one can derive the relation

$$
\begin{equation*}
\Lambda^{n m}{ }_{i j} f^{i}{ }_{p} f^{j}{ }_{q}=f^{n}{ }_{i} f^{m}{ }_{j} \Lambda^{i j}{ }_{p q} . \tag{2.1.68}
\end{equation*}
$$

Applying both members of this equation to the element $M_{r}{ }^{s}$ yields the braid relation for $\Lambda$ :

$$
\begin{equation*}
\Lambda^{n m}{ }_{i j} \Lambda^{i k}{ }_{r p} \Lambda^{j s}{ }_{k q}=\Lambda^{n k}{ }_{r i} \Lambda^{m s}{ }_{k j} \Lambda^{i j}{ }_{p q}, \text { i.e. } \Lambda_{12} \Lambda_{23} \Lambda_{12}=\Lambda_{23} \Lambda_{12} \Lambda_{23} \tag{2.1.69}
\end{equation*}
$$

which is sufficient for the consistency of (2.1.68). Taking $a=M_{p}{ }^{q}$ in (2.1.51), and using (2.1.64), we find the relation dual to (2.1.69):

$$
\begin{equation*}
M_{i}{ }^{j} M_{r}{ }^{q} \Lambda^{i r}{ }_{p k}=\Lambda^{j q}{ }_{r i} M_{p}{ }^{r} M_{k}{ }^{i} . \tag{2.1.70}
\end{equation*}
$$

This last formula explicitly shows that $W$ commutes with the coaction $\Delta_{\Gamma}$ [the commutation of $W$ with ${ }_{\Gamma} \Delta$ is implicit in (2.1.63)]; the new tensor $\omega^{i} \wedge \omega^{j} \equiv$ $W_{k l}^{i j} \omega^{k} \otimes \omega^{l}$ transforms covariantly according to its index structure:

$$
\begin{equation*}
{ }_{\Gamma} \Delta\left(\omega^{i} \wedge \omega^{j}\right) \equiv{ }_{\Gamma} \Delta\left(\omega^{k} \otimes \omega^{l}\right) W_{k l}{ }^{i j}=\omega^{k} \wedge \omega^{l} \otimes M_{k}{ }^{i} M_{l}{ }^{j} . \tag{2.1.71}
\end{equation*}
$$

Using also (2.1.68) we conclude that the action of $\Delta_{\Gamma}$ and ${ }_{\Gamma} \Delta$ on the tensor $\rho \wedge \rho^{\prime}$ has the same expression as in (2.1.57) and (2.1.58) with the tensor product replaced by the wedge product.

Defining

$$
\begin{equation*}
R_{k l}^{j i} \equiv \Lambda_{k l}^{i j}, \tag{2.1.72}
\end{equation*}
$$

we see that $R^{i j}{ }_{k l}$ satisfies the quantum Yang-Baxter equation (1.2.3), sufficient for the consistency of (2.1.70). Notice that the quantum Yang-Baxter equation is typically associated to a quasitriangular Hopf algebra with universal $\mathcal{R}$-matrix. In this case, as shown in [64] and 46], $\Lambda^{i j}{ }_{p q}$ is a representation of the universal $\mathcal{R}$-matrix of the quantum double associated to the generic Hopf algebra A. In other words, ( $\sqrt{2.1 .70}$ ) does not rely on the existence of "RTT" equations (1.2.1) used to define specific examples of Hopf algebras.

Generalizing equation (2.1.66), wedge products of $n$ forms are again expressed in terms of tensorfields:

$$
\begin{equation*}
\omega_{1} \wedge \ldots \wedge \omega_{n}=W_{1 \ldots n} \omega_{1} \otimes \ldots \otimes \omega_{n} \tag{2.1.73}
\end{equation*}
$$

The numerical coefficients $W_{1 \ldots . .}$ are given through a recursion relation

$$
\begin{equation*}
W_{1 \ldots n}=\mathcal{I}_{1 \ldots n} W_{1 \ldots n-1}, \tag{2.1.74}
\end{equation*}
$$

where

$$
\begin{equation*}
\mathcal{I}_{1 \ldots n}=1-\Lambda_{n-1, n}+\Lambda_{n-2, n-1} \Lambda_{n-1, n} \ldots-(-1)^{n} \Lambda_{12} \Lambda_{23} \cdots \Lambda_{n-1, n} \tag{2.1.75}
\end{equation*}
$$

and $W^{i}{ }_{j}=\mathcal{I}^{i}{ }_{j}=\delta_{j}^{i}$. The space of $n$-forms $\Gamma^{\wedge n}$ is therefore defined as in the classical case but with the quantum permutation operator $\Lambda$.
As is easily seen writing

$$
\mathcal{I}_{s \ldots n}=1-\Lambda_{n-1, n}+\Lambda_{n-2, n-1} \Lambda_{n-1, n} \ldots-(-1)^{n-s+1} \Lambda_{s, s+1} \Lambda_{s+1, s+2} \ldots \Lambda_{n-1, n},
$$

$\mathcal{I}$ has the following decomposition property that we will use later on:

$$
\begin{equation*}
\mathcal{I}_{1 \ldots n}=\mathcal{I}_{s \ldots n}+(-1)^{n-s+1} \mathcal{I}_{1 \ldots s-1} \Lambda_{s-1, s} \Lambda_{s, s+1} \cdots \Lambda_{n-1, n} \tag{2.1.76}
\end{equation*}
$$

Due to (2.1.70) and (2.1.68), the action of $\Delta_{\Gamma}$ and ${ }_{\Gamma} \Delta$ on the tensor $\vartheta \in \Gamma^{\wedge n} \subset \Gamma^{\otimes n}$ has the same expression as in (2.1.61) and (2.1.62) with the tensor product replaced by the wedge product. Following Note 2.1.1, $\Gamma^{\wedge n}$ is a bicovariant bimodule with left and right coactions $\Delta_{\Gamma}$ and ${ }_{\Gamma} \Delta$. We call the algebra $\Gamma^{\wedge}$ of exterior forms, $\Gamma^{\wedge} \equiv \Gamma^{0} \oplus \Gamma \oplus \Gamma^{\wedge 2} \oplus \Gamma^{\wedge 3} \oplus \ldots$ (with $A \equiv \Gamma^{0}$ ), a bicovariant graded algebra because it is a graded algebra with $\Delta_{\Gamma}$ and ${ }_{\Gamma} \Delta$ that are grade preserving.
v) Having the exterior product we can define the exterior differential

$$
\begin{gather*}
d: \Gamma \rightarrow \Gamma \wedge \Gamma  \tag{2.1.77}\\
d\left(a_{k} d b_{k}\right)=d a_{k} \wedge d b_{k} \tag{2.1.78}
\end{gather*}
$$

which can easily be extended to $\Gamma^{\wedge n}$ :

$$
\begin{gather*}
d: \Gamma^{\wedge n} \rightarrow \Gamma^{\wedge(n+1)}  \tag{2.1.79}\\
d\left(a_{k_{1} k_{2} \ldots k_{n}} d b_{k_{1}} \wedge d b_{k_{2}} \wedge \ldots d b_{k_{n}}\right)=d a_{k_{1} k_{2}, \ldots k_{n}} \wedge d b_{k_{1}} \wedge d b_{k_{2}} \wedge \ldots d b_{k_{n}} \tag{2.1.80}
\end{gather*}
$$

and has the following properties:

$$
\begin{gather*}
d\left(\theta \wedge \theta^{\prime}\right)=d \theta \wedge \theta^{\prime}+(-1)^{k} \theta \wedge d \theta^{\prime}  \tag{2.1.81}\\
d(d \theta)=0  \tag{2.1.82}\\
\Delta_{\Gamma}(d \theta)=(i d \otimes d) \Delta_{\Gamma}(\theta)  \tag{2.1.83}\\
{ }_{\Gamma} \Delta(d \theta)=(d \otimes i d)_{\Gamma} \Delta(\theta), \tag{2.1.84}
\end{gather*}
$$

where $\theta \in \Gamma^{\wedge k}, \theta^{\prime} \in \Gamma^{\wedge n}$. The last two properties express the fact that $d$ commutes with the left and right action of the quantum group, as in the classical case.
vi) The $q$-tangent space $T$, dual to the left invariant subspace ${ }_{\text {inv }} \Gamma$ can be introduced as a linear subspace of $A^{\prime}$, whose basis elements $\chi_{i} \in T \subset A^{\prime}$ are defined by

$$
\begin{equation*}
d a=\left(\chi_{i} * a\right) \omega^{i}, \quad \forall a \in A \tag{2.1.85}
\end{equation*}
$$

In the commutative case we write

$$
\begin{equation*}
d a=\frac{\partial}{\partial y^{\mu}} a(y) d y^{\mu}=\left(\frac{\partial}{\partial y^{\mu}} a\right) e_{i}^{\mu}(y) e^{i}{ }_{\nu}(y) d y^{\nu}=\left(\frac{\partial}{\partial y^{\mu}} a\right) e^{\mu}(y) \omega^{i}(y)=\left.t_{i}\right|_{y} \omega^{i} \tag{2.1.86}
\end{equation*}
$$

where $e^{i}{ }_{\nu}(y)$ is the vielbein of the group manifold and $e^{\mu}{ }_{i}$ is its inverse. Now recalling (1.3.6) we write

$$
\begin{equation*}
d a=\left(\left.t_{i}\right|_{1_{G}} * a\right) \omega^{i} \tag{2.1.87}
\end{equation*}
$$

where $t_{i}$ are left invariant vectorfields. Therefore $\chi_{i} *$ is the $q$-analogue of left invariant vectorfields, while $\chi_{i}$ is the $q$-analogue of the tangent vector at the origin $1_{G}$ of $G$ :

$$
\begin{equation*}
\chi_{i} * a \xrightarrow{q \rightarrow 1} \frac{\partial}{\partial y^{\mu}} a(y) e_{i}^{\mu} \equiv \partial_{i} a(y),\left.\quad \chi_{i}(a) \xrightarrow{q \rightarrow 1} \frac{\partial}{\partial x^{i}} a(x)\right|_{x=1_{G}} \tag{2.1.88}
\end{equation*}
$$

i.e. $T \xrightarrow{q \rightarrow 1} g$ where $g$ is the Lie algebra of $G$ (and here the Hopf algebra $A$ is the $q$-deformation of $\operatorname{Fun}(G)$ ).
vii) Given the basis $\left\{\chi_{i}\right\}$ of the $q$-tangent space $T$, we can introduce the "coordinates" $\left\{x^{i}\right\}$ via the following definition: consider the linear space $R$ (Woronowicz right ideal) given by $R=\{a \in A / \varepsilon(a)=0$ and $T(a)=0\}$, define the linear space $X$ by the relation

$$
\begin{equation*}
A=X \oplus R \oplus\{I\} \tag{2.1.89}
\end{equation*}
$$

i.e. $X$ is maximal in the (ordered) set of all linear subspaces of $A$ disjoint from $R \oplus\{I\}$. From (2.1.89) it follows that the dual vector space $X^{\prime}$ is isomorphic to $T$ and therefore there are $n$ elements $x^{i} \in X \subset$ ker $\varepsilon$ uniquely defined by the duality

$$
\begin{equation*}
\left\langle\chi_{i}, x^{j}\right\rangle=\delta_{i}^{j} . \tag{2.1.90}
\end{equation*}
$$

Note that $\varepsilon\left(x^{i}\right)=0$ since $X \subset \operatorname{ker} \varepsilon$ because $A=\operatorname{ker} \varepsilon \oplus\{I\}$. In the classical limit, in a neighbourhood of the identity $1_{G} \in G$, we have $\forall g \in G, g=\prod_{i} e^{x^{i}(g) \chi_{i}}$, see for ex. [81], the $x^{i}$ are called canonical coordinates of the second kind on the group $G$ (while those of the first kind are given by $g=e^{\sum_{i} y^{i}(g) \chi_{i}}$ ).
viii) The $\chi_{i}$ functionals close on the $q$-Lie algebra:

$$
\begin{equation*}
\chi_{i} \chi_{j}-\Lambda^{k l}{ }_{i j} \chi_{k} \chi_{l}=\mathbf{C}_{i j}{ }^{k} \chi_{k} \tag{2.1.91}
\end{equation*}
$$

with $\Lambda^{k l}{ }_{i j}$ as given in (2.1.64). The product $\chi_{i} \chi_{j}$ is defined by [cf. (1.3.1)]

$$
\begin{equation*}
\chi_{i} \chi_{j} \equiv\left(\chi_{i} \otimes \chi_{j}\right) \Delta \tag{2.1.92}
\end{equation*}
$$

and sometimes indicated by $\chi_{i} * \chi_{j}$. Note that this $*$ product (called also convolution product) is associative:

$$
\begin{gather*}
\chi_{i} *\left(\chi_{j} * \chi_{k}\right)=\left(\chi_{i} * \chi_{j}\right) * \chi_{k}  \tag{2.1.93}\\
\chi_{i} *\left(\chi_{j} * a\right)=\left(\chi_{i} * \chi_{j}\right) * a, \quad a \in A . \tag{2.1.94}
\end{gather*}
$$

We leave the easy proof to the reader. The $q$-structure constants $\mathbf{C}_{i j}{ }^{k}$ are given by

$$
\begin{equation*}
\mathbf{C}_{i j}{ }^{k}=\chi_{j}\left(M_{i}^{k}\right) . \tag{2.1.95}
\end{equation*}
$$

This last equation is easily seen to hold in the $q=1$ limit, since the $\left(\chi_{j}\right)_{i}{ }^{k} \equiv \mathbf{C}_{i j}{ }^{k}$ are indeed in this case the infinitesimal generators of the adjoint representation:

$$
\begin{equation*}
M_{i}^{k}=\delta_{i}^{k}+\mathbf{C}_{i j}{ }^{k} x^{j}+O\left(x^{2}\right) \tag{2.1.96}
\end{equation*}
$$

Using $\left.\chi_{j} \xrightarrow{q \rightarrow 1} \frac{\partial}{\partial x^{j}}\right|_{x=1_{G}}$ indeed yields (2.1.95).
By applying both sides of (2.1.91) to $M_{r}{ }^{s} \in A$, we find the $q$-Jacobi identities:

$$
\begin{equation*}
\mathbf{C}_{r i}{ }^{n} \mathbf{C}_{n j}{ }^{s}-\Lambda^{k l}{ }_{i j} \mathbf{C}_{r k}{ }^{n} \mathbf{C}_{n l}{ }^{s}=\mathbf{C}_{i j}{ }^{k} \mathbf{C}_{r k}{ }^{s} \tag{2.1.97}
\end{equation*}
$$

which give an explicit matrix realization (the adjoint representation) of the generators $\chi_{i}$ :

$$
\begin{equation*}
\left(\chi_{i}\right)_{k}^{l}=\chi_{i}\left(M_{k}^{l}\right)=\mathbf{C}_{k i}^{l} . \tag{2.1.98}
\end{equation*}
$$

Note that the $q$-Jacobi identities (2.1.97) can also be given in terms of the $q$-Lie algebra generators $\chi_{i}$ as :

$$
\begin{equation*}
\left[\left[\chi_{r}, \chi_{i}\right], \chi_{j}\right]-\Lambda^{k l}{ }_{i j}\left[\left[\chi_{r}, \chi_{k}\right], \chi_{l}\right]=\left[\chi_{r},\left[\chi_{i}, \chi_{j}\right]\right] \tag{2.1.99}
\end{equation*}
$$

where

$$
\begin{equation*}
\left[\chi_{i}, \chi_{j}\right] \equiv \chi_{i} \chi_{j}-\Lambda^{k l}{ }_{i j} \chi_{k} \chi_{l} \tag{2.1.100}
\end{equation*}
$$

is the deformed commutator of eq. (2.1.91).
ix) The left invariant $\omega^{i}$ satisfy the $q$-analogue of the Cartan-Maurer equations:

$$
\begin{equation*}
d \omega^{i}+\frac{1}{2} C_{j k}{ }^{i} \omega^{j} \wedge \omega^{k}=0 \tag{2.1.101}
\end{equation*}
$$

where

$$
\begin{equation*}
C_{j k}{ }^{i} \equiv 2 \chi_{j} \chi_{k}\left(x^{i}\right) \tag{2.1.102}
\end{equation*}
$$

The structure constants $C$ satisfy the Jacobi identities obtained by taking the exterior derivative of (2.1.101):

$$
\begin{equation*}
\left(C_{j k}{ }^{i} C_{r s}{ }^{j}-C_{r j}{ }^{i} C_{s k}{ }^{j}\right) \omega^{r} \wedge \omega^{s} \wedge \omega^{k}=0 . \tag{2.1.103}
\end{equation*}
$$

In the $q=1$ limit, $\omega^{j} \wedge \omega^{k}$ becomes antisymmetric in $j$ and $k$, and we have

$$
\begin{equation*}
C_{j k} \xrightarrow{i} \xrightarrow{q \rightarrow 1}=\left(\chi_{j} \chi_{k}-\chi_{k} \chi_{j}\right)\left(x^{i}\right)=\mathbf{C}_{j k}^{l} \chi_{l}\left(x^{i}\right)=\mathbf{C}_{j k}^{i}, \tag{2.1.104}
\end{equation*}
$$

where $\mathbf{C}_{j k}{ }^{l}$ are now the classical structure constants. Thus when $q=1$ we have $C_{j k}{ }^{i}=\mathbf{C}_{j k}{ }^{i}$ and (2.1.101) reproduces the classical Cartan-Maurer equations.

For $q \neq 1$, we find the following relation:

$$
\begin{equation*}
\mathbf{C}_{j k}{ }^{i}=\frac{1}{2} C_{j k}{ }^{i}-\frac{1}{2} \Lambda^{r s}{ }_{j k} C_{r s}{ }^{i} \tag{2.1.105}
\end{equation*}
$$

after applying both members of eq. (2.1.91) to $x^{i}$. Note that, using (2.1.105), the Cartan-Maurer equations (2.1.101) can also be written as:

$$
\begin{equation*}
d \omega^{i}+\mathbf{C}_{j k}{ }^{i} \omega^{j} \otimes \omega^{k}=0 \tag{2.1.106}
\end{equation*}
$$

x) Finally, we derive two operatorial identities that become trivial in the limit $q \rightarrow 1$. From the formula

$$
\begin{equation*}
d(h * \theta)=h * d \theta, \quad h \in A^{\prime}, \theta \in \Gamma^{\wedge n} \tag{2.1.107}
\end{equation*}
$$

[a direct consequence of (2.1.84)] with $h=f^{n}{ }_{l}$, we find

$$
\begin{equation*}
\chi_{k} f^{n}{ }_{l}=\Lambda^{i j}{ }_{k l} f^{n}{ }_{i} \chi_{j} . \tag{2.1.108}
\end{equation*}
$$

By requiring consistency between the external derivative and the bimodule structure of $\Gamma$, i.e. requiring that

$$
\begin{equation*}
d\left(\omega^{i} a\right)=d\left[\left(f_{j}^{i} * a\right) \omega^{j}\right] \tag{2.1.109}
\end{equation*}
$$

one finds the identity

$$
\begin{equation*}
\mathbf{C}_{m n}{ }^{i} f_{j}^{m} f_{k}^{n}+f_{j}^{i} \chi_{k}=\Lambda^{p q}{ }_{j k} \chi_{p} f^{i}{ }_{q}+\mathbf{C}_{j k}{ }^{l} f^{i}{ }_{l} . \tag{2.1.110}
\end{equation*}
$$

See Appendix A for the derivation of (2.1.108) and (2.1.110); see Subsection 2.3.5 for an alternative derivation.

In summary, a bicovariant calculus on a Hopf algebra $A$ ("the algebra of functions on the quantum group") is characterized by functionals $\chi_{i}$ and $f^{i}{ }_{j}$ on $A$ satisfying, cf. [22],

$$
\begin{gather*}
\chi_{i} \chi_{j}-\Lambda^{k l}{ }_{i j} \chi_{k} \chi_{l}=\mathbf{C}_{i j}{ }^{k} \chi_{k}  \tag{2.1.111}\\
\Lambda^{n m}{ }_{i j} f^{i}{ }_{p} f^{j}{ }_{q}=f^{n}{ }_{i} f^{m}{ }_{j} \Lambda^{i j}{ }_{p q}  \tag{2.1.112}\\
\mathbf{C}_{m n}{ }^{i} f^{m}{ }_{j} f^{n}{ }_{k}+f^{i}{ }_{j} \chi_{k}=\Lambda^{p q}{ }_{j k} \chi_{p} f^{i}{ }_{q}+\mathbf{C}_{j k}{ }^{l} f^{i}{ }_{l}  \tag{2.1.113}\\
\chi_{k} f^{n}{ }_{l}=\Lambda^{i j}{ }_{k l} f^{n}{ }_{i} \chi_{j}, \tag{2.1.114}
\end{gather*}
$$

where the $q$-structure constants are given by $\mathbf{C}_{j k}{ }^{i}=\chi_{k}\left(M_{j}{ }^{i}\right)$ and the braiding matrix by $\Lambda^{i j}{ }_{k l}=f^{i}{ }_{l}\left(M_{k}{ }^{j}\right)$.

The co-structures on the quantum Lie algebra generators $\chi_{i}$ are:

$$
\begin{align*}
& \Delta^{\prime}\left(\chi_{i}\right)=\chi_{j} \otimes f^{j}{ }_{i}+\varepsilon \otimes \chi_{i}  \tag{2.1.115}\\
& \varepsilon^{\prime}\left(\chi_{i}\right)=0  \tag{2.1.116}\\
& \kappa^{\prime}\left(\chi_{i}\right)=-\chi_{j} \kappa^{\prime}\left(f^{j}{ }_{i}\right), \tag{2.1.117}
\end{align*}
$$

which $q$-generalize the ones given in (1.1.19)-(1.1.21). These co-structures derive from the duality relations (1.3.2) and (1.3.3). For example, using the Leibniz rule
for the exterior differential and (2.1.30), we have $\chi_{i}(a b)=\chi_{j}(a) f^{j}{ }_{i}(b)+\varepsilon(a) \chi_{i}(b)$ i.e. (2.1.115); a straighforward way to obtain (2.1.117) is to apply $m(i d \otimes \kappa)$ to (2.1.115). The co-structures on the functionals $f^{i}{ }_{j}$ have been given in (2.1.35)-2.1.37) and can be easily derived from (2.1.115) and (2.1.116) using the coassociativity of the coproduct [eq. (1.1.4)]. These costructures are consistent with the bicovariance conditions (2.1.111)-(2.1.114).

Relations (2.1.111), (2.1.114) and (2.1.115) are also sufficient to construct a bicovariant calculus on $A$ :

Proposition 2.1.1 Consider a set $\left\{\chi_{i}, f^{i}{ }_{j}\right\}$ of functionals on $A$ that satisfies:

$$
\begin{align*}
& \chi_{i} \chi_{j}-\Lambda_{i j}^{e f} \chi_{e} \chi_{f} \in T  \tag{2.1.118}\\
& \chi_{k} f^{n}{ }_{l}=\Lambda_{j}^{i j}{ }_{k l} f^{n}{ }_{i} \chi_{j}  \tag{2.1.119}\\
& \chi_{i}(a b)=\chi_{j}(a) f^{j}{ }_{i}(b)+\varepsilon(a) \chi_{i}(b) \quad \forall a, b \in A \tag{2.1.120}
\end{align*}
$$

where $T$ is the vector space spanned by the $\chi_{i}$, and assume that the algebra $U$ of polynomials in $\chi_{i}$ and $f^{i}{ }_{j}$ separates the points of $A$. Then these data determine a bicovariant differential calculus on $A$.

Proof This proposition is easily proven in the framework of Section 2.3. Formula (2.1.114) can also be written

$$
\begin{equation*}
a d_{f^{k}} \chi_{i}=\Lambda_{i j}^{k h} \chi_{h} \tag{2.1.121}
\end{equation*}
$$

where $a d$ is the adjoint action: $\forall \psi, \phi \in U, a d_{\psi} \phi \equiv \kappa^{\prime}\left(\psi_{1}\right) \phi \psi_{2}$. We similarly have [see the first three terms in (2.3.47)]:

$$
\begin{equation*}
a d_{\chi_{j}} \chi_{i} \equiv \kappa^{\prime}\left(\chi_{j_{1}}\right) \chi_{i} \chi_{j_{2}}=\chi_{i} \chi_{j}-\Lambda_{i j}^{e f} \chi_{e} \chi_{f} \in T \tag{2.1.122}
\end{equation*}
$$

Notice that the ad action is a right representation of $U$ on $U: \operatorname{ad}_{\psi \zeta} \varphi=a d_{\zeta}\left(a d_{\psi} \varphi\right)$ and therefore we conclude that, $\forall \psi \in U, a d_{\psi} \chi_{k}$ is a linear combination of $\chi_{i}$ elements. This last condition and (2.1.120) are formulae (2.3.18) and (2.3.7). In Section 2.3 the differential calculus is explicitly constructed out of these two conditions.

By applying (2.1.111)-(2.1.114) to the element $M_{r}{ }^{s}$ we express these relations in the adjoint representation, thus obtaining a set of numerical equations necessary for the existence of a bicovariant calculus:

$$
\begin{array}{ll}
\mathbf{C}_{r i}{ }^{n} \mathbf{C}_{n j}{ }^{s}-\Lambda^{k l}{ }_{i j} \mathbf{C}_{r k}{ }^{n} \mathbf{C}_{n l}{ }^{s}=\mathbf{C}_{i j}{ }^{k} \mathbf{C}_{r k}{ }^{s} & (q \text {-Jacobi identities) }) \\
\Lambda^{n m}{ }_{i j} \Lambda^{i k}{ }_{r p} \Lambda^{j s}{ }_{k q}=\Lambda^{n k}{ }_{r i} \Lambda^{m s}{ }_{k j} \Lambda^{i j}{ }_{p q} & \text { (Yang-Baxter) } \\
\mathbf{C}_{m n}{ }^{i} \Lambda^{m l}{ }_{r j} \Lambda^{n s}{ }_{l k}+\Lambda^{i l}{ }_{r j} \mathbf{C}_{l k}{ }^{s}=\Lambda^{p q}{ }_{j k} \Lambda^{i l}{ }_{r q} \mathbf{C}_{l p}{ }^{s}+\mathbf{C}_{j k}{ }^{m} \Lambda^{i s}{ }_{r m}( \\
\mathbf{C}_{r k}{ }^{m} \Lambda^{n s}{ }_{m l}=\Lambda^{i j}{ }_{k l} \Lambda^{n m}{ }_{r i} \mathbf{C}_{m j}{ }^{s} & \tag{2.1.126}
\end{array}
$$

In the next section, we describe a constructive procedure due to Jurčo [23] for a bicovariant differential calculus on any $q$-group of the $A, B, C, D$ series considered in [19]. The procedure is illustrated on the example of $G L_{q}(2)$, for which all the objects $f^{i}{ }_{j}, M_{r}{ }^{s}, \Lambda^{i j}{ }_{k l}, C_{j k}{ }^{i}$ and $\mathbf{C}_{j k}{ }^{i}$ are explicitly computed.

### 2.2 Constructive procedure and the example of $G L_{q}(2)$

The $q$-groups discussed in Section 1.2 are characterized by the matrix $R^{a b}{ }_{c d}$. In terms of this matrix, it is possible to construct a bicovariant differential calculus on these $q$-groups [23], see also [24], 25]. The general procedure is described in this section, and the results for the specific case of $G L_{q}(2)$ are collected in the table. For a detailed study of the $G L_{q}(3)$ case see 29.

## The $L^{ \pm}$functionals

We start by introducing the linear functionals $L^{ \pm a}{ }_{b}$, defined by their value on the elements $T^{a}{ }_{b}$ :

$$
\begin{equation*}
L^{ \pm a}{ }_{b}\left(T^{c}{ }_{d}\right)=\left(R^{ \pm}\right)^{a c}{ }_{b d}, \tag{2.2.1}
\end{equation*}
$$

where

$$
\begin{gather*}
\left(R^{+}\right)^{a c}{ }_{b d} \equiv c^{+} R^{c a}{ }_{d b}  \tag{2.2.2}\\
\left(R^{-}\right)^{a c}{ }_{b d} \equiv c^{-}\left(R^{-1}\right)^{a c}{ }_{b d}, \tag{2.2.3}
\end{gather*}
$$

where $c^{+}, c^{-}$are free parameters (see later). The inverse matrix $R^{-1}$ is defined by

$$
\begin{equation*}
\left(R^{-1}\right)^{a b}{ }_{c d} R^{c d}{ }_{e f} \equiv \delta_{e}^{a} \delta_{f}^{b} \equiv R_{c d}^{a b}\left(R^{-1}\right)^{c d}{ }_{e f} . \tag{2.2.4}
\end{equation*}
$$

We see that the $L^{ \pm a}{ }_{b}$ functionals are dual to the $T^{a}{ }_{b}$ elements (fundamental representation) in the same way the $f^{i}{ }_{j}$ functionals are dual to the $M_{i}{ }^{j}$ elements of the adjoint representation. To extend the definition (2.2.1) to the whole algebra $A$, we set:

$$
\begin{equation*}
L^{ \pm a}{ }_{b}(a b)=L^{ \pm a}{ }_{g}(a) L^{ \pm g}{ }_{b}(b), \quad \forall a, b \in A \tag{2.2.5}
\end{equation*}
$$

so that, for example,

$$
\begin{equation*}
L^{ \pm a}{ }_{b}\left(T^{c}{ }_{d} T^{e}{ }_{f}\right)=\left(R^{ \pm}\right)^{a c}{ }_{g d}\left(R^{ \pm}\right)^{g e}{ }_{b f} . \tag{2.2.6}
\end{equation*}
$$

In general, using the compact notation introduced in Section 1.2,

$$
\begin{equation*}
L_{1}^{ \pm}\left(T_{2} T_{3} \ldots T_{n}\right)=R_{12}^{ \pm} R_{13}^{ \pm} \ldots R_{1 n}^{ \pm} . \tag{2.2.7}
\end{equation*}
$$

As it is esily seen from (2.2.6), the quantum Yang-Baxter equation (2.1.69) is a necessary and sufficient condition for the compatibility of (2.2.1) and (2.2.5) with the $R T T$ relations: $L_{1}^{ \pm}\left(R_{23} T_{2} T_{3}-T_{3} T_{2} R_{23}\right)=0$

Finally, the value of $L^{ \pm}$on the unit $I$ is defined by

$$
\begin{equation*}
L^{ \pm a}{ }_{b}(I)=\delta_{b}^{a} . \tag{2.2.8}
\end{equation*}
$$

Thus the functionals $L^{ \pm a}{ }_{b}$ have the same properties as their adjoint counterpart $f^{i}{ }_{j}$, and not surprisingly the latter will be constructed in terms of the former.

From (2.2.7) we can also find the action of $L^{ \pm a}{ }_{b}$ on $a \in A$, i.e. $L^{ \pm a}{ }_{b} * a$. Indeed

$$
\begin{align*}
& L^{ \pm a}{ }_{b} *\left(T_{d_{1}}^{c_{1}} T_{d_{2}}^{c_{2}} \cdots T_{d_{n}}^{c_{n}}\right)=\left[i d \otimes L^{ \pm a}{ }_{b}\right] \Delta\left(T_{d_{1}}^{c_{1}} T_{d_{2}}^{c_{2}} \cdots T_{d_{n}}^{c_{n}}\right)= \\
& {\left[i d \otimes L^{ \pm a}{ }_{b}\right] \Delta\left(T_{d_{1}}^{c_{1}}\right) \cdots \Delta\left(T_{d_{n}}^{c_{n}}\right)=} \\
& {\left[i d \otimes L^{ \pm a}{ }_{b}\right]\left(T_{e_{1}}^{c_{1}} \cdots T_{e_{n}}^{c_{n}} \otimes T_{d_{1}}^{e_{1}} \cdots T_{d_{n}}^{e_{n}}\right)} \\
& T_{e_{1}}^{c_{1}} \cdots T_{e_{n}}^{c_{n}} L^{ \pm a}{ }_{b}\left(T_{d_{1}}^{e_{1}} \cdots T_{d_{n}}^{e_{n}}\right)= \\
& T_{e_{1}}^{c_{1}} \cdots T_{e_{n}}^{c_{n}}\left(R^{ \pm}\right)^{a e_{1}}{ }_{g_{1} d_{1}}\left(R^{ \pm}\right)^{g_{1} e_{2}}{ }_{g_{2} d_{2}} \cdots\left(R^{ \pm}\right)^{g_{n-1} e_{n}}{ }_{b d_{n}} \tag{2.2.9}
\end{align*}
$$

or, more compactly,

$$
\begin{equation*}
L_{1}^{ \pm} * T_{2} \ldots T_{n}=T_{2} \ldots T_{n} R_{12}^{ \pm} R_{13}^{ \pm} \ldots R_{1 n}^{ \pm} \tag{2.2.10}
\end{equation*}
$$

which can also be written as the cross-commutation relation

$$
\begin{equation*}
L_{1}^{ \pm} T_{2}=T_{2} R_{12}^{ \pm} L_{1}^{ \pm} \tag{2.2.11}
\end{equation*}
$$

It is not difficult to find the commutations between $L^{ \pm a}{ }_{b}$ and $L^{ \pm c}{ }_{d}$ :

$$
\begin{align*}
& R_{12} L_{2}^{ \pm} L_{1}^{ \pm}=L_{1}^{ \pm} L_{2}^{ \pm} R_{12}  \tag{2.2.12}\\
& R_{12} L_{2}^{+} L_{1}^{-}=L_{1}^{-} L_{2}^{+} R_{12} \tag{2.2.13}
\end{align*}
$$

where as usual the product $L_{2}^{ \pm} L_{1}^{ \pm}$is the convolution product: $L_{2}^{ \pm} L_{1}^{ \pm}(a) \equiv\left(L_{2}^{ \pm} \otimes\right.$ $\left.L_{1}^{ \pm}\right) \Delta(a) \forall a \in A$. Consider
$R_{12}\left(L_{2}^{+} L_{1}^{+}\right)\left(T_{3}\right)=R_{12}\left(L_{2}^{+} \otimes L_{1}^{+}\right) \Delta\left(T_{3}\right)=R_{12}\left(L_{2}^{+} \otimes L_{1}^{+}\right)\left(T_{3} \otimes T_{3}\right)=\left(c^{+}\right)^{2} R_{12} R_{32} R_{31}$
and

$$
\begin{equation*}
L_{1}^{+} L_{2}^{+}\left(T_{3}\right) R_{12}=\left(c^{+}\right)^{2} R_{31} R_{32} R_{12} \tag{2.2.14}
\end{equation*}
$$

so that the equation (2.2.12) is proven for $L^{+}$by virtue of the quantum YangBaxter equation (1.2.3), where the indices have been renamed $2 \rightarrow 1,3 \rightarrow 2,1 \rightarrow 3$. Similarly, one proves the remaining "RLL" relations.

Note 2.2.1 As mentioned in [19], $L^{+}$is upper triangular, $L^{-}$is lower triangular (this is due to the upper and lower triangularity of $R^{+}$and $R^{-}$, respectively). From (2.2.12) and (2.2.13) we have

$$
\begin{equation*}
L^{ \pm A}{ }_{A} L^{ \pm B}{ }_{B}=L^{ \pm B}{ }_{B} L^{ \pm A}{ }_{A} ; \quad L^{+A}{ }_{A} L^{-B}{ }_{B}=L^{-B}{ }_{B} L^{+A}{ }_{A} \tag{2.2.16}
\end{equation*}
$$

Note 2.2.2 A determinant can be defined for the matrix $L^{ \pm A}{ }_{B}$ as in Note 1.2.5, with $q \rightarrow q^{-1}$. Indeed the " $R L L$ " relations are identical to the " $R T T$ " with $R \rightarrow$ $R^{-1}$ (which means $q \rightarrow q^{-1}, r \rightarrow r^{-1}$, cf. eq. (3.1.9)). Then, because of the upper or lower triangularity of $L^{+}$and $L^{-}$respectively, we have

$$
\begin{equation*}
\operatorname{det}_{q} L^{ \pm}=L^{ \pm 1}{ }_{1} L^{ \pm 2}{ }_{2} \cdots L^{ \pm N}{ }_{N} \tag{2.2.17}
\end{equation*}
$$

Note 2.2.3 From (2.2.1) we deduce:

$$
\begin{equation*}
L^{ \pm A}{ }_{B}\left(\operatorname{det}_{q} T\right)=\delta_{B}^{A}\left(c^{ \pm}\right)^{N} r^{ \pm 1} \tag{2.2.18}
\end{equation*}
$$

Proof: observe that $L^{ \pm}{ }_{B}{ }_{B}\left(\operatorname{det}_{q} T\right)=L^{ \pm A}{ }_{B}\left(T_{1}^{1} T^{2}{ }_{2} \cdots T_{N}^{N}\right)$ since all the other permutations do not contribute, due to the structure of the $R^{ \pm}$matrix. Then it is easy to see that

$$
\begin{gather*}
L^{ \pm A}{ }_{B}\left(T_{1}^{1} T_{1} T_{2} \cdots T_{N}^{N}\right)=  \tag{2.2.19}\\
\delta_{B}^{A}\left(c^{ \pm}\right)^{N}\left(R^{ \pm}\right)^{A 1}{ }_{A 1}\left(R^{ \pm}\right)^{A 2}{ }_{A 2} \cdots\left(R^{ \pm}\right)^{A N}{ }_{A N}=\delta_{B}^{A}\left(c^{ \pm}\right)^{N} r^{ \pm 1} \tag{2.2.20}
\end{gather*}
$$

If we set $\operatorname{det}_{q} T=I$, then $L^{ \pm A}{ }_{B}\left(\operatorname{det}_{q} T\right)=\delta_{B}^{A}\left(c^{ \pm}\right)^{N} r^{ \pm 1}$ must be equal to $\delta_{B}^{A}$, or $c^{ \pm}=r^{\mp \frac{1}{N}} \alpha^{ \pm}$with $\left(\alpha^{ \pm}\right)^{N}=1$. In this case $\left[\operatorname{det}_{q} L^{ \pm}\right]\left(T_{B}^{A}\right)=\delta_{B}^{A}$ so that $\operatorname{det} L^{ \pm}=\varepsilon$ [Proof: $\left.\operatorname{det}_{q} L^{ \pm}\left(T_{B}^{A}\right)=\delta_{B}^{A}\left(c^{ \pm}\right)^{N}\left(R^{ \pm}\right)^{1 A}{ }_{1 A} \cdots\left(R^{ \pm}\right)^{N A}{ }_{N A}=\delta_{B}^{A}\left(c^{ \pm}\right)^{N} r^{ \pm 1}\right]$. Thus for $\left(c^{ \pm}\right)^{N} r^{ \pm 1}=1$, the functionals $L^{ \pm}$and $\varepsilon$ generate the Hopf algebra $U\left(s l_{q}(N)\right)$. In the case of $G L_{q}(n), c^{ \pm}$are extra free parameters. In fact, they appear only in the combination $s=\left(c^{+}\right)^{-1} c^{-}$. They do not enter in the $\Lambda$ matrix, nor in the structure constants or the Cartan-Maurer equations, they however enter the $\omega-T$ commutation relations (see the table), so that different values of $s$ give different bimodules of 1-forms and different bicovariant differential calculi on $G L_{q}(n)$. (This accounts for the one parameter family of differential calculi found in the classification of $G L_{q}(n)$ calculi [32]).

The co-structures are defined by the duality (2.2.1):

$$
\begin{gather*}
\Delta^{\prime}\left(L^{ \pm a}{ }_{b}\right)\left(T_{d}^{c} \otimes T_{f}^{e}\right) \equiv L^{ \pm a}{ }_{b}\left(T_{d}^{c} T^{e}{ }_{f}\right)=L^{ \pm a}{ }_{g}\left(T^{c}{ }_{d}\right) L^{ \pm g}{ }_{b}\left(T^{e}{ }_{f}\right)  \tag{2.2.21}\\
\varepsilon^{\prime}\left(L^{ \pm a}{ }_{b}\right) \equiv L^{ \pm a}{ }_{b}(I)  \tag{2.2.22}\\
\kappa^{\prime}\left(L^{ \pm a}{ }_{b}\right)\left(T^{c}{ }_{d}\right) \equiv L^{ \pm a}{ }_{b}\left(\kappa\left(T^{c}{ }_{d}\right)\right) \tag{2.2.23}
\end{gather*}
$$

cf. $[(1.3 .3),(1.3 .3)]$, so that

$$
\begin{align*}
& \Delta^{\prime}\left(L^{ \pm a}{ }_{b}\right)=L^{ \pm a}{ }_{g} \otimes L^{ \pm g}{ }_{b}  \tag{2.2.24}\\
& \varepsilon^{\prime}\left(L^{ \pm a}{ }_{b}\right)=\delta_{b}^{a}  \tag{2.2.25}\\
& \kappa^{\prime}\left(L^{ \pm a}{ }_{b}\right)=L^{ \pm a}{ }_{b} \circ \kappa \tag{2.2.26}
\end{align*}
$$

The matrix $\kappa^{\prime}\left(L^{ \pm}\right)=\left(L^{ \pm}\right)^{-1}$ is a polynomial in the $L^{ \pm a}{ }_{b}$ elements and therefore the $L^{ \pm a}{ }_{b}$ generate a Hopf algebra, the Hopf algebra $U_{q}(g l(n))$ paired to the quantum $\operatorname{group} G L_{q}(n) \rrbracket$. Note that

$$
\begin{equation*}
L^{ \pm a}{ }_{b}\left(\kappa\left(T^{c}{ }_{d}\right)\right)=\left(\left(R^{ \pm}\right)^{-1}\right)^{a c}{ }_{b d}, \tag{2.2.27}
\end{equation*}
$$

since

$$
\begin{equation*}
L^{ \pm a}{ }_{b}\left(\kappa\left(T^{c}{ }_{d}\right) T_{e}^{d}{ }_{e}\right)=\delta_{d}^{c} L^{ \pm a}{ }_{b}(I)=\delta_{e}^{c} \delta_{b}^{a} \tag{2.2.28}
\end{equation*}
$$

and

$$
\begin{align*}
L^{ \pm a}{ }_{b}\left(\kappa\left(T_{d}^{c}\right) T^{d}{ }_{e}\right) & =L^{ \pm a}{ }_{f}\left(\kappa\left(T_{d}^{c}\right)\right) L^{ \pm}{ }_{b}\left(T^{d}{ }_{e}\right) \\
& =L^{ \pm a}{ }_{f}\left(\kappa\left(T^{c}{ }_{d}\right)\right)\left(R^{ \pm}\right)^{f d}{ }_{b e} . \tag{2.2.29}
\end{align*}
$$

## The space of quantum 1-forms

The bimodule $\Gamma$ ("space of quantum 1-forms") can be constructed as follows. First we define $\omega_{a}{ }^{b}$ to be a basis of left invariant quantum 1-forms. The index pairs ${ }_{a}^{b}$ or ${ }_{b}{ }_{b}$ will replace in the sequel the indices ${ }^{i}$ or ${ }_{i}$ of the previous section. The dimension of ${ }_{\text {inv }} \Gamma$ is therefore $N^{2}$ at this stage. Since the $\omega_{a}{ }^{b}$ are left invariant, we have:

$$
\begin{equation*}
\Delta_{\Gamma}\left(\omega_{a}^{b}\right)=I \otimes \omega_{a}^{b}, \quad a, b=1, \ldots, N \tag{2.2.30}
\end{equation*}
$$

The left action $\Delta_{\Gamma}$ on the whole of $\Gamma$ is then defined by (2.2.30), since $\omega_{a}{ }^{b}$ is a basis for $\Gamma$. The bimodule $\Gamma$ is further characterized by the commutations between $\omega_{a}{ }^{b}$ and $a \in A$ [cf. eq. (2.1.30)]:

$$
\begin{equation*}
\omega_{a_{1}}^{a_{2}} b=\left(f_{a_{1}}^{a_{2} b_{1}}{ }_{b_{2}} * b\right) \omega_{b_{1}}^{b_{2}}, \tag{2.2.31}
\end{equation*}
$$

where

$$
\begin{equation*}
f_{a_{1}}^{a_{2} b_{1}} \equiv \kappa_{b_{2}}^{\prime}\left(L^{+b_{1}}{ }_{a_{1}}\right) L_{b_{2}}^{-a_{2}} . \tag{2.2.32}
\end{equation*}
$$

Finally, the right action ${ }_{\Gamma} \Delta$ on $\Gamma$ is defined by

$$
\begin{equation*}
{ }_{\Gamma} \Delta\left(\omega_{a_{1}}^{a_{2}}\right)=\omega_{b_{1}}^{b_{2}} \otimes M_{b_{2} a_{1}}^{b_{1}} a_{2} \tag{2.2.33}
\end{equation*}
$$

where $M_{b_{2} a_{1}}^{b_{1}}{ }^{a_{2}}$, the adjoint representation, is given by

$$
\begin{equation*}
M_{b_{2} a_{1}}^{b_{1}} \equiv T_{a_{1}}^{a_{1}} \kappa\left(T_{b_{2}}^{a_{2}}\right) \tag{2.2.34}
\end{equation*}
$$

It is easy to check that $f_{a_{1}}^{a_{2} b_{1}} b_{2}$ fulfill the consistency conditions (2.1.32)-(2.1.34), where the $i, j, \ldots$ indices stand for pairs of $a, b, \ldots$ indices. Also, the co-structures of

[^3]$M_{b_{2} a_{1}}^{b_{1}}{ }^{a_{2}}$ are as given in (2.1.44)-(2.1.46). The last compatibility condition between the bimodule $\Gamma$ and the action ${ }_{\Gamma} \Delta$, as explained in Note 2.1.1, is (2.1.51). This relation is easily checked for $a=T_{B}^{A}$ since in this case it is implied by the $R T T$ relations; it holds for a generic $a$ because of property (2.1.32).

## The $\Lambda$ tensor and the exterior product

The $\Lambda$ tensor defined in (2.1.72) can now be computed:

$$
\begin{align*}
& \left.\Lambda_{a_{1} d_{1}}^{a_{2} d_{2}}\right|_{c_{2} b_{2}} ^{c_{1}} b_{b_{1}} \equiv f_{a_{1}}^{a_{2} b_{1}}{ }_{b_{2}}\left(M_{c_{2} d_{1}}^{c_{1}}{ }^{d_{2}}\right)=\kappa^{\prime}\left(L^{+b_{1}}{ }_{a_{1}}\right) L^{-a_{2}}{ }_{b_{2}}\left(T_{d_{1}}^{c_{1}} \kappa\left(T_{c_{2}}^{d_{2}}\right)\right) \\
& =\left[\kappa^{\prime}\left(L^{+b_{1}}{ }_{a_{1}}\right) \otimes L^{-a_{2}}{ }_{b_{2}}\right] \Delta\left(T_{d_{1}}^{c_{1}} \kappa\left(T_{c_{2}}^{d_{2}}\right)\right) \\
& =\left[\kappa^{\prime}\left(L^{+b_{1}}{ }_{a_{1}}\right) \otimes L^{-a_{2}}{ }_{b_{2}}\right]\left(T_{e_{1}}^{c_{1}} \otimes T_{d_{1}}^{e_{1}}\right)\left(\kappa\left(T_{c_{2}}^{f_{2}}\right) \otimes \kappa\left(T_{f_{2}}^{d_{2}}\right)\right) \\
& =\left[\kappa^{\prime}\left(L^{+b_{1}}{ }_{a_{1}}\right) \otimes L^{-a_{2}}{ }_{b_{2}}\right]\left[T_{e_{1}}^{c_{1}} \kappa\left(T_{c_{2}}^{f_{2}}\right) \otimes T_{d_{1}}^{e_{1}} \kappa\left(T_{f_{2}}^{d_{2}}\right)\right] \\
& =\quad L^{+b_{1}}{ }_{a_{1}}\left(\kappa^{2}\left(T_{c_{2}}^{f_{2}}\right) \kappa\left(T_{e_{1}}^{c_{1}}\right)\right) L^{-a_{2}}{ }_{b_{2}}\left(T_{d_{1}}^{e_{1}} \kappa\left(T_{f_{2}}^{d_{2}}\right)\right) \\
& =d^{f_{2}} d_{c_{2}}^{-1} L^{+b_{1}}{ }_{a_{1}}\left(T_{c_{2}}^{f_{2}} \kappa\left(T_{e_{1}}^{c_{1}}\right)\right) L^{-a_{2}}{ }_{b_{2}}\left(T_{d_{1}}^{e_{1}} \kappa\left(T_{f_{2}}^{d_{2}}\right)\right. \\
& =\quad d^{f_{2}} d_{c_{2}}^{-1} L^{+b_{1}}{ }_{g_{1}}\left(T_{c_{2}}^{f_{2}}\right) L^{+g_{1}}{ }_{a_{1}}\left(\kappa\left(T_{e_{1}}^{c_{1}}\right)\right) L^{-a_{2}}{ }_{g_{2}}\left(T_{d_{1}}^{e_{1}}\right) L^{-g_{2}}{ }_{b_{2}}\left(\kappa\left(T_{f_{2}}^{d_{2}}\right)\right) \\
& =d^{f_{2}} d_{c_{2}}^{-1} R_{c_{2} g_{1}}^{f_{2} b_{1}}\left(R^{-1}\right)^{c_{1} g_{1}}{ }_{e_{1} a_{1}}\left(R^{-1}\right)^{a_{2} e_{1}}{ }_{g_{2} d_{1}} R_{b_{2} f_{2}}^{g_{2} d_{2}} \tag{2.2.35}
\end{align*}
$$

where we made use of relations (1.1.12), (1.3.3), (1.2.15), (2.2.1) and (2.2.27). The $\Lambda$ tensor allows the definition of the exterior product as in (2.1.66). For future use we give here also the inverse $\Lambda^{-1}$ of the $\Lambda$ tensor, defined by:

$$
\begin{equation*}
\left.\left.\left.\left(\Lambda^{-1}\right)_{a_{1} d_{1}}^{a_{2}}\right|_{b_{2}} ^{d_{2}}\right|_{b_{2}} ^{b_{1}} \Lambda_{b_{1} c_{1}}^{b_{2}}\right|_{e_{2}} ^{c_{1}} f_{f_{2}}=\delta_{e_{2}}^{a_{2}} \delta_{a_{1}}^{e_{1}} \delta_{d_{1}}^{f_{1}} \delta_{f_{2}}^{d_{2}} \tag{2.2.36}
\end{equation*}
$$

It is not difficult to see that

$$
\begin{align*}
& \left(\Lambda^{-1}\right)_{a_{1} d_{1}}^{a_{2}} d_{2} \mid{ }_{b_{2} c_{1} c_{1}}^{b_{2}}=f_{d_{1}}{ }_{d_{2} b_{1}}^{b_{2}}\left(T_{c_{2}}^{a_{2}} \kappa^{-1}\left(T_{a_{1}}^{c_{1}}\right)\right)= \\
& \quad R_{a_{1}{ }_{1} g_{1}}^{f_{1} b_{1}}\left(R^{-1}\right)^{a_{2} g_{1}}{ }_{e_{2} d_{1}}\left(R^{-1}\right)^{d_{2} e_{2}}{ }_{g_{2} c_{2}} R^{g_{2} c_{1}}{ }_{b_{2} f_{1}}\left(d^{-1}\right)^{c_{1}} d_{f_{1}} \tag{2.2.37}
\end{align*}
$$

does the trick. Another useful relation gives a particular trace of the $\Lambda$ matrix:

$$
\begin{equation*}
\Lambda_{c_{1} b}^{\left.c_{2}{ }^{b}\right|_{a_{2} b_{2}} ^{a_{1}} b_{1} b_{1}} \delta_{a_{2}}^{a_{1}} \delta_{c_{1}}^{b_{1}} \delta_{b_{2}}^{c_{2}} . \tag{2.2.38}
\end{equation*}
$$

This identity is simply proven. Indeed:

$$
\begin{align*}
& \Lambda_{c_{1} b}^{\left.c_{2}{ }^{b}\right|_{a_{1}} ^{a_{1}} b_{1_{1}} b_{2} \equiv f_{c_{1}}^{c_{2} b_{1}}{ }_{b_{2}}\left(M_{a_{2} b}^{a_{1}}{ }^{b}\right)=} \\
& \quad \kappa^{\prime}\left(L^{+b_{1}}{ }_{c_{1}}\right) L^{-c_{2}}{ }_{b_{2}}\left(T^{a_{1}} \kappa\left(T_{{ }_{2}}^{b}\right)\right)=\kappa^{\prime}\left(L^{+b_{1}}{ }_{c_{1}}\right) L^{-c_{2}}{ }_{b_{2}}\left(\delta_{a_{2}}^{a_{1}} I\right)= \\
& \quad \delta_{a_{2}}^{a_{1}}\left[\kappa^{\prime}\left(L^{+b_{1}}{ }_{c_{1}}\right) \otimes L^{-c_{2}}{ }_{b_{2}}\right](I \otimes I)=\delta_{a_{2}}^{a_{1}} \delta_{c_{1}}^{b_{1}} \delta_{b_{2}}^{c_{2}} . \tag{2.2.39}
\end{align*}
$$

The relations (1.2.17), (1.2.18) for the $R$ matrix reflect themselves in relations for the $\Lambda$ matrix (2.2.35). For example, the Hecke condition (1.2.17) implies:

$$
\begin{equation*}
\left(\Lambda+q^{2}\right)\left(\Lambda+q^{-2}\right)(\Lambda-I)=0 \tag{2.2.40}
\end{equation*}
$$

for the $A_{n-1} q$-groups, and replaces the classical relation $(\Lambda-1)(\Lambda+1)=0, \Lambda$ being for $q=1$ the ordinary permutation operator, cf. (2.1.67).

With the help of (2.2.40) we can give explicitly the commutations of the left invariant forms $\omega$. Indeed, reverting to the $i, j .$. indices, relation (2.2.40) implies:

$$
\begin{align*}
& \left(\Lambda^{i j}{ }_{k l}+q^{2} \delta_{k}^{i} \delta_{l}^{j}\right)\left(\Lambda^{k l}{ }_{m n}+q^{-2} \delta_{m}^{k} \delta_{n}^{l}\right)\left(\Lambda_{r s}^{m n}-\delta_{r}^{m} \delta_{s}^{n}\right) \omega^{r} \otimes \omega^{s}= \\
& \quad\left(\Lambda_{k l}^{i j}+q^{2} \delta_{k}^{i} \delta_{l}^{j}\right)\left(\Lambda^{k l}{ }_{m n}+q^{-2} \delta_{m}^{k} \delta_{n}^{l}\right) \omega^{m} \wedge \omega^{n}=0 \tag{2.2.41}
\end{align*}
$$

and it is easy to see that the last equality can be rewritten as

$$
\begin{gather*}
\omega^{i} \wedge \omega^{j}=-Z^{i j}{ }_{k l} \omega^{k} \wedge \omega^{l}  \tag{2.2.42}\\
Z_{k l}^{i j} \equiv \frac{1}{q^{2}+q^{-2}}\left[\Lambda^{i j}{ }_{k l}+\left(\Lambda^{-1}\right)^{i j}{ }_{k l}\right] . \tag{2.2.43}
\end{gather*}
$$

## The exterior differential

The exterior differential on $\Gamma^{\wedge k}$ is defined by means of the bi-invariant (i.e. left and right invariant) element $\tau=\sum_{a} \omega_{a}{ }^{a} \in \Gamma$ as follows:

$$
\begin{equation*}
d \theta \equiv \frac{1}{\lambda}\left[\tau \wedge \theta-(-1)^{k} \theta \wedge \tau\right] \tag{2.2.44}
\end{equation*}
$$

where $\theta \in \Gamma^{\wedge k}$, and $\lambda$ is a normalization factor depending on $q$, necessary in order to obtain the correct classical limit. It will be later determined to be $\lambda=q-q^{-1}$. Here we can only see that it has to vanish for $q=1$, since otherwise $d \theta$ would vanish in the classical limit. For $a \in A$ we have

$$
\begin{equation*}
d a=\frac{1}{\lambda}[\tau a-a \tau] . \tag{2.2.45}
\end{equation*}
$$

This linear map satisfies the Leibniz rule (2.1.1), and properties (2.1.81)-(2.1.84), as the reader can easily check (use the definition of exterior product and the biinvariance of $\tau$ ). A proof that also the property (2.1.2) holds can be obtained by considering the exterior differential of the adjoint representation:

$$
\begin{equation*}
d M_{j}^{i}=\left(\chi_{k} * M_{j}^{i}\right) \omega^{k}=M_{j}^{l} \mathbf{C}_{k l}{ }^{i} \omega^{k} \tag{2.2.46}
\end{equation*}
$$

or

$$
\begin{equation*}
\kappa\left(M_{l}^{j}\right) d M_{j}^{i}=\mathbf{C}_{k l}{ }^{i} \omega^{k} \tag{2.2.47}
\end{equation*}
$$

Multiplying by $\mathbf{C}_{n i}{ }^{l}$, we have:

$$
\begin{equation*}
\mathbf{C}_{n i}^{l} \kappa\left(M_{l}^{j}\right) d M_{j}^{i}=\mathbf{C}_{k l}^{i} \mathbf{C}_{n i}^{l} \omega^{k} \equiv g_{n k} \omega^{k} \tag{2.2.48}
\end{equation*}
$$

where $g_{n k}$ is the $q$-Killing metric. The explicit example of this section being $G L_{q}(2)$, one may wonder what happens to the invertibility of the $q$-Killing metric, since its
classical limit is no more invertible [ $G L(2)$ being nonsemisimple]. The answer is that for $q \neq 1$ the $q$-Killing metric of $G L_{q}(2)$ is invertible, as can be checked explicitly from the values of the structure constants given in the table. Therefore $G L_{q}(2)$ could be said to be " $q$-semisimple". With an analogous procedure (using $T^{a}{ }_{b}$ instead of $M_{j}{ }^{i}$ ) we have derived in the table the explicit expression of the $\omega^{i}$ in terms of the $d T^{a}{ }_{b}$ for $G L_{q}(2)$.

## The $q$-Lie algebra

The "quantum generators" $\chi_{a_{2}}^{a_{1}}$ are introduced as in (2.1.85):

$$
\begin{equation*}
d a=\frac{1}{\lambda}[\tau a-a \tau]=\left(\chi_{a_{2}}^{a_{1}} * a\right) \omega_{a_{1}}^{a_{2}} . \tag{2.2.49}
\end{equation*}
$$

Using (2.2.31) we can find an explicit expression for the $\chi_{a_{2}}^{a_{1}}$ in terms of the $L^{ \pm}$ functionals. Indeed

$$
\begin{equation*}
\tau a=\omega_{b}{ }^{b} a=\left(f_{b}^{b c_{1}}{ }_{c_{2}} * a\right) \omega_{c_{1}}^{c_{2}}=\left(\left[\kappa^{\prime}\left(L^{+c_{1}}{ }_{b}\right) L^{-b}{ }_{c_{2}}\right] * a\right) \omega_{c_{1}}^{c_{2}} . \tag{2.2.50}
\end{equation*}
$$

Therefore

$$
\begin{equation*}
d a=\frac{1}{\lambda}\left[\left(\kappa^{\prime}\left(L^{+c_{1}}\right) L^{-b}{ }_{c_{2}}-\delta_{c_{2}}^{c_{1}} \varepsilon\right) * a\right] \omega_{c_{1}}^{c_{2}} \tag{2.2.51}
\end{equation*}
$$

(recall $\varepsilon * a=a$ ), so that the $q$-generators take the explicit form

$$
\begin{equation*}
\chi_{c_{2}}^{c_{1}}=\frac{1}{\lambda}\left[\kappa^{\prime}\left(L^{+c_{1}}{ }_{b}\right) L_{c_{2}}^{-b}-\delta_{c_{2}}^{c_{1}} \varepsilon\right]=\frac{1}{\lambda}\left(f_{b}{ }^{b c_{1}}{ }_{c_{2}}-\delta_{c_{2}}^{c_{1}} \varepsilon\right) . \tag{2.2.52}
\end{equation*}
$$

The commutations between the $\chi$ 's can now be obtained by taking the exterior derivative of eq. (2.2.51). We find

$$
\begin{align*}
& d^{2}(a)=0=d\left[\left(\chi_{c_{2}}^{c_{1}} * a\right) \omega_{c_{1}}^{c_{2}}\right]=\left(\chi_{d_{2}}^{d_{1}} * \chi_{c_{2}}^{c_{1}} * a\right) \omega_{d_{1}}^{d_{2}} \wedge \omega_{c_{1}}^{c_{2}}+\left(\chi_{c_{2}}^{c_{1}} * a\right) d \omega_{c_{1}}^{c_{2}} \\
& \quad=\left(\chi_{d_{2}}^{d_{1}} * \chi_{c_{2}}^{c_{1}} * a\right)\left(\omega_{d_{1}}^{d_{2}} \otimes \omega_{c_{1}}^{c_{2}}-\left.\Lambda_{d_{1} c_{1} c_{2}}^{d_{2}}\right|_{e_{2} f_{1} f_{2}} ^{e_{2}} \omega_{e_{1}}^{e_{2}} \otimes \omega_{f_{1}}^{f_{2}}\right) \\
& \quad+\frac{1}{\lambda}\left(\chi_{c_{2}}^{c_{1}} * a\right)\left(\omega_{b}^{b} \wedge \omega_{c_{1}}^{c_{2}}+\omega_{c_{1}}^{c_{2}} \wedge \omega_{b}^{b}\right) . \tag{2.2.53}
\end{align*}
$$

Now we use the fact that $\tau=\omega_{b}{ }^{b}$ is bi-invariant, and therefore also right-invariant, so that we can write

$$
\begin{align*}
& \omega_{b}^{b} \wedge \omega_{c_{1}}^{c_{2}}+\omega_{c_{1}}^{c_{2}} \wedge \omega_{b}^{b} \equiv \\
& \quad \omega_{b}^{b} \otimes \omega_{c_{1}}^{c_{2}}-\Lambda\left(\omega_{b}^{b} \otimes \omega_{c_{1}}^{c_{2}}\right)+\omega_{c_{1}}^{c_{2}} \otimes \omega_{b}^{b}-\Lambda\left(\omega_{c_{1}}^{c_{2}} \otimes \omega_{b}^{b}\right)= \\
& \quad \omega_{c_{1}}^{c_{2}} \otimes \omega_{b}^{b}-\Lambda\left(\omega_{b}^{b} \otimes \omega_{c_{1}}^{c_{2}}\right)= \\
& \quad \omega_{c_{1}}^{c_{2}} \otimes \omega_{b}^{b}-\left.\left.\Lambda_{b}^{b c_{1}}\right|_{c_{1}}\right|_{e_{2}} ^{e_{1}} f_{f_{2}} \omega_{e_{1}}^{e_{2}} \otimes \omega_{f_{1}}^{f_{2}}, \tag{2.2.54}
\end{align*}
$$

where we have used $\Lambda\left(\omega_{c_{1}}^{c_{2}} \otimes \tau\right)=\tau \otimes \omega_{c_{1}}^{c_{2}}$, cf. (2.1.54). After substituting (2.2.54) in (2.2.53), and factorizing $\omega_{d_{1}}^{d_{2}} \otimes \omega_{c_{1}}^{c_{2}}$, we arrive at the $q$-Lie algebra relations:

$$
\begin{equation*}
\chi_{d_{2}}^{d_{1}} \chi_{c_{2}}^{c_{1}}-\left.\Lambda_{e_{1}}^{e_{2}} f_{1}\right|_{d_{2}} ^{d_{1}}{ }_{d_{2} c_{2}}^{c_{1}} \chi_{e_{2}}^{e_{1}} \chi_{f_{2}}^{f_{1}}=\frac{1}{\lambda}\left[-\delta_{c_{2}}^{c_{1}} \chi_{d_{2}}^{d_{1}}+\left.\Lambda_{b e_{1}}^{b e_{2}}\right|_{d_{2} c_{2}} ^{d_{1} c_{1}} \chi_{e_{2}}^{e_{1}}\right] . \tag{2.2.55}
\end{equation*}
$$

The structure constants are then explicitly given by:

$$
\begin{equation*}
\mathbf{C}_{a_{2} b_{2}}^{a_{1}} b_{1} \left\lvert\, c_{c_{1}}^{c_{2}}=\frac{1}{\lambda}\left[-\delta_{b_{2}}^{b_{1}} \delta_{c_{1}}^{a_{1}} \delta_{a_{2}}^{c_{2}}+\left.\Lambda_{b c_{1}}^{b c_{2}}\right|_{a_{2}} ^{a_{1}} b_{1} b_{2}\right] .\right. \tag{2.2.56}
\end{equation*}
$$

Here we determine $\lambda$. Indeed we first observe that

$$
\begin{equation*}
\left.\left.\Lambda_{a_{1} d_{1}}^{a_{2}}\right|_{c_{2} b_{2}} ^{c_{1} b_{1}}=\delta_{a_{1}}^{b_{1}} \delta_{b_{2}}^{a_{2}} \delta_{d_{1}}^{c_{1}} d_{c_{2}}^{d_{2}}+q^{-1}\right)\left.\left.U_{a_{1} d_{1}}^{a_{2}}\right|_{c_{2} b_{2}} ^{d_{2}}\right|_{1} ^{c_{1}} b_{1}, \tag{2.2.57}
\end{equation*}
$$

where the matrix $U$ is finite and different from zero in the limit $q=1$. This can be proven by considering the explicit form of the $R$ and $R^{-1}$ matrices. In the case of the $A_{n-1} q$-groups, for example, these matrices have the form [19]:

$$
\begin{gather*}
R_{c d}^{a b}=\delta_{c}^{a} \delta_{d}^{b}+\left(q-q^{-1}\right)\left[\frac{q-1}{q-q^{-1}} \delta_{c}^{a} \delta_{d}^{b} \delta^{a b}+\delta_{c}^{b} \delta_{d}^{a} \theta(a-b)\right]  \tag{2.2.58}\\
\left(R^{-1}\right)^{a b}{ }_{c d}=\delta_{c}^{a} \delta_{d}^{b}-\left(q-q^{-1}\right)\left[\frac{1-q^{-1}}{q-q^{-1}} \delta_{c}^{a} \delta_{d}^{b} \delta^{a b}+\delta_{c}^{b} \delta_{d}^{a} \theta(a-b)\right], \tag{2.2.59}
\end{gather*}
$$

where $\theta(x)=1$ for $x>0$ and vanishes for $x \leq 0$. Substituting these expressions in the formula for $\Lambda(2.2 .35)$ we find (2.2.57). Using (2.2.57) in the expression (2.2.56) for the $q$-structure constants $\mathbf{C}$, we find that the terms proportional to $\frac{1}{\lambda}$ do cancel, and we are left with:

$$
\begin{equation*}
\left.\mathbf{C}_{a_{2} b_{2}}^{a_{1}} b_{1}\right|_{c_{1}} ^{c_{2}}=-\left.\frac{1}{\lambda}\left(q-q^{-1}\right) U_{b}^{b c_{1}}{ }_{c_{2}}^{c_{2}}\right|_{a_{2}} ^{a_{1}} b_{1} b_{2} . \tag{2.2.60}
\end{equation*}
$$

A simple choice for $\lambda$ is therefore $\lambda=q-q^{-1}$, ensuring that $\mathbf{C}$ remains finite in the limit $q \rightarrow 1$; moreover with this normalization the differential $d$ reduces for $q \rightarrow 1$ to the classical differential, cf. Section 4.6.

## The Cartan-Maurer equations

The Cartan-Maurer equations are found as follows:

$$
\begin{equation*}
d \omega_{c_{1}}^{c_{2}}=\frac{1}{\lambda}\left(\omega_{b}^{b} \wedge \omega_{c_{1}}^{c_{2}}+\omega_{c_{1}}^{c_{2}} \wedge \omega_{b}^{b}\right) \equiv-\left.\frac{1}{2} C_{a_{2}}^{a_{1}} b_{b_{2}}\right|_{c_{1}} ^{c_{2}} \omega_{a_{1}}^{a_{2}} \wedge \omega_{b_{1}}^{b_{2}} . \tag{2.2.61}
\end{equation*}
$$

In order to obtain an explicit and, for $q \rightarrow 1$, well defined expression for the $C$ structure constants in (2.2.61), we must use the relation (2.2.42) for the commutations of $\omega_{a_{1}}^{a_{2}}$ with $\omega_{b_{1}}^{b_{2}}$. Then the term $\omega_{c_{1}}^{c_{2}} \wedge \omega_{b}^{b}$ in (2.2.61) can be written as $-Z \omega \omega$ via formula (2.2.42), and we find the $C$-structure constants to be:

$$
\begin{align*}
& \left.C_{a_{2} b_{2}}^{a_{1} b_{1}}\right|_{c_{1}} ^{c_{2}}=-\frac{2}{\lambda}\left(\delta_{a_{2}}^{a_{1}} \delta_{c_{1}}^{b_{1}} \delta_{b_{2}}^{c_{2}}-\frac{1}{q^{2}+q^{-2}}\left[\left.\Lambda_{c_{1} b}^{c_{2} b}\right|_{a_{2}} ^{a_{1}} b_{1} b_{1}+\left.\left(\Lambda^{-1}\right)_{c_{1} b}^{c_{2}}{ }^{c_{2}}\right|_{a_{2}} ^{a_{1}} \begin{array}{l}
b_{1} \\
a_{2}
\end{array}\right]\right) \\
& =-\frac{2}{\lambda}\left(\delta_{a_{2}}^{a_{1}} \delta_{c_{1}}^{b_{1}} \delta_{b_{2}}^{c_{2}}-\frac{1}{q^{2}+q^{-2}}\left[\delta_{a_{2}}^{a_{1}} \delta_{c_{1}}^{b_{1}} \delta_{b_{2}}^{c_{2}}+\left.\left(\Lambda^{-1}\right)_{c_{1} b}^{c_{2}}\right|_{\mid} ^{a_{1}} \begin{array}{l}
a_{1} \\
a_{2}
\end{array} b_{2}\right]\right), \tag{2.2.62}
\end{align*}
$$

where we have also used eq. (2.2.38). By considering the analogue of (2.2.57) for $\Lambda^{-1}$, it is not difficult to see that the terms proportional to $\frac{1}{\lambda}$ cancel, and the $q \rightarrow 1$ limit of (2.2.62) is well defined. For a similar result on the $B_{n}, C_{n}$ and $D_{n}$ $q$-groups see 4.5.16) and ref. [30].

In the table we summarize the results of this section for the case of $G L_{q}(2)$. The composite indices ${ }_{a}{ }^{b}$ are translated into the corresponding indices ${ }^{i}, i=1,+,-, 2$, according to the convention:

$$
\begin{equation*}
1^{1} \rightarrow^{1}, 1^{2} \rightarrow^{+}, 2^{1} \rightarrow^{-}, 2^{2} \rightarrow^{2} . \tag{2.2.63}
\end{equation*}
$$

A similar convention holds for ${ }^{a}{ }_{b} \rightarrow_{i}$.

### 2.2.1 Table of $G L_{q}(2)$

The bicovariant $G L_{q}(2)$ algebra
$R$ and $D$-matrices:

$$
\begin{gathered}
R^{a b}{ }_{c d}=\left(\begin{array}{cccc}
q & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & q-q^{-1} & 1 & 0 \\
0 & 0 & 0 & q
\end{array}\right) \\
\left(R^{-}\right)^{a b}{ }_{c d} \equiv c^{-}\left(R^{-1}\right)^{a b}{ }_{c d}=c^{-}\left(\begin{array}{cccc}
q^{-1} & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & -\left(q-q^{-1}\right) & 1 & 0 \\
0 & 0 & 0 & q^{-1}
\end{array}\right) \\
\left(R^{+}\right)^{a b}{ }_{c d} \equiv c^{+} R^{b a}{ }_{d c}=c^{+}\left(\begin{array}{cccc}
q & 0 & 0 & 0 \\
0 & 1 & q-q^{-1} & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & q
\end{array}\right), \quad D^{a}{ }_{b}=\left(\begin{array}{cc}
q & 0 \\
0 & q^{3}
\end{array}\right)
\end{gathered}
$$

Non-vanishing components of the $\Lambda$ matrix:
$\Lambda^{11}{ }_{11}=1$
$\Lambda^{1+}{ }_{+1}=q^{-2}$
$\Lambda^{1-}{ }_{-1}=q^{2} \quad \Lambda^{12}{ }_{21}=1$
$\Lambda^{+1}{ }_{1+}=1 \quad \Lambda^{+1}{ }_{+1}=1-q^{-2}$
$\Lambda^{++}{ }_{++}=1 \quad \Lambda^{+-}{ }_{11}=1-q^{2}$
$\Lambda^{+-}{ }_{-+}=1$
$\Lambda^{+-}{ }_{21}=1-q^{-2}$
$\Lambda^{+2}{ }_{+1}=-1+q^{-2} \quad \Lambda^{+2}{ }_{2+}=1$
$\Lambda^{-1}{ }_{1-}=1 \quad \Lambda^{-1}{ }_{-1}=1-q^{2}$
$\Lambda^{-+}{ }_{11}=-1+q^{2} \quad \Lambda^{-+}{ }_{+-}=1$
$\Lambda^{-+}{ }_{21}=-1+q^{-2} \quad \Lambda^{--}=1$
$\Lambda^{-2}{ }_{-1}=-1+q^{2} \quad \Lambda^{-2}{ }_{2-}=1$
$\Lambda^{21}{ }_{11}=\left(q^{2}-1\right)^{2} \quad \Lambda^{21}{ }_{12}=1$
$\Lambda^{21}{ }^{2+-}=q^{2}-1 \quad \Lambda^{21}{ }^{2}{ }^{2+}=1-q^{2}$
$\Lambda^{21}{ }_{21}=2-q^{2}-q^{-2} \quad \Lambda^{2+}{ }_{1+}=-q^{2}+q^{4}$
$\Lambda^{2+}{ }_{+2}=q^{2} \quad \Lambda^{2+}{ }_{2+}=1-q^{2}$
$\Lambda^{2-}{ }_{1-}=1-q^{2} \quad \Lambda^{2-}{ }_{-1}=q^{-2}-1-q^{2}+q^{4} \quad \Lambda^{2-}{ }_{-2}=q^{-2} \quad \Lambda^{2-}{ }_{2-}=1-q^{-2}$
$\Lambda^{22}{ }_{11}=-\left(q^{2}-1\right)^{2} \quad \Lambda^{22}{ }_{+-}=1-q^{2} \quad \Lambda^{22}{ }_{-+}=q^{2}-1 \quad \Lambda^{22}{ }_{21}=\left(q^{-1}-q\right)^{2}$
$\Lambda_{22}^{22}=1$

Non-vanishing components of the $\mathbf{C}$ structure constants:
$\mathbf{C}_{11}{ }^{1}=q\left(q^{2}-1\right)$
$\mathbf{C}_{11}{ }^{2}=-q\left(q^{2}-1\right)$
$\mathbf{C}_{1+}{ }^{+}=q^{3}$
$\mathbf{C}_{1-}{ }^{-}=-q$
$\mathbf{C}_{21}{ }^{1}=q^{-1}-q$
$\mathbf{C}_{21}{ }^{2}=q-q^{-1}$
$\mathrm{C}_{2+}{ }^{+}=-q$
$\mathbf{C}_{2-}{ }^{-}=q^{-1}$
$\mathbf{C}_{+1}^{+}=-q^{-1}$
$\mathrm{C}_{+2}{ }^{+}=q$
$\mathrm{C}_{+-}{ }^{1}=q$
$\mathbf{C}_{+-}{ }^{2}=-q$
$\mathbf{C}_{-1}{ }^{-}=q\left(q^{2}+1\right)-q^{-1}$
$\mathbf{C}_{-2}{ }^{-}=-q^{-1}$
$\mathbf{C}_{-+}{ }^{1}=-q$
$\mathrm{C}_{-+}{ }^{2}=q$

Non-vanishing components of the $C$ structure constants:

$$
\begin{array}{llll}
C_{11}{ }^{1}=\frac{q\left(q^{2}-1\right)^{2}}{1+q^{4}} & C_{11}{ }^{2}=\frac{q^{3}\left(1-q^{2}\right)}{1+q^{4}} & C_{1+}{ }^{+}=\frac{q^{5}}{1+q^{4}} & C_{1-}{ }^{-}=\frac{-q^{3}}{1+q^{4}} \\
C_{12}{ }^{1}=\frac{q\left(1-q^{2}\right)}{1+q^{4}} & C_{+1}{ }^{+}=\frac{-q^{3}}{1+q^{4}} & C_{+-}{ }^{1}=\frac{q^{3}}{1+q^{4}} & C_{+-}{ }^{2}=\frac{-q^{3}}{1+q^{4}} \\
C_{+2}{ }^{+}=\frac{q}{1+q^{4}} & C_{-1}-=\frac{q^{4}}{1+q^{4}} & C_{-+}{ }^{1}=\frac{-q^{3}}{1+q^{4}} & C_{-+}{ }^{2}=\frac{q^{3}}{1+q^{4}} \\
C_{-2}^{-}=\frac{-q^{4}}{1+q^{4}} & C_{21}{ }^{1}=\frac{q\left(1-q^{2}\right)}{1+q^{4}} & C_{2+}{ }^{+}=\frac{-q^{4}}{1+q^{4}} & C_{2-}=\frac{}{1+q^{4}} \\
C_{22}{ }^{2}=\frac{q\left(1-q^{2}\right)}{1+q^{4}} & & &
\end{array}
$$

Cartan-Maurer equations:

$$
\begin{gathered}
d \omega^{1}+q \omega^{+} \wedge \omega^{-}=0 \\
d \omega^{+}+q \omega^{+}\left(-q^{2} \omega^{1}+\omega^{2}\right)=0 \\
d \omega^{-}+q\left(-q^{2} \omega^{1}+\omega^{2}\right) \omega^{-}=0 \\
d \omega^{2}-q \omega^{+} \wedge \omega^{-}=0
\end{gathered}
$$

The q-Lie algebra:

$$
\begin{gathered}
\chi_{1} \chi_{+}-\chi_{+} \chi_{1}-\left(q^{4}-q^{2}\right) \chi_{2} \chi_{+}=q^{3} \chi_{+} \\
\chi_{1} \chi_{-}-\chi_{-} \chi_{1}+\left(q^{2}-1\right) \chi_{2} \chi_{-}=-q \chi_{-} \\
\chi_{1} \chi_{2}-\chi_{2} \chi_{1}=0 \\
\chi_{+} \chi_{-}-\chi_{-} \chi_{+}+\left(1-q^{2}\right) \chi_{2} \chi_{1}-\left(1-q^{2}\right) \chi_{2} \chi_{2}=q\left(\chi_{1}-\chi_{2}\right) \\
\chi_{+} \chi_{2}-q^{2} \chi_{2} \chi_{+}=q \chi_{+} \\
\chi_{-} \chi_{2}-q^{-2} \chi_{2} \chi_{-}=-q^{-1} \chi_{-}
\end{gathered}
$$

Commutation relations between left invariant $\omega^{i}$ and $\omega^{j}$ :

$$
\begin{gathered}
\omega^{1} \wedge \omega^{+}+\omega^{+} \wedge \omega^{1}=0 \\
\omega^{1} \wedge \omega^{-}+\omega^{-} \wedge \omega^{1}=0 \\
\omega^{1} \wedge \omega^{2}+\omega^{2} \wedge \omega^{1}=\left(1-q^{2}\right) \omega^{+} \wedge \omega^{-} \\
\omega^{+} \wedge \omega^{-}+\omega^{-} \wedge \omega^{+}=0 \\
\omega^{2} \wedge \omega^{+}+q^{2} \omega^{+} \wedge \omega^{2}=q^{2}\left(q^{2}-1\right) \omega^{+} \wedge \omega^{1} \\
\omega^{2} \wedge \omega^{-}+q^{-2} \omega^{-} \wedge \omega^{2}=\left(1-q^{2}\right) \omega^{-} \wedge \omega^{1} \\
\omega^{2} \wedge \omega^{2}=\left(q^{2}-1\right) \omega^{+} \wedge \omega^{-} \\
\omega^{1} \wedge \omega^{1}=\omega^{+} \wedge \omega^{+}=\omega^{-} \wedge \omega^{-}=0
\end{gathered}
$$

Commutation relations between $\omega^{i}$ and the basic elements of $A\left(s=\left(c^{+}\right)^{-1} c^{-}\right)$:

$$
\begin{array}{ll}
\omega^{1} \alpha=s q^{-2} \alpha \omega^{1} & \omega^{+} \alpha=s q^{-1} \alpha \omega^{+} \\
\omega^{1} \beta=s \beta \omega^{1} & \omega^{+} \beta=s q^{-1} \beta \omega^{+}+s\left(q^{-2}-1\right) \alpha \omega^{1} \\
\omega^{1} \gamma=s q^{-2} \gamma \omega^{1} & \omega^{+} \gamma=s q^{-1} \gamma \omega^{+} \\
\omega^{1} \delta=s \delta \omega^{1} & \omega^{+} \delta=s q^{-1} \delta \omega^{+}+s\left(q^{-2}-1\right) \gamma \omega^{1} \\
\omega^{-} \alpha=s q^{-1} \alpha \omega^{-}+s\left(q^{-2}-1\right) \beta \omega^{1} & \omega^{2} \alpha=s \alpha \omega^{2}+s\left(q^{-1}-q\right) \beta \omega^{+} \\
\omega^{-} \beta=s q^{-1} \beta \omega^{-} & \omega^{2} \beta=s q^{-2} \beta \omega^{2}+s\left(q^{-1}-q\right) \alpha \omega^{-}+s\left(q^{-1}-q\right)^{2} \beta \omega^{1} \\
\omega^{-} \gamma=s q^{-1} \gamma \omega^{-}+s\left(q^{-2}-1\right) \delta \omega^{1} & \omega^{2} \gamma=s \gamma \omega^{2}+s\left(q^{-1}-q\right) \delta \omega^{+} \\
\omega^{-} \delta=s q^{-1} \delta \omega^{-} & \omega^{2} \delta=s q^{-2} \delta \omega^{2}+s\left(q^{-1}-q\right) \gamma \omega^{-}+s\left(q^{-1}-q\right)^{2} \delta \omega^{1}
\end{array}
$$

Values and action of the generators on the q-group elements:

$$
\begin{array}{llll}
\chi_{1}(\alpha)=\frac{s-q^{2}}{q^{3}-q} & \chi_{+}(\alpha)=0 & \chi_{-}(\alpha)=0 & \chi_{2}(\alpha)=\frac{s-1}{q-q^{-1}} \\
\chi_{1}(\beta)=0 & \chi_{+}(\beta)=0 & \chi_{-}(\beta)=-s & \chi_{2}(\beta)=0 \\
\chi_{1}(\gamma)=0 & \chi_{+}(\gamma)=-s & \chi_{-}(\gamma)=0 & \chi_{2}(\gamma)=0 \\
\chi_{1}(\delta)=\frac{-q^{2}+s\left(1-q^{2}+q^{4}\right)}{q^{3}-q} & \chi_{+}(\delta)=0 & \chi_{-}(\delta)=0 & \chi_{2}(\delta)=\frac{s-q^{2}}{q^{3}-q} \\
\chi_{1} * \alpha=\frac{s-q^{2}}{q^{3}-q} \alpha & \chi_{+} * \alpha=-s \beta & \chi_{-} * \alpha=0 & \chi_{2} * \alpha=\frac{s-1}{q-q^{-1}} \alpha \\
\chi_{1} * \beta=\frac{-q^{2}+s\left(1-q^{2}+q^{4}\right)}{q^{3}-q} \beta & \chi_{+} * \beta=0 & \chi_{-} * \beta=-s \alpha & \chi_{2} * \beta=\frac{\left(s-q^{2}\right)}{q^{3}-q} \beta \\
\chi_{1} * \gamma=\frac{s-q^{2}}{q^{3}-q} \gamma & \chi_{+} * \gamma=-s \delta & \chi_{-} * \gamma=0 & \chi_{2} * \gamma=\frac{s-1}{q-q^{-1}} \gamma \\
\chi_{1} * \delta=\frac{-q^{2}+s\left(1-q^{2}+q^{4}\right)}{q^{3}-q} \delta & \chi_{+} * \delta=0 & \chi_{-} * \delta=-s \gamma & \chi_{2} * \delta=\frac{s-q^{2}}{q^{3}-q} \delta
\end{array}
$$

Exterior derivatives of the basic elements of $A$ :

$$
\begin{aligned}
& d \alpha=\frac{s-q^{2}}{q^{3}-q} \alpha \omega^{1}-s \beta \omega^{+}+\frac{s-1}{q-q^{-1}} \alpha \omega^{2} \\
& d \beta=\frac{q^{2}+s\left(1-q^{2}+q^{4}\right)}{q^{3}-q} \beta \omega^{1}-s \alpha \omega^{-}+\frac{s-q^{2}}{q^{3}-q} \beta \omega^{2} \\
& d \gamma=\frac{s-q^{2}}{q^{3}-q} \gamma \omega^{1}-s \delta \omega^{+}+\frac{s-1}{q-q^{-1}} \gamma \omega^{2} \\
& d \delta=\frac{-q^{2}+s\left(1-q^{2}+q^{4}\right)}{q^{3}-q} \delta \omega^{1}-s \gamma \omega^{-}+\frac{s-q^{2}}{q^{3}-q} \delta \omega^{2}
\end{aligned}
$$

The $\omega^{i}$ in terms of the exterior derivatives on $\alpha, \beta, \gamma, \delta$ :

$$
\begin{aligned}
& \omega^{1}=\frac{q}{s\left(-q^{2}-q^{4}+s+s q^{4}\right)}\left[\left(q^{2}-s\right)(\kappa(\alpha) d \alpha+\kappa(\beta) d \gamma)+q^{2}(s-1)(\kappa(\gamma) d \beta+\kappa(\delta) d \delta)\right] \\
& \omega^{+}=-\frac{1}{s}[\kappa(\gamma) d \alpha+\kappa(\delta) d \gamma] \\
& \omega^{-}=-\frac{1}{s}[\kappa(\alpha) d \beta+\kappa(\beta) d \delta] \\
& \omega^{2}=\frac{q}{s\left(-q^{2}-q^{4}+s+s q^{4}\right)}\left[\left(s-q^{2}-s q^{2}+s q^{4}\right)(\kappa(\alpha) d \alpha+\kappa(\beta) d \gamma)+\left(q^{2}-s\right)(\kappa(\gamma) d \beta+\kappa(\delta) d \delta)\right]
\end{aligned}
$$

Lie derivative on $\omega^{i}$ : (See Subsection 2.4.5)

$$
\begin{array}{lll}
\chi_{1} * \omega^{1}=q\left(q^{2}-1\right) \omega^{1}+\left(q^{-1}-q\right) \omega^{2} & & \chi_{+} * \omega^{1}=-q \omega^{-} \\
\chi_{1} * \omega^{+}=-q^{-1} \omega^{+} & & \chi_{+} * \omega^{+}=-q \omega^{2}+q^{3} \omega^{1} \\
\chi_{1} * \omega^{-}=\left[q\left(q^{2}+1\right)-q^{-1}\right] \omega^{-} & & \chi_{+} * \omega^{-}=0 \\
\chi_{1} * \omega^{2}=-q\left(q^{2}-1\right) \omega^{1}-\left(q^{-1}-q\right) \omega^{2} & \chi_{+} * \omega^{2}=q \omega^{-} \\
& & \\
& \chi_{2} * \omega^{1}=0 \\
\chi_{-} * \omega^{+}=0 & \omega^{+} & \chi_{2} * \omega^{+}=q \omega^{+} \\
\chi_{-} * \omega^{-}=q^{-1} \omega^{2}-q \omega^{1} & \chi_{2} * \omega^{-}=-q^{-1} \omega^{-} \\
\chi_{-} * \omega^{2}=-q \omega^{+} & \chi_{2} * \omega^{2}=0
\end{array}
$$

### 2.3 Differential calculus from the $q$-Lie Algebra. (A more intuitive presentation of the differential calculus on $q$-groups)

In the previous sections we have analized the differential calculus on $q$-groups starting from the properties of the exterior differential and the space of 1 -forms. The left invariant vectorfields $\chi_{i}$ and their $q$-Lie algebra were then introduced at the very end. Here we would like to invert the exposition procedure and following 45, (44] and in the spirit of [36, 34, 35], [37, 38], [42], we derive differential calculi on $q$-groups from basic properties of $q$-Lie algebras.

This clarify the important role played by the adjoint action in the $q$-Lie algebra and in the construction of a bicovariant differential calculus. In this way we also give an alternative proof of the Woronowicz theorems that we stated in Section 2.1.

This approach is also suitable for the study of generalizations of the Woronowicz theory. As is evident from Subsection 2.3.3 bicovariant calculi that do not satisfy the undeformed Leibniz rule can be found studying quantum Lie algebras that are closed under the adjoint action [44].

In this section we consider a generic Hopf algebra $A$ and a Hopf algebra $U$ paired to $A$, we also consider the pairing non-degenerate. Intuitively $A$ and $U$ are the quantum analogue of $\operatorname{Fun}(G)$ and of the universal enveloping algebra $U(g)$. The differential calculus on $A$ and the quantum Lie algebra structure can be formulated, as in Section 2.1, without the introduction of $U$, however to gain a better geometrical understanding of the structures we are condisering, the universal enveloping algebra $U$ is helpful. We think that this presentation is more intuitive than the one in Section 2.1, because it is closer to the classical case, where the exterior differential on a group manifold can be introduced via a basis of left invariant vectorfields and the dual basis of 1 -forms. In this way we emphasize the role played by left invariant vectorfields i.e. the $q$-tangent space, a more intuitive and basic concept than that of left invariant 1 -forms ( $q$-cotangent space). The $q$-tangent bundle of general vectorfields will be studied in the next section.

### 2.3.1 Left invariant Vectorfields

Classically the differential calculus on a group is uniquely determined by the Lie algebra of the tangent vectors to the origin of the group. Locally we write a basis as $\left\{\left.\partial_{i}\right|_{1_{G}}\right\}$. Once we have this basis, using the tangent map (namely $T L_{g}$ ) induced by the left multiplication of the group on itself: $L_{g} g^{\prime}=g g^{\prime}, \forall g, g^{\prime} \in G$ we can construct a basis of left invariant vectorfields $\left\{t_{i}\right\}$. The action of these vectorfields on a generic function $a$ on the group manifold is

$$
\begin{equation*}
t_{i}(a)=\left.a_{1}\left(\left.\partial_{i} a_{2}\right|_{1_{G}}\right) \equiv \partial_{i}\right|_{1_{G}} * a \tag{2.3.1}
\end{equation*}
$$

in compliance with the following picture:

where $L_{g}^{*}(a)(h) \equiv a(g h)=a_{1}(g) a_{2}(h)$ [cf. (2.1.10)]. Explicitly, $t$ is left invariant if $T L_{g}\left(\left.t\right|_{1_{G}}\right)=\left.t\right|_{g}$, then we have

$$
\left.t(a)\right|_{g}=\left(\left.T L_{g} t\right|_{1_{G}}\right)(a)=\left.t[a(g \tilde{g})]\right|_{\tilde{g}=1_{G}}=\left.t\left[a_{1}(g) a_{2}(\tilde{g})\right]\right|_{\tilde{g}=1_{G}}=\left.a_{1}(g) t\left(a_{2}\right)\right|_{1_{G}}
$$

and 2.3.1 follows [cf. (1.3.6)].
In the commutative case, since the space ${ }_{\text {inv }} \Xi$ of left invariant vectorfields provides a trivialization of the tangent bundle of the group manifold the space $\Xi$ of vectorfields is isomorphic to $C^{\infty}(G) \otimes_{\mathrm{inv}} \Xi \simeq{ }_{\mathrm{inv}} \Xi \otimes C^{\infty}(G)$, i.e., a generic vectorfield $V$ can be written as $V=b^{i} t_{i}$ where $b^{i}$ are functions on the group manifold. Similarly a generic 1-form can be written $\rho=b_{i} \omega^{i} \quad\left[b_{i} \in C^{\infty}(G)\right]$ where $\left\{\omega^{i}\right\}$ is the dual basis of $\left\{t_{i}\right\}$. Finally, the exterior differential on a generic function $b$ is

$$
\begin{equation*}
d b=t_{i}(b) \omega^{i} \tag{2.3.2}
\end{equation*}
$$

and is compatible with the left and right action of the group on the space of 1-forms: $L_{x}^{*}(a d b)=L_{x}^{*}(a) L_{x}^{*}(d b)=L_{x}^{*}(a) d L_{x}^{*}(b)$ and $R_{x}^{*}(a d b)=R_{x}^{*}(a) R_{x}^{*}(d b)=R_{x}^{*}(a) d R_{x}^{*}(b)$.

Following this classical construction, in this section we show that a differential calculus on a $q$-group $A$, with universal enveloping algebra $U\left(U \equiv U_{q}(\mathrm{~g})\right)$, is determined by a $q$-Lie algebra $T$ : the $q$-deformation of g . The exterior differential is then given by (2.3.2) where now $t_{i}$ are left invariant vectorfield on $A$ and $\left\{\omega^{i}\right\}$ is the dual basis of $\left\{t_{i}\right\}$.

It is natural to look for a linear space $T, T \subset \operatorname{ker} \varepsilon \subset U$ satisfying the following three conditions:

$$
\begin{gather*}
T \text { generates } U  \tag{2.3.3}\\
\Delta^{\prime}(T) \subset T \otimes U+\varepsilon \otimes T,  \tag{2.3.4}\\
{[T, T] \subset T} \tag{2.3.5}
\end{gather*}
$$

where the bracket is the adjoint action defined by

$$
\begin{equation*}
\forall \chi, \tilde{\chi} \in T, \quad[\tilde{\chi}, \chi] \equiv \kappa^{\prime}\left(\chi_{1}\right) \tilde{\chi} \chi_{2} . \tag{2.3.6}
\end{equation*}
$$

Conditions (2.3.3) and (2.3.5) encode the quantum group properties of the $q$-tangent space because they involve the product and the antipode $\kappa^{\prime}$ of $U$. Condition (2.3.4) states that the elements of $T$ are generalized tangent vectors, and in fact, if $\left\{\chi_{i}\right\}$ is a basis of the linear space $T$, we have

$$
\begin{equation*}
\Delta\left(\chi_{i}\right)=\chi_{j} \otimes f^{j}{ }_{i}+\varepsilon \otimes \chi_{j} \tag{2.3.7}
\end{equation*}
$$

that is equivalent to

$$
\begin{equation*}
\chi_{i}(a b)=\chi_{j}(a) f^{j}{ }_{i}(b)+\varepsilon(a) \chi_{j}(b) \tag{2.3.8}
\end{equation*}
$$

where $f^{j}{ }_{i} \in U$ and $\varepsilon^{\prime}\left(f^{j}{ }_{i}\right) \equiv f^{j}{ }_{i}(I)=\delta_{i}^{j}$. [Hint: apply $\left(i d \otimes \varepsilon^{\prime}\right)$ to (2.3.4)]. In the commutative limit we expect $f_{i}{ }^{j} \rightarrow \varepsilon$. Notice that we follow the historical convention which consider derivative operators acting from the right to the left, as is seen from their deformed Leibniz rule (2.3.7). Of course one can consider deformed derivative operators $\check{\chi}_{i}$ acting from the left to the right, they are for example given by $\check{\chi}_{i}=-\kappa^{\prime-1}\left(\chi_{i}\right)$, similarly $\check{f}_{j}{ }^{i}=\kappa^{\prime-1}\left(f^{i}{ }_{j}\right)$ and then $\Delta\left(\check{\chi}_{i}\right)=\check{\chi}_{i} \otimes \varepsilon+\check{f_{i}}{ }^{j} \otimes \check{\chi_{j}}$.

Following (2.3.1) we can also consider the $q$-deformed left invariant vectorfields

$$
\begin{equation*}
t_{i} \equiv \chi_{i} * \tag{2.3.9}
\end{equation*}
$$

defined by $\chi_{i} * a \equiv a_{1} \chi_{i}\left(a_{2}\right)$, then (2.3.4) states that the $\chi_{i} *$ are generalized derivations

$$
\begin{equation*}
\chi_{i} *(a b)=\left(\chi_{j} * a\right)\left(f^{j}{ }_{i} * b\right)+a \chi_{j} * b \tag{2.3.10}
\end{equation*}
$$

where we have also defined $f^{j}{ }_{i} * b \equiv b_{1} f^{j}{ }_{i}\left(b_{2}\right)$, and $\varepsilon * a \equiv a_{1} \varepsilon\left(a_{2}\right)=a .$.
There is a one-to-one correspondence $\chi_{i} \leftrightarrow t_{i}=\chi_{i} *$. In order to obtain $\chi_{i}$ from $\chi_{i} *$ we simply apply $\varepsilon$ :
$\left(\varepsilon \circ t_{i}\right)(a)=\varepsilon\left(i d \otimes \chi_{i}\right) \Delta(a)=\varepsilon\left(a_{1} \chi_{i}\left(a_{2}\right)\right)=\varepsilon\left(a_{1}\right) \chi_{i}\left(a_{2}\right)=\chi_{i}(\varepsilon \otimes i d) \Delta(a)=\chi_{i}(a)$.

### 2.3.2 Adjoint action

In this subsection we examine and study the consequences of conditions (2.3.3) and (2.3.5). We see that they define the adjoint representation $M_{i}{ }^{j}$ that we will later identify with the one studied in Section 2.1; we rewrite (2.3.3) and (2.3.5) in a more geometric language using left and right invariant vectorfields and finally, in Note 2.3.1, we establish the equivalence between (2.3.3)-(2.3.5) and Woronowicz theory.

Condition (2.3.5) is the closure of $T$ under the adjoint action, in the classical case, if $\chi$ is a tangent vector: $\Delta(\chi)=\chi \otimes \varepsilon+\varepsilon \otimes \chi, \kappa^{\prime}(\chi)=-\chi$ and the adjoint action of $\chi$ on $\tilde{\chi}$ is given by the commutator $\tilde{\chi} \chi-\chi \tilde{\chi}$. Expression (2.3.6) is a natural
and simple way to write, both at the quantum and at the classical level, the adjoint action. We can derive (2.3.6) from the classical conjugation on the group elements. First we notice that the conjugation Conj $^{-1}: G \times G \rightarrow G$, Conj $_{\tilde{g}}^{-1}(g)=\tilde{g}^{-1}(g) \tilde{g}$ induces the following action on $A=\operatorname{Fun}(G)$ :

$$
\begin{equation*}
\operatorname{ad}(a)=a_{2} \otimes \kappa\left(a_{1}\right) a_{3} \tag{2.3.11}
\end{equation*}
$$

Proof: $\operatorname{ad}(a)(g, \tilde{g})=a_{2}(g)\left(a_{1}\right)\left(\tilde{g}^{-1}\right) a_{3}(\tilde{g})=a\left(\tilde{g}^{-1} g \tilde{g}\right)$. Expression (2.3.11) is independent from the points $g$ of $G$ and therefore holds also for a generic Hopf algebra $A$. Now we use the pairing between $A$ and $U \subseteq A^{\prime}$, discussed in Section 1.3, to deduce the adjoint action of the universal enveloping algebra $U$ on itself : $\forall \psi, \varphi \in U, \forall a \in A$

$$
\begin{align*}
\left\langle a d_{\psi} \varphi, a\right\rangle & \equiv\langle\varphi \otimes \psi, a d a\rangle  \tag{2.3.12}\\
& =\left\langle\varphi \otimes \kappa^{\prime}\left(\psi_{1}\right) \otimes \psi_{2}, a_{2} \otimes a_{1} \otimes a_{3}\right\rangle  \tag{2.3.13}\\
& =\left\langle\kappa^{\prime}\left(\psi_{1}\right) \varphi \psi_{2}, a\right\rangle \tag{2.3.14}
\end{align*}
$$

so that

$$
\begin{equation*}
a d_{\psi} \varphi=\kappa^{\prime}\left(\psi_{1}\right) \varphi \psi_{2} . \tag{2.3.15}
\end{equation*}
$$

Notice that ad is a right action of $U$ on $U, \forall \varphi, \psi, \zeta \in U$ :

$$
\begin{equation*}
a d_{\psi \zeta} \varphi=a d_{\zeta}\left(a d_{\psi} \varphi\right) ; \tag{2.3.16}
\end{equation*}
$$

in particular, for $\chi, \tilde{\chi}, \chi^{\prime}, \ldots \chi^{\prime \prime} \in T$, formulae (2.3.15) and (2.3.16) read:

$$
\begin{equation*}
a d_{\chi} \tilde{\chi}=[\tilde{\chi}, \chi] \quad \text { and } \quad a d_{\left(\chi \chi^{\prime} \ldots \chi^{\prime \prime}\right)} \tilde{\chi}=\left[\ldots\left[[\tilde{\chi}, \chi], \chi^{\prime}\right], \ldots \chi^{\prime \prime}\right] . \tag{2.3.17}
\end{equation*}
$$

The first expression proves that the bracket in (2.3.6) is indeed the adjoint action; from the second expression, (2.3.3) and (2.3.5), we have

$$
\begin{equation*}
\forall \psi \in U, \forall \chi \in T, \quad a d_{\psi} \chi \in T \quad \text { i.e. } \quad a d_{\psi} \chi_{i}=M_{i}{ }^{j}(\psi) \chi_{j} \tag{2.3.18}
\end{equation*}
$$

where we have introduced the basis $\left\{\chi_{i}\right\}_{i=1, \ldots n}$ of $T$ and $M_{i}{ }^{j}(\psi)$ are complex numbers depending on $\psi$. The linearity of the adjoint map imply that the functionals $M_{i}{ }^{j}$ are linear: $M_{i}{ }^{j}(\alpha \psi+\phi)=\alpha M_{i}{ }^{j}(\psi)+M_{i}{ }^{j}(\phi)$ while, due to (2.3.16), they are a representation of $U: M_{i}{ }^{j}(\psi \phi)=M_{i}{ }^{k}(\psi) M_{k}{ }^{j}(\phi)$. Since the pairing $A \leftrightarrow U$ is nondegenerate and $\psi$ is a generic element of $U$, the second expression in (2.3.18) uniquely defines the functionals $M_{i}{ }^{j}$ as elements of $A$. They are the adjoint representation, in Hopf algebra notations [see (2.1.46)]:

$$
\begin{equation*}
\varepsilon\left(M_{i}{ }^{j}\right)=\delta_{i}^{j} \quad, \quad \Delta\left(M_{i}{ }^{j}\right)=M_{i}{ }^{l} \otimes M_{l}{ }^{j} . \tag{2.3.19}
\end{equation*}
$$

We can also obtain an explicit expression for the elements $M_{i}{ }^{j} \in A$; since $A$ separates the points of $U$, and therefore of $T$, we can consider $n$ elements $y^{i} \in A$ such that $\left\langle\chi_{i}, y^{j}\right\rangle=\chi_{i}\left(y^{j}\right)=\delta_{i}^{j}$. Then

$$
\begin{equation*}
M_{i}^{j}=\left(\chi_{i} \otimes i d\right) a d y^{j}=\chi_{i}\left(y_{2}^{j}\right) \kappa\left(y_{1}^{j}\right) y_{3}^{j} \tag{2.3.20}
\end{equation*}
$$

Proof: apply a generic element $\psi \in U$ to (2.3.20) and recall (2.3.12).
In particular, formula (2.3.20) holds if we consider the coordinates $x^{i}$ on the quantum group, as defined in (2.1.89) and (2.1.90), we therefore have:

$$
\begin{equation*}
M_{i}^{j}=\left(\chi_{i} \otimes i d\right) \operatorname{ad} x^{j}=\chi_{i}\left(x_{2}^{j}\right) \kappa\left(x_{1}^{j}\right) x_{3}^{j} . \tag{2.3.21}
\end{equation*}
$$

There is an equivalent expression for (2.3.18) that shows its $q$-group geometric content. We have shown that $t=\chi *$ is a left-invariant vectorfield, similarly

$$
\begin{equation*}
h \equiv * \chi \quad \text { i.e. } \quad \forall a \in A \quad h(a) \equiv \chi\left(a_{1}\right) a_{2} \tag{2.3.22}
\end{equation*}
$$

is a right invariant vectorfield.
Theorem 2.3.1 Relation (2.3.18) is equivalent to, $\forall a \in A t_{j}(a) M_{i}{ }^{j}=h_{i}(a)$ i.e.

$$
\begin{equation*}
\left(\chi_{j} * a\right) M_{i}{ }^{j}=a * \chi_{i} \quad \text { i.e. } \quad a_{1} \chi_{j}\left(a_{2}\right) M_{i}{ }^{j}=\chi_{i}\left(a_{1}\right) a_{2} \tag{2.3.23}
\end{equation*}
$$

Proof Multiplying (2.3.18) i.e. $\quad a d_{\psi} \chi_{i}=\kappa^{\prime}\left(\psi_{1}\right) \chi_{i} \psi_{2}=\psi\left(M_{i}{ }^{j}\right) \chi_{j}$ by $\psi_{0}$, where $\left(\Delta^{\prime} \otimes i d\right) \Delta^{\prime}(\psi)=\psi_{0} \otimes \psi_{1} \otimes \psi_{2}$, we obtain the equivalent expression

$$
\begin{equation*}
\forall \psi \in U \quad \chi_{i} \psi=\psi_{1} \chi_{j} \psi_{2}\left(M_{i}{ }^{j}\right) \tag{2.3.24}
\end{equation*}
$$

This relation gives the $q$-commutation relations between any $\psi \in U$ and the $\chi_{j}$ elements. We apply a generic element $a \in A$ to (2.3.24) and rewrite the right hand side as, $\forall \psi \in U, \forall a \in A$

$$
\begin{align*}
\left\langle\psi_{1} \chi_{j} \psi_{2}\left(M_{i}{ }^{j}\right), a\right\rangle & =\left\langle\psi_{1} \chi_{i} \otimes \psi_{2}, a \otimes M_{j}{ }^{i}\right\rangle  \tag{2.3.25}\\
& =\left\langle\psi \otimes \chi_{j}, a_{1} M_{j}{ }^{i} \otimes a_{2}\right\rangle \tag{2.3.26}
\end{align*}
$$

Since $\psi \in U$ and $a \in A$ are arbitrary elements and since the pairing $U \leftrightarrow A$ is nondegenerate (we actually only need $U$ to separate the points of $A$ ) we conclude

$$
\begin{equation*}
\left\langle\chi_{i} \otimes \psi, a_{1} \otimes a_{2}\right\rangle=\left\langle\psi \otimes \chi_{j}, a_{1} M_{j}^{i} \otimes a_{2}\right\rangle \Leftrightarrow a * \chi_{i}=\left(\chi_{j} * a\right) M_{i}^{j} \tag{2.3.27}
\end{equation*}
$$

that proves the theorem.
Formula (2.3.23) relates the left invariant vectorfields $t_{i}=\chi_{i} *$ to the right invariant ones $h_{i}=* \chi$ via the adjoint representation $M_{i}{ }^{j}$. We can write $h_{i}=t_{j 口} M_{i}{ }^{j}$ where $\left(t_{j} \square M_{i}{ }^{j}\right)(a) \equiv t_{j}(a) M_{i}{ }^{j} \forall a \in A$. This formula is the analogue of (2.1.47). The space of vectorfields is analized in the next section.

Note 2.3.1 In [21] Woronowicz has shown that bicovariant differential calculi are in one-to-one correspondence with ad-invariant right ideals $R$ of $A: R a \subset R \forall a \in A$ $\operatorname{ad}(R) \subset R \otimes A$. These two conditions are slightly weaker than (2.3.3)-(2.3.5). Relation (2.3.4) can also be written $\Delta(T \oplus\{\varepsilon\}) \subset(T \oplus\{\varepsilon\}) \otimes U$, where $T \oplus\{\varepsilon\}$
is the vector space spanned by $\chi_{i}$ and $\varepsilon$; therefore $(T \oplus\{\varepsilon\})$ is a right co-ideal, it is the space orthogonal to the Woronowicz [21] right ideal $R \equiv\{a \in A / \varepsilon(a)=$ 0 and $T(a)=0\}$. We have seen that relations (2.3.3) and (2.3.5) imply (2.3.18) this condition is then equivalent to the ad invariance of $R: \operatorname{ad}(R) \subset R \otimes A$.
Proof: $\forall r \in R, \forall \chi \in T, \forall \psi \in U$,

$$
\begin{equation*}
0=\left\langle a d_{\psi} \chi, r\right\rangle=\langle\chi \otimes \psi, a d r\rangle \Rightarrow a d r \in(R \oplus\{I\}) \otimes A \Rightarrow a d r \in R \otimes A \tag{2.3.28}
\end{equation*}
$$

where the last implication holds because $\langle\varepsilon \otimes i d$, ad $r\rangle=0$. Viceversa ad $R \subset R \otimes$ $A \Rightarrow a d_{\psi} \chi \in T \oplus\{\varepsilon\} \Rightarrow a d_{\psi} \chi \in T$ since $\left\langle a d_{\psi} \chi, I\right\rangle=0$

Notice that a Woronowicz type bicovariant differential calculus is given by a set $\left\{\chi_{i}\right\}$ of linear functionals on $A$ satisfying (2.3.23) and (2.3.8), the full structure of the dual Hopf algebra $U$ and the nondegeneracy of the $A \leftrightarrow U$ pairing is not needed to formulate the calculus. In particular (2.3.19) can be derived from (2.3.23). $\cdot$ •

### 2.3.3 The space of 1 -forms and the exterior differential

We now proceed in the construction of the differential calculus introducing the space $\Gamma$ of 1 -forms. The space of left-invariant 1 -forms ${ }_{\text {inv }} \Gamma$ is defined as the space dual to that of the tangent vectors $T$, let $\left\{\omega^{i}\right\}$ be the base of ${ }_{\text {inv }} \Gamma$ dual to $\left\{\chi_{i}\right\}$, we use the notation

$$
\begin{equation*}
\left\langle\chi_{i}, \omega^{j}\right\rangle=\delta_{i}^{j} . \tag{2.3.29}
\end{equation*}
$$

By definition a generic 1 -form is then uniquely written as [see (2.1.28)] $\rho=a_{i} \omega^{i}$ i.e. the space of 1 -forms is the left $A$-module freely generated by the elements $\omega^{i}$. This corresponds to the classical property that the cotangent bundle of a group manifold is trivial. The differential is defined by

$$
\begin{equation*}
\forall a \in A \quad d a=\left(\chi_{i} * a\right) \omega^{i} . \tag{2.3.30}
\end{equation*}
$$

Note 2.3.2 We can rewrite the exterior differential using right-invariant vectorfields:

$$
\begin{equation*}
d a=\left(a * \chi_{i}\right) \kappa^{-1}\left(M_{j}{ }^{i}\right) \omega^{j}=\left(a * \chi_{i}\right) \eta^{i} \tag{2.3.31}
\end{equation*}
$$

where we have defined the 1 -forms $\eta^{i}=\kappa^{-1}\left(M_{j}{ }^{i}\right) \omega^{j}$. It is easy to check that the $\eta^{i}$ are right invariant, see (2.1.47). Using (2.1.50) we also have:

$$
\begin{equation*}
d a=-\eta^{i}\left(a * \kappa^{\prime}\left(\chi_{i}\right)\right) . \tag{2.3.32}
\end{equation*}
$$

[^4]Any 1-form $\rho \in \Gamma$ can be written as $\rho=\sum_{k} a_{k} d b_{k}$ for some $a_{k}, b_{k} \in A$ because we have the following expression for the left invariant 1-forms:

$$
\begin{equation*}
\omega^{i}=\kappa\left(y_{1}^{i}\right) d y_{2}^{i} ; \quad \text { in particular } \quad \omega^{i}=\kappa\left(x_{1}^{i}\right) d x_{2}^{i} \tag{2.3.33}
\end{equation*}
$$

where $y^{i}$ and $x^{i}$ are the same elements that appear in (2.3.20) and (2.3.21).
Proof: $\kappa\left(y_{1}^{i}\right) d y_{2}^{i}=\kappa\left(y_{1}^{i}\right) y_{2}^{i} \chi_{j}\left(y_{3}^{i}\right) \omega^{j}=\chi_{j}\left(y^{i}\right) \omega^{j}=\omega^{i}$
On the space $\Gamma$ of 1-forms we can introduce a left and a right coaction of $A$ [the analogue of the left and right pullback on 1 -forms, see (2.1.10)-(2.1.11)] by the following definitions, [see (2.1.20) and (2.1.38)]:

$$
\begin{equation*}
\Delta_{\Gamma}\left(a_{i} \omega^{i}\right)=\Delta\left(a_{i}\right)\left(I \otimes \omega^{i}\right) \quad ; \quad{ }_{\Gamma} \Delta\left(a_{i} \omega^{i}\right)=\Delta(a)\left(\omega^{j} \otimes M_{j}{ }^{i}\right) \tag{2.3.34}
\end{equation*}
$$

notice that the right $A$ coaction on the left-invariant 1 -forms inv $\Gamma$ corresponds to the (left) adjoint action of $U$ on ${ }_{\mathrm{inv}} \Gamma: \forall \psi \in U, a d_{\psi} \omega^{i} \equiv \omega^{j} \psi\left(M_{j}{ }^{i}\right)$. We say that $\Gamma$ is a left and right covariant left-module because properties (2.1.17), (2.1.18) and (2.1.19) are satisfied. [Hint: use (2.3.19)]. We are now able to prove that the differential calculus is left and right covariant i.e. it is bicovariant on the left module $\Gamma$ :

Proposition 2.3.1 The exterior differential defined in (2.3.30) is bicovariant on the left module $\Gamma$ :

$$
\begin{array}{lll}
\Delta_{\Gamma}(a d b)=\Delta(a)(i d \otimes d) \Delta(b), & \Delta_{\Gamma}: \Gamma \rightarrow A \otimes \Gamma & \text { (left covariance) } \\
{ }_{\Gamma} \Delta(a d b)=\Delta(a)(d \otimes i d) \Delta(b), & \Gamma \Delta: \Gamma \rightarrow \Gamma \otimes A & (\text { right covariance })(2.3 .36)
\end{array}
$$

Proof: since $\Delta_{\Gamma}(a \rho)=\Delta(a) \Delta_{\Gamma}(\rho)$ and ${ }_{\Gamma} \Delta(a \rho)=\Delta(a)_{\Gamma} \Delta(\rho)$ where $\rho$ is a generic 1 -form it is sufficient to prove:

$$
\begin{align*}
\Delta_{\Gamma}(d b) & =\Delta\left(\chi_{i} * b\right) I \otimes \omega^{i}=b_{1} \otimes b_{2} \chi_{i}\left(b_{3}\right) \omega^{i}=(i d \otimes d) \Delta(b)  \tag{2.3.37}\\
{ }_{\Gamma} \Delta(d b) & =\Delta\left(\chi_{i} * b\right) \omega^{j} \otimes M_{j}^{i}=b_{1} \omega^{j} \otimes b_{2} \chi_{i}\left(b_{3}\right) M_{j}{ }^{i}=b_{1} \omega^{j} \otimes \chi_{j}\left(b_{2}\right) b_{3} \\
& =(d \otimes i d) \Delta(b) \tag{2.3.38}
\end{align*}
$$

We have seen that from the closure of the $q$-Lie algebra $T$ under the adjoint action of $U$ on $T$, equation (2.3.18) [or from (2.3.3) and (2.3.5)] or equivalently from the relation (2.3.23) between left and right invariant vectorfields, one can construct an exterior differential $d: A \rightarrow \Gamma$; where $\Gamma$ is the left $A$-module of 1 -forms freely generated by the space of left-invariant one forms ${ }_{\text {inv }} \Gamma$. We have introduced a left and a right coaction of the quantum group $A$ on $\Gamma$ and proved that the exterior differential is compatible with these coactions, see (2.3.35)-(2.3.36). This clarify the importance of the adjoint action in the construction of a differential calculus on a quantum group.

We now analize the consequences of (2.3.4) that, so far, we have never used in this section. We show that (2.3.4) is equivalent to the Leibniz rule for the exterior differential and that it implies the $q$-antisymmetry of the $q$-Lie algebra.

### 2.3.4 The Leibniz rule and the bicovariant bimodule of 1-forms

Lemma The deformed Leibniz rule (2.3.4) and (2.3.23) imply [see (2.1.51)]:

$$
\begin{equation*}
M_{i}^{j}\left(a * f_{k}^{i}\right)=\left(f_{i}^{j} * a\right) M_{k}^{i}, \tag{2.3.39}
\end{equation*}
$$

Proof: from (2.3.23) we have, $\forall b \in A$ :

$$
\begin{aligned}
\kappa\left(x_{1}^{l}\right)\left(\chi_{j} * x_{2}^{l} b\right) M_{i}{ }^{j}=\kappa\left(x_{1}^{l}\right)\left(x_{2}^{l} b * \chi_{i}\right) & \Leftrightarrow \\
\kappa\left(x_{1}^{l}\right) x_{2}^{l} b_{1} \chi_{j}\left(x_{3}^{l} b_{2}\right) M_{i}{ }^{j}=\kappa\left(x_{1}^{l}\right) \chi_{i}\left(x_{2}^{l} b_{1}\right)\left(x_{3}^{l} b_{2}\right) & \Leftrightarrow \\
\left(f^{l}{ }_{j} * b\right) M_{i}{ }^{j}=\kappa\left(x_{1}^{l}\right)\left[\chi_{n}\left(x_{2}^{l}\right) f^{n}{ }_{i}\left(b_{1}\right)+\varepsilon\left(x_{2}^{l}\right) \chi_{i}\left(b_{1}\right) x_{3}^{l} b_{2}\right. & \Leftrightarrow \\
\left(f_{j}^{l} * b\right) M_{i}{ }^{j}=\kappa\left(x_{1}^{l}\right) \chi_{n}\left(x_{2}^{l}\right) f^{n}{ }_{i}\left(b_{1}\right) x_{3}^{l} b_{2} & \Leftrightarrow \\
\left(f^{l}{ }_{j} * b\right) M_{i}{ }^{j}=M_{n}{ }^{l}\left(b * f^{n}{ }_{i}\right) &
\end{aligned}
$$

where in the left hand side of the second passage we have used $f^{l}{ }_{j}(b)=\chi_{j}\left(x^{l} b\right)$ that is obtained from (2.3.7) when $x^{i}=a$.

The Leibniz rule on the left $A$-module $\Gamma$ can be introduced if we know how to multiply 1 -forms with functions from the right, i.e. if $\Gamma$ is also a right module. Consider the functionals $f^{i}{ }_{j}$ given in (2.3.7), we define the following right product:

Definition

$$
\begin{equation*}
\omega^{i} c=\left(f_{j}^{i} * c\right) \omega^{j} \quad, \quad\left(a_{i} \omega^{i}\right) c=a_{i}\left(f_{j}^{i} * c\right) \omega^{j} \tag{2.3.40}
\end{equation*}
$$

the definition is well given because

$$
\begin{equation*}
\Delta^{\prime}\left(f_{j}^{i}\right)=f_{k}^{i} \otimes f_{j}^{k}, \quad \varepsilon^{\prime}\left(f_{j}^{i}\right)=\delta_{j}^{i}, \tag{2.3.41}
\end{equation*}
$$

[see (2.1.35)-(2.1.36)]; these two properties immediately follow, respectively, from the coassociativity of the coproduct on the $\chi_{i}$ elements, and from $\chi_{i}\left(x^{j}\right)=\delta_{i}^{j}$.

We now prove the compatibility of (2.3.40) with the left and right coactions $\Delta_{\Gamma}$ and ${ }_{\Gamma} \Delta$; i.e. we prove that $\Delta_{\Gamma}$ and ${ }_{\Gamma} \Delta$ are also, respectively, left and right coactions on $\Gamma$ seen as a right module:

$$
\begin{equation*}
\forall \rho \in \Gamma, \forall a \in A, \quad \Delta_{\Gamma}(\rho a)=\Delta_{\Gamma}(\rho) \Delta(a), \quad{ }_{\Gamma} \Delta(\rho a)={ }_{\Gamma} \Delta(\rho) \Delta(a) \tag{2.3.42}
\end{equation*}
$$

Since any $\rho \in \Gamma$ is of the form $\rho=a_{i} \omega^{i}$ and since $\Delta_{\Gamma} \omega^{i}=I \otimes \omega^{i}$, the only nontrivial espression in (2.3.42) is ${ }_{\Gamma} \Delta\left(a_{i} \omega^{i} a\right)={ }_{\Gamma} \Delta\left(a_{i} \omega^{i}\right) \Delta(a)$. As proven in Note 2.1.1, this is equivalent to (2.3.39) and we conclude that $\Gamma$ is a bicovariant bimodule, i.e. that $\Delta_{\Gamma}$ and ${ }_{\Gamma} \Delta$ are compatible with the bimodule structure of $\Gamma$.

From the deformed Leibniz rule for the tangent vectors $\chi_{i}$, see (2.3.7) or (2.3.10), and from (2.3.40), the Leibniz rule for the exterior differential immediately follows.

Viceversa, suppose that on $\Gamma$ a right module structure can be introduced such that $d$ satisfies the Leibniz rule and is well defined in the following sense:

$$
a d b=a^{\prime} d b^{\prime} \Rightarrow(a d b) c=\left(a^{\prime} d b^{\prime}\right) c \quad \text { i.e. } \quad a d(b c)-a b d c=a^{\prime} d\left(b^{\prime} c\right)-a^{\prime} b^{\prime} d c
$$

( $a d b$ is a shorthand notation for $\sum_{k} a_{k} d b_{k} ; a, b, c$ are generic elements). Then we can use the Leibniz rule to express the right module structure on $\Gamma$ as : $(a d b) c=$ $a d(b c)-a b d c$. In the particular case $a d b=\omega^{i}$ we have, see (2.3.33),

$$
\begin{align*}
\omega^{i} c & =\kappa\left(x_{1}^{i}\right) d x_{2}^{i} c=\kappa\left(x_{1}^{i}\right) d\left(x_{2}^{i} c\right)=\kappa\left(x_{1}^{i}\right) x_{2}^{i} c_{1} \chi_{j}\left(x_{3}^{i} c_{2}\right) \omega^{j}  \tag{2.3.43}\\
& =c_{1} \chi_{j}\left(x^{i} c_{2}\right) \omega^{j} \equiv c_{1} f^{j}{ }_{i}\left(c_{2}\right) \omega^{j}=\left(f^{j}{ }_{i} * c\right) \omega^{j} \tag{2.3.44}
\end{align*}
$$

where, in the last but one passage we have defined $\forall c \in A \quad f^{j}{ }_{i}(c) \equiv \chi_{j}\left(x^{i} c\right)$. Now from $d(a b)=d(a) b+a d b$ and (2.3.44) we obtain:

$$
\begin{equation*}
\chi_{i} * a b=\left(\chi_{j} * a\right)\left(f^{j}{ }_{i} * b\right)+a\left(\chi_{i} * b\right) \tag{2.3.45}
\end{equation*}
$$

that is equivalent to (2.3.10).

### 2.3.5 $\quad q$-antisymmetry of the $q$-Lie algebra bracket

The coproduct (2.3.4) implies that the espression $\left[\chi_{i}, \chi_{j}\right]$ is quadratic and $q$-antisymmetric. We first write

$$
\begin{equation*}
\left[\chi_{i}, \chi_{j}\right]=\kappa^{\prime}\left(\chi_{j_{1}}\right) \chi_{i} \chi_{j_{2}}=\kappa^{\prime}\left(\chi_{l}\right) \chi_{i} f_{j}^{l}+\chi_{i} \chi_{j} \tag{2.3.46}
\end{equation*}
$$

now we apply $m\left(i d \otimes \kappa^{\prime}\right)$ to $\Delta\left(\chi_{l}\right)=\chi_{n} \otimes f^{n}{ }_{l}+\varepsilon \otimes \chi_{l}$ to obtain $\kappa^{\prime}\left(\chi_{l}\right)=-\chi_{n} \kappa^{\prime}\left(f^{n}{ }_{l}\right)$ and therefore

$$
\begin{equation*}
\kappa^{\prime}\left(\chi_{l}\right) \chi_{i} f^{l}{ }_{j}=-\chi_{n} \kappa^{\prime}\left(f^{n}\right) \chi_{l} f^{l}{ }_{j}=-\chi_{n} a d_{\left(f^{n}{ }_{j}\right)} \chi_{i}=-\chi_{n} f^{n}{ }_{j}\left(M_{i}{ }^{l}\right) \chi_{l} \tag{2.3.47}
\end{equation*}
$$

so that

$$
\begin{equation*}
\left[\chi_{i}, \chi_{j}\right]=\chi_{i} \chi_{j}-f^{n}{ }_{j}\left(M_{i}^{l}\right) \chi_{n} \chi_{l} . \tag{2.3.48}
\end{equation*}
$$

In the above framework it is easy to derive the bicovariance conditions (2.1.111)(2.1.114); indeed recalling equations (2.1.64): $\Lambda^{i j}{ }_{k l}=f^{i}{ }_{l}\left(M_{k}{ }^{j}\right)$ and (2.1.95): $\mathbf{C}_{i j}{ }^{k}=\chi_{j}\left(M_{i}{ }^{k}\right)$ we immediately derive from (2.3.48) the bicovariance condition (2.1.111) and from [recall (2.3.18)] $\operatorname{ad}_{\left(f^{n}{ }_{j}\right)} \chi_{i}=f^{n}{ }_{j}\left(M_{i}{ }^{l}\right) \chi_{l}$ the bicovariance condition (2.1.114). Relation (2.1.113) can be derived applying to $\left(x^{i} \otimes i d\right)$ the coproduct of (2.1.111) and then using (2.1.114) and (2.1.105). Finally (2.1.112) can be obtained applying the functionals $f^{l}{ }_{n}$ to (2.3.39).

### 2.3.6 $q$-Jacoby identities

We end this section briefly commenting on the $q$-Jacoby identities. We have seen that the ad map given in (2.3.15) is a right action of $U$ on $U$ [see (2.3.16)]: $\forall \varphi, \psi, \zeta$ $a d_{\psi \zeta} \varphi=a d_{\zeta}\left(a d_{\psi} \varphi\right)$. We use the identity $\psi \zeta=\zeta_{1} a d_{\zeta_{2}} \psi$ to find

$$
\begin{equation*}
a d_{\zeta}\left(a d_{\psi} \varphi\right)=a d_{\psi \zeta} \varphi=a d_{\zeta_{1} a d_{\zeta_{2}} \psi} \varphi=a d_{\left(a d d_{\zeta_{2}} \psi\right)}\left(a d_{\zeta_{1}} \varphi\right) \tag{2.3.49}
\end{equation*}
$$

The above relation, written for elements $\chi_{i}, \chi_{j}, \chi_{l}$ of the $q$-Lie algebra $T$, is the $q$-Jacobi identity (with abuse of notation we define, $\forall \chi \in T,\left[\chi, f^{i}{ }_{j}\right] \equiv \operatorname{ad}_{\left(f^{i}{ }_{j}\right)} \chi$, $\left.[\chi, \varepsilon] \equiv a d_{\varepsilon} \chi=\chi\right):$

$$
\begin{equation*}
\left[\left[\chi_{i}, \chi_{j}\right], \chi_{l}\right]=\left[\left[\chi_{i}, \chi_{l_{1}}\right],\left[\chi_{j}, \chi_{l_{2}}\right]\right] ; \tag{2.3.50}
\end{equation*}
$$

it express the property that the bracket operation is a derivation of the $q$-Lie algebra $T$ (i.e. $a d_{\zeta}$ is a generalized derivation with respect to the product in $U$ given by the ad map). Using the explicit coproduct expression $\Delta\left(\chi_{i}\right)=\chi_{j} \otimes f^{j}{ }_{i}+\varepsilon \otimes \chi_{j}$ in (2.3.50), we obtain (2.1.99). There is also a second Jacobi identity : $\operatorname{ad}_{a d_{(\varsigma)} \psi} \varphi=a d_{\kappa\left(\zeta_{1}\right) \psi \zeta_{2}} \varphi=$ $a d_{\zeta_{2}}\left(a d_{\psi}\left(a d_{\kappa\left(\zeta_{1}\right)} \varphi\right)\right)$. On the $\chi$ elements it reads: $\left[\chi_{i},\left[\chi_{j}, \chi_{l}\right]\right]=\left[\left[\left[\chi_{i}, \kappa\left(\chi_{l_{1}}\right)\right], \chi_{j}\right], \chi_{l_{2}}\right]$. The two Jacobi identities are not independent because $a d_{\zeta}\left(a d_{\psi} \varphi\right)=a d_{\left[a \zeta_{\zeta_{2}} \kappa^{2}\left(\zeta_{1}\right) \psi\right]} \varphi$.

Notice also that the map ad is compatible with the product of $U$ in the sense that: $a d_{\zeta}(\psi \varphi)=a d_{\zeta_{1}}(\psi) a d_{\zeta_{2}}(\varphi)$ (i.e. $a d_{\zeta}$ is a generalized derivation with respect to the product of $U$ ); in particular $a d_{\chi_{l}}\left(\chi_{i} \chi_{j}\right) \equiv\left[\chi_{i} \chi_{j}, \chi_{l}\right]=\left[\chi_{i}, \chi_{s}\right] f^{s}{ }_{l}\left(M_{j}{ }^{n}\right) \chi_{n}+\chi_{i}\left[\chi_{j}, \chi_{l}\right]$.

### 2.3.7 *-Structure

Given a $*$-Hopf algebra $A$ we have a canonical $*$-structure on the dual $\mathcal{U}$. This is compatible with the quantum Lie algebra $T$ if $T^{*} \subseteq T$, i.e., if the tangent vectors $\left(\chi_{i}\right)^{*}$ are linear combination of the $\chi_{i}$, so that we have a real form of the $q$-Lie algebra. In this case we can construct a differential calculus that is real:

$$
\begin{equation*}
(d b)^{*}=d b^{*} \text { and more in general }(a d b)^{*}=d b^{*} a^{*} . \tag{2.3.51}
\end{equation*}
$$

We now explicitly perform this construction. There is a canonical $*$-structure on the space of 1 -forms. We first define a $*$-involution on ${ }_{\text {inv }} \Gamma$ via the expression:

$$
\begin{equation*}
\forall \chi \in T, \forall \omega \in \operatorname{inv} \Gamma, \quad\left\langle\omega^{*}, \chi\right\rangle \equiv-\overline{\left\langle\omega, \chi^{*}\right\rangle} \tag{2.3.52}
\end{equation*}
$$

and generalize it to $\Gamma$ as

$$
\begin{equation*}
\forall a \in A, \forall \omega \in \operatorname{inv} \Gamma, \quad(a \omega)^{*}=\omega^{*} a^{*} . \tag{2.3.53}
\end{equation*}
$$

We have to check that these definitions are consistent with the bicovariant bimodule structure on $\Gamma$. We recall from Section 1.3 that the $*$ operation becomes the hermitian conjugation ${ }^{\dagger}$ when we realize the elements of $A$ and $U$ as operators on Hilbert space (in the $q \rightarrow 1$ limit the elements of $A$ commute and correspond to diagonal operators, so that the $*$-operation becomes complex conjugation). It is then natural
to consider a basis of antihermitian $q$-Lie algebra generators $\chi_{i}:\left(\chi_{i}\right)^{*}=-\chi_{i}$, then the dual basis of 1-forms is real: $\omega^{i *}=\omega^{i}$. From $\Delta\left(\chi_{j}\right)=-\Delta\left(\chi_{j}^{*}\right)=-\left(\Delta \chi_{j}\right)^{* \otimes *}$ it follows that the $f^{i}{ }_{j}$ are real and we have

$$
\begin{equation*}
\omega^{i *} a=\left(f_{j}^{i} * a\right) \omega^{j *} \tag{2.3.54}
\end{equation*}
$$

that is compatible with $\omega^{i *}=\omega^{i}$. Proof of (2.3.54): $\left(\omega^{i *} a\right)^{*}=a^{*} \omega^{i}=\omega^{j} f^{i}{ }_{j}{ }^{\circ} \kappa^{-1} *$ $\left(a^{*}\right)=\omega^{j} a_{1}^{*} f^{i}{ }_{j}\left(\kappa^{-1}\left(a_{2}^{*}\right)\right)=\omega^{j} a_{1}^{*} \overline{f^{i}{ }_{j}\left(a_{2}\right)}=\left[\left(f^{i}{ }_{j} * a\right) \omega^{j *}\right]^{*}$, where we have used (1.3.9).

Also the elements $M_{i}{ }^{j}$ are real so that ${ }_{\Gamma} \Delta\left(\omega^{i}\right)=\omega^{j} \otimes M_{i}{ }^{j}$ is well defined.
Proof: $M_{i}{ }^{j}{ }^{*}(\psi) \chi_{j}=\overline{M_{i}{ }^{j}\left(\kappa^{\prime-1}\left(\psi^{*}\right)\right)} \chi_{j}=-\left[M_{i}{ }^{j}\left(\kappa^{\prime-1}\left(\psi^{*}\right)\right) \chi_{j}\right]^{*}=-\left[a d_{\kappa^{\prime-1}\left(\psi^{*}\right)} \chi_{i}\right]^{*}=$ $-\left[\psi_{2}^{*} \chi_{i} \kappa^{\prime-1}\left(\psi_{1}^{*}\right)\right]^{*}=M_{i}{ }^{j}(\psi) \chi_{j}$.

We are now able to show that the differential, given by $d a=\left(\chi_{i} * a\right) \omega^{i}$ is real:

$$
\begin{aligned}
\left(d a^{*}\right)^{*} & =\omega^{i}\left(\chi_{i} * a^{*}\right)^{*}=\left[f^{i}{ }_{j} *\left(\chi_{i} * a^{*}\right)^{*}\right] \omega^{j}=\left(f_{j}^{i} * a_{1}\right) \overline{\chi_{i}\left(a_{2}^{*}\right)} \omega^{j} \\
& =\left(f^{i}{ }_{j} * a_{1}\right)\left(\kappa^{\prime-1} \chi_{i}^{*}\right)\left(a_{2}\right)=-\left[f^{i}{ }_{j}\left(\kappa^{\prime-1} \chi_{i}\right) * a\right] \omega^{j}=\left(\chi_{j} * a\right) \omega^{j} \\
& =d a
\end{aligned}
$$

where we have used $m\left[\tau\left(\kappa^{\prime-1} \otimes i d\right) \Delta^{\prime}(\chi)\right]=\varepsilon^{\prime}(\chi)=0$, a consequence of (A.4).

## Conclusions

We have seen, from (2.3.3) $-(\sqrt{2.3 .5})$, or more in general from (2.3.4) and (2.3.18), or from (2.3.4) and (2.3.23), that the construction of the differential calculus associated to the $q$-Lie algebra $T$ spanned by the $\chi_{i}$ elements is quite straighforward, the main ingredients are
i) the left invariant vectorfields $t_{i}=\chi_{i} *$, with deformed Leibniz rule: $t_{i}(a b)=$ $t_{j}(a) f^{j}{ }_{i}(b)+a t_{i}(b)$
ii) the adjoint representation $M_{i}{ }^{j}$ defined via (2.3.18) [or explicilty via the coordinates $\left.x^{i}(2.3 .21)\right]$. The adjoint representation satisfies $\Delta\left(M_{i}{ }^{j}\right)=M_{i}{ }^{k} \otimes M_{k}{ }^{j}$ and $\varepsilon\left(M_{i}{ }^{j}\right)=\delta_{j}^{i}$.
iii) the space of left invariant 1-forms, defined as the space dual to that of the tangent vectors: $\left\langle\chi_{i}, \omega^{j}\right\rangle=\delta_{i}^{j}$. A generic 1 -form is then given by $\rho=a_{i} \omega^{i}$. [The space of 1 -forms is the bicovariant bimodule freely generated by the $\omega^{i}$ with $\left.\omega^{i} a=\left(f^{i}{ }_{j} * a\right) \omega^{j}, \quad \Delta_{L} \omega^{i} \equiv I \otimes \omega^{i}, \Delta_{R} \omega^{i} \equiv \omega^{j} \otimes M_{j}{ }^{i}\right]$.
iv) The differential, defined by $d a=\left(\chi_{i} * a\right) \omega^{i}$; it satisfies the undeformed Leibniz rule.

Note 2.3.3 Following [46] we here briefly characterize in a cohomological context the bicovariant differential calculus on quantum groups. For any $\omega \in{ }_{\mathrm{inv}} \Gamma, a \in A$,
we define the left and right products

$$
a \cdot \omega=\varepsilon(a) \omega \quad ; \quad \omega \cdot a=\kappa\left(a_{1}\right) \omega a_{2} .
$$

In particular $\omega^{i} . a=\kappa\left(a_{1}\right) \omega^{i} a_{2}=\kappa\left(a_{1}\right)\left(f^{i}{ }_{j} * a_{2}\right) \omega^{j}=f^{i}{ }_{j}(a) \omega^{j}$, this shows that the right product is well defined and, using the property (2.1.35) and (2.1.36) of the $f$ functionals, that ${ }_{\text {inv }} \Gamma$ is a left and right $A$-module. The projection $P: \Gamma \rightarrow{ }_{\text {inv }} \Gamma$ defined in Note 2.1.1 is an epimorphism between the two bimodules $\Gamma$ and ${ }_{\text {inv }} \Gamma$.

We now characterize the differential $d$ through a 1 -cocycle of the Hochschild coboundary operator $\delta$ relative to the $A$-bimodule inv $\Gamma$. Given an algebra $\mathcal{A}$ and a bimodule $M$ over $\mathcal{A}$, a Hochschild $k$-cochain $C \in C^{k}(\mathcal{A}, M)$ is a $k$-multilinear map from $\mathcal{A} \otimes \mathcal{A} \otimes \ldots \mathcal{A}\left(k\right.$-times) to $M$, with $C^{0}(\mathcal{A}, M)=M$. The coboundary operator $\delta: C^{k}(\mathcal{A}, M) \rightarrow C^{k+1}(\mathcal{A}, M)$ is defined by

$$
\begin{aligned}
\delta C\left(a_{1}, \ldots a_{k+1}\right)= & a_{1} \cdot C\left(a_{2}, \ldots a_{k+1}\right) \\
& +\sum_{i=1}^{k}(-1)^{i} C\left(a_{1}, \ldots a_{i} a_{i+1}, \ldots a_{k+1}\right)+(-1)^{k+1} C\left(a_{1}, \ldots a_{k}\right) \cdot a_{k+1}
\end{aligned}
$$

and satisfies $\delta^{2}=0$. [ We have denoted by "." the multiplication in the bimodule M]

To a bicovariant differential calculus with differential $d$, we associate the map

$$
\begin{array}{ll}
c: & A \rightarrow \operatorname{inv} \Gamma \\
& a \mapsto P(d a)=\kappa\left(a_{1}\right) d a_{2} .
\end{array}
$$

It is easy to see that $\delta c=0$, i.e., $c$ is a 1-cocycle : $c(a b)=c(a) b+a c(b)$. Viceversa, given a 1-cocycle $c$ we immediately obtain a left covariant differential calculus defining

$$
d a \equiv a_{1} c\left(a_{2}\right)
$$

[Proof of the left covariance: $\left.\Delta_{\Gamma}(d a)=a_{1} \otimes a_{2} c\left(a_{3}\right)=(i d \otimes d) \Delta a\right]$.
The right covariance (2.1.4) of a differential calculus is equivalent to the following property for the cocycle $c$ :

$$
\begin{equation*}
\forall \psi \in U \quad\left(i d \otimes \psi_{2}\right)_{\Gamma} \Delta\left[c\left(a * \psi_{1}\right)\right]=c(\psi * a) \tag{2.3.55}
\end{equation*}
$$

[Hint: (2.1.4) is equivalent to $\left(\kappa\left(a_{1}\right) \otimes i d\right)_{\Gamma} \Delta\left(d a_{2}\right)=\kappa\left(a_{1}\right) d a_{2} \otimes a_{3}$; apply $(i d \otimes \psi)$ to this last expression]. Therefore 1-cocycles satisfying (2.3.55) are in one-to-one correspondence with bicovariant differential calculi. In the notations of Subsection 2.4.5 (2.3.55) reads $\ell_{\psi_{2}} c\left(a * \psi_{1}\right)=c(\psi * a)$. In 46] it is shown that there is a one-to-one correspondence between bicovariant $A$-bimodules on $\Gamma$ and $\mathcal{D}$-bimodules on ${ }_{i n v} \Gamma$ where $\mathcal{D}$ is the quantum double of $A$; moreover the cocycles satisfying (2.3.55) correspond to cocycles $c$ in the set of the Hochschild cochains $C^{1}\left(\mathcal{D},{ }_{\text {inv }} \Gamma\right)$ that have the simple property $c(U)=0$.

Notice also that the 0 -cochains are the left invariant one forms: $C^{0}\left(A,{ }_{i n v} \Gamma\right)=$ ${ }_{\text {inv }} \Gamma$, it can be checked that the coboundary of any bi-invariant 1 -form, i.e. of
any right invariant 0 -cochain satisfies (2.3.55) and therefore defines a bicovariant differential calculus. The differential studied in (2.2.44) and (2.2.45) corresponds to the 1-cocycle $\delta\left(\frac{-1}{\lambda} \tau\right)$. Indeed $\delta\left(\frac{-1}{\lambda} \tau\right)(a)=\frac{-1}{\lambda}(a . \tau-\tau \cdot a)=\frac{-1}{\lambda} \varepsilon(a) \tau+\frac{1}{\lambda} \kappa\left(a_{1}\right) \tau a_{2}$ and $d a=a_{1} \delta\left(\frac{-1}{\lambda} \tau\right)\left(a_{2}\right)=\frac{1}{\lambda}(\tau a-a \tau)$ as in (2.2.45).

The differential calculus on classical Lie groups corresponds to a nontrivial 1cocycle since in the commutative case $\delta \omega=0$ for any $\omega \in \operatorname{inv} \Gamma$. All the differential calculi we will examine correspond to 1 -cocycles that are coboundaries, the only exception being those on the twisted homogeneous and inhomogeneous orthogonal groups of sections 4.6 and 4.7.

The existence of a bi-invariant 1 -form trivializes the calculus from the Hochschild cohomology viewpoint (it is associated to a coboundary) but it is interesting geometrically and for physical speculations because introduces a discretized geometry; indeed $d$ given by (2.2.45) is a finite difference operator as well as the partial derivatives $\chi_{i}$ in (2.2.52).

### 2.4 More $q$-Geometry: vectorfields, inner derivative and Lie derivative

In the previous section we have studied the space of left invariant vectorfields i.e. the $q$-tangent space, we now construct, for a generic quantum group, the space of vectorfields. Its elements are products of elements of the quantum group itself with left invariant vectorfields. We study the duality between vectorfields and 1forms and generalize the construction to tensorfields. As in the classical case, using the duality between covariant and contravariant tensorfields, we can introduce the contraction operator. This is defined on the space of covariant tensorfields, and therefore acts in particular on forms; indeed the algebra of forms, as defined in (2.1.73), is a subalgebra of the algebra of covariant tensorfields. We then prove that the contraction operator is a (inner) derivation in the space of forms. On the other hand the right action of the $q$-group on the space of 1 -forms naturally define the Lie derivative along left invariant vectorfields. The Cartan identity $\ell_{t_{i}}=$ $i_{t_{i}} d+d i_{t_{i}}$ is proven and the Cartan calculus of inner derivatives, Lie derivatives and the exterior derivative generalized to $q$-group geometry. Not all properties of the classical Cartan Calculus can however be generalized, while the contraction operator is defined for general vectorfields, there is no completely satisfactory expression for the Lie derivative along general vectorfields $V$. We propose the definition $\ell_{V} \equiv$ $i_{V} d+d i_{V}$ and analize and discuss its properties. The topics discussed in this sections have been studied in [26], [27] and more extensively in [38, [34], [39], 40], [37], 41]. We follow [37] and [27. Here we give a self-contained exposition, and all the theorems are proved starting from only one data: a bicovariant differential calculus on a generic Hopf algebra.

### 2.4.1 From Left invariant Vectorfields to general Vectorfields

In this subsection we study the space $\Xi$ of vectorfields over the generic Hopf algebra $A$ defining a right product between left invariant vectorfields and elements of $A$.

In the commutative case a generic vectorfield can be written in the form $f^{i} t_{i}$ where $\left\{t_{i}\right\} i=1, \ldots, n$ is a basis of left invariant vectorfields and $f^{i}$ are $n$ smooth functions on the group manifold. In the commutative case $f^{i} t_{i}=t_{i} \square f^{i}$ i.e. left and right products (that we have denoted with $\quad$ ) are the same, indeed $\left(t_{i} \square f^{i}\right)(h) \equiv$ $t_{i}(h) f^{i}=f^{i} t_{i}(h)$. These considerations lead to the following definition.

Let $t_{i}=\chi_{i} *$ be a basis in ${ }_{\text {inv }} \Xi$, the space of left invariant vectorfields, and let $a^{i}, i=1, \ldots, n$ be generic elements of $A$ :

## Definition

$$
\begin{equation*}
\Xi \equiv\left\{V / V: A \longrightarrow A ; V=t_{i} \square a^{i}\right\} \tag{2.4.1}
\end{equation*}
$$

where the definition of the right product $\square$ is given below:

## Definition

$$
\begin{equation*}
\forall a, b \in A, \forall t \in_{i n v} \Xi \quad\left(t_{\square} a\right) b \equiv t(b) a=(\chi * b) a \tag{2.4.2}
\end{equation*}
$$

The product $\quad$ has a natural generalization to the whole $\Xi$ :

$$
\begin{align*}
\square: \quad \Xi \times A & \longrightarrow  \tag{2.4.3}\\
(V, a) & \longmapsto V \square a
\end{align*} \quad \text { where } \quad \forall b \in A \quad(V \square a)(b) \equiv V(b) a .
$$

It is easy to prove that $(\Xi, \square)$ is a right $A$-module:

$$
\begin{equation*}
V_{\square}(a+b)=V \square a+V \square b ; \quad V_{\square}(a b)=\left(V_{\square} a\right) \square b ; \quad V_{\square}(a+b)=V_{\square} a+V \square b \tag{2.4.4}
\end{equation*}
$$

(we have also $V_{\square} \lambda a=\lambda V_{\square} a$ with $\lambda \in \boldsymbol{C}$ ).
For example $V \square(a b)=(V \square a) \square b$ because

$$
\forall c \in A \quad\left[\left(V_{\square} a\right) \square b\right] c=\left[\left(V_{\square} a\right)(c)\right] b=(V(c) a) b=V(c) a b=\left[V_{\square} a b\right] c .
$$

Notice that to distinguish the elements $V_{\square}(a b) \in \Xi$ and $V(a b) \in A$ we have not omitted the simbol $\square$ representing the right product.
$\Xi$ is the analogue of the space of derivations on the ring $C^{\infty}(G)$ of the smooth functions on the group $G$. Indeed we have:

$$
\begin{array}{ll}
V(a+b)=V(a)+V(b), \quad V(\lambda a)=\lambda V(a) & \text { Linearity } \\
V(a b) \equiv\left(t_{i} \square c^{i}\right)(a b)=t_{j}(a)\left(f^{j}{ }_{i} * b\right) c^{i}+a V(b) & \text { Leibniz rule } \tag{2.4.6}
\end{array}
$$

in the classical case $t_{j}(a)\left(f^{j}{ }_{i} * b\right) c^{i}=V(a) b$ (recall $f^{j}{ }_{i}=\delta_{i}^{j} \varepsilon ; \quad \varepsilon * b=b$ ).

We have seen the duality between ${ }_{\text {inv }} \Gamma$ and $\operatorname{inv} \Xi$. We now extend it to $\Gamma$ and $\Xi$, where $\Gamma$ is seen as a left $A$-module (not necessarily a bimodule) and $\Xi$ is our right $A$-module.

Theorem 2.4.1 There exists a unique map

$$
\langle,\rangle: \quad \Gamma \times \Xi \longrightarrow A
$$

such that:

1) $\forall V \in \Xi$; the application

$$
\langle, V\rangle: \Gamma \longrightarrow A
$$

is a left $A$-module morphism, i.e. is linear and $\langle a \rho, V\rangle=a\langle\rho, V\rangle$.
2) $\forall \rho \in \Gamma$; the application

$$
\langle\rho,\rangle: \Xi \longrightarrow A
$$

is a right $A$-module morphism, i.e. is linear and $\langle\rho, V b\rangle=\langle\rho, V\rangle b$.
3) Given $\rho \in \Gamma$

$$
\begin{equation*}
\langle\rho, \quad\rangle=0 \Rightarrow \rho=0 \tag{2.4.7}
\end{equation*}
$$

where $\langle\rho, \quad\rangle=0$ means $\langle\rho, V\rangle=0 \quad \forall V \in \Xi$.
4) Given $V \in \Xi$

$$
\begin{equation*}
\langle, V\rangle=0 \Rightarrow V=0 \tag{2.4.8}
\end{equation*}
$$

where $\langle, V\rangle=0$ means $\langle\rho, V\rangle=0 \quad \forall \rho \in \Gamma$.
5) On ${ }_{\text {inv }} \Gamma \times{ }_{\text {inv }} \Xi$ the bracket $\langle$,$\rangle acts as the one introduced in the previous$ section.

Remark Properties 3) and 4) state that $\Gamma$ and $\Xi$ are dual $A$-moduli, in the sense that they are dual with respect to $A$.

Proof
Properties 1), 2) and 5) uniquely characterize this map . To prove the existence of such a map we show that the following bracket

## Definition

$$
\begin{equation*}
\langle\rho, V\rangle=\left\langle a_{\alpha} d b_{\beta}, V\right\rangle \equiv a_{\alpha} V\left(b_{\alpha}\right), \tag{2.4.9}
\end{equation*}
$$

where $a_{\alpha}, b_{\alpha}$ are elements of $A$ such that $\rho=a_{\alpha} d b_{\alpha}$, satisfies 1$\left.), 2\right)$ and 5).
We first verify that the above definition is well given, that is:

$$
\text { Let } \rho=a_{\alpha} d b_{\alpha}=a_{\beta}^{\prime} d b_{\beta}^{\prime} \quad \text { then } \quad a_{\alpha} V\left(b_{\alpha}\right)=a_{\beta}^{\prime} V\left(b_{\beta}^{\prime}\right) .
$$

Indeed, since

$$
a_{\alpha} d b_{\alpha}=a_{\beta}^{\prime} d b_{\beta}^{\prime} \Leftrightarrow a_{\alpha} t_{i}\left(b_{\alpha}\right) \omega^{i}=a_{\beta}^{\prime} t_{i}\left(b_{\beta}^{\prime}\right) \omega^{i} \Leftrightarrow a_{\alpha} t_{i}\left(b_{\alpha}\right)=a_{\beta}^{\prime} t_{i}\left(b_{\beta}^{\prime}\right)
$$

[we used the uniqueness of the decomposition (2.1.28)] the definition is consistent because

$$
a_{\alpha} V\left(b_{\alpha}\right)=a_{\beta}^{\prime} V\left(b_{\beta}^{\prime}\right) \Leftrightarrow a_{\alpha} t_{i}\left(b_{\alpha}\right) c^{i}=a_{\beta}^{\prime} t_{i}\left(b_{\beta}^{\prime}\right) c^{i}
$$

where $V=t_{i} \square c^{i}$.
Property 1) is trivial since $a \rho=a\left(a_{\alpha} d b_{\alpha}\right)=\left(a a_{\alpha}\right) d b_{\alpha}$.
Property 2) holds since

$$
\langle\rho, V \square c\rangle=a_{\alpha}(V \square c)\left(b_{\alpha}\right)=a_{\alpha} V\left(b_{\alpha}\right) c=\langle\rho, V\rangle c .
$$

Property 5). Let $\left\{\omega^{i}\right\}$ and $\left\{t_{i}\right\}$ be dual bases in inv $\Gamma$ and inv $\Xi$. Since $\omega^{i} \in \Gamma, \omega^{i}=$ $a_{\alpha} d b_{\alpha}$ for some $a_{\alpha}$ and $b_{\alpha}$ in $A$. We can also write $\omega^{i}=a_{\alpha} d b_{\alpha}=a_{\alpha} t_{k}\left(b_{\alpha}\right) \omega^{k}$, so that, due to the uniqueness of the decomposition (2.1.28), we have

$$
a_{\alpha} t_{k}\left(b_{\alpha}\right)=\delta_{k}^{i} I \quad(I \text { unit of } A) ;
$$

we then obtain

$$
\left\langle\omega^{i}, t_{j}\right\rangle=a_{\alpha} t_{j}\left(b_{\alpha}\right)=\delta^{i}{ }_{j} I
$$

Property 3). Let $\rho=a_{i} \omega^{i} \in \Gamma$.
If $\langle\rho, V\rangle=0 \quad \forall V \in \Xi$, in particular $\left\langle\rho, t_{j}\right\rangle=0 \quad \forall j=1, \ldots, n$; then $a_{i}\left\langle\omega^{i}, t_{j}\right\rangle=0 \Leftrightarrow$ $a_{j}=0$, and therefore $\rho=0$.

Property 4). Let $V=t_{i} \square a^{i} \in \Xi$.
If $\langle\rho, V\rangle=0 \quad \forall \rho \in \Gamma$, in particular $\left\langle\omega^{j}, V\right\rangle=0 \quad \forall j=1, \ldots, n$; then $\left\langle\omega^{j}, t_{i}\right\rangle a^{i}=0 \Leftrightarrow$ $a^{j}=0$, and therefore $V=0$.

By construction every $V$ is of the form

$$
V=t_{i} \square a^{i}
$$

We can now show the unicity of such a decomposition.
Theorem 2.4.2 Any $V \in \Xi$ can be uniquely written in the form

$$
V=t_{i} \square a^{i}
$$

Proof
Let $V=t_{i} \square a^{i}=t_{i} \square a^{i i}$ then

$$
\forall i=1, \ldots, n \quad a^{i}=\left\langle\omega^{i}, t_{j}\right\rangle a^{j}=\left\langle\omega^{i}, V\right\rangle=\left\langle\omega^{i}, t_{j}\right\rangle a^{j}=a^{i}
$$

Notice that once we know the decomposition of $\rho$ and $V$ in terms of $\omega^{i}$ and $t_{i}$, the evaluation of $\langle$,$\rangle is trivial:$

$$
\langle\rho, V\rangle=\left\langle a_{i} \omega^{i}, t_{j} \square b^{j}\right\rangle=a_{i}\left\langle\omega^{i}, t_{j}\right\rangle b^{j}=a_{i} b^{i} .
$$

Viceversa from the previous theorem $V=t_{i} \square\left\langle\omega^{i}, V\right\rangle$ and $\rho=\left\langle\rho, t_{i}\right\rangle \omega^{i}$.

We conclude this section by remarking the three different ways of looking at $\Xi$. (I) $\quad \Xi$ as the set of all deformed derivations over $A$ [see (2.4.1), (2.4.5) and (2.4.6)].
(II) $\quad \Xi$ as the right $A$-module freely generated by the elements $t_{i}, i=1, \ldots, n$. The latter is the set of all the formal products and sums of the type $t_{i} a^{i}$, where $a^{i}$ are generic elements of $A$. Indeed, by virtue of Theorem 2.4.2, the map that associates to each $V=t_{i} \square a^{i}$ in $\Xi$ the corresponding element $t_{i} a^{i}$ is an isomorphism between right $A$-moduli.
(III) $\quad \Xi$ as $\Xi^{\prime}=\{U: \Gamma \longrightarrow A, U$ linear and $U(a \rho)=a U(\rho) \forall a \in A\}$, i.e. $\Xi$ as the dual (with respect to $A$ ) of the space of 1-forms $\Gamma$. The space $\Xi^{\prime}$ has a trivial right $A$-module structure: $(U a)(\rho) \equiv U(\rho) a . \Xi$ and $\Xi^{\prime}$ are isomorphic right $A$ moduli because of property (2.4.8) which states that to each $\langle, V\rangle: \Gamma \rightarrow A$ there corresponds one and only one $V \cdot\left[\langle, V\rangle=\left\langle, V^{\prime}\right\rangle \Rightarrow V=V^{\prime}\right]$. Every $U \in \Xi^{\prime}$ is of the form $U=\langle, V\rangle$; more precisely, if $a^{i}$ is such that $U\left(\omega^{i}\right)=a^{i}$ then $U=\left\langle, t_{i} \square a^{i}\right\rangle$.

These three ways of looking at $\Xi$ will correspond to different aspects of the Cartan Calculus: the Lie derivatives $\ell_{V}$ will generalize (I), inner derivations $i_{V}$ will correspond to (III), while the transformation properties of $\ell_{V}$ and $i_{V}$ are governed by (II).

### 2.4.2 Bicovariant Bimodule Structure

In Section 2.1 we have studied the space $\Gamma$ of 1 -forms, we have seen that $\Gamma$ is a bimodule over $A$ because there is a right and a left product between elements of $\Gamma$ and of $A$. The left and the right product are related by $\omega^{i} a=\left(f^{i}{ }_{j} * a\right) \omega^{j}$. Since the coactions $\Delta_{\Gamma}$ and ${ }_{\Gamma} \Delta$ are compatible with the bimodule structure and since they commute:

$$
\left(i d \otimes_{\Gamma} \Delta\right) \Delta_{\Gamma}=\left(\Delta_{\Gamma} \otimes i d\right)_{\Gamma} \Delta
$$

the bimodule $\Gamma$ is a bicovariant bimodule (cf. Note 2.1.1).
In the previous subsection we have studied the right product a and we have seen that $\Xi$ is a right module over $A$ [see (2.4.4)]. Here we introduce a left product and a left and right coaction of the Hopf algebra $A$ on $\Xi$. The left and right coactions $\Delta_{\Xi}$ and $\Xi \Delta$ are the $q$-analogue of the push-forward of tensorfields on a group manifold. Similarly to $\Gamma$ also $\Xi$ is a bicovariant bimodule.

The construction of the left product on $\Xi$, of the right coaction $\Xi \Delta$ and of the left coaction $\Delta_{\Xi}$ will be effected along the lines of Woronowicz' Theorem 2.5 in 21, whose statement can be explained in the following steps (cf. Note 2.1.1):

Theorem 2.4.3 Consider the symbols $t_{i}(i=1, \ldots, n)$ and let $\Xi$ be the right $A$-module freely generated by them:

$$
\Xi \equiv\left\{t_{i} a^{i} / a^{i} \in A\right\}
$$

Consider functionals $O_{i}{ }^{j}: A \longrightarrow \boldsymbol{C}$ satisfying [see (2.1.32) and (2.1.33)]

$$
\begin{align*}
& O_{i}{ }^{j}(a b)=O_{i}{ }^{k}(a) O_{k}{ }^{j}(b)  \tag{2.4.10}\\
& O_{i}{ }^{j}(I)=\delta_{j}^{i} \tag{2.4.11}
\end{align*}
$$

Introduce a left product via the definition [see (2.1.31)]
Definition

$$
\begin{equation*}
b\left(t_{i} a^{i}\right) \equiv t_{j}\left[\left(O_{i}{ }^{j} \circ \kappa^{-1}\right) * b\right] a^{i} . \tag{2.4.12}
\end{equation*}
$$

It is easy to prove that
i) $\Xi$ is a bimodule over $A$. (A proof of this first statement as well as of the following ones is contained in [21]).

Introduce an action (push-forward) of the Hopf algebra $A$ on $\Xi$
Definition

$$
\begin{equation*}
\Delta_{\Xi}\left(t_{i} a^{i}\right) \equiv\left(I \otimes t_{i}\right) \Delta\left(a^{i}\right) \tag{2.4.13}
\end{equation*}
$$

It follows that
ii) $\left(\Xi, \Delta_{\Xi}\right)$ is a left covariant bimodule over $A$, that is
$\Delta_{\Xi}(a V b)=\Delta(a) \Delta_{\Xi}(V) \Delta(b) ; \quad(\varepsilon \otimes i d) \Delta_{\Xi}(V)=V ; \quad(\Delta \otimes i d) \Delta_{\Xi}=\left(i d \otimes \Delta_{\Xi}\right) \Delta_{\Xi}$.

Introduce $n^{2}$ elements $N^{i}{ }_{j} \in A$ satisfying [see (2.1.51),(2.1.44) and (2.1.45)]

$$
\begin{gather*}
N^{i}{ }_{j}\left(a * O_{i}{ }^{k}\right)=\left(O_{j}{ }^{i} * a\right) N^{k}{ }_{i}  \tag{2.4.14}\\
\Delta\left(N^{j}{ }_{i}\right)=N^{j}{ }_{l} \otimes N^{l}{ }_{i}  \tag{2.4.15}\\
\varepsilon\left(N^{j}{ }_{i}\right)=\delta_{j}^{i}, \tag{2.4.16}
\end{gather*}
$$

and introduce $\Xi \Delta$ such that $[$ see (2.1.38) $]$

## Definition

$$
\begin{equation*}
\Xi \Delta\left(a^{i} t_{i}\right) \equiv \Delta\left(a^{i}\right) t_{j} \otimes N_{i}^{j} . \tag{2.4.17}
\end{equation*}
$$

Then it can be proven that
iii) The elements [see (2.1.47)]

$$
\begin{equation*}
h_{i} \equiv t_{j} \kappa\left(N^{j}{ }_{i}\right) \tag{2.4.18}
\end{equation*}
$$

are right invariant：$\Xi \Delta\left(h_{i}\right)=h_{i} \otimes I$ ．Moreover any $V \in \Xi$ can be expressed in a unique way respectively as $V=h_{i} a^{i}$ and as $V=b^{i} h_{i}$ ，where $a^{i}, b^{i} \in A$ ．
iv）$\quad(\Xi, \Xi \Delta)$ is a right covariant bimodule over $A$ ，that is
$\Xi \Delta(a V b)=\Delta(a)_{\Xi} \Delta(V) \Delta(b) ; \quad(i d \otimes \varepsilon)_{\Xi} \Delta(V)=V ; \quad(i d \otimes \Delta)_{\Xi} \Delta=(\Xi \Delta \otimes i d)_{\Xi} \Delta$.
v）The left and right covariant bimodule $\left(\Xi, \Delta_{\Xi, \Xi} \Delta\right)$ is a bicovariant bimodule， that is left and right coactions are compatible：

$$
\left(i d \otimes_{\Xi} \Delta\right) \Delta_{\Xi}=\left(\Delta_{\Xi} \otimes i d\right)_{\Xi} \Delta .
$$

In the previous section we have seen［remark（II）］that the space of vectorfields $\Xi$ is the free right $A$－module generated by the symbols $t_{i}$ ，so that the above theorem applies to our case．

There are many bimodule structures（i．e．choices of $O_{i}{ }^{j}$ ）$\Xi$ can be endowed with． Using the fact that $\Xi$ is dual to $\Gamma$ we request compatibility with the $\Gamma$ bimodule． In the commutative case $\left\langle f \omega^{i}, t_{j}\right\rangle=\left\langle\omega^{i} f, t_{j}\right\rangle=\left\langle\omega^{i}, f t_{j}\right\rangle=\left\langle\omega^{i}, t_{j} f\right\rangle$ ． In the quantum case we know that $\left\langle a \omega^{i}, t_{j}\right\rangle=\left\langle\omega^{i}, t_{j} \square a\right\rangle$ and we require

$$
\begin{equation*}
\left\langle\omega^{i} a, t_{j}\right\rangle=\left\langle\omega^{i}, a t_{j}\right\rangle ; \tag{2.4.19}
\end{equation*}
$$

this condition uniquely determines the bimodule structure of $\Xi$ ．Indeed we have

$$
\begin{align*}
\left\langle\omega^{i}, a t_{j}\right\rangle & =\left\langle\omega^{i} a, t_{j}\right\rangle=\left\langle\left(f^{i}{ }_{k} * a\right) \omega^{k}, t_{j}\right\rangle=\left(f^{i}{ }_{k} * a\right)\left\langle\omega^{k}, t_{j}\right\rangle=f_{k}^{i} * a \delta_{j}^{k}=\delta_{l}^{i} f_{j}^{l}{ }_{j} * a \\
& =\left\langle\omega^{i}, t_{l 口}\left(f^{l}{ }_{j} * a\right)\right\rangle \tag{2.4.20}
\end{align*}
$$

so that

$$
\begin{equation*}
a t_{i}=t_{j 口}\left(f_{i}^{j} * a\right) . \tag{2.4.21}
\end{equation*}
$$

We then define

$$
\begin{equation*}
O_{i}{ }^{j} \equiv f^{j}{ }_{i} \circ \kappa \tag{2.4.22}
\end{equation*}
$$

it follows that $O_{i}{ }^{j} \circ \kappa^{-1}=f^{j}{ }_{i}$ and（2．4．21）can be rewritten［see（2．1．31）and （2．4．12）］

$$
\begin{equation*}
a t_{j}=t_{j 口}\left[\left(O_{i}{ }^{j} \circ \kappa^{-1}\right) * a\right] . \tag{2.4.23}
\end{equation*}
$$

Theorem 2．4．4 The functionals $O_{i}{ }^{j}$ satisfy conditions（2．4．10）and（2．4．11）．
Proof The first condition $O_{i}{ }^{j}(I)=\delta_{i}^{j}$ holds trivially．
The second one is also easily checked：

$$
\begin{aligned}
O_{i}{ }^{j}(a b) & =\left(f^{j}{ }_{i} \circ \kappa\right)(a b)=f^{j}{ }_{i}[\kappa(b) \kappa(a)]=f_{k}^{j}[\kappa(b)] f^{k}{ }_{i}[\kappa(a)]=f_{i}^{k}{ }_{i}[\kappa(a)] f^{j}{ }_{k}[(\kappa(b)] \\
& ={ }_{i}{ }^{k}(a) O_{k}{ }^{j}(b)
\end{aligned}
$$

So far $\Xi$ has a bimodule structure. We now define a left coaction $\Delta_{\Xi}$ so that $\Xi$ becomes a left covariant bimodule. The left invariant vectorfields were characterized in (2.3.9) and (2.3.1) through their action $t_{i}(a)=\chi_{i} * a$ on functions; following the same derivation as in (2.1.20)-(2.1.27) the left invariant property of the $t_{i}$ can also be expressed via the coaction $\Delta_{\Xi}$ as defined in (2.4.13):

$$
\begin{equation*}
\Delta_{\Xi}\left(t_{i} a^{i}\right) \equiv\left(I \otimes t_{i}\right) \Delta\left(a^{i}\right) . \tag{2.4.24}
\end{equation*}
$$

Similarly the right coaction ${ }_{\Gamma} \Delta$ is defined to act trivially on the right invariant vectorfields $h_{i}=* \chi_{i}$. This uniquely defines the elements $N^{l}{ }_{k} \in A$; indeed we want relation (2.4.18) and (2.3.23) to coincide and therefore:

$$
\begin{equation*}
N^{l}{ }_{k}=\kappa^{-1}\left(M_{k}^{l}\right) . \tag{2.4.25}
\end{equation*}
$$

Notice that (2.4.25) implies

$$
\begin{equation*}
\left\langle t_{i}, \omega^{j}\right\rangle=\delta_{i}^{j}=\left\langle h_{i}, \eta^{j}\right\rangle, \tag{2.4.26}
\end{equation*}
$$

where $t_{i}$ and $\omega^{j}$ are left-invariant and $h_{i}$ and $\eta^{j}$ are the canonically associated rightinvariant objects; see (2.4.18) and (2.1.47). Notice also that $M_{k}{ }^{l}$ and $f^{i}{ }_{j}$ are dual, and likewise $N^{l}{ }_{k}$ and $O_{j}{ }^{i}$, in the sense that $f^{i}{ }_{j}\left(M_{k}{ }^{l}\right)=O_{j}{ }^{i}\left(N^{l}{ }_{k}\right)=\Lambda^{i l}{ }_{k j}$ with $\Lambda^{i l}{ }_{k j}=\delta_{j}^{i} \delta_{k}^{l}$ when $q=1$.

Theorem 2.4.5 The $N^{l}{ }_{k}$ elements defined above satisfy relations (2.4.16), (2.4.15) and (2.4.14):

1) $\varepsilon\left(N^{j}{ }_{i}\right)=\delta_{j}^{i}$
2) $\Delta\left(N^{j}{ }_{i}\right)=N^{j}{ }_{l} \otimes N^{l}{ }_{i}$
3) $N^{i}{ }_{k}\left(a * O_{i}{ }^{j}\right)=\left(O_{k}{ }^{i} * a\right) N^{j}{ }_{i}$

## Proof

1) This expression is trivial.
2) Use $N^{i}{ }_{j}=\kappa^{-1} M_{j}{ }^{i}$ and $\Delta \circ \kappa^{-1}=\sigma \circ\left(\kappa^{-1} \otimes \kappa^{-1}\right) \circ \Delta$, where $\sigma_{A}$ is the flip map in $A \otimes A$.
3) We know that $[$ see (2.1.51)]

$$
\forall a \in A \quad M_{i}{ }^{j}\left(a * f_{k}^{i}\right)=\left(f_{i}^{j}{ }_{i} * a\right) M_{k}{ }^{i}
$$

or equivalently,

$$
M_{i}{ }^{j}\left[\kappa(a) * f_{k}^{i}\right]=\left[f^{j}{ }_{i} * \kappa(a)\right] M_{k}{ }^{i} .
$$

Now

$$
\begin{aligned}
{\left[\kappa(a) * f^{i}{ }_{k}\right] } & =\left(f^{i}{ }_{k} \otimes i d\right) \Delta[\kappa(a)]=\left(i d \otimes f^{i}{ }_{k}\right)(\kappa \otimes \kappa) \Delta(a)=\kappa\left(i d \otimes f^{i}{ }_{k} \circ \kappa\right) \Delta(a) \\
& =\kappa\left(O_{k}{ }^{i} * a\right) .
\end{aligned}
$$

Similarly,

$$
\left[f_{i}^{j} * \kappa(a)\right]=\kappa\left(a * O_{i}{ }^{j}\right) .
$$

So we can write

$$
\kappa\left(a * O_{i}{ }^{j}\right) M_{k}{ }^{i}=M_{i}{ }^{j} \kappa\left(O_{k}{ }^{i} * a\right)
$$

for all $a \in A$. Applying $\kappa^{-1}$ to both members of this last expression we obtain relation 3$)$.

Following Theorem 2.4.3 the construction of the bicovariant bimodule $\Xi$ is now easy and straightforward, and we can conclude that $\left(\Xi, \Delta_{\Xi, \Xi \Delta}\right)$ is a bicovariant bimodule.

We end this subsection observing that in the expression (2.3.30) for the exterior differential, elements of $\Xi$ and $\Gamma$ make a joint appearance. To be still able to talk about transformation properties of such expressions we need to combine the previously introduced coactions into one object, $\Delta_{A}$, simply by putting $\Delta_{A} \equiv \Xi \Delta$ on $\Xi$ and $\Delta_{A} \equiv{ }_{\Gamma} \Delta$ on $\Gamma$ and requiring $\Delta_{A}$ to be an algebra homomorphism. From this definition we get the following important corollary:

Corollary. The expression $\omega^{i} t_{i}$ in (2.3.2) is invariant in the sense that

$$
\Delta_{A}\left(t_{i} \omega^{i}\right)=\Xi \Delta\left(t_{i}\right)_{\Gamma} \Delta\left(\omega^{i}\right)=t_{k} \omega^{j} \otimes N^{k}{ }_{i} M_{j}{ }^{i}=t_{i} \omega^{i} \otimes 1
$$

Similar statements apply to ${ }_{A} \Delta$.
Notice that, since Theorem 2.4.3 completely characterizes a bicovariant bimodule all the formulas containing the symbols $f^{i}{ }_{j}$ or $M_{k}{ }^{l}$ or elements of $\Gamma$ are still valid under the substitutions $f^{i}{ }_{j} \rightarrow O_{i}{ }^{j}, M_{k}{ }^{l} \rightarrow N^{k}{ }_{l}$ and $\Gamma \rightarrow \Xi$.

### 2.4.3 Tensorfields

The construction completed for vectorfields is readily generalized to $p$-times contravariant tensorfields. We proceed as in (2.1.57)-(2.1.62) and define $\Xi \otimes \Xi$ to be the space of all elements that can be written as finite sums of the kind $\sum_{i} V_{i} \otimes V_{i}^{\prime}$ with $V_{i}, V_{i}^{\prime} \in \Xi$. The tensor product (in the algebra $A$ ) between $V_{i}$ and $V_{i}^{\prime}$ has the following properties:

$$
V_{\square} a \otimes V^{\prime}=V \otimes a V^{\prime}, a\left(V \otimes V^{\prime}\right)=(a V) \otimes V^{\prime} \text { and }\left(V \otimes V^{\prime}\right)_{\square} a=V \otimes\left(V^{\prime} a\right)
$$ so that $\Xi \otimes \Xi$ is naturally a bimodule over $A$.

Left and right coactions on $\Xi \otimes \Xi$ are defined by:

$$
\begin{align*}
& \Delta_{\Xi}\left(V \otimes V^{\prime}\right) \equiv V_{1} V_{1}^{\prime} \otimes V_{2} \otimes V_{2}^{\prime}, \quad \Delta_{\Xi}: \Xi \otimes \Xi \rightarrow A \otimes \Xi \otimes \Xi  \tag{2.4.27}\\
& \Xi \Delta\left(V \otimes V^{\prime}\right) \equiv V_{1} \otimes V_{1}^{\prime} \otimes V_{2} V_{2}^{\prime}, \quad \Xi \Delta: \Xi \otimes \Xi \rightarrow \Xi \otimes \Xi \otimes A \tag{2.4.28}
\end{align*}
$$

where as usual $V_{1}, V_{2}$ etc. are defined by

$$
\begin{align*}
& \Delta_{\Xi}(V)=V_{1} \otimes V_{2}, \quad V_{1} \in A, V_{2} \in \Xi  \tag{2.4.29}\\
& \Xi \Delta(V)=V_{1} \otimes V_{2}, \quad V_{1} \in \Xi, V_{2} \in A \tag{2.4.30}
\end{align*}
$$

More generally, we can introduce the coaction of $\Delta_{\Xi}$ on $\Xi^{\otimes p} \equiv \underbrace{\Xi \otimes \Xi \otimes \cdots \otimes \Xi}_{p \text {-times }}$ as

$$
\begin{gather*}
\Delta_{\Xi}\left(V \otimes V^{\prime} \otimes \cdots \otimes V^{\prime \prime}\right) \equiv V_{1} V_{1}^{\prime} \cdots V^{\prime \prime}{ }_{1} \otimes V_{2} \otimes V^{\prime}{ }_{2} \otimes \cdots \otimes V^{\prime \prime}{ }_{2} \\
\Delta_{\Xi}: \Xi^{\otimes p} \longrightarrow A \otimes \Xi^{\otimes p} ;  \tag{2.4.31}\\
\Xi \Delta\left(V \otimes V^{\prime} \otimes \cdots \otimes V^{\prime \prime}\right) \equiv V_{1} \otimes V_{1}^{\prime} \otimes \cdots \otimes V^{\prime \prime}{ }_{1} \otimes V_{2} V^{\prime}{ }_{2} \cdots V^{\prime \prime}{ }_{2} \\
\Xi \Delta: \quad \Xi^{\otimes p} \longrightarrow \Xi^{\otimes p} \otimes A . \tag{2.4.32}
\end{gather*}
$$

Left invariance on $\Xi \otimes \Xi$ is naturally defined as $\Delta_{\Xi}\left(V \otimes V^{\prime}\right)=I \otimes V \otimes V^{\prime}$ (similar definition for right invariance), so that for example $t_{i} \otimes t_{j}$ is left invariant, and is in fact a left invariant basis for $\Xi \otimes \Xi$ : each element can be written as $t_{i} \otimes t_{j} \square a^{i j}$ in a unique way.

It is not difficult to show that $\Xi \otimes \Xi$ is a bicovariant bimodule. In the same way also ( $\Xi^{\otimes p}, \Delta_{\Xi}, \Xi \Delta$ ) is a bicovariant bimodule.

Any element $v \in \Xi^{\otimes p}$ can be written as $v=t_{i_{1}} \otimes \ldots t_{1_{p}} \square b^{i_{1} \ldots i_{p}}$ in a unique way, similarly any element $\tau \in \Gamma^{\otimes n}$, the $n$-times tensor product of 1 -forms, can be written as $\tau=a_{i_{n} \ldots i_{1}} \omega^{i_{n}} \otimes \ldots \omega^{i_{1}}$ in a unique way.

It is now possible to generalize the previous bracket $\langle\rangle:, \Gamma \times \Xi \rightarrow A$ to $\Gamma^{\otimes n}$ and $\Xi^{\otimes p}$ :

$$
\begin{align*}
\langle,\rangle: \quad \begin{aligned}
\Gamma^{\otimes n} \times \Xi^{\otimes p} & \longrightarrow A \\
(\tau, v) & \longmapsto\langle\tau, v\rangle
\end{aligned} & =a_{i_{n} \ldots i_{1}}\left\langle\omega^{i_{n}} \otimes \ldots \omega^{i_{1}}, t_{j_{1}} \otimes \ldots t_{j_{p}}\right\rangle b^{j_{1} \ldots j_{p}} \\
& =a_{i_{n} \ldots i_{1}} \omega^{i_{n}} \otimes \ldots \omega^{i_{p+1}} b^{i_{1} \ldots i_{p}}
\end{align*}
$$

where $\Gamma^{\otimes 0} \equiv A, \Gamma^{\otimes 1} \equiv \Gamma$ and we have defined

$$
\begin{align*}
\left\langle\omega^{i_{n}} \otimes \ldots \omega^{i_{1}}, t_{j_{1}} \otimes \ldots t_{j_{p}}\right\rangle & \equiv \omega^{i_{n}} \otimes \ldots \omega^{i_{p+1}}\left\langle\omega^{i_{p}} \otimes \ldots \omega^{i_{1}}, t_{j_{1}} \otimes \ldots t_{j_{p}}\right\rangle  \tag{2.4.34}\\
& \equiv \omega^{i_{n}} \otimes \ldots \omega^{i_{p+1}}\left\langle\omega^{i_{1}}, t_{j_{1}}\right\rangle \ldots\left\langle\omega^{i_{p}}, t_{j_{p}}\right\rangle \\
& =\delta_{j_{1}}^{i_{1}} \ldots \delta_{j_{p}}^{i_{p}} \omega^{i_{n}} \otimes \ldots \omega^{i_{p+1}}
\end{align*}
$$

Using definition (2.4.34) it is easy to prove that

$$
\begin{equation*}
\langle\tau a, v\rangle=\langle\tau, a v\rangle, \tag{2.4.35}
\end{equation*}
$$

namely

$$
\begin{aligned}
& \left\langle\omega^{i_{n}} \otimes \ldots \omega^{i_{p+1}} \otimes \omega^{i_{p}} \otimes \ldots \omega^{i_{1}} a, t_{j_{1}} \otimes \ldots t_{j_{p}}\right\rangle= \\
& \quad=\omega^{i_{n}} \otimes \ldots \omega^{p_{p+1}}\left(f_{k_{p}}^{i_{p}} * \ldots f_{k_{1}}^{i_{1}} * a\right)\left\langle\omega^{k_{p}} \otimes \ldots \omega^{k_{1}}, t_{j_{1}} \otimes \ldots t_{j_{p}}\right\rangle \\
& \begin{aligned}
\left\langle\omega^{i_{n}} \otimes \ldots \omega^{i_{p+1}} \otimes \omega^{i_{p}} \otimes \ldots \omega^{i_{1}}\right. & \left., a t_{j_{1}} \otimes \ldots t_{j_{p}}\right\rangle= \\
& =\omega^{i_{n}} \otimes \ldots \omega^{i_{p+1}}\left\langle\omega^{i_{p}} \otimes \ldots \omega^{i_{1}}, t_{l_{1}} \otimes \ldots t_{l_{p}}\right\rangle\left(f_{j_{p}}^{l_{p}} * \ldots f_{j_{1}} * a\right)
\end{aligned}
\end{aligned}
$$

and these last two expressions are equal if and only if (2.4.34) holds.
Therefore we have also shown that definition (2.4.34) is the only one compatible with property (2.4.35), i.e. property (2.4.35) uniquely determines the coupling between $\Xi^{\otimes}$ and $\Gamma^{\otimes}$.

It is easy to prove that the bracket $\langle$,$\rangle extends to \Gamma^{\otimes p}$ and $\Xi^{\otimes p}$ the duality between $\Gamma$ and $\Xi$.

More generally we can define $\Xi^{\otimes} \equiv A \oplus \Xi \oplus \Xi^{\otimes 2} \oplus \Xi^{\otimes 3} \ldots$ to be the algebra of contravariant tensorfields. The coactions $\Delta_{\Xi}$ and $\Xi \Delta$ have a natural generalization to $\Xi^{\otimes}$ so that we can conclude that $\left(\Xi^{\otimes}, \Delta_{\Xi}, \Xi \Delta\right)$ is a bicovariant graded algebra, the graded algebra of tensorfields over the ring "of functions on the group" $A$, with the left and right "push-forward" $\Delta_{\Xi}$ and $\Xi \Delta$. Similarly $\Gamma^{\otimes}$ is the bicovariant graded algebra of covariant tensorfields on $A$.

### 2.4.4 Contraction operator

In this subsection we study the contraction operator $i_{V}$ along a generic vectorfield $V \in \Xi$ and we prove that it acts as a (deformed) derivative operator on the space of 1-forms. The definition of the contraction operator $i_{V}$ with $V \in \Xi$ is based on equation (2.4.33). For a generic vectorfield $V=b^{j} t_{j}$ we define:

## Definition of right inner derivative

$$
(\vartheta) \overleftarrow{V_{V}} \equiv\langle\vartheta, V\rangle \quad \forall \vartheta \in \Gamma^{\otimes}
$$

this definition applies when $\vartheta$ is a generic covariant tensorfield and in particular when $\vartheta$ is a generic form.

Theorem 2.4.6 The contraction operator $\overleftarrow{i}_{V}$ satisfies the following properties: $a, a_{i_{1} \ldots i_{n}} \in A ; V=t_{i} \square b^{i} ; \lambda \in \mathbf{C}$, property d) holds only if $\vartheta, \vartheta^{\prime}$ are forms;
a) $(\vartheta) \overleftarrow{\imath_{V}}=(\vartheta) \overleftarrow{i_{t_{j} \square b j}}=(\vartheta) \overleftarrow{\imath_{j}} b^{j}$
b) $\left(\right.$ a) $\overleftarrow{\imath_{V}}=0$
c) $\left(\omega^{j}\right) \overleftarrow{\imath_{V}}=b^{j}$
d) $\left(a_{i_{1} \ldots i_{n}} \omega_{1} \wedge \ldots \wedge \omega_{n}\right) \overleftarrow{\imath_{V}}=\left(a_{i_{1} \ldots i_{n}} \omega_{1} \wedge \ldots \wedge \omega_{s-1}\right) \wedge\left(\omega_{s} \wedge \ldots \wedge \omega_{n}\right) \overleftarrow{t_{t_{i}}}$ $+(-1)^{n-s+1}\left(a_{i_{1} \ldots i_{n}} \omega_{1} \wedge \ldots \wedge \omega_{s-1}\right){\overleftarrow{t_{j}}}^{\overleftarrow{ }} \wedge f^{j}{ }_{i} *\left(\omega_{s} \wedge \omega_{s+1} \ldots \wedge \omega_{n}\right) b^{i}$
e) $\left(a \vartheta+\vartheta^{\prime}\right) \overleftarrow{\imath_{V}}=a(\vartheta) \overleftarrow{\imath_{V}}+\left(\vartheta^{\prime}\right) \overleftarrow{\imath_{V}}$
f) $(\vartheta a) \overleftarrow{\imath_{V}}=(\vartheta) \overleftarrow{t_{t_{j}}}\left(f^{j}{ }_{i} * a\right) b^{i}$
g) $l_{\lambda V}^{\overleftarrow{ }}=\lambda \overleftarrow{i_{V}}$

## Proof

Properties a), b), c), f), g) are direct consequences of (2.4.33), e) follows from (2.4.35). To proof d ) we have to use the definition of the wedge product (2.1.73)(2.1.75): first we note that (in tensor product notation)

$$
\begin{aligned}
\left(\omega_{1} \wedge \ldots \wedge \omega_{n}\right) \overleftarrow{i_{V}} & =W_{1 \ldots n}\left(\omega_{1} \otimes \ldots \otimes \omega_{n}\right) \overleftarrow{\imath_{V}} \\
& =W_{1 \ldots n} \omega_{1} \otimes \ldots \otimes \omega_{n-1}\left(\omega_{n}\right) \overleftarrow{V_{V}} \\
& =\mathcal{I}_{1 \ldots n} \omega_{1} \wedge \ldots \wedge \omega_{n-1}\left(\omega_{n}\right) \overleftarrow{\imath_{V}}
\end{aligned}
$$

where we have used (2.1.74) in the last step - in index notation:

$$
\left(\omega^{i_{1}} \wedge \ldots \wedge \omega^{i_{n}}\right) \overleftarrow{i_{t_{i}}}=\mathcal{I}_{j_{1} \ldots j_{n-1} i}^{i_{1} \ldots i_{n}} \omega^{j_{1}} \wedge \ldots \wedge \omega^{j_{n-1}}
$$

Next we can show

$$
\begin{aligned}
f_{i}^{i_{s-1}} *\left(\omega^{i_{s}} \wedge \ldots \wedge \omega^{i_{n}}\right) & =\omega^{k_{s-1}} \wedge \ldots \wedge \omega^{k_{n-1}} f_{i}^{i_{s-1}}\left(M_{k_{s-1}}^{i_{s}} \ldots M_{k_{n-1}}^{i_{n}}\right) \\
& =\Lambda^{i_{s-1} i_{s}}{ }_{k_{s-1} l_{s}} \Lambda^{l_{s} i_{s+1}}{ }_{k_{s} l_{s+1}}^{l_{s+1}} \ldots \Lambda^{l_{n} i_{n}} k_{n-1} \omega^{k_{s-1}} \wedge \omega^{k_{s}} \wedge \ldots \omega^{k_{n-1}}
\end{aligned}
$$

that in tensor product notation can be written:
$\left(\omega_{s-1}\right) \overleftarrow{i_{j}} f^{j}{ }_{i} *\left(\omega_{s} \wedge \omega_{s+1} \wedge \ldots \omega_{n}\right)=\Lambda_{s-1, s} \Lambda_{s, s+1} \ldots \Lambda_{n-1, n}\left(\omega_{s-1} \wedge \omega_{s} \wedge \ldots \omega_{n-1}\right)\left(\omega_{n}\right) \overleftarrow{i_{t_{i}}}$
Finally we utilize the decomposition property (2.1.76) and associativity of the wedge product (in tensor product notation)

$$
\begin{aligned}
&\left(\omega_{1} \wedge \ldots \wedge \omega_{n}\right) \overleftarrow{\imath_{V}}= \\
&= \mathcal{I}_{1 \ldots n} \omega_{1} \wedge \ldots \omega_{n-1}\left(\omega_{n}\right) \overleftarrow{\imath_{V}} \\
&= {\left[\mathcal{I}_{s \ldots n}+(-1)^{n-s+1} \mathcal{I}_{1 \ldots s-1} \Lambda_{s-1, s} \cdots \Lambda_{n-1, n}\right]\left(\omega_{1} \wedge \ldots \omega_{s-1}\right) \wedge\left(\omega_{s} \wedge \ldots \omega_{n-1}\right)\left(\omega_{n}\right) \overleftarrow{\imath_{V}} } \\
&=\left(\omega_{1} \wedge \ldots \wedge \omega_{s-1}\right) \wedge\left(\omega_{s} \wedge \ldots \wedge \omega_{n}\right) \overleftarrow{\imath_{V}} \\
&+(-1)^{n-s+1} \mathcal{I}_{1 \ldots s-1}\left(\omega_{1} \wedge \ldots \omega_{s-2}\right) \wedge \Lambda_{s-1, s} \Lambda_{s, s+1} \ldots \Lambda_{n-1, n}\left(\omega_{s-1} \wedge \ldots \omega_{n-1}\right)\left(\omega_{n}\right) \overleftarrow{\imath_{t_{i}}} b^{i} \\
&=\left(\omega_{1} \wedge \ldots \wedge \omega_{s-1}\right) \wedge\left(\omega_{s} \wedge \ldots \wedge \omega_{n}\right) \overleftarrow{\imath_{t_{i}}} \\
&+(-1)^{n-s+1} \mathcal{I}_{1 \ldots s-1}\left(\omega_{1} \wedge \ldots \wedge \omega_{s-2}\right)\left(\omega_{s-1}\right) \overleftarrow{\imath_{t_{j}}} \wedge f^{j}{ }_{i} *\left(\omega_{s} \wedge \omega_{s+1} \ldots \wedge \omega_{n}\right) b^{i} \\
&=\left(\omega_{1} \wedge \ldots \wedge \omega_{s-1}\right) \wedge\left(\omega_{s} \wedge \ldots \wedge \omega_{n}\right) \overleftarrow{\imath_{t_{i}}} \\
&+(-1)^{n-s+1}\left(\omega_{1} \wedge \ldots \wedge \omega_{s-1}\right) \overleftarrow{\imath_{t_{j}}} \wedge f^{j}{ }_{i} *\left(\omega_{s} \wedge \omega_{s+1} \ldots \wedge \omega_{n}\right) b^{i}
\end{aligned}
$$

With property e) this proves d).

Remark A slight generalization of property d) for two generic forms $\vartheta$ and $\vartheta^{\prime}$ is also true [use f)]:

$$
\begin{equation*}
\left(\vartheta \wedge \vartheta^{\prime}\right) \overleftarrow{i_{V}}=\vartheta \wedge\left(\vartheta^{\prime}\right) \overleftarrow{i_{V}}+(-1)^{\operatorname{deg}}\left(\vartheta^{\prime}\right) \overleftarrow{i_{t_{j}}} \wedge\left(f_{i}^{j} * \vartheta^{\prime}\right) b^{i} \tag{2.4.36}
\end{equation*}
$$

We have defined the exterior differential as an operator acting from the left to the right, indeed we have the following behaviour under grading, as opposed to the one in (2.4.36):

$$
\begin{equation*}
d\left(\vartheta \wedge \vartheta^{\prime}\right)=d \vartheta \wedge \vartheta^{\prime}+(-1)^{\operatorname{deg}(\vartheta)} \vartheta \wedge d \vartheta^{\prime} \tag{2.4.37}
\end{equation*}
$$

In order to find the Cartan expression for the Lie derivative : $\ell_{V}=i_{V} d+d i_{V}$, we therefore have to introduce an inner derivation $i_{V}$ that has the same behaviour as in (2.4.37). This motivates the following

## Definition of inner derivative

$$
\begin{equation*}
i_{V}(\vartheta) \equiv(-1)^{\operatorname{deg}(\vartheta-1)}(\vartheta) \overleftarrow{\imath_{V}} \quad \forall \vartheta \in \Gamma^{\otimes} \tag{2.4.38}
\end{equation*}
$$

this definition applies when $\vartheta$ is a generic covariant tensorfield and in particular when $\vartheta$ generic form. We immediately have:

Theorem 2.4.7 The $i_{V}$ contraction operator satisfies the following properties: $a, a_{i_{1} \ldots i_{n}} \in A ; V=t_{i} \square b^{i} ; \lambda \in \mathbf{C}$, property d) holds only if $\vartheta, \vartheta^{\prime}$ are forms
$\left.\mathrm{a}^{\prime}\right) i_{V}(\vartheta)=i_{t_{j} \square b^{j}}(\vartheta)=i_{t_{j}}(\vartheta) b^{j}$
$\left.\mathrm{b}^{\prime}\right) i_{V}(a)=0$
c') $i_{V}\left(\omega^{j}\right)=b^{j}$
$\left.\mathrm{d}^{\prime}\right) i_{V}\left(\vartheta \wedge \vartheta^{\prime}\right)=i_{t_{j}}(\vartheta) \wedge\left(f^{j}{ }_{i} * \vartheta^{\prime}\right) b^{i}+(-1)^{\operatorname{deg}(\vartheta)} \vartheta \wedge i_{V}\left(\vartheta^{\prime}\right)$
$\left.\mathrm{e}^{\prime}\right) i_{V}\left(a \vartheta+\vartheta^{\prime}\right)=a i_{V}(\vartheta)+i_{V}\left(\vartheta^{\prime}\right)$
$\left.\mathrm{f}^{\prime}\right) i_{V}(\vartheta a)=i_{t_{j}}(\vartheta)\left(f^{j}{ }_{i} * a\right) b^{i}$
$\left.\mathrm{g}^{\prime}\right) i_{\lambda V}=\lambda i_{V}$

Notice that properties $\left.a^{\prime}\right) e^{\prime}$ ) and $f^{\prime}$ ) reduce in the commutative case to the familiar formulae:

$$
i_{f V} \vartheta=f i_{V} \vartheta \quad \text { and } \quad i_{V}(f \vartheta)=f i_{V} \vartheta
$$

It is also straightforward to see that

$$
\begin{equation*}
\left(i d \otimes i_{t}\right) \Delta_{\Gamma}(\vartheta)=\Delta_{\Gamma} i_{t}(\vartheta) \quad \forall \vartheta \in \Gamma^{\otimes} \tag{2.4.39}
\end{equation*}
$$

This formula $q$-generalizes the classical commutativity of $i_{t}$ with the left coaction $\Delta_{\Gamma}$, when $t$ is a left invariant vectorfield.

### 2.4.5 Lie Derivative and Cartan identity

In (2.3.8), or in (2.1.88), we have seen that the $\chi_{i}$ are the quantum analogues of the tangent vectors at the origin of the group :

$$
\begin{equation*}
\left.\chi_{i} \xrightarrow{q \rightarrow 1} \frac{\partial}{\partial x^{i}}\right|_{x=0} \tag{2.4.40}
\end{equation*}
$$

and that the left-invariant vectorfields $t_{i}$ constructed from the $\chi_{i}$ are :

$$
\begin{equation*}
t_{i}=\chi_{i} *=\left(i d \otimes \chi_{i}\right) \Delta \tag{2.4.41}
\end{equation*}
$$

In the commutative case, the Lie derivative along a generic vectorfield $V$ is given by:

$$
\begin{equation*}
\ell_{V} \tau=\lim _{\varepsilon \rightarrow 1} \frac{1}{\varepsilon}\left[\varphi_{\varepsilon}^{V^{*}}(\tau)-\tau\right] \quad \forall \tau \in \Gamma^{\otimes} \tag{2.4.42}
\end{equation*}
$$

where $\varphi_{\varepsilon}^{V}$ is the flow of the vectorfield $V$ and $\varphi_{\varepsilon}^{V^{*}}$ the pullback. If $t$ is a left invariant vectorfield then

$$
\begin{equation*}
\varphi_{\varepsilon}^{t}=R_{e^{\varepsilon t}} \quad \text { i.e. } \quad \varphi_{\varepsilon}^{t}(g)=g e^{\varepsilon t} \quad \forall g \in G . \tag{2.4.43}
\end{equation*}
$$

We have $\ell_{t} \vartheta=\lim _{\varepsilon \rightarrow 0} \frac{1}{\varepsilon}\left[R_{e^{\varepsilon t}}{ }^{*}(\vartheta)-\vartheta\right]$ and therefore the Lie derivative $\ell_{t}$ is given by the right action $R_{e^{e t}}{ }^{*}$ of the group on covariant tensorfields. At the quantum level, recalling (2.1.16) and that ${ }_{\Gamma} \Delta \rightarrow R^{*}$ when $q \rightarrow 1$, it is natural to define:

Definition The quantum Lie derivative along the left-invariant vectorfield $t=$ $(i d \otimes \chi) \Delta$ is the operator:

$$
\begin{equation*}
\ell_{t} \equiv(i d \otimes \chi)_{\Gamma} \Delta \tag{2.4.44}
\end{equation*}
$$

that is

$$
\forall \tau \in \Gamma^{\otimes} \quad \ell_{t}(\tau) \equiv(i d \otimes \chi)_{\Gamma} \Delta(\tau) \quad \ell_{t}: \quad \Gamma^{\otimes n} \longrightarrow \Gamma^{\otimes n}
$$

For example we have :

$$
\begin{gather*}
\ell_{t}(a)=t(a), \quad a \in A  \tag{2.4.45}\\
\ell_{t_{i}}\left(\omega^{j}\right)=\left(i d \otimes \chi_{i}\right)_{\Gamma} \Delta\left(\omega^{j}\right)=\omega^{k} \chi_{i}\left(M_{k}^{j}\right)=\mathbf{C}_{k i}{ }^{j} \omega^{k} \tag{2.4.46}
\end{gather*}
$$

the classical limit being evident.
It is useful to define the $*$ product of a functional with any $\tau \in \Gamma^{\otimes n}$ as

$$
\begin{equation*}
\chi * \tau \equiv(i d \otimes \chi)_{\Gamma} \Delta(\tau) \tag{2.4.47}
\end{equation*}
$$

where the ${ }_{\Gamma} \Delta$ acts on a generic element $\tau=\rho^{1} \otimes \rho^{2} \otimes \cdots \rho^{n} \in \Gamma^{\otimes n}$ as in (2.1.62). In these notations we then have

$$
\begin{equation*}
\ell_{t}=\chi * \tag{2.4.48}
\end{equation*}
$$

The quantum Lie derivative has properties analogous to that of the ordinary Lie derivative:
i) it is linear in $\tau$ :

$$
\begin{equation*}
\ell_{t}\left(\lambda \tau+\tau^{\prime}\right)=\lambda \ell_{t}(\tau)+\ell_{t}\left(\tau^{\prime}\right) \tag{2.4.49}
\end{equation*}
$$

ii) it is linear in $t$ :

$$
\begin{equation*}
\ell_{\lambda t+t^{\prime}}=\lambda \ell_{t}+\ell_{t^{\prime}}, \quad \lambda \in \mathbf{C} \tag{2.4.50}
\end{equation*}
$$

By virtue of this last property we can just study $\ell_{t_{i}}$, where $\left\{t_{i}\right\}$ is a basis of inv $\Xi$.
Theorem 2.4.8 The following relation holds:

$$
\begin{equation*}
\ell_{t_{i}}\left(\tau \otimes \tau^{\prime}\right)=\ell_{t_{j}}(\tau) \otimes f^{j}{ }_{i} * \tau^{\prime}+\tau \otimes \ell_{t_{i}}\left(\tau^{\prime}\right) \tag{2.4.51}
\end{equation*}
$$

Proof

$$
\begin{aligned}
\ell_{t_{i}}\left(\tau \otimes \tau^{\prime}\right) & =\left(i d \otimes \chi_{i}\right)_{\Gamma} \Delta\left(\tau \otimes \tau^{\prime}\right) \\
& =\left(i d \otimes \chi_{i}\right)\left(\tau_{1} \otimes \tau_{1}^{\prime} \otimes \tau_{2} \tau_{2}^{\prime}\right) \\
& =\left(\tau_{1} \otimes \tau_{1}^{\prime}\right) \chi_{i}\left(\tau_{2} \tau_{2}^{\prime}\right)=\left(\tau_{1} \otimes \tau_{1}^{\prime}\right)\left[\chi_{j}\left(\tau_{2}\right) f_{i}^{j}\left(\tau_{2}^{\prime}\right)+\varepsilon\left(\tau_{2}\right) \chi_{i}\left(\tau_{2}^{\prime}\right)\right] \\
& =\tau_{1} \chi_{j}\left(\tau_{2}\right) \otimes \tau_{1}^{\prime} f^{j}{ }_{i}\left(\tau_{2}^{\prime}\right)+\tau_{1} \varepsilon\left(\tau_{2}\right) \otimes \tau_{1}^{\prime} \chi_{i}\left(\tau_{2}^{\prime}\right) \\
& =\ell_{t_{j}}(\tau) \otimes\left(i d \otimes f^{j}{ }_{i}\right) * \tau^{\prime}+\tau \otimes \ell_{t_{i}}\left(\tau^{\prime}\right)
\end{aligned}
$$

[remember that $\chi_{j}(a)$ and $f^{j}{ }_{i}(a)$ are $\mathbf{C}$ numbers]. The same argument leads to:

$$
\begin{align*}
& \ell_{t_{i}}\left(a \omega^{j}\right)=\ell_{t_{k}}(a)\left(f_{i}^{k} * \omega^{j}\right)+a \ell_{t_{i}}\left(\omega^{j}\right)  \tag{2.4.52}\\
& \ell_{t_{i}}\left(\omega^{j} a\right)=\ell_{t_{k}}\left(\omega^{j}\right)\left(f_{i}^{k} * a\right)+\omega^{j} \ell_{t_{i}}(a) . \tag{2.4.53}
\end{align*}
$$

The classical limit of (2.4.51) is easy to recover if we remember that $\varepsilon * \tau=\tau$. Formulas (2.4.51), (2.4.45) and (2.4.46) uniquely define the quantum $\ell_{t}$, which reduces, for $q \rightarrow 1$, to the classical Lie derivative.

Theorem 2.4.9 The Lie derivative commutes with the exterior derivative:

$$
\begin{equation*}
\ell_{t_{i}}(d \vartheta)=d\left(\ell_{t_{i}} \vartheta\right), \quad \vartheta \in \Gamma^{\wedge} \subset \Gamma^{\otimes}: \text { generic form } \tag{2.4.54}
\end{equation*}
$$

Proof:

$$
\begin{gathered}
\ell_{t_{i}}(d \vartheta)=\left(i d \otimes \chi_{i}\right)_{\Gamma} \Delta(d \vartheta)=\left(i d \otimes \chi_{i}\right)(d \otimes i d)_{\Gamma} \Delta(\vartheta)= \\
\left(d \otimes \chi_{i}\right)_{\Gamma} \Delta(\vartheta)=d \vartheta_{1} \underbrace{\chi_{i}\left(\vartheta_{2}\right)}_{\in \mathbf{C}}=d\left[\vartheta_{1} \chi_{i}\left(\vartheta_{2}\right)\right]=d\left(\ell_{t_{i}} \vartheta\right),
\end{gathered}
$$

where in the second equality we have used property (2.1.84).
Theorem 2.4.10 The Lie derivative commutes with the left and right coactions $\Delta_{\Gamma}$ and ${ }_{\Gamma} \Delta, \forall \tau \in \Gamma^{\otimes}$ :

$$
\begin{equation*}
\left(i d \otimes \ell_{t}\right) \Delta_{\Gamma}(\tau)=\Delta_{\Gamma}\left(\ell_{t} \tau\right) \tag{2.4.55}
\end{equation*}
$$

$$
\begin{equation*}
\left(i d \otimes \ell_{t}\right)_{\Gamma} \Delta(\tau)={ }_{\Gamma} \Delta\left(\ell_{t} \tau\right) . \tag{2.4.56}
\end{equation*}
$$

The proof is easy and relies on the fact that left and right coactions commute, cf. eq. (2.1.19). In the classical limit, eq. (2.4.55) becomes :

$$
\begin{equation*}
\ell_{t}\left(L_{g}^{*} \theta\right)=L_{g}^{*}\left(\ell_{t} \theta\right) \tag{2.4.57}
\end{equation*}
$$

Note 2.4.1 It is not difficult to prove the associativity of the generalized $*$ product, for example that $\left(\chi * \chi^{\prime}\right) * \tau=\chi *\left(\chi^{\prime} * \tau\right)$. From this property it follows that the $q$-Lie derivative is a representation of the $q$-Lie algebra:

$$
\left[\ell_{t}, \ell_{t^{\prime}}\right](\tau)=\ell_{\left[t, t^{\prime}\right]}(\tau),
$$

where the left hand side is defined via the adjoint action :

$$
\left[\ell_{t}, \ell_{t^{\prime}}\right](\tau) \equiv \ell_{\kappa^{\prime}\left(\chi_{1}^{\prime}\right) *^{\circ}} \ell_{t^{\circ}} \ell_{t_{2}^{\prime}}
$$

In the $\left\{t_{i}\right\}$ basis: $\left[\ell_{t_{i}}, \ell_{t_{k}}\right]=\ell_{t_{i}} \circ \ell_{t_{k}}-\Lambda_{i k}^{e f} \ell_{t_{e}} \circ \ell_{t_{f}}$.
We can now prove the Cartan identity:
Theorem 2.4.11 The contraction operator $i_{t}$ defined in (2.4.38), the Lie derivative and the exterior differential satisfy (we omit the composition product $\circ$ ) :

$$
\begin{equation*}
\ell_{t_{i}}=i_{t_{i}} d+d i_{t_{i}} . \tag{2.4.58}
\end{equation*}
$$

A proof of this theorem is given in Appendix B.
Led by Theorem 2.4.11, it is natural to introduce the Lie derivative along a generic vectorfield $V$ through the following

## Definition

$$
\begin{equation*}
\ell_{V}=i_{V} d+d i_{V} \tag{2.4.59}
\end{equation*}
$$

Theorem 2.4.12 The Lie derivative satisfies the following properties:

1) $\quad \ell_{V} a=V(a)$
2) $\quad \ell_{V} d \vartheta=d \ell_{V} \vartheta$
3) $\quad \ell_{V}\left(\lambda \vartheta+\vartheta^{\prime}\right)=\lambda \ell_{V}(\vartheta)+\ell_{V}\left(\vartheta^{\prime}\right)$
4) $\quad \ell_{V \square b}(\vartheta)=\left(\ell_{V} \vartheta\right) b-(-1)^{p} i_{V}(\vartheta) \wedge d b$
5) $\quad \ell_{V}\left(\vartheta \wedge \vartheta^{\prime}\right)=\vartheta \wedge \ell_{V}\left(\vartheta^{\prime}\right)+\ell_{t_{k}}(\vartheta) \wedge\left(f^{k}{ }_{j} * \vartheta^{\prime}\right) b^{j}+(-1)^{\operatorname{deg}\left(\vartheta^{\prime}\right)} i_{t_{k}}(\vartheta) \wedge\left(f_{j}^{k} * \vartheta^{\prime}\right) \wedge d b^{j}$
where $\vartheta$ and $\vartheta^{\prime}$ are generic forms and $V=t_{j} \square b^{j}$.
Proof

Properties 1), 2), 3) and 4) follow directly from the definition (2.4.59).
Property 5) is also a consequence of definition (2.4.59); the proof uses relation $\mathrm{d}^{\prime}$ ) and the identity $d\left(f^{k}{ }_{j} * \vartheta\right)=f^{k}{ }_{j} * d \vartheta[$ see (2.1.107)].

Note 2.4.2 It is natural to define a Lie derivative $\ell_{h_{i}}^{\mathcal{R}}$ of a generic covariant tensorfield $\tau \in \Gamma^{\otimes}$ along a right-invariant vectorfield $h_{i}$ in terms of the left coaction $\Delta_{\Gamma}$ :

$$
\ell_{h}^{\mathcal{R}}(\tau) \equiv(\chi \otimes \dot{i d}) \Delta_{\Gamma}(\tau) \equiv \tau * \chi,
$$

just like it was natural that we used the right coaction, when we defined $\ell_{t_{i}}$ in (2.4.44). In this note we compare the two definitions.

From the above definition we find

$$
\begin{align*}
\ell_{h_{i}}^{\mathcal{R}}\left(\vartheta \wedge \vartheta^{\prime}\right) & \left.=\chi_{i}\left(\vartheta_{1} \vartheta^{\prime}\right){ }_{1}\right) \vartheta_{2} \wedge \vartheta_{2}^{\prime} \\
& =\chi_{j}\left(\vartheta_{1}\right) f_{i}^{j}{ }_{i}\left(\vartheta_{1}^{\prime}\right) \vartheta_{2} \wedge \vartheta_{2}^{\prime}+\varepsilon\left(\vartheta_{1}\right) \chi_{i}\left(\vartheta^{\prime}\right) \vartheta_{2} \wedge \vartheta^{\prime}{ }_{2}  \tag{2.4.60}\\
& =\ell_{h_{j}}^{\mathcal{R}}(\vartheta) \wedge\left(\vartheta^{\prime} * f^{j}{ }_{i}\right)+\vartheta \wedge \ell_{h_{i}}^{\mathcal{R}}\left(\vartheta^{\prime}\right)
\end{align*}
$$

where $\vartheta^{\prime} * f^{j}{ }_{i} \equiv\left(f^{j}{ }_{i} \otimes i d\right) \Delta_{\Gamma}\left(\vartheta^{\prime}\right)$. In particular:

$$
\begin{equation*}
\ell_{h_{i}}^{\mathcal{R}}(a d b)=h_{i}(a) d\left(b * f^{j}{ }_{i}\right)+a d\left(h_{j}(b)\right) . \tag{2.4.61}
\end{equation*}
$$

where we have used (2.1.83). On the other hand, since $h_{i}=t_{j 口} M_{i}{ }^{j}$, we can give an alternative expression for the Lie derivative along the right invariant vectorfield $h_{i}$ :

$$
\begin{align*}
\ell_{h_{i}}(a d b)=\ell_{t_{j} \square M_{i} j}(a d b) & =a \ell_{t_{j} \square M_{i}}(d b)+\ell_{t_{k}}(a) \wedge\left(f_{j}^{k} * d b\right) M_{i}{ }^{j} \\
& =a d\left(h_{i}(b)\right)+t_{k}(a) d\left(f^{k}{ }_{j} * b\right) M_{i}{ }^{j} . \tag{2.4.62}
\end{align*}
$$

The difference between expressions (2.4.61) and (2.4.62) is a good index for the "defect" between left and right transports on a quantum group:

$$
\begin{align*}
\left(\ell_{h_{i}}-\ell_{h_{i}}^{\mathcal{R}}\right)(a d b) & =t_{k}(a)\left[\left(f_{j}^{k} * d b\right) M_{i}^{j}-M_{j}{ }^{k}\left(d b * f_{i}^{j}\right)\right]  \tag{2.4.63}\\
& =-t_{k}(a) D I_{i}^{k}(b)
\end{align*}
$$

where

$$
\begin{equation*}
D I^{k}{ }_{i}(b) \equiv\left[\left(f^{k}{ }_{j} * b\right) d\left(M_{i}{ }^{j}\right)-d\left(M_{j}{ }^{k}\right)\left(b * f^{j}{ }_{i}\right)\right] \quad \text { (Defect Index) } \tag{2.4.64}
\end{equation*}
$$

In the last passage we have used the Leibniz rule for $d$ combined with the bicovariance condition (2.1.51). The term in the square brackets is always zero in the classical (undeformed) case. Note that $\left(\ell_{h_{i}}-\ell_{h_{i}}^{\mathcal{R}}\right)$ vanishes on $a$ and $d b$ separately but not necessarily on $a d b$. The case of " $a$ " confirms (2.3.23):

$$
\begin{equation*}
\ell_{h_{i}}(a)=t_{j}(a) M_{i}{ }^{j}=h_{i}(a)=\ell_{h_{i}}^{\mathcal{R}}(a) \tag{2.4.65}
\end{equation*}
$$

and shows that we will not encounter any ambiguities or inconsistencies as long as we deal with general vectorfields and functions alone. Problems can occur however when we start to introduce forms. For example in the $G L_{q}(2)$ differential calculus of Section 2.2 we have, sum over $a$ understood, $\kappa\left(x_{a}{ }_{a}{ }_{1}\right)\left(\ell_{h^{i}}{ }_{j}-\ell_{h^{i}{ }_{j}}^{\mathcal{R}}\right)\left(x_{a}{ }^{a}{ }_{2} d b\right)=-\left(f_{k}{ }^{k e}{ }_{f} *\right.$ b) $d M^{i}{ }_{j e}{ }^{f}=\lambda t^{e}{ }_{f}(b) d M^{i}{ }_{j e}{ }^{f}$ for any $b$ such that $\varepsilon(b)=0$. This expression is clearly $\neq 0$ in general.

### 2.4.6 Algebra of Differential Operators

In the previous sections, given a Woronowicz differential calculus on a generic Hopf algebra $A$, we have defined the quantum analogue of Lie derivative and of inner derivative by a natural generalization of their defining classical formulae. The Lie derivative and contraction operators act on the space $\Gamma^{\otimes}$ of covariant tensorfields, we have in particular studied their properties on the space $\Gamma^{\wedge} \subset \Gamma^{\otimes}$ of forms where the exterior differential is also present.

These operators form a graded quantum Lie algebra

$$
\begin{align*}
\{d, d\} & =0  \tag{2.4.66}\\
{\left[d, \ell_{V}\right] } & =0  \tag{2.4.67}\\
\left\{d, i_{V}\right\} & =\ell_{V} \tag{2.4.68}
\end{align*}
$$

which is supplemented by two more relations

$$
\begin{align*}
& {\left[\ell_{t_{i}}, \ell_{t_{k}}\right]=\ell_{\left[t_{i}, t_{k}\right]}=\mathbf{C}_{i k}{ }^{l} \ell_{t_{l}}}  \tag{2.4.69}\\
& {\left[i_{t_{i}}, \ell_{t_{k}}\right]=i_{\left[t_{i}, t_{k}\right]}=\mathbf{C}_{i k}{ }^{l} i_{t_{l}}} \tag{2.4.70}
\end{align*}
$$

where the definition of the brackets in the left hand side of (2.4.69) and (2.4.70) is the generalization of the adjoint action:

$$
\left[\ell_{t_{i}}, \ell_{t_{k}}\right] \equiv \ell_{\kappa^{\prime}\left(\chi_{k 1}\right) *} \circ \ell_{t_{i}} \circ \ell_{\chi_{k 2^{*}}}=\ell_{t_{i}} \circ \circ \ell_{t_{k}}+\ell_{\kappa^{\prime}\left(\chi_{e}\right) *^{\circ}} \ell_{t_{i}} \circ f_{k}^{e}{ }_{k} *=\ell_{t_{i}} \circ \ell_{t_{k}}-\Lambda_{i k}^{e f} \ell_{t_{e}} \circ \ell_{t_{f}}
$$

(this last equality is explained in Note 2.4.1)

$$
\begin{equation*}
\left[i_{t_{i}}, \ell_{t_{k}},\right] \equiv \ell_{\kappa^{\prime}\left(\chi_{k 1}\right) *} \circ i_{t_{i}} \circ \ell_{\chi_{k 2^{*}}}=i_{t_{i}} \circ \ell_{t_{k}}-\Lambda_{i k}^{e f} \ell_{t_{e}} \circ i_{t_{f}} \tag{2.4.71}
\end{equation*}
$$

The proof of (2.4.70) and of the last equality in (2.4.71), similarly to the proof of the Cartan identity, is by induction. It is given in Appendix B.

The cross-commutation relations between forms, exterior derivative, Lie derivative and inner derivative, that we have derived from the actions of $i_{V}$ and $\ell_{t}$ on generic tensors $\tau \in \Gamma^{\otimes}$ and essentially (see the definition of $i_{V}$ ) from the $\Gamma^{\otimes} \leftrightarrow \Xi^{\otimes}$ duality -i.e. the bicovariant bimodule structure of $\Gamma^{\otimes}$ and $\Xi^{\otimes}$ - can be formally derived also from the cross product algebra $\Gamma^{\wedge} \rtimes \Gamma^{\wedge *}$ 40, 41]. Here $\Gamma^{\wedge}$ is seen as a graded Hopf algebra: the product in $\Gamma^{\wedge} \otimes \Gamma^{\wedge}$ is given by $(I \otimes$ $\mu)(\nu \otimes I)=(-1)^{\operatorname{deg}(\mu) \operatorname{deg}(\nu)}(\nu \otimes \mu)$, the costructures generalize those of $A$ and are: $\Delta\left(\omega^{i}\right)=\left(\Gamma \Delta+\Delta_{\Gamma}\right)\left(\omega^{i}\right)=\omega^{i} \otimes M_{j}{ }^{i}+I \otimes \omega^{i}, \varepsilon\left(\omega^{i}\right)=0, \kappa\left(\omega^{i}\right)=-\omega^{j} \kappa\left(M_{j}{ }^{i}\right)$ 477. $\Gamma^{\wedge *}$ is the graded Hopf algebra dual to $\Gamma^{\wedge}, \Gamma^{\wedge *}=U \oplus \Gamma^{*} \oplus \Gamma^{\wedge 2^{*}} \oplus \ldots$. For example $\chi_{i} \vartheta=\vartheta_{1}\left\langle\chi_{i 1}, \vartheta_{2}\right\rangle \chi_{i 2}=\left(\chi_{j} * \vartheta\right) f^{j}{ }_{i}+\vartheta \chi_{i}$ corresponds to $\ell\left(\vartheta \wedge \vartheta^{\prime}\right)=$ $\ell_{\chi_{i}}(\vartheta) \wedge\left(f_{i}^{j}{ }^{*} \vartheta^{\prime}\right)+\vartheta \wedge \ell_{\chi_{i}}\left(\vartheta^{\prime}\right)$. As shown in 37] the graded $q$-Lie algebra of the operators $i_{V}, d, \ell$ can also be interpreted as a braided tensor algebra.

## Chapter 3

## Geometry of the quantum Inhomogeneous Linear Groups $I G L_{q, r}(N)$

In this chapter, following [60], we analize the geometry of the inhomogeneous quantum linear groups $I G L_{q, r}(N)$. Quantum deformations of inhomogeneous Lie groups have been studied in [65] [58] [57]. An $R$-matrix approach has been independently proposed for $I G L_{q}(N)$ in ref.s [58] and [57].

We construct the multiparametric $I G L_{q, r}(N) q$-groups, their universal enveloping algebra and their bicovariant differential calculus using a projection $P: G L_{q, r}(N$ $+1) \rightarrow I G L_{q, r}(N)$; this projection procedure was first introduced in 59.

All the quantities relevant to the $I G L_{q, r}(N)$ (bicovariant) differential calculus are given explicitly: exterior derivatives, left-invariant 1-forms, Cartan-Maurer equations, tangent vectors and their $q$-Lie algebra and so on. The method is illustrated in the case of $I G L_{q, r}(2)$ : the general formulas are applied and tested on this example.

In this framework we construct the differential geometry of the (multiparametric) quantum plane in a novel and easy way.

Deformations of inhomogeneous Lie groups and Lie algebras usually include a dilatation generator, moreover the determinant of the fundamental representation of the $q$-group is in general not central. It is studying the most general (multiparametric) deformation that we understand the interplay between the absence or presence of the dilatation and the properties of the determinant. This also clarify the relation between the non-commutativity of the quantum plane coordinates $x^{a}$ discussed in Section 3.7 (due to the auxiliary deformation parameters $q_{i}$ ), the non-comutativity of the generators $T^{a}{ }_{b}$ of the homogeneous linear subgroup and the finite difference structure of the differential calculus, that is due to the main deformation parameter $r$ (called $q$ in the previous chapters), cf. [77].

In Section 3.1 we recall the basics of the linear quantum groups and in Section 3.2 we discuss their duals in some detail. In fact, Sections 3.1 and 3.2 are a short review of the multiparametric deformations of $G L_{q, r}(N)$, where $q$ indicates a set of parameters $q_{i}$, and of their universal enveloping algebras. The usual uniparametric case is recovered for $r=q_{i}=q$. For references on multiparametric deformations, see [74, [55, 76].

In Section 3.3, we first present the quantum group $I G L_{q, r}(N)$ as a Hopf algebra with given generators, commutation relations and co-structures. We then reobtain it as the image of a projection $P$ from $G L_{q, r}(N+1)$, and show how the "mother" Hopf algebra $G L_{q, r}(N+1)$ determines the Hopf algebra structure on $I G L_{q, r}(N)$. In the language of Hopf algebra ideals $I G L_{q, r}(N)$ is seen as the quotient of $G L_{q, r}(N+1)$ with respect to a suitable Hopf ideal.

The fundamental representation of $I G L_{q, r}(N)$ contains the $G L_{q, r}(N)$ elements $T^{a}{ }_{b}$ and the "coordinates" $x^{a}$ as in the classical case, in addition, there is also an element $u$ playing the role of a dilatation. By fixing some of the parameters $q$, we find that this element $u$ can be made central, and hence consistently set equal to the identity $I$.

A quantum determinant can be defined, and is central only in a subclass of the multiparametric deformations. In this subclass, however, the element $u$ is not central. We end the section analizing the semidirect product structure of $I G L_{q, r}(N)$ given by $G L_{q, r}(N)$ and the quantum plane: this construction is based on the observation that $G L_{q, r}(N)$ is both a Hopf subalgebra in $I G L_{q, r}(N)$ and a quotient of $I G L_{q, r}(N)$ obtained projecting to zero the quantum plane coordinates $x^{a}$.

The explicit construction of the bicovariant differential calculus for $G L_{q, r}(N)$, in terms of the dual algebra, is given in Section 3.4. In Section 3.5 we project the bicovariant differential calculus of $G L_{q, r}(N+1)$ to $I G L_{q, r}(N)$ and study the bicovariant bimodules of 1 -forms and tangent vectors on $I G L_{q, r}(N)$. In particular, the $q$-Lie algebra is given explicitly. We also study in detail the exterior algebra and the exterior derivative, and find the Cartan-Maurer equations. In Section 3.6 we then study the universal enveloping algebra $U_{q, r}(i g l(N))$ its semidirect product structure [given by $U_{q, r}(g l(N))$ and the translation generators] and the duality with $I G L_{q, r}(N)$. The Universal enveloping algebra $U_{q, r}(i g l(N))$ is the natural setting where to study $q$-Lie algebras and therefore differential calculi. Using the general theory of Section 2.3, we easily obtain another differential calculus on $\operatorname{IGL} L_{q, r}(N)$ that differs from the previous one by the presence of a dilatation generator corresponding to the dilatation $u \in I G L_{q, r}(N)$.

In Section 3.7 we discuss the multiparametric quantum plane, i.e. the quantum coset space $I G L_{q, r}(N) / G L_{q, r}(N)$ spanned by the coordinates $x^{a}$, and find a generalization of the differential geometry of the $q$-plane of 48], [50], see also Schirrmacher in [76].

In the Table at the end of the chapter we specialize our general treatment to $I G L_{q, r}(2)$ and collect all the relevant formulas for its bicovariant differential calculus.

## 3.1 $G L_{q, r}(N)$ and its real forms

We here introduce the multiparametric $q$-group $G L_{q, r}(N)$, where now the index $q \equiv q_{a b}$ represents a set of parameters, and $r$ is the parameter we called $q$ in the previous chapters. $G L_{q, r}(N)$ is the algebra (over the complex field) freely generated by the non-commuting matrix elements $T^{A}{ }_{B},(A, B=1, . . N)$, the identity $I$ and the inverse $\Xi$ of the $q$-determinant of $T$ defined in (3.1.6), modulo the " $R T T$ " relations:

$$
\begin{equation*}
R^{A B}{ }_{E F} T_{C}^{E} T^{F}{ }_{D}=T_{F}^{B} T_{E}^{A} R_{C D}^{E F} \tag{3.1.1}
\end{equation*}
$$

where the $R$-matrix is given by 774,75 :

$$
\begin{equation*}
R_{C D}^{A B}=\delta_{C}^{A} \delta_{D}^{B}\left[\frac{r}{q_{A B}}+(r-1) \delta^{A B}\right]+\left(r-r^{-1}\right) \delta_{D}^{A} \delta_{C}^{B} \theta^{A B} \tag{3.1.2}
\end{equation*}
$$

with $\theta^{A B}=1$ for $A>B$ and zero otherwise, and

$$
\begin{equation*}
q_{A B}=\frac{r^{2}}{q_{B A}}, \quad q_{A A}=r \tag{3.1.3}
\end{equation*}
$$

It is useful to list the nonzero complex components of the $R$ matrix (no sum on repeated indices):

$$
\begin{array}{ll}
R_{A A}^{A A}=r & \\
R_{A B}^{A B}=\frac{r}{q_{A B}}, & A \neq B \\
R^{B A}{ }_{A B}=r-r^{-1}, & B>A \tag{3.1.4}
\end{array}
$$

The $R$ matrix in (3.1.2) satisfies the quantum Yang-Baxter equation.
The standard uniparametric $R$ matrix [19] is obtained from (3.1.2) by setting all deformation parameters $q_{A B}, r$ equal to a single parameter $q$. For a further insight about the relationship between the multiparametric and the uniparametric $R$-matrix see Section 4.1.

The quantum determinant of $T$ and its inverse $\Xi$ are defined by:

$$
\begin{gather*}
\Xi \operatorname{det} T=\operatorname{det} T \Xi=I  \tag{3.1.5}\\
\operatorname{det} T \equiv \sum_{\sigma}\left[\prod_{A<B, \sigma(A)>\sigma(B)}\left(-\frac{r^{2}}{q_{\sigma(B) \sigma(A)}}\right)\right] T_{\sigma(1)}^{1} \cdots T_{\sigma(N)}^{N} \tag{3.1.6}
\end{gather*}
$$

Note 3.1.1 In the uniparametric case $r=q_{A B}=q$ we recover the usual formula

$$
\begin{equation*}
\operatorname{det} T \equiv \sum_{\sigma}(-q)^{l(\sigma)} T_{\sigma(1)}^{1} \cdots T_{\sigma(N)}^{N} \tag{3.1.7}
\end{equation*}
$$

where $l(\sigma)$ is the minimum number of transpositions in the permutation $\sigma$.
Note 3.1.2 In more mathematical terms, the algebra $G L_{q, r}(N)$ is the quotient of the non-commuting algebra $\mathbf{C}\left\langle T_{B}^{A}, I, \Xi\right\rangle$ freely generated by the elements $T^{A}{ }_{B}, I, \Xi$ with respect to the two-sided ideal in $\mathbf{C}\left\langle T^{A}{ }_{B}, I, \Xi\right\rangle$ generated by the $R T T$ relations (3.1.1).

Note 3.1.3 The inverse matrix $R^{-1}$, defined as

$$
\begin{equation*}
\left(R^{-1}\right)^{A B}{ }_{C D} R_{E F}^{C D} \equiv \delta_{E}^{A} \delta_{F}^{B} \equiv R_{C D}^{A B}\left(R^{-1}\right)^{C D}{ }_{E F} \tag{3.1.8}
\end{equation*}
$$

is given by

$$
\begin{equation*}
R_{q, r}^{-1}=R_{q^{-1}, r^{-1}} \tag{3.1.9}
\end{equation*}
$$

Note 3.1.4 The $\hat{R}$ matrix defined by $\hat{R}^{A B}{ }_{C D} \equiv R^{B A}{ }_{C D}$ satisfies the spectral decomposition (Hecke condition):

$$
\begin{equation*}
(\hat{R}-r I)\left(\hat{R}+r^{-1} I\right)=0 \tag{3.1.10}
\end{equation*}
$$

Note 3.1.5 The determinant in (3.1.6) is central if and only if the following conditions on the parameters are satisfied (see ref. [74]):

$$
\begin{equation*}
q_{1, A} q_{2, A} \cdots q_{A-1, A} \frac{r^{2}}{q_{A, A+1}} \frac{r^{2}}{q_{A, A+2}} \cdots \frac{r^{2}}{q_{A, N}}=\text { const. } \tag{3.1.11}
\end{equation*}
$$

for all $\mathrm{A}=1, \ldots \mathrm{~N}$. This results in $\mathrm{N}-1$ conditions among the $q_{A B}$ and determines const $=r^{N-1}$. Using (3.1.3), and defining

$$
\begin{equation*}
Q_{A} \equiv \prod_{C=1}^{N}\left(\frac{q_{C A}}{r}\right) \tag{3.1.12}
\end{equation*}
$$

the centrality conditions (3.1.11) become:

$$
\begin{equation*}
Q_{A}=1 \tag{3.1.13}
\end{equation*}
$$

We have used also const $=r^{N-1}$, so that only $N-1$ of the above conditions are independent. Indeed the $Q_{A}$ satisfy the relation

$$
\begin{equation*}
Q_{1} Q_{2} \cdots Q_{N}=1 \tag{3.1.14}
\end{equation*}
$$

In general we have:

$$
\begin{equation*}
(\operatorname{det} T) T_{B}^{A}=\frac{Q_{A}}{Q_{B}} T_{B}^{A}(\operatorname{det} T), \quad \Xi T_{B}^{A}=\frac{Q_{B}}{Q_{A}} T_{B}^{A} \Xi \tag{3.1.15}
\end{equation*}
$$

When (3.1.13) holdsf, we can consistently set $\operatorname{det} T^{A}{ }_{B}=I=\Xi$, and obtain the multiparametric deformations $S L_{q, r}(N)$.

The algebra $G L_{q, r}(N)$ becomes a Hopf algebra with the following coproduct $\Delta$, counit $\varepsilon$ and coinverse $\kappa$ :

$$
\begin{align*}
& \Delta\left(T_{B}^{A}\right)=T_{B}^{A} \otimes T_{C}^{B}  \tag{3.1.16}\\
& \varepsilon\left(T_{B}^{A}\right)=\delta_{B}^{A}  \tag{3.1.17}\\
& \kappa\left(T_{B}^{A}\right)=\left(T^{-1}\right)^{A}{ }_{B}  \tag{3.1.18}\\
& \Delta(\operatorname{det} T)=\operatorname{det} T \otimes \operatorname{det} T, \quad \Delta(\Xi)=\Xi \otimes \Xi, \quad \Delta(I)=I \otimes I  \tag{3.1.19}\\
& \varepsilon(\operatorname{det} T)=1, \quad \varepsilon(\Xi)=1, \quad \varepsilon(I)=1  \tag{3.1.20}\\
& \kappa(\operatorname{det} T)=\Xi, \quad \kappa(\Xi)=\operatorname{det} T, \quad \kappa(I)=I \tag{3.1.21}
\end{align*}
$$

The quantum inverse of $T^{A}{ }_{B}$ in (3.1.18) is given by:

$$
\begin{equation*}
\left(T^{-1}\right)^{A}{ }_{B}=\Xi \Pi_{A B}^{(1, N)} t_{B}^{A} \tag{3.1.22}
\end{equation*}
$$

where $t_{B}{ }^{A}$ is the quantum minor, i.e. the quantum determinant of the submatrix of $T$ obtained by removing the $B$-th row and the $A$-th column, and $\Pi_{A B}^{(1, N)}$ is a function of the parameters $q$ :

$$
\begin{equation*}
\Pi_{A B}^{(1, N)} \equiv \frac{\prod_{C=B+1}^{N}\left(-q_{B C}\right)}{\prod_{D=A+1}^{N}\left(-q_{A D}\right)} \tag{3.1.23}
\end{equation*}
$$

The superscript $(1, N)$ reminds the range of the indices $\mathrm{A}, \mathrm{B}, \mathrm{C}, \ldots$ In the uniparametric case, the quantum inverse has the simpler expression:

$$
\begin{equation*}
\left(T^{-1}\right)_{B}^{A}=\Xi(-q)^{A-B} t_{B}^{A} \tag{3.1.24}
\end{equation*}
$$

Note 3.1.6 As in Note 1.2.1, we recall that in general $\kappa^{2} \neq 1$ and

$$
\begin{equation*}
\kappa^{2}\left(T_{B}^{A}\right)=D_{C}^{A} T_{D}^{C}\left(D^{-1}\right)_{B}^{D}=d^{A} d_{B}^{-1} T_{B}^{A} \tag{3.1.25}
\end{equation*}
$$

where $D$ is a diagonal matrix, $D_{B}^{A}=d^{A} \delta_{B}^{A}$, given by $d^{A}=r^{2 A-1}$ for $G L_{q, r}(N)$. This matrix satisfies:

$$
\begin{array}{ll}
d^{A} d_{C}^{-1}\left(R^{-1}\right)^{B A}{ }_{D C} R^{E C}{ }_{B F}=\delta_{F}^{A} \delta_{D}^{E}, & d^{A} d_{C}^{-1} R^{A B}{ }_{C D}\left(R^{-1}\right)^{C E}{ }_{F B}=\delta_{F}^{A} \delta_{D}^{E} \\
d^{B} d_{D}^{-1}\left(R^{-1}\right)^{A B}{ }_{C D} R^{C E}{ }_{F B}=\delta_{F}^{A} \delta_{D}^{E}, & d^{B} d_{D}^{-1} R_{D C}^{B A}\left(R^{-1}\right)^{E C}{ }_{B F}=\delta_{F}^{A} \delta_{D}^{E} \tag{3.1.27}
\end{array}
$$

[^5]\[

$$
\begin{equation*}
R_{C B}^{A C} d_{C}^{-1}=\delta_{B}^{A}=\left(R^{-1}\right)^{A C}{ }_{C B} d_{C} \tag{3.1.28}
\end{equation*}
$$

\]

This last condition fixes the normalization of $D$. Relations (3.1.26) and (3.1.27) define a second inverse $R^{\sim 1}$ of the $R$ matrix and a second inverse $\left(R^{-1}\right)^{\sim 1}$ of the $R^{-1}$ matrix as:

$$
\begin{align*}
& \left(R^{\sim 1}\right)^{A B}{ }_{C D} \equiv d^{B} d_{D}^{-1}\left(R^{-1}\right)^{A B}{ }_{C D}  \tag{3.1.29}\\
& \left(\left(R^{-1}\right)^{\sim 1}\right)^{A B}{ }_{C D} \equiv d^{A} d_{C}^{-1} R^{A B}{ }_{C D} \tag{3.1.30}
\end{align*}
$$

Using (3.1.28) we can relate the $D$ matrix to this second inverse:

$$
\begin{equation*}
\left(D^{-1}\right)_{B}^{A}=\left(R^{\sim 1}\right)^{A C} C_{C B}, \quad D_{B}^{A}=\left(\left(R^{-1}\right)^{\sim 1}\right)^{A C}{ }_{C B} \tag{3.1.31}
\end{equation*}
$$

This generalizes the analogous discussion for the uniparametric $D$ matrix given in (19.

We turn now to the real forms of $G L_{q, r}(N)$, that are defined by *-conjugations of the $G L_{q, r}(N)$ Hopf algebra; see Section 1.3. These conjugations must be compatible with the $R T T$ relations: this restricts the range of the parameters $q, r$. Three such conjugations are known (cf. [74]):
i) $\quad T^{*}=T$, i.e. the elements $T_{B}^{A}$ are "real". Applying the $*$-conjugation to the $R T T$ equations (3.1.1) yields again the $R T T$ relations if the $R$ matrix satisfies $\bar{R}=R^{-1}$. This happens for $\left|q_{A B}\right|=|r|=1$, i.e. for deformation parameters lying on the unit circle in $\mathbf{C}$ (cf. eq. (3.1.9)). The quantum group is then denoted by $G L_{q, r}(N ; \mathbf{R})$.
ii) $\quad\left(T_{B}^{A}\right)^{*}=T_{B^{\prime}}^{A^{\prime}}$ with primed indices defined as $A^{\prime}=N+1-A$. Here compatibility with the $R T T$ relations requires $\bar{R}^{A B}{ }_{C D}=R^{B^{\prime} A^{\prime}}{ }_{D^{\prime} C^{\prime}}$, satisfied when $\bar{q}_{A B}=q_{B^{\prime} A^{\prime}}, r \in \mathbf{R}$.
iii) $\quad\left(T_{B}^{A}\right)^{*}=\kappa\left(T_{A}^{B}\right)$, the generalization of the unitarity condition for the matrix $T$. In this case (left as an exercise in [74]) the restriction on the $R$ matrix is $\bar{R}_{C D}^{A B}=R_{B A}^{D C}$, leading to the conditions $\bar{q}_{A B}=q_{B A}, r \in \mathbf{R}$. The corresponding quantum groups are denoted by $U_{q, r}(N)$.

Imposing also $\operatorname{det} T=I$ yields the quantum groups $S L_{q, r}(N ; \mathbf{R})$ or $S U_{q, r}(N)$.

### 3.2 The universal enveloping algebra of $G L_{q, r}(N)$

We construct the universal enveloping algebra of $G L_{q, r}(N)$ as the algebra of regular functionals 19] on $G L_{q, r}(N)$ : it is generated by the functionals $L^{ \pm}, \varepsilon$ and $\Phi$ defined below.

The $L^{ \pm}$functionals are defined as in Section 2.2 where the uniparametric $R$ matrix is now replaced by the multiparametric one.

A determinant can be defined for the matrix $L^{ \pm A}{ }_{B}$, as in Note 2.2.1, this is given by:

$$
\begin{equation*}
\operatorname{det} L^{ \pm}=L^{ \pm 1}{ }_{1} L^{ \pm 2}{ }_{2} \cdots L^{ \pm N}{ }_{N} . \tag{3.2.1}
\end{equation*}
$$

A quantum inverse for $L^{ \pm A}{ }_{B}$ can be found, using an expression analogous to (3.1.22) with $q_{A B} \rightarrow q_{A B}^{-1}$. For this we need to introduce the element $\Phi$ defined by:

$$
\begin{equation*}
\Phi \operatorname{det} L^{+} \operatorname{det} L^{-}=\operatorname{det} L^{+} \operatorname{det} L^{-} \Phi=\varepsilon . \tag{3.2.2}
\end{equation*}
$$

Then the quantum inverse of $L^{ \pm A}{ }_{B}$ is given by:

$$
\begin{equation*}
\left(L_{B}^{ \pm A}\right)^{-1}=\Phi \operatorname{det} L^{\mp} \Pi_{B A}^{(1, N)} \ell_{B}^{A} \tag{3.2.3}
\end{equation*}
$$

where $\ell_{B}^{A}$ is the quantum minor and $\Pi_{B A}^{(1, N)}$ is given in (3.1.23). Notice that $\Phi \operatorname{det} L^{\mp}$ is the inverse of $\operatorname{det} L^{ \pm}$because of property (3.2.13) below.

The co-structures of the algebra generated by the functionals $L^{ \pm}, \varepsilon$ and $\Phi$ are as in Section 2.2 :

$$
\begin{align*}
& \Delta^{\prime}\left(L^{ \pm A}{ }_{B}\right)=L^{ \pm A}{ }_{G} \otimes L_{B}^{ \pm G}  \tag{3.2.4}\\
& \varepsilon^{\prime}\left(L^{ \pm A}{ }_{B}\right)=\delta_{B}^{A}  \tag{3.2.5}\\
& \kappa^{\prime}\left(L^{ \pm A}{ }_{B}\right)=L_{B}^{ \pm A} \circ \kappa  \tag{3.2.6}\\
& \Delta^{\prime}\left(\operatorname{det} L^{ \pm}\right)=\operatorname{det} L^{ \pm} \otimes \operatorname{det} L^{ \pm}  \tag{3.2.7}\\
& \Delta^{\prime}(\Phi)=\Phi \otimes \Phi, \Delta^{\prime}(\varepsilon)=\varepsilon \otimes \varepsilon  \tag{3.2.8}\\
& \varepsilon^{\prime}\left(\operatorname{det} L^{ \pm}\right)=1, \varepsilon^{\prime}(\Phi)=1, \varepsilon^{\prime}(\varepsilon)=1  \tag{3.2.9}\\
& \kappa^{\prime}\left(\operatorname{det} L^{ \pm}\right)=\Phi \operatorname{det} L^{\mp},  \tag{3.2.10}\\
& \kappa^{\prime}(\Phi)=\operatorname{det} L^{+} \operatorname{det} L^{-}, \kappa^{\prime}(\varepsilon)=\varepsilon \tag{3.2.11}
\end{align*}
$$

Note 3.2.1 In (3.2.6) we have defined $\kappa^{\prime}$ using $\kappa$, we now prove that $\kappa^{\prime}\left(L^{ \pm A}{ }_{B}\right)=$ $\left(L^{ \pm A}{ }_{B}\right)^{-1}$ as defined in (3.2.3). This shows that $\kappa^{\prime}\left(L^{ \pm A}{ }_{B}\right)$ is expressible by polynomials in $L^{ \pm A}{ }_{B}, \Phi$.

Proof: From $\left(L^{ \pm}\right)^{-1} L^{ \pm}=\varepsilon$ we have $1=\left[\left(L_{1}^{ \pm}\right)^{-1} L_{1}^{ \pm}\right](T)=\left(L_{1}^{ \pm}\right)^{-1}\left(T_{2}\right) L_{1}^{ \pm}\left(T_{2}\right)=$ $\left(L_{1}^{ \pm}\right)^{-1}\left(T_{2}\right) R_{12}^{ \pm}$so that $\left(L_{1}^{ \pm}\right)^{-1}\left(T_{2}\right)=R_{12}^{ \pm-1}$.
From $\kappa(T) T=1$ we similarly have $\left[\kappa^{\prime}\left(L_{1}^{ \pm}\right)\right]\left(T_{2}\right)=R_{12}^{ \pm-1}$ and therefore $\kappa^{\prime}\left(L^{ \pm A}{ }_{B}\right)=$ $\left(L^{ \pm A}{ }_{B}\right)^{-1}$.

Since $\kappa^{\prime}$ is an inner operation in the algebra generated by the functionals $L^{ \pm A}{ }_{B}, \varepsilon$ and $\phi$ we conclude that these elements generate the Hopf algebra $U_{q, r}(g l(N))$ of the regular functionals on the quantum group $G L_{q, r}(N)$.

In the following we list some useful properties of the $L^{ \pm}$functionals.

## Properties of $L^{ \pm}$

i) Similarly to the uniparametric case, cf. Note 2.2.1 - Note 2.2.3, we have

$$
\begin{equation*}
L^{ \pm A}{ }_{A} L^{ \pm B}{ }_{B}=L^{ \pm B}{ }_{B} L^{ \pm A}{ }_{A} ; \quad L^{+A}{ }_{A} L^{-B}{ }_{B}=L^{-B}{ }_{B} L^{+A}{ }_{A} \tag{3.2.12}
\end{equation*}
$$

As a consequence:

$$
\begin{equation*}
\operatorname{det} L^{+} \operatorname{det} L^{-}=\operatorname{det} L^{-} \operatorname{det} L^{+} \tag{3.2.13}
\end{equation*}
$$

We also have

$$
\begin{align*}
& L^{ \pm A}{ }_{B}(\operatorname{det} T)=\delta_{B}^{A}\left(c^{ \pm}\right)^{N} r^{ \pm 1} Q_{A}^{-1}  \tag{3.2.14}\\
& \operatorname{det} L^{ \pm}\left(T^{A}{ }_{B}\right)=\delta_{B}^{A}\left(c^{ \pm}\right)^{N} r^{ \pm 1} Q_{A}  \tag{3.2.15}\\
& \operatorname{det} L^{ \pm}\left(T_{B}^{A}\right)=L^{ \pm A}{ }_{B}(\operatorname{det} T) Q_{A}^{2} . \tag{3.2.16}
\end{align*}
$$

From (3.2.1) it is easy to see that $\operatorname{det} L^{ \pm}(I)=1$.
ii) Since the $R L L$ relations are the same as the $R T T$ relations with $q_{A B} \rightarrow\left(q_{A B}\right)^{-1}$, $r \rightarrow r^{-1}$, we obtain a formula analogous to (3.1.15):

$$
\begin{equation*}
\left(\operatorname{det} L^{ \pm}\right) L_{B}^{ \pm A}=\frac{Q_{B}}{Q_{A}} L_{B}^{ \pm A}\left(\operatorname{det} L^{ \pm}\right) \tag{3.2.17}
\end{equation*}
$$

moreover

$$
\begin{equation*}
\left(\operatorname{det} L^{\mp}\right) L^{ \pm A}=\frac{Q_{B}}{Q_{A}} L^{ \pm A}\left(\operatorname{det} L^{\mp}\right) . \tag{3.2.18}
\end{equation*}
$$

iii) From (3.2.17) and (3.2.18) the following element:

$$
\begin{equation*}
\operatorname{det} L^{+}\left(\operatorname{det} L^{-}\right)^{-1}=\left(\operatorname{det} L^{-}\right)^{-1} \operatorname{det} L^{+} \tag{3.2.19}
\end{equation*}
$$

is seen to be central. Notice that it is also group-like since

$$
\begin{equation*}
\Delta^{\prime}\left(\operatorname{det} L^{ \pm}\right)=\operatorname{det} L^{ \pm} \otimes \operatorname{det} L^{ \pm} \tag{3.2.20}
\end{equation*}
$$

In general even if $\operatorname{det} L^{+}\left(\operatorname{det} L^{-}\right)^{-1}$ is central and group-like it is not equal to $\varepsilon$ because

$$
\begin{equation*}
\operatorname{det} L^{+}\left(\operatorname{det} L^{-}\right)^{-1}\left(T_{B}^{A}\right)=\left(c^{+}\right)^{N}\left(c^{-}\right)^{-N} r^{2} \delta_{B}^{A} . \tag{3.2.21}
\end{equation*}
$$

iv) The elements $L^{+A}{ }_{A} L^{-A}{ }_{A}$ (no sum on $A$ ) play a special role for particular values of the deformation parameters $q_{A B}, r$; if we set

$$
\begin{equation*}
L^{+A}{ }_{A} L^{-A}{ }_{A} \equiv \varepsilon_{A} \tag{3.2.22}
\end{equation*}
$$

we leave as an exercise to deduce that (no sum on repeated indices):

$$
\begin{equation*}
\varepsilon_{A}\left(T^{B}{ }_{C}\right) \equiv c^{+} c^{-} \delta_{C}^{B} \frac{q_{A B}^{2}}{r^{2}}, \quad \varepsilon_{A}(I)=1, \quad \varepsilon_{A}(\Xi)=\left[\varepsilon_{A}(\operatorname{det} T)\right]^{-1} \tag{3.2.23}
\end{equation*}
$$

$$
\begin{gather*}
\varepsilon_{A}(a b)=\varepsilon_{A}(a) \varepsilon_{A}(b), \quad a, b \in G L_{q, r}(N)  \tag{3.2.24}\\
\kappa^{\prime}\left(L^{ \pm A}{ }_{A}\right)=L^{\mp A} A_{A} \varepsilon_{A}^{-1}  \tag{3.2.25}\\
\varepsilon_{A} \varepsilon_{B}=\varepsilon_{B} \varepsilon_{A}, \quad \varepsilon_{A} L^{ \pm B}{ }_{B}=L^{ \pm B}{ }_{B \varepsilon_{A}}  \tag{3.2.26}\\
\operatorname{det} L^{+} \operatorname{det} L^{-}=\varepsilon_{1} \cdots \varepsilon_{N} ;  \tag{3.2.27}\\
\kappa^{\prime}\left(\operatorname{det} L^{ \pm}\right)=\operatorname{det} L^{\mp}\left(\varepsilon_{1} \cdots \varepsilon_{N}\right)^{-1}=\left(\varepsilon_{1} \cdots \varepsilon_{N}\right)^{-1} \operatorname{det} L^{\mp} \tag{3.2.28}
\end{gather*}
$$

Note 3.2.2 When $\operatorname{det} T$ is central $\left(Q_{A}=1\right)$ we also have that $\operatorname{det} L^{ \pm}$is central (cf. (3.2.17) and (3.2.18) ). As in Note 2.2.2, for $Q_{A}=1$ and $\left(c^{ \pm}\right)^{N} r^{ \pm 1}=1$, the functionals $L^{ \pm}$and $\varepsilon$ generate the Hopf algebra $U\left(s l_{q, r}(N)\right)$, and we have the simplified relations:

$$
\begin{align*}
& \operatorname{det} L^{+}\left(\operatorname{det} L^{-}\right)^{-1}=\varepsilon  \tag{3.2.29}\\
& {\left[L^{ \pm A}{ }_{B}\right](\operatorname{det} T)=\delta_{B}^{A} \quad \text { no sum on } A}  \tag{3.2.30}\\
& {\left[\operatorname{det} L^{ \pm}\right]\left(T_{B}^{A}\right)=\delta_{B}^{A}}  \tag{3.2.31}\\
& {\left[\operatorname{det} L^{ \pm}\right](\operatorname{det} T)=1} \tag{3.2.32}
\end{align*}
$$

Note 3.2.3 When $q_{A B}=r$ we recover the standard uniparametric $R$ matrix, we have also $Q_{A}=1$ and, for $c^{+} c^{-}=1$,

$$
\begin{equation*}
\forall A \varepsilon_{A}=\varepsilon \quad \text { i.e. } L^{+A}{ }_{A} L^{-A}{ }_{A}=L^{-A}{ }_{A} L^{+A}{ }_{A}=\varepsilon . \tag{3.2.33}
\end{equation*}
$$

In this case the Hopf algebra of functionals $U_{q, r}(g l(N))$ is equivalent to the algebra generated by the symbols $L^{ \pm}, \Phi$ and $\varepsilon$ modulo relations (2.2.12), (2.2.13) and (3.2.33) (19).

Note 3.2.4 $G L_{q, r}(N)$ and $U_{q, r}(g l(N))$ are graded Hopf algebras: $T^{A}{ }_{B}$ has grade +1 , $\kappa\left(T_{B}^{A}\right)$ has grade $-1, I$ has grade 0 , $\operatorname{det} T$ has grade $+N$ etc., and similarly for $L^{ \pm}$。

## Conjugation

The canonical *-conjugation on $U_{q, r}(g l(N))$ induced by the $*$-conjugation on $G L_{q, r}(N)$ is given by:

$$
\begin{equation*}
\psi^{*}(a) \equiv \overline{\psi\left(\kappa^{-1}\left(a^{*}\right)\right)} \tag{3.2.34}
\end{equation*}
$$

where $\psi \in U_{q, r}(g l(N)), a \in G L_{q, r}(N)$, and the overline denotes the usual complex conjugation. It is not difficult to determine the action on the basis elements $L^{ \pm A}{ }_{B}$. The three $G L_{q, r}(N) *$-conjugations i), ii), iii) of the previous section induce respectively the following conjugations on the $L^{ \pm A}{ }_{B}$ :

$$
\begin{align*}
& \text { i) } \begin{array}{l}
\left(L^{ \pm A}\right)^{*}=\kappa^{\prime 2}\left(L^{ \pm A}\right) \\
\text { ii) } \left.\left(L^{ \pm A}\right)^{*}\right)^{*}=\kappa^{\prime 2}\left(L^{\mp A^{\prime}}{ }^{B^{\prime}}\right) \\
\text { iii) }\left(L^{ \pm A}{ }_{B}\right)^{*}=\kappa^{\prime}\left(L^{\mp B}{ }_{A}\right) .
\end{array} .
\end{align*}
$$

### 3.3 The quantum group $I G L_{q, r}(N)$

The $q$-inhomogeneous group $I G L_{q, r}(N)$ is freely generated by the non-commuting matrix elements $T^{A}{ }_{B}[A=(0, a) ; a: 1, . . N]$, the identity $I$ and the inverse $\xi$ of the $q$-determinant of $T$ as defined in (3.1.6), modulo the relations:

$$
\begin{equation*}
T_{a}^{0}=0 \tag{3.3.1}
\end{equation*}
$$

and the relations:

$$
\begin{align*}
& R^{a b}{ }_{e f} T^{e}{ }_{c} T^{f}{ }_{d}=T^{b}{ }_{f} T^{a}{ }_{e} R^{e f}{ }_{c d}  \tag{3.3.2}\\
& R^{a b}{ }_{e f} T^{e}{ }_{c} x^{f}=\frac{q_{0 c}}{r} x^{b} T^{a}{ }_{c}  \tag{3.3.3}\\
& R^{a b}{ }_{e f} x^{e} x^{f}=r x^{b} x^{a}  \tag{3.3.4}\\
& q_{0 a} T^{a}{ }_{c} u=q_{0 c} u T^{a}{ }_{c}  \tag{3.3.5}\\
& q_{0 a} x^{a} u=u x^{a} \tag{3.3.6}
\end{align*}
$$

where $x^{a} \equiv T^{a}{ }_{0}$ and $u \equiv T_{0}^{0}$.
It is not difficult to check that this algebra, endowed with the coproduct $\Delta$, the counit $\varepsilon$ and the coinverse $\kappa$ defined by :

$$
\begin{array}{rcl}
\Delta\left(T_{B}^{A}\right)=T_{C}^{A} \otimes T_{A}^{C} ; & \varepsilon\left(T_{B}^{A}\right)=\delta_{B}^{A} ; & \kappa(T)=T^{-1} \\
\Delta(\xi)=\xi \otimes \xi ; & \varepsilon(\xi)=1 ; & \kappa(\xi)=\operatorname{det} T \\
\Delta(I)=I \otimes I ; & \varepsilon(I)=1 ; & \kappa(I)=I \tag{3.3.9}
\end{array}
$$

where the quantum inverse of $T^{A}{ }_{B}$ is given by $\left(T^{-1}\right)^{A}{ }_{B}=\xi \Pi_{A B}^{(0, N)} t_{B}^{A}$ [see eq. (3.1.23): $t_{B}{ }^{A}$ is the quantum minor ], is a Hopf algebra. The proof goes as in uniparametric case (see the second ref. of [65]).

In the commutative limit it is the algebra of functions on $\operatorname{IGL}(N)$ plus the dilatation $T^{0}{ }_{0}$.

Relations (3.3.7)-(3.3.9) explicity read:

$$
\begin{align*}
& \Delta\left(T^{a}{ }_{b}\right)=T^{a}{ }_{c} \otimes T^{c}{ }_{b}, \quad \Delta(I)=I \otimes I,  \tag{3.3.10}\\
& \Delta\left(x^{a}\right)=T^{a}{ }_{b} \otimes x^{b}+x^{a} \otimes u  \tag{3.3.11}\\
& \Delta(u)=u \otimes u, \quad \Delta(\xi)=\xi \otimes \xi  \tag{3.3.12}\\
& \Delta\left(\operatorname{det} T^{a}{ }_{b}\right)=\operatorname{det} T^{a}{ }_{b} \otimes \operatorname{det} T^{a}{ }_{b}  \tag{3.3.13}\\
& \quad \varepsilon\left(T^{a}{ }_{b}\right)=\delta_{b}^{a}, \quad \varepsilon(I)=1,  \tag{3.3.14}\\
& \varepsilon\left(x^{a}\right)=0  \tag{3.3.15}\\
& \varepsilon(u)=\varepsilon(\xi)=1  \tag{3.3.16}\\
& \quad \varepsilon\left(\operatorname{det} T^{a}{ }_{b}\right)=1 \tag{3.3.17}
\end{align*}
$$

$$
\begin{align*}
& \kappa\left(T^{a}{ }_{b}\right)=\left(T^{-1}\right)^{a}{ }_{b}=\xi u \Pi_{a b}^{(1, N)} t_{b}{ }^{a}  \tag{3.3.18}\\
& \kappa(I)=I,  \tag{3.3.19}\\
& \kappa\left(x^{a}\right)=-\kappa\left(T^{a}{ }_{b}\right) x^{b} \kappa(u)  \tag{3.3.20}\\
& \kappa(u)=\operatorname{det} T^{a}{ }_{b}{ }_{\xi}  \tag{3.3.21}\\
& \kappa(\xi)=u \operatorname{det} T^{a}{ }_{b}, \quad \kappa\left(\operatorname{det} T^{a}{ }_{b}\right)=\xi u \tag{3.3.22}
\end{align*}
$$

where for completeness we have included the expressions for the $q$-determinant of $T$. Note that $\kappa(u) u=I=u \kappa(u)$.

This procedure is very similar to that discussed for $G L_{q, r}(N+1)$ in Section 3.1: indeed both these Hopf algebrae are obtained from the algebra freely generated by $T^{A}{ }_{B}, I, \Xi$ or $\xi$ through the introduction of moduli relations i.e. as quotients of suitable two-sided ideals: the one generated by the $R T T$ relations in the $G L_{q, r}(N+$ 1) case, and the one generated by the (3.3.1)-(3.3.6) relations in the $I G L_{q, r}(N)$ case.

We now rederive the quantum group $I G L_{q, r}(N)$ as a quotient of $G L_{q, r}(N+1)$ : all Hopf algebra properties of $I G L_{q, r}(N)$ will descend from those of $G L_{q, r}(N+1)$. The formalism employed will be useful in the next section to deduce the differential calculus on $I G L_{q, r}(N)$ from the one on $G L_{q, r}(N+1)$.

We start from the observation that the $R$-matrix of $G L_{q, r}(N+1)$ can be written as $(\mathrm{A}=(0, \mathrm{a}))$ :

$$
R_{C D}^{A B}=\left(\begin{array}{cccc}
r & 0 & 0 & 0  \tag{3.3.23}\\
0 & \frac{r}{q_{0 b}} \delta_{d}^{b} & 0 & 0 \\
0 & \left(r-r^{-1}\right) \delta_{d}^{a} & \frac{q_{0 a}}{r} \delta_{c}^{a} & 0 \\
0 & 0 & 0 & R_{c d}^{a b}
\end{array}\right)
$$

where $R^{a b}{ }_{c d}$ is the $R$-matrix of $G L_{q, r}(N)$, and the indices AB are ordered as $00,0 b, a 0, a b$.

It is apparent that the $G L_{q, r}(N+1) R$ matrix contains the information on $G L_{q, r}(N)$. We will show that it also contains the information about the quantum group $I G L_{q, r}(N)$.

In the index notation $A=(0, a)$ the $R T T$ relations explicity read:

$$
\begin{align*}
& R^{a b}{ }_{e f} T^{e}{ }_{c} T^{f}{ }_{d}=T^{b}{ }_{f} T^{a}{ }_{e} R^{e f}{ }_{c d}  \tag{3.3.24}\\
& T^{a}{ }_{c} T^{b}{ }_{0}=\frac{q_{a b}}{q_{c 0}} T_{0}^{b} T^{a}{ }_{c}  \tag{3.3.25}\\
& T^{a}{ }_{0} T^{b}{ }_{d}=\frac{q_{a b}}{q_{0 d}} T^{b}{ }_{d} T^{a}{ }_{0}+\frac{r}{q_{0 d}}\left(r-r^{-1}\right) T^{a}{ }_{d} T^{b}{ }_{0}  \tag{3.3.26}\\
& T^{a}{ }_{c} T^{0}{ }_{d}=\frac{q_{a 0}}{q_{c d}} T^{0}{ }_{d} T^{a}{ }_{c}  \tag{3.3.27}\\
& T^{0}{ }_{c} T^{b}{ }_{d}=\frac{q_{0 b}}{q_{c d}} T^{b}{ }_{d} T^{0}{ }_{c}+\frac{r}{q_{c d}}\left(r-r^{-1}\right) T^{0}{ }_{d} T^{b}{ }_{c} \tag{3.3.28}
\end{align*}
$$

$$
\begin{align*}
& T^{a}{ }_{0} T^{b}{ }_{0}=q_{a b} T^{b}{ }_{0} T^{a}  \tag{3.3.29}\\
& T^{0}{ }_{c} T_{0}^{b}=\frac{q_{0 b}}{q_{c 0}} T_{0}^{b} T^{0}{ }_{c}  \tag{3.3.30}\\
& T^{0}{ }_{c} T^{0}{ }_{d}=q_{d c} T^{0}{ }_{d} T^{0}{ }_{c}  \tag{3.3.31}\\
& T_{0}^{0}{ }_{0}^{b}{ }^{b}{ }_{d}=\frac{q_{0 b}}{q_{0 d}} T^{b}{ }_{d} T^{0}{ }_{0}+\frac{r}{q_{0 d}}\left(r-r^{-1}\right) T^{0}{ }_{d} T^{b}{ }_{0}  \tag{3.3.32}\\
& T_{0}^{0}{ }_{0}^{b}{ }_{0}{ }_{0}=q_{0 b} T_{0}^{b} T_{0}^{0}  \tag{3.3.33}\\
& T_{0}^{0} T^{0}{ }_{d}=q_{d 0} T^{0}{ }_{d} T^{0}{ }_{0} \tag{3.3.34}
\end{align*}
$$

where $a<b$ and $c<d$.
Consider now in $G L_{q, r}(N)$ the space $H$ of all sums of monomials containing at least an element of the kind $T^{0}{ }_{a}$ (i.e. $H$ is the ideal in $G L_{q, r}(N+1)$ generated by the elements $T^{0}{ }_{a}$ as we will see). Notice that $T^{0}{ }_{0} T^{b}{ }_{d}-\frac{q_{0 b}}{q_{0 d}} T^{b}{ }_{d} T^{0}{ }_{0}$ is an element of $H$ because of relation (3.3.32).

We now prove that $H$ is a Hopf ideal, i.e. an ideal in the $G L_{q, r}(N+1)$ algebra that is also compatible with the co-structures of $G L_{q, r}(N+1)$; this allows to structure $G L_{q, r}(N+1) / H$ as a Hopf algebra [83]. We denote by $\Delta_{N+1}, \varepsilon_{N+1}$ and $\kappa_{N+1}$ the co-structures of $G L_{q, r}(N+1)$.

Theorem 3.3.1 The space $H$ is a Hopf ideal in $G L_{q, r}(N+1)$, that is:
i) $\quad H$ is a two-sided ideal in $G L_{q, r}(N+1)$
ii) $\quad H$ is a co-ideal i.e.

$$
\begin{equation*}
\Delta_{N+1}(H) \subseteq H \otimes G L_{q, r}(N+1)+G L_{q, r}(N+1) \otimes H ; \quad \varepsilon_{N+1}(H)=0 \tag{3.3.35}
\end{equation*}
$$

iii) $\quad H$ is compatible with $\kappa_{N+1}$ :

$$
\begin{equation*}
\kappa_{N+1}(H) \subseteq H . \tag{3.3.36}
\end{equation*}
$$

Proof:
i) $H$ is trivially a subalgebra of $G L_{q, r}(N+1)$. It is a right and left ideal since $\forall h \in H, \forall a \in G L_{q, r}(N+1) h a \in H$ and $a h \in H$. This follows immediately from the definition of $H$ as sums of monomials containing at least a factor $T^{0}{ }_{a} . H$ is the ideal in $G L_{q, r}(N+1)$ generated by the elements $T^{0}{ }_{a}$.
ii) First notice that $\Delta_{N+1}\left(T^{0}{ }_{b}\right) \in H \otimes G L_{q, r}(N+1)+G L_{q, r}(N+1) \otimes H$. Now by definition of $H$ we have

$$
\begin{equation*}
\forall h \in H, \quad h=a T^{0}{ }_{b} c, \quad a, c \in G L_{q, r}(N+1) . \tag{3.3.37}
\end{equation*}
$$

where $a T^{0}{ }_{b} c$ represents a sum of monomials. Then we find
$\Delta_{N+1}(h)=\Delta_{N+1}(a) \Delta_{N+1}\left(T^{0}{ }_{b}\right) \Delta_{N+1}(c) \in H \otimes G L_{q, r}(N+1)+G L_{q, r}(N+1) \otimes H$.
Moreover, since $\varepsilon_{N+1}$ vanishes on $T^{0}{ }_{b}$ we have:

$$
\begin{equation*}
\varepsilon_{N+1}(h)=0, \quad \forall h \in H . \tag{3.3.39}
\end{equation*}
$$

These relations ensure that (3.3.35) hold.
iii)

$$
\begin{equation*}
\kappa_{N+1}\left(T_{b}^{0}\right)=\Xi \Pi_{o b}^{(0, N)} t_{b}{ }^{0} \tag{3.3.40}
\end{equation*}
$$

where $\Pi_{o b}^{(0, N)}$ is defined in (3.1.23) and it is easy to see that the quantum minor $t_{b}{ }^{0} \in H$ since it is the determinant of a matrix that has elements $T^{0}{ }_{a}$ in the first row. Then

$$
\begin{equation*}
\kappa_{N+1}(h)=\kappa_{N+1}\left(a T_{b}^{0} c\right)=\kappa_{N+1}(c) \kappa_{N+1}\left(T_{b}^{0}\right) \kappa_{N+1}(a) \in H \tag{3.3.41}
\end{equation*}
$$

and Theorem 3.3.1 is proved.

We now consider the quotient

$$
\begin{equation*}
\frac{G L_{q, r}(N+1)}{H}, \tag{3.3.42}
\end{equation*}
$$

and the canonical projection

$$
\begin{equation*}
P: G L_{q, r}(N+1) \longrightarrow G L_{q, r}(N+1) / H \tag{3.3.43}
\end{equation*}
$$

Any element of $G L_{q, r}(N+1) / H$ is of the form $P(a)$. Also, $P(H)=0$, i.e. $H=$ $\operatorname{Ker}(P)$.

Since $H$ is a two-sided ideal, $G L_{q, r}(N+1) / H$ is an algebra with the following sum and products:

$$
\begin{equation*}
P(a)+P(b) \equiv P(a+b) ; \quad P(a) P(b) \equiv P(a b) ; \quad \mu P(a) \equiv P(\mu a), \quad \mu \in \mathbf{C} \tag{3.3.44}
\end{equation*}
$$

We will use the following notation:

$$
\begin{equation*}
x^{a} \equiv P\left(T_{0}^{a}\right) ; \quad u \equiv P\left(T_{0}^{0}\right) ; \quad \xi \equiv P(\Xi) \tag{3.3.45}
\end{equation*}
$$

and with abuse of symbols:

$$
\begin{equation*}
T^{a}{ }_{b} \equiv P\left(T^{a}{ }_{b}\right) ; \quad I \equiv P(I) ; \quad 0 \equiv P(0) \tag{3.3.46}
\end{equation*}
$$

notice that $P\left(T^{0}{ }_{a}\right)=P(0)=0$. Using (3.3.44) it is easy to show that $T^{a}{ }_{b}, x^{a}, u, \xi$ and $I$ generate the algebra $G L_{q, r}(N+1) / H$. From the $R T T$ relations $R_{12} T_{1} T_{2}=$ $T_{2} T_{1} R_{12}$ in $G L_{q, r}(N+1)$ we find the " $P(R T T)$ " relations in $G L_{q, r}(N+1) / H$ :

$$
\begin{equation*}
P\left(R_{12} T_{1} T_{2}\right)=P\left(T_{2} T_{1} R_{12}\right) \quad \text { i.e. } \quad R_{12} P\left(T_{1}\right) P\left(T_{2}\right)=P\left(T_{2}\right) P\left(T_{1}\right) R_{12} \tag{3.3.47}
\end{equation*}
$$

that are explicity given in (3.3.2)-(3.3.6).
Since H is a Hopf ideal then $G L_{q, r}(N+1) / H$ is also a Hopf algebra with costructures:

$$
\begin{equation*}
\Delta(P(a)) \equiv(P \otimes P) \Delta_{N+1}(a) ; \quad \varepsilon(P(a)) \equiv \varepsilon_{N+1}(a) ; \quad \kappa(P(a)) \equiv P\left(\kappa_{N+1}(a)\right) \tag{3.3.48}
\end{equation*}
$$

Indeed (3.3.35) and (3.3.36) ensure that $\Delta, \varepsilon$, and $\kappa$ are well defined. For example

$$
\begin{equation*}
(P \otimes P) \Delta_{N+1}(a)=(P \otimes P) \Delta_{N+1}(b) \quad \text { if } \quad P(a)=P(b) . \tag{3.3.49}
\end{equation*}
$$

In order to prove the Hopf algebra axioms of Appendix A for $\Delta, \varepsilon, \kappa$ we just have to project those for $\Delta_{N+1}, \varepsilon_{N+1}, \kappa_{N+1}$. For example, the first axiom is proved by applying $P \otimes P \otimes P$ to $\left(\Delta_{N+1} \otimes i d\right) \Delta_{N+1}(a)=\left(i d \otimes \Delta_{N+1}\right) \Delta_{N+1}(a)$. The other axioms are proved in a similar way.

Notice that on the generators $T^{a}{ }_{b}, x^{a}, u, \xi$ and $I$ the co-structures (3.3.48) act as in (3.3.7)-(3.3.9).

In conclusion: the elements $T^{a}{ }_{b}, x^{a}, u, \xi$ and $I$ generate the Hopf algebra $G L_{q, r}(N+1) / H$ and satisfy the " $P(R T T)$ " commutation rules (3.3.2)-(3.3.6). The co-structures act on them exactly as the co-structures defined in (3.3.7)-(3.3.9). Therefore the quotient $G L_{q, r}(N+1) / H$ is the $q$-inhomogeneous group defined at the beginning of this section:

$$
\begin{equation*}
I G L_{q, r}(N)=\frac{G L_{q, r}(N+1)}{H} . \tag{3.3.50}
\end{equation*}
$$

The canonical projection $P: G L_{q, r}(N+1) \rightarrow I G L_{q, r}(N)$ is an epimorphism between these two Hopf algebrae.

Note 3.3.1 The consistency of the $P(R T T)$ relations with the co-structures $\Delta, \varepsilon$ and $\kappa$ is easily proved. For example,

$$
\begin{equation*}
\Delta\left(P\left(R_{12} T_{1} T_{2}\right)-P\left(T_{2} T_{1} R_{12}\right)\right)=0 \tag{3.3.51}
\end{equation*}
$$

is a particular case of eq. (3.3.49). Similarly for $\varepsilon$ and $\kappa$.
We have thus obtained a $R$ matrix formulation of the inhomogeneous $I G L_{q, r}(N)$ quantum groups. Indeed the results of this section can be summarized in the following theorem:

Theorem 3.3.2 The quantum inhomogeneous groups $I G L_{q, r}(N)$ are freely generated by the non-commuting matrix elements $T^{A}{ }_{B}[\mathrm{~A}=(0, a)$, with $\left.a=1, \ldots N)\right]$ and the identity $I$, modulo the relations:

$$
\begin{equation*}
T_{b}^{0}=0 \tag{3.3.52}
\end{equation*}
$$

and the $R T T$ relations

$$
\begin{equation*}
R^{A B}{ }_{E F} T_{C}^{E} T^{F}{ }_{D}=T_{F}^{B} T_{E}^{A} R_{C D}^{E F} \tag{3.3.53}
\end{equation*}
$$

The co-structures of $I G L_{q, r}(N)$ are simply given by:

$$
\begin{align*}
& \Delta\left(T_{B}^{A}\right)=T_{C}^{A} \otimes T_{B}^{C}  \tag{3.3.54}\\
& \kappa\left(T_{B}^{A}\right)=T^{-1}{ }_{C}^{D}  \tag{3.3.55}\\
& \varepsilon\left(T_{B}^{A}\right)=\delta_{B}^{A} \tag{3.3.56}
\end{align*}
$$

Note 3.3.2 From the commutations (3.3.5) - (3.3.6) we see that one can set $u=I$ only when $q_{0 a}=1$ for all $a$.

Note 3.3.3 $P\left(\operatorname{det} T^{A}{ }_{B}\right)=u \operatorname{det} T^{a}{ }_{b}$ is central in $I G L_{q, r}(N)$ only when $Q_{A}=1$, $A=0,1, \ldots N$ (apply the projection $P$ to eq. (3.1.15)). Note that here we have $Q_{A} \equiv$ $\prod_{C=0}^{N}\left(\frac{q_{C A}}{r}\right)$.

Note 3.3.4 It is not difficult to see how the real forms of $G L_{q, r}(N+1)$ are inherited by $I G L_{q, r}(N)$. In fact, only the conjugation i) of $G L_{q, r}(N+1)$, discussed in Section 3.1, is compatible with the coset structure of $I G L_{q, r}(N)$. More precisely, $H$ is a *-Hopf ideal, i.e. $(H)^{*} \subseteq H$, only for $T^{*}=T$. Then we can define a $*$-structure on $I G L_{q, r}(N)$ as $[P(a)]^{*} \equiv P\left(a^{*}\right)$.

Theorem 3.3.3 The centrality of $u$ is incompatible with the centrality of $\operatorname{det} T^{a}{ }_{b}$.
Proof: Suppose that $q_{0 a}=1$ so that $u$ is central. Then the centrality of $\operatorname{det} T^{a}{ }_{b}$ is equivalent to the centrality of $P\left(\operatorname{det} T_{B}^{A}\right)$ and requires $Q_{A}=1$ (Note 3.3.3); in particular $Q_{0} \equiv \prod_{c=1}^{N} \frac{r}{q_{0 c}}=1$, which cannot be since for $q_{0 a}=1$ we find $Q_{0}=r^{N}$.

The commutations of $\operatorname{det} T^{a}{ }_{b}$ and $\xi$ with all the generators are given by:

$$
\begin{array}{rlrl}
\left(\operatorname{det} T^{c}{ }_{d}\right) T^{a}{ }_{b}=\frac{Q_{a}}{Q_{b}} T^{a}{ }_{b}\left(\operatorname{det} T^{c}{ }_{d}\right), & \zeta T_{b}^{a} & =\frac{Q_{b}}{Q_{a}} T^{a}{ }_{b} \zeta \\
\left(\operatorname{det} T_{d}^{c}\right) x^{a}= & \frac{Q_{a}}{Q_{0}} x^{a}\left(\operatorname{det} T^{c}{ }_{d}\right), & \zeta x^{a} & =\frac{Q_{0}}{Q_{a}} x^{a} \zeta \\
\left(\operatorname{det} T_{d}^{c}\right) u=u\left(\operatorname{det} T_{d}^{c}\right), & \zeta u & =u \zeta \tag{3.3.59}
\end{array}
$$

where here $Q_{a} \equiv \prod_{c=1}^{N}\left(\frac{q_{c a}}{r}\right)$ and $\zeta$ is the inverse of $\operatorname{det} T_{d}^{c}$, i.e. $\zeta \equiv u \xi$. We see that the commutations of $\operatorname{det} T^{c}{ }_{d}$ with $T^{a}{ }_{b}$ are the correct ones for $G L_{q, r}(N)$ (i.e. are identical to the ones deduced in Section 3.1). In the standard uniparametric case $Q_{a}=1$, and the $q$-determinant $\operatorname{det} T^{c}{ }_{d}$ becomes central (and likewise $\zeta$ ), provided that also $Q_{0}=1$.

We have derived the properties of the quantum group $I G L_{q, r}(N)$ from those of $I G L_{q, r}(N+1)$, we now study the structure of $I G L_{q, r}(N)$ with respect to its Hopf subalgebra $G L_{q, r}(N)$; this is explicitly done in Theorem 3.3.4, while in Theorem 3.3.5 the same construction is seen in a more general and abstract setting.

We first notice that the $x^{0} \equiv u$ and $x^{a}$ elements generate a subalgebra of $I G L_{q, r}(N)$ because their commutation relations do not involve the $T^{a}{ }_{b}$ elements. Moreover these elements can be ordered using (3.3.4) and (3.3.6), and the Poincaré series of this subalgebra is the same as that of the commutative algebra in $N+1$ indeterminates, indeed (3.3.4) and (3.3.6) read

$$
\begin{equation*}
x^{A} x^{B}=q_{A B} x^{B} x^{A} \quad \forall A<B \tag{3.3.60}
\end{equation*}
$$

A linear basis of this subalgebra is therefore given by the ordered monomials: $\zeta^{i} \equiv$ $u^{i_{0}}\left(x^{1}\right)^{i_{1}} \ldots\left(x^{N}\right)^{i_{N}}$. Then, using (3.3.3) and (3.3.5), a generic element of $I G L_{q, r}(N)$ can be written as $\zeta^{i} a_{i}$ where $a_{i} \in G L_{q, r}(N)$ and we conclude that $I G L_{q, r}(N)$ is a right $G L_{q, r}(N)$-module generated by the ordered monomials $\zeta^{i}$. Since the $R T T$ relations of $I G L_{q, r}(N)(3.3 .2)-(3.3 .6)$ are homogeneous both in the $x^{a}$ and in $x^{0}$ we can naturally introduce a ( $\mathbf{Z}, \mathbf{N}$ ) grading : the generators $x^{a}$ have grade $(0,1), x^{0}$ has degree $(1,0),\left(x^{0}\right)^{-1}$ has degree $(-1,0)$, the elements of $G L_{q, r}(N)$ have degree $(0,0)$. Then

$$
\begin{equation*}
I G L_{q, r}(N)=\sum_{(h, k) \in(\mathbf{Z}, \mathbf{N})}^{\oplus} \Gamma^{(h, k)} \tag{3.3.61}
\end{equation*}
$$

where $\Gamma^{(0,0)}=G L_{q, r}(N)$,

$$
\begin{aligned}
& \Gamma^{(0,1)}=\left\{x^{a} b_{a} / b_{a} \in G L_{q, r}(N)\right\}, \quad \Gamma^{( \pm 1,0)}=\left\{\left(x^{0}\right)^{ \pm 1} b / b \in G L_{q, r}(N)\right\} \\
& \Gamma^{(h, k)}=\left\{\left(x^{0}\right)^{h} x^{a_{1}} x^{a_{2}} \ldots x^{a_{k}} b_{a_{1} a_{2} \ldots a_{k}} / b_{a_{1} a_{2} \ldots a_{k}} \in G L_{q, r}(N)\right\} \quad \forall h \in \mathbf{Z}, k \in \mathbf{N} .
\end{aligned}
$$

Therefore $I G L_{q, r}(N)$ is a direct sum of right $G L_{q, r}(N)$-modules; it is also a graded algebra with the product $\zeta^{i} b_{i} \cdot \zeta^{\prime \prime} b_{j}^{\prime}$ trivially inherited from the $I G L_{q, r}(N)$ algebra structure (in the sequel we will omit the ".").

We now show that each right module $\Gamma^{(h, k)}$ is a bicovariant bimodule on $G L_{q, r}(N)$, also $I G L_{q, r}(N)=\sum_{(h, k) \in(\mathbf{Z}, \mathbf{N})}^{\oplus} \Gamma^{(h, k)}$ is a bicovariant bimodule with left and right coactions $\delta_{L}$ and $\delta_{R}$ that are multiplicative: forall $a, b \in I G L_{q, r}(N), \delta_{L}(a b)=$ $\delta_{L}(a) \delta_{L}(b), \delta_{R}(a b)=\delta_{R}(a) \delta_{R}(b)$. This shows that the structure of a inhomogeneous quantum group is similar to that of the exterior algebra of a generic Hopf algebra [as discussed at the end of point iv), Section 2.1]; also recall that, as noticed in the end of Subsection 2.4.6, the exterior algebra of forms is a Hopf algebra.

Theorem 3.3.4 $I G L_{q, r}(N)$, when $q_{a 0}=$ const $\forall a$, is a bicovariant graded algebra, i.e. it is a graded algebra with left and right coactions

$$
\begin{aligned}
& \delta_{L}: \quad I G L_{q, r}(N) \rightarrow G L_{q, r}(N) \otimes I G L_{q, r}(N) \\
& \delta_{R}: \quad I G L_{q, r}(N) \rightarrow I G L_{q, r}(N) \otimes G L_{q, r}(N)
\end{aligned}
$$

that commute, see (3.3.67), are multiplicative: $\delta_{L}(a b)=\delta_{L}(a) \delta_{L}(b), \delta_{R}(a b)=$ $\delta_{R}(\mathrm{a}) \delta_{R}(b), \forall \mathrm{a}, \mathrm{b} \in I G L_{q, r}(N)$, and preserve the grading .

Proof Consider the linear map $\delta_{R}: I G L_{q, r}(N) \rightarrow I G L_{q, r}(N) \otimes G L_{q, r}(N)$ defined by

$$
\begin{equation*}
\delta_{R}\left(x^{A}\right)=x^{A} \otimes I ; \quad \delta_{R}(a)=\Delta(a) \quad \forall a \in G L_{q, r}(N) \tag{3.3.62}
\end{equation*}
$$

and extended multiplicatively on all $I G L_{q, r}(N)$. This grade preserving map is obviously well defined on $G L_{q, r}(N)$ because it coincides with the coproduct on $G L_{q, r}(N)\left[G L_{q, r}(N)\right.$ is the Hopf subalgebra of $I G L_{q, r}(N)$ with degree zero]; it is also well defined on all $I G L_{q, r}(N)$ since it is multiplicative and compatible with (3.3.2)-(3.3.6). We check for example (3.3.3) with $q_{a 0}=$ const $\equiv q_{0} \quad \forall a$ :

$$
\delta_{R}\left(x^{a} T^{b}{ }_{d}\right)=x^{a} T^{b}{ }_{c} \otimes T_{d}^{c}=\frac{q_{0}}{r} R^{b a}{ }_{e f} T^{e}{ }_{c} x^{f} \otimes T^{c}{ }_{d}=\delta_{R}\left(\frac{q_{0}}{r} R^{b a}{ }_{e f} T^{e}{ }_{d} x^{f}\right) .
$$

This shows that $\delta_{R}: I G L_{q, r}(N) \rightarrow I G L_{q, r}(N) \otimes G L_{q, r}(N)$ is well defined.
To show that $\delta_{R}$ is a right coaction notice that

$$
\begin{equation*}
\forall \zeta^{i} a_{i}, \quad\left(\delta_{R} \otimes i d\right) \delta_{R}\left(\zeta^{i} a_{i}\right)=(i d \otimes \Delta) \delta_{R}\left(\zeta^{i} a_{i}\right) ; \quad(i d \otimes \varepsilon) \delta_{R}\left(\zeta^{i} a_{i}\right)=\zeta^{i} a_{i} \tag{3.3.63}
\end{equation*}
$$

For the left coaction we proceed as in the previous case, defining the linear map $\delta_{L}: I G L_{q, r}(N) \rightarrow G L_{q, r}(N) \otimes I G L_{q, r}(N)$,

$$
\begin{equation*}
\delta_{L}\left(x^{a}\right)=T^{a}{ }_{b} \otimes x^{b} ; \quad \delta_{L}\left(x^{0}\right)=I \otimes x^{0} ; \quad \delta_{L}(a)=\Delta(a) \quad \forall a \in G L_{q, r}(N) \tag{3.3.64}
\end{equation*}
$$

which is extended multiplicatively on all $I G L_{q, r}(N)$. As was the case for $\delta_{R}$, it is well defined on $G L_{q, r}(N)$ and it is also well defined on all $I G L_{q, r}(N)$ because it is multiplicative and compatible with (3.3.2)-(3.3.6).

To prove that $\delta_{L}$ is a left coaction notice that

$$
\begin{equation*}
(\varepsilon \otimes i d) \delta_{L}\left(x^{a}\right)=x^{a},(\Delta \otimes i d) \delta_{L}\left(x^{a}\right)=T^{a}{ }_{d} \otimes T^{d}{ }_{b} \otimes x^{b}=\left(i d \otimes \delta_{L}\right) \delta_{L}\left(x^{a}\right) \tag{3.3.65}
\end{equation*}
$$

and similarly for $x^{0}$. Now since $\delta_{L}(a)=\Delta(a)$ if $a \in G L_{q, r}(N)$, and since $\delta_{L}$ is multiplicative, we have on all $I G L_{q, r}(N)$ :

$$
\begin{equation*}
(\varepsilon \otimes i d) \delta_{L}=i d ; \quad(\Delta \otimes i d) \delta_{L}=\left(i d \otimes \delta_{L}\right) \delta_{L} \tag{3.3.66}
\end{equation*}
$$

Finally, the compatibility of $\delta_{L}$ and $\delta_{R}$ :

$$
\begin{equation*}
\left(i d \otimes \delta_{R}\right) \delta_{L}=\left(\delta_{L} \otimes i d\right) \delta_{R} \tag{3.3.67}
\end{equation*}
$$

follows directly from:

$$
\begin{gathered}
\left(i d \otimes \delta_{R}\right) \delta_{L}\left(x^{a}\right)=T_{b}^{a} \otimes x^{b} \otimes I=\left(\delta_{L} \otimes i d\right) \delta_{R}\left(x^{a}\right) \\
\left(i d \otimes \delta_{R}\right) \delta_{L}\left(x^{0}\right)=I \otimes x^{0} \otimes I=\left(\delta_{L} \otimes i d\right) \delta_{R}\left(x^{0}\right)
\end{gathered}
$$

Corollary 3.3.5 $I G L_{q, r}(N)$, for $q_{a 0}=$ const $\forall a$, is a bicovariant bimodule over $G L_{q, r}(N)$ freely generated, as a right module, by the elements $\zeta^{i}$; also any submodule $\Gamma^{(h, k)}$ is a bicovariant bimodule freely generated by the elements $\zeta^{i}$ with degree $(h, k)$.

Proof We immediately have that $I G L_{q, r}(N)$ and $\Gamma^{(h, k)}$ are bimodules with the left module structure trivially inherited from the algebra $I G L_{q, r}(N)$. $I G L_{q, r}(N)$ is a bicovariant bimodule because, since the left and right coactions $\delta_{L}$ and $\delta_{R}$ are multiplicative, they are compatible with the left and right product of $G L_{q, r}(N)$ on $I G L_{q, r}(N)$; moreover they satisfy (3.3.67). Also the submodules $\Gamma^{(h, k)}$ are bicovariant bimodules since the coactions $\delta_{L}$ and $\delta_{R}$ are grade preserving.

We now recall that a bicovariant bimodule is always freely generated by a basis of right invariant elements, [cf. the text after (2.1.47)]. We also know that the $\zeta^{i}$ are right invariant. Now, since they generate $I G L_{q, r}(N)$, they linearly span the space of right invariant elements $\left[I G L_{q, r}(N)\right]_{\text {inv }}$, and since they are linearly independent, they form a basis of $\left[I G L_{q, r}(N)\right]_{\text {inv }}$. We conclude that $I G L_{q, r}(N)$ is freely generated by the $\zeta^{i}: \zeta^{i} a_{i}=0 \Rightarrow a_{i}=0 \forall i$. The same arguments apply also to each submodule $\Gamma^{(h, k)}$.

In conclusion, the Hopf algebra $I G L_{q, r}(N)$ is very rich because it is both a bicovariant and a graded algebra on $G L_{q, r}(N)$. The bicovariant structure of $I G L_{q, r}(N)$ can be seen as an example of a general theory by Radford 61] on the properties of Hopf algebras $A$ with a Hopf subalgebra $H$ that is also a quotient of $A$. On the structure of inhomogeneous quantum groups see also the last reference in 65]. We summarize some results of 61] in the following

Theorem 3.3.6 Let $A$ and $H$ be Hopf algebras and suppose there exist Hopf algebras homomorphisms $\pi: A \rightarrow H$ and $i: H \hookrightarrow A$ such that $\pi \circ i=i d_{H}$. Consider the projection $\Pi$ on $A$ defined by:

$$
\begin{equation*}
\Pi(a)=a_{1} i\left[\kappa \pi\left(a_{2}\right)\right] \quad a \in A \tag{3.3.68}
\end{equation*}
$$

and let

$$
\begin{equation*}
B \equiv \Pi(A) \tag{3.3.69}
\end{equation*}
$$

Then:
a) $B$ is a subalgebra of $A, \Delta(B) \subseteq A \otimes B$ and

$$
\begin{equation*}
B \equiv \Pi(A)=\left\{b / \quad b_{1} \otimes \pi\left(b_{2}\right)=b \otimes I\right\} \tag{3.3.70}
\end{equation*}
$$

b) $B$ is also a coalgebra with counit $\underline{\varepsilon}$ that is the restriction to $B$ of the counit $\varepsilon$ of $A$, and with coproduct $\underline{\Delta}$ given by

$$
\begin{equation*}
\underline{\Delta}(\Pi(a))=\Pi\left(a_{1}\right) \otimes \Pi\left(a_{2}\right) \tag{3.3.71}
\end{equation*}
$$

[Notice that $\underline{\Delta}$ is in general not compatible with the algebra structure of $B$, only (1.1.4) and (1.1.5) hold].
c) $B$ is an $H$-bicovariant algebra with trivial right action and coaction and with left action given by the adjoint map $a d_{h} b=i\left(h_{1}\right) b i\left(\kappa\left(h_{2}\right)\right) \quad \forall h \in H, \forall b \in B$, and left coaction given by $\delta_{L}(b)=\pi\left(b_{1}\right) \otimes b_{2} \in H \otimes B, \forall b \in B$.
d) As a coalgebra $B$ is compatible with the left action ad and with the left coaction $\delta_{L}$ (we use the notation $\underline{\Delta}(b)=b_{\underline{1}} \otimes b_{\underline{2}}$ ):

$$
\begin{align*}
& \Delta\left(a d_{h} b\right)=a d_{h_{1}} b_{\underline{1}} \otimes a d_{h_{2}} b_{2}, \quad \underline{\varepsilon}\left(a d_{h} b\right)=\varepsilon(h) \underline{\varepsilon}(b), \\
& (i d \otimes \underline{\Delta}) \delta_{L}(b)=\left(m_{H} \otimes i d\right)\left(\delta_{L} \otimes \delta_{L}\right) \underline{\Delta}(b) \\
& (i d \otimes \underline{\varepsilon}) \delta_{L}(b)=\underline{\varepsilon}(b) I_{H} \tag{3.3.72}
\end{align*}
$$

Moreover

$$
\begin{equation*}
\underline{\Delta}\left(b b^{\prime}\right)=b_{\underline{1}} a d_{b_{\underline{2}}(1)} b_{\underline{1}}^{\prime} \otimes b_{\underline{2}}{ }^{(2)} \underline{b}_{\underline{2}}^{\prime} \tag{3.3.73}
\end{equation*}
$$

where we have used the notations $\delta_{L}(b)=b^{(1)} \otimes b^{(2)}$.
e) $B \otimes H$ has a canonical Hopf algebra structure (cross-product and crosscoproduct construction) denoted $B \rtimes H$. The product is given by:

$$
\begin{equation*}
(b \otimes h)\left(b^{\prime} \otimes h^{\prime}\right)=b\left(a d_{h_{1}} b^{\prime}\right) \otimes h_{2} h^{\prime} \quad \forall h \in H, b \in B \tag{3.3.74}
\end{equation*}
$$

the counit is given by $\underline{\varepsilon} \otimes \varepsilon$ and the coproduct is given by

$$
\begin{equation*}
\Delta(b \otimes h)=\left(b_{\underline{1}} \otimes{b_{\underline{2}}}^{(1)} h_{1}\right) \otimes\left(b_{\underline{2}}^{(2)} \otimes h_{2}\right) . \tag{3.3.75}
\end{equation*}
$$

d) $B \rtimes H$ and $A$ are isomorphic Hopf algebras via the isomorphism $\vartheta$ :

$$
\begin{equation*}
\vartheta(b \otimes h)=b i(h) \quad, \quad \vartheta^{-1}(a)=\Pi\left(a_{1}\right) \otimes \pi\left(a_{2}\right) \tag{3.3.76}
\end{equation*}
$$

Note 3.3.5 The algebra $B$ has a braided Hopf algebra structure, and the quantum group $A$ has a natural interpretation via Majid bosonization procedure [62], 63]. Since $B$ is a bicovariant bimodule over $H$, with trivial right action and right coaction [i.e. $B$ is a bimodule on the quantum double $\mathcal{D}(H)$, cf. Note 2.3.3] the braiding $\Psi$ is given via the left action and the left coaction of $H$ on $B$ :

$$
\begin{equation*}
\Psi\left(b \otimes b^{\prime}\right)=a d_{b^{(1)}} b^{\prime} \otimes b^{(2)} \tag{3.3.77}
\end{equation*}
$$

then (3.3.73) states that $\underline{\Delta}$ as defined in (3.3.71) is braided multiplicative:

$$
\begin{equation*}
\underline{\Delta}\left(b b^{\prime}\right)=b_{\underline{1}} \Psi\left(b_{\underline{2}} \otimes b_{\underline{1}}^{\prime}\right) b_{\underline{2}}^{\prime} . \tag{3.3.78}
\end{equation*}
$$

Finally $B$ is a braided Hopf algebra with antipode $\underline{\kappa}(b)=i\left[\pi\left(b_{1}\right)\right] \kappa\left(b_{2}\right)$.
In our case $A=I G L_{q, r}(N)$, the projection $\pi: I G L_{q, r}(N) \rightarrow G L_{q, r}(N)$, that is well defined only if $q_{a 0}=$ const $\equiv q_{0} \forall a$, is given by

$$
\begin{equation*}
\pi\left(T_{b}^{a}\right)=T_{b}^{a}, \quad \pi(u)=I, \quad \pi\left(x^{a}\right)=0, \tag{3.3.79}
\end{equation*}
$$

the subalgebra $B$ is generated by the $x^{0} \equiv u$ and $x^{a}$ elements that satisfy (3.3.4) and (3.3.6) i.e. $x^{A} x^{B}=r R_{C D}^{-1 A B} x^{D} x^{C}$. The braiding is: $\Psi\left(x^{a} \otimes x^{b}\right)=\frac{r}{q_{0}} R^{-1 A B} x_{C D}^{D} x^{C}$, $\Psi(x \otimes u)=u \otimes x, \Psi(u \otimes x)=x \otimes u$, the coproduct (coaddition) is $\underline{\Delta}(u)=u \otimes u$, $\underline{\Delta}\left(x^{a}\right)=x^{a} \otimes I+I \otimes x^{a}$ and the braided antipode and counit are $\underline{\kappa}(u)=u^{-1}$, $\underline{\kappa}\left(x^{a}\right)=-x^{a}$ and $\underline{\varepsilon}(u)=1, \underline{\varepsilon}\left(x^{a}\right)=0$.

Note 3.3.6 We also have $I G L_{q, r}(N)=M \rtimes G L_{q, r}^{u}(N)$ where $M$ is the subalgebra of $I G L_{q, r}(N)$ generated by the elements $x^{a} u^{-1}$ and $G L_{q, r}^{u}(N)$ is the quantum group generated by $G L_{q, r}(N)$ and the dilatation $u$.

### 3.4 Differential calculus on $G L_{q, r}(N)$

The bicovariant differential calculus on the uniparametric $q$-groups of the $A, B, C, D$ series can be formulated in terms of the corresponding $R$-matrix and the associated $L^{ \pm}$functionals. This holds also for the multiparametric case. In fact all formulas are the same, modulo substituting the $q$ parameter with $r$ when it appears explicitly (typically as $\frac{1}{q-q^{-1}}$ ).

We list here some relevant formulae that do not appear in Section 2.2:

$$
\begin{gather*}
\omega_{A_{1}}^{A_{2}} T_{S}^{R}=s\left(R^{-1}\right)^{T B_{1}}{ }_{C A_{1}}\left(R^{-1}\right)^{A_{2} C}{ }_{B_{2} S} T_{T^{R}}^{R} \omega_{B_{1}}^{B_{2}}  \tag{3.4.1}\\
\omega_{A_{1}}^{A_{2}} \operatorname{det} T=s^{N} r^{-2} \frac{Q_{A_{1}}}{Q_{A_{2}}}(\operatorname{det} T) \omega_{A_{1}}^{A_{2}}  \tag{3.4.2}\\
\omega_{A_{1}}^{A_{2}} \Xi=s^{-N} r^{2} \frac{Q_{A_{2}}}{Q_{A_{1}}}(\Xi) \omega_{A_{1}}^{A_{2}} \tag{3.4.3}
\end{gather*}
$$

where we recall that $s \equiv\left(c^{+}\right)^{-1} c^{-}$, cf. eq.s (2.2.2) and (2.2.3).
Notice that $\operatorname{det} T$ and $\Xi$ commute with all the $\omega$ (and thus can be set to $I$ ) iff all $Q_{A}$ are equal and for $s^{N} r^{-2}=1$, or $s=r^{\frac{2}{N}} \alpha$ with $\alpha^{N}=1$, which agrees with the condition found in Note 3.1.5.

Using

$$
\begin{equation*}
d a=\left(\chi_{A_{2}}^{A_{1}} * a\right) \omega_{A_{1}}^{A_{2}} \tag{3.4.4}
\end{equation*}
$$

we compute the exterior derivative on the basis elements of $G L_{q, r}(N)$, and on the $q$-determinant:

$$
\begin{gather*}
d T_{B}^{A}=\frac{1}{r-r^{-1}}\left[s\left(R^{-1}\right)^{C R}{ }_{E T}\left(R^{-1}\right)^{T E}{ }_{S B} T_{C}^{A}-\delta_{R}^{S} T_{B}^{A}\right] \omega_{R}^{S}  \tag{3.4.5}\\
d \Xi=\frac{s^{-N} r^{2}-1}{r-r^{-1}} \Xi \tau  \tag{3.4.6}\\
d \operatorname{det} T=\frac{s^{N} r^{-2}-1}{r-r^{-1}}(\operatorname{det} T) \tau \tag{3.4.7}
\end{gather*}
$$

The reader can verify via the Leibniz rule, and with the help of eq. (3.4.2), that $d[(\operatorname{det} T) \Xi]=d[\Xi(\operatorname{det} T)]=0$. From (3.4.7) we find that the bi-invariant 1-form $\tau$ that defines the exterior differential via $d a=\frac{1}{r-r^{-1}}[\tau a-a \tau]$ is given by

$$
\begin{equation*}
\tau=\frac{r-r^{1}}{s^{N} r^{-2}-1} \Xi d \operatorname{det} T . \tag{3.4.8}
\end{equation*}
$$

again, $\operatorname{det} T=I=\Xi$ requires $s^{N} r^{-2}=1$.
The expression of the $\omega$ in terms of a linear combination of $\kappa(T) d T$, similar to the classical case is:

$$
\begin{array}{rlrl}
\omega_{A}^{A}= & \frac{r}{s\left(s-r^{2}-r^{4}+s r^{4}\right)}\left[\left(r^{2}-s\right) \kappa\left(T^{A}{ }_{B}\right) d T_{A}^{B}+r^{2}(s-1) \kappa\left(T^{C}{ }_{B}\right) d T_{C}^{B}{ }_{C} \theta^{C A}+\right. \\
& \left.+\left(-r^{2}-s r^{2}+s+s r^{4}\right) \kappa\left(T^{C}{ }_{B}\right) d T^{B}{ }_{C} \theta^{A C}\right], & \text { no sum on A } \\
\omega_{A}{ }^{B}= & -s^{-1} \frac{r}{q_{B A}} \kappa\left(T^{B}{ }_{C}\right) d T^{C}{ }_{A}, & A \neq B \tag{3.4.10}
\end{array}
$$

When $s=1$, the classical limit $\omega_{A}^{B} \xrightarrow{q=r \rightarrow 1}-\kappa\left(T^{A}{ }_{C}\right) d T^{C}{ }_{B}$ reproduces the familiar formula $\omega=-g^{-1} d g$ for the left-invariant 1-forms on the group manifold. More generally, for $s=r^{\alpha}, \alpha \in \mathbf{C}$, we have:
$\omega_{A}^{A} \xrightarrow{r \rightarrow 1}\left[\frac{2-\alpha}{2(\alpha-1)} \sum_{B} \kappa\left(T^{A}{ }_{B}\right) d T^{B}{ }_{A}+\frac{\alpha}{2(\alpha-1)} \sum_{B} \sum_{C \neq A} \kappa\left(T_{B}^{C}{ }_{B}\right) d T^{B}{ }_{C}\right]$, no sum on A,
which shows that the inversion formula (3.4.9) diverges in the classical limit for $s=r$.

## Conjugation

Compatibility of the conjugation defined in (3.2.34) with the differential calculus requires $\left(\chi_{i}\right)^{*}$ to be a linear combination of the $\chi_{i}$. From (3.2.35) and (2.2.52), it is straightforward to find how the $*$-conjugation acts on the tangent vectors $\chi$. Only the conjugations i) and iii) are compatible with the differential calculus:

$$
\begin{align*}
& \text { i) } \quad\left(\chi_{B}^{A}\right)^{*}=-r^{-2 N} d_{C} R_{B C}^{D A}\left(\chi_{D}^{C}\right) \\
& \text { iii) } \quad\left(\chi_{B}^{A}\right)^{*}=\left(\chi_{A}^{B}\right) \tag{3.4.12}
\end{align*}
$$

Using the inversion formulae (3.4.10) and (3.4.5), or using (2.3.52), one finds the induced $*$-conjugation on the left-invariant 1-forms (here $s=r^{\alpha}, \alpha \in \mathbf{R}$ ):

$$
\begin{align*}
& \text { i) } \quad\left(\omega_{A}^{B}\right)^{*}=r^{2 N}\left(R^{-1}\right)^{B C}{ }_{D A} d_{B}^{-1} \omega_{C}^{D}, \\
& \text { iii) } \quad\left(\omega_{A}^{B}\right)^{*}=-\omega_{B}^{A} . \tag{3.4.13}
\end{align*}
$$

### 3.5 Differential calculus on $I G L_{q, r}(N)$

In this section we present a bicovariant differential calculus on $\operatorname{IG} L_{q, r}(N)$, based on the following set of functionals $f$ and elements $M$ :

$$
\begin{gather*}
f_{a_{1}}^{a_{2} b_{1}}{ }_{b_{2}}=\kappa^{\prime}\left(L^{+b_{1}}{ }_{a_{1}}\right) L^{-a_{2}}{ }_{b_{2}} \\
f_{a_{1}}^{a_{2}}{ }_{b_{2}}=\kappa^{\prime}\left(L^{+0}{ }_{a_{1}}\right) L^{-a_{2}}{ }_{b_{2}} \\
f_{0}{ }_{0}{ }_{2} b_{1}=\kappa^{\prime}\left(L^{+b_{1}}\right) L^{-a_{2}}{ }_{b_{2}} \equiv 0 \\
f_{0}{ }_{2} 0{ }_{b_{2}}=\kappa^{\prime}\left(L^{+0}{ }_{0}\right) L^{-a_{2}}{ }_{b_{2}}  \tag{3.5.1}\\
M_{b_{2} a_{1}}^{b_{2}}=T^{b_{1}}{ }_{a_{1}} \kappa\left(T^{a_{2}}{ }_{b_{2}}\right) \\
M_{b_{2} 0}^{b_{2}}=T^{b_{1}} \kappa\left(T_{0}^{a_{2}}{ }_{b_{2}}\right) \\
M_{b_{2} a_{1}}^{0}=0 \\
M_{b_{2} 0}^{0}{ }_{a}=T^{0}{ }_{0} \kappa\left(T^{a_{2}}{ }_{b_{2}}\right) \tag{3.5.2}
\end{gather*}
$$

The $f$ in (3.5.1) are a subset of the $f$ functionals of $G L_{q, r}(N+1)$, obtained by restricting the indices of $f^{i}{ }_{j}$ to $i=a b$ and $i=0 b$. The third $f$ is identically zero because of upper triangularity of $L^{+}$, i.e. $L^{+b_{1}}=0$.

The elements $M \in I G L_{q, r}(N)$ in (3.5.2) are obtained with the same restriction on the adjoint indices, and by projecting with $P$. The effect of the projection is to replace the coinverse in $G L_{q, r}(N+1)$, i.e. $\kappa_{N+1}$, with the coinverse $\kappa$ of $I G L_{q, r}(N)$ (see the last of (3.3.48)). The third element in (3.5.2) becomes zero because of $P$.

Theorem 3.5.1 The functionals in (3.5.1) vanish when applied to elements of $\operatorname{Ker}(P) \subset G L_{q, r}(N+1)$.

Proof: first one checks directly that the functionals (3.5.1) vanish when applied to $T^{0}{ }_{b}$. This extends to any element of the form $T^{0}{ }_{b} a(a \in A)$, i.e. to any element of $\operatorname{Ker}(P)$, because of the property (2.1.32) and the vanishing of the functionals in (3.5.7).

The theorem states that the $f$ functionals are well defined on the quotient $I G L_{q, r}(N)=G L_{q, r}(N+1) / \operatorname{Ker}(P)$, in the sense that the "projected" functionals

$$
\begin{equation*}
\bar{f}: I G L_{q, r}(N) \rightarrow \mathbf{C}, \quad \bar{f}(P(a)) \equiv f(a), \quad \forall a \in G L_{q, r}(N+1) \tag{3.5.3}
\end{equation*}
$$

are well defined. Indeed if $P(a)=P(b)$, then $f(a)=f(b)$ because $f(\operatorname{Ker}(P))=$ 0 . This holds for any functional $f$ vanishing on $\operatorname{Ker}(P)$, not only for the $f^{i}{ }_{j}$ functionals.

The product $f g$ of two generic functionals vanishing on $\operatorname{KerP}$ also vanishes on $\operatorname{Ker} P$, because $\operatorname{Ker} P$ is a co-ideal (see Theorem 3.3.1): $f g(\operatorname{Ker} P)=(f \otimes$ g) $\Delta_{N+1}(\operatorname{Ker} P)=0$. Therefore $\overline{f g}$ is well defined on $I G L_{q, r}(N)$, and
$\overline{f g}[P(a)]=f g(a)=(f \otimes g) \Delta_{N+1}(a)=(\bar{f} P \otimes \bar{g} P) \Delta_{N+1}(a)=(\bar{f} \otimes \bar{g}) \Delta(P(a)) \equiv \bar{f} \bar{g}[P(a)]$
(use the first of (3.3.48)) so that the product of $\bar{f}$ and $\bar{g}$ involves the coproduct $\Delta$ of $I G L_{q, r}(N)$.

There is a natural way to introduce a coproduct on the $\bar{f}$ 's :

$$
\begin{equation*}
\Delta^{\prime} \bar{f}[P(a) \otimes P(b)] \equiv \bar{f}[P(a) P(b)]=\bar{f}[P(a b)]=f(a b)=\Delta_{N+1}^{\prime} f(a \otimes b) \tag{3.5.5}
\end{equation*}
$$

It is also easy to show that

$$
\begin{equation*}
\Delta^{\prime} \bar{f}^{i}{ }_{j}=\bar{f}^{i}{ }_{k} \otimes \bar{f}^{k}{ }_{j} \quad \text { i.e. } \quad \bar{f}^{i}{ }_{j}[P(a) P(b)]=\bar{f}^{i}{ }_{k}[P(a)] \bar{f}^{k}{ }_{j}[P(b)] \tag{3.5.6}
\end{equation*}
$$

with $i, j, k$ running over the restricted set of indices $a b, 0 b$. Indeed due to

$$
\begin{equation*}
f_{0}{ }^{A_{2} b_{1}} \equiv 0, \quad f_{A_{2}}^{0 B_{1}}{ }_{b_{2}} \equiv 0 \tag{3.5.7}
\end{equation*}
$$

(a consequence of upper and lower triangularity of $L^{+}$and $L^{-}$respectively ), formulae (2.1.35) and (2.1.32) involve only the $f^{i}{ }_{j}$ listed in (3.5.1), which annihilate KerP. Then

$$
\begin{equation*}
\bar{f}_{j}^{i}[P(a) P(b)]=\bar{f}_{j}^{i}[P(a b)]=f_{j}^{i}{ }_{j}(a b)=f^{i}{ }_{k}(a) f^{k}{ }_{j}(b)=\bar{f}^{i}{ }_{k}[P(a)] \bar{f}^{k}{ }_{j}[P(b)] \tag{3.5.8}
\end{equation*}
$$

and (3.5.6) is proved.
With abuse of notations we will simply write $f$ instead of $\bar{f}$. Then the $f$ in (3.5.1) will be seen as functionals on $I G L_{q, r}(N)$. Notice that with the same abuse of notations, the product, coproduct and antipode of the $f$ and $\bar{f}$ functionals coincide.

Theorem 3.5.2 The right $A$-module $\left(A=I G L_{q, r}(N)\right) \Gamma$ freely generated by $\omega^{i} \equiv \omega_{a_{1}}^{a_{2}}, \omega_{0}^{a_{2}}$ is a bicovariant bimodule over $I G L_{q, r}(N)$ with right multiplication:

$$
\begin{equation*}
\omega^{i} a=\left(f_{j}^{i} * a\right) \omega^{j}, \quad a \in I G L_{q, r}(N) \tag{3.5.9}
\end{equation*}
$$

where the $f^{i}{ }_{j}$ are given in (3.5.1), the $*$-product is computed with the co-product $\Delta$ of $I G L_{q, r}(N)$, and the left and right actions of $I G L_{q, r}(N)$ on $\Gamma$ are given by

$$
\begin{align*}
\Delta_{L}\left(a_{i} \omega^{i}\right) & \equiv \Delta\left(a_{i}\right) I \otimes \omega^{i}  \tag{3.5.10}\\
\Delta_{R}\left(a_{i} \omega^{i}\right) & \equiv \Delta\left(a_{i}\right) \omega^{j} \otimes M_{j}{ }^{i} \tag{3.5.11}
\end{align*}
$$

where the $M_{j}{ }^{i}$ are given in (3.5.2) and from now on we use the notation $\Delta_{L}=\Delta_{\Gamma}$ and $\Delta_{R}={ }_{\Gamma} \Delta$.

Proof: we prove the theorem by showing that the functionals $f$ and the elements $M$ listed in (3.5.1) and (3.5.2) satisfy the properties (2.1.32)-(2.1.51) (cf. the theorem by Woronowicz discussed in the Section 2.1). It is straightforward to verify directly that the elements $M$ in (3.5.2) do satisfy the properties (2.1.44) and (2.1.45). We have already shown that the functionals $f$ in (3.5.1) satisfy (2.1.32), and property (2.1.33) obviously also holds for this subset.

Consider now the last property (2.1.51). We know that it holds for $G L_{q, r}(N+1)$. Take the free indices $j$ and $k$ as $a b$ and $0 b$, and apply the projection $P$ on both members of the equation. It is an easy matter to show that only the $f$ 's in (3.5.1) and the $M$ 's in (3.5.2) enter the sums: this is due to the vanishing of some $P(M)$ and to (3.5.7). We still have to prove that the $*$ product in (2.1.51) can be computed via the coproduct $\Delta$ in $I G L_{q, r}(N)$. Consider the projection of property (2.1.51), written symbolically as:

$$
\begin{equation*}
P\left[M(f \otimes i d) \Delta_{N+1}(a)\right]=P\left[(i d \otimes f) \Delta_{N+1}(a) M\right] \tag{3.5.12}
\end{equation*}
$$

Now apply the definition (3.5.3) and the first of (3.3.48) to rewrite (3.5.12) as

$$
\begin{equation*}
P(M)(\bar{f} \otimes i d) \Delta(P(a))=(i d \otimes \bar{f}) \Delta(P(a)) P(M) \tag{3.5.13}
\end{equation*}
$$

This projected equation then becomes property (2.1.51) for the $I G L_{q, r}(N)$ functionals $f$ and adjoint elements $M$, with the correct coproduct $\Delta$ of $I G L_{q, r}(N) \square$

Using the general formula (3.5.9) we can deduce the $\omega, T$ commutations for $I G L_{q, r}(N)$ :

$$
\begin{align*}
& \omega_{a_{1}}^{a_{2}} T^{r}{ }_{s}=s\left(R^{-1}\right)^{t b_{1}}{ }_{{ }_{c} a_{1}}\left(R^{-1}\right)^{a_{2} c}{ }_{b_{2} s} T^{r}{ }_{t} \omega_{b_{1}}^{b_{2}}  \tag{3.5.14}\\
& \omega_{a_{1}}^{a_{2}} x^{r}=s \frac{q_{0 a_{1}}}{q_{0 a_{2}}} x^{r} \omega_{a_{1}}^{a_{2}}-\left(r-r^{-1}\right) \frac{s r}{q_{0 a_{2}}} T_{a_{1}}^{r} \omega_{0}^{a_{2}}  \tag{3.5.15}\\
& \omega_{a_{1}}^{a_{2}} u=s \frac{q_{0 a_{1}}}{q_{0 a_{2}}} u \omega_{a_{1}}^{a_{2}}  \tag{3.5.16}\\
& \omega_{a_{1}}^{a_{2}} \operatorname{det} T^{a}{ }_{b}=s^{N} r^{-2} \frac{Q_{a_{1}}}{Q_{a_{2}}}\left(\operatorname{det} T^{a}{ }_{b}\right) \omega_{a_{1}}^{a_{2}}  \tag{3.5.17}\\
& \zeta \omega_{a_{1}}^{a_{2}}=s^{N} r^{-2} \frac{Q_{a_{1}}}{Q_{a_{2}}} \omega_{a_{1}}^{a_{2}} \zeta  \tag{3.5.18}\\
& \omega_{0}^{a_{2}} T^{r}{ }_{s}=s \frac{r}{q_{0 t}}\left(R^{-1}\right)^{a_{2} t}{ }_{b_{2} s} T^{r}{ }_{t} \omega_{0}^{b_{2}}  \tag{3.5.19}\\
& \omega_{0}^{a_{2}} x^{r}=\frac{s}{q_{0 a_{2}}} x^{r} \omega_{0}^{a_{2}}  \tag{3.5.20}\\
& \omega_{0}^{a_{2}} u=\frac{s}{q_{0 a_{2}}} u \omega_{0}{ }^{a_{2}} \tag{3.5.21}
\end{align*}
$$

$$
\begin{align*}
& \omega_{0}{ }^{a_{2}} \operatorname{det} T^{a}{ }_{b}=s^{N} r^{-2} \frac{Q_{0}}{Q_{a_{2}}}\left(\operatorname{det} T^{a}{ }_{b}\right) \omega_{0}^{a_{2}}  \tag{3.5.22}\\
& \zeta \omega_{0}^{a_{2}}=s^{N} r^{-2} \frac{Q_{0}}{Q_{a_{2}}} \omega_{0}^{a_{2}} \zeta \tag{3.5.23}
\end{align*}
$$

Note 3.5.1 $u$ commutes with all $\omega$ 's only if $q_{0 a}=1$ (cf. Note 3.3.2) and $s=1$. This means that $u=I$ is consistent with the differential calculus on $I G L_{q_{0 a}=1, r}(N)$ only if the additional condition $s=1$ is satisfied.

The 1 -form $\tau \equiv \sum_{a} \omega_{a}{ }^{a}$ is bi-invariant, as one can check by using (3.5.10)(3.5.11). Then an exterior derivative on $I G L_{q, r}(N)$ can be defined as in eq. (2.2.45), and satisfies the Leibniz rule. The alternative expression $d a=\left(\chi_{i} * a\right) \omega^{i}$ (cf. (3.4.4)) continues to hold, where

$$
\begin{align*}
\chi^{a}{ }_{b} & =\frac{1}{r-r^{-1}}\left[f_{c}{ }^{c a}{ }_{b}-\delta_{b}^{a} \varepsilon\right] \\
\chi^{0}{ }_{b} & =\frac{1}{r-r^{-1}}\left[f_{c}{ }^{c 0}{ }_{b}\right] \tag{3.5.24}
\end{align*}
$$

are the left-invariant vectors dual to the left-invariant 1-forms $\omega_{a}{ }^{b}$ and $\omega_{0}{ }^{b}$. They are functionals on $I G L_{q, r}(N)$ and as a consequence of (3.5.6) we have

$$
\begin{align*}
& \Delta^{\prime}\left(\chi^{a}{ }_{b}\right)=\chi^{c}{ }_{d} \otimes f_{c}{ }_{c}^{d a}{ }_{b}+\varepsilon \otimes \chi^{a}{ }_{b}  \tag{3.5.25}\\
& \Delta^{\prime}\left(\chi^{0}{ }_{b}\right)=\chi^{c}{ }_{d} \otimes f_{c}{ }_{c}{ }^{00}+\chi^{0}{ }_{d} \otimes f_{0}{ }^{d 0}{ }_{b}+\varepsilon \otimes \chi^{0}{ }_{b} \tag{3.5.26}
\end{align*}
$$

The exterior derivative on the generators $T^{a}{ }_{b}$ is given by formula (3.4.5) with lower case indices. For the other generators we find:

$$
\begin{align*}
& d x^{a}=-s \frac{r}{q_{0 s}} T^{a}{ }_{s} \omega_{0}{ }^{s}+\frac{s-1}{r-r^{-1}} x^{a} \tau  \tag{3.5.27}\\
& d u=\frac{s-1}{r-r^{-1}} u \tau  \tag{3.5.28}\\
& d \xi=\frac{s^{-N-1} r^{2}-1}{r-r^{-1}} \xi \tau \tag{3.5.29}
\end{align*}
$$

Moreover:

$$
\begin{align*}
d\left(\operatorname{det} T^{a}{ }_{b}\right) & =\frac{s^{N} r^{-2}-1}{r-r^{-1}}\left(\operatorname{det} T^{a}{ }_{b}\right) \tau  \tag{3.5.30}\\
d \zeta & =\frac{s^{-N} r^{2}-1}{r-r^{-1}} \zeta \tau \tag{3.5.31}
\end{align*}
$$

$(\zeta \equiv u \xi)$. Again we find that $u=I$ implies $s=1$, and $\operatorname{det} T^{a}{ }_{b}=\zeta=I$ requires $s^{N} r^{-2}=1$.

Every element $\rho$ of $\Gamma$ can be written as $\rho=a_{k} d b_{k}$ for some $a_{k}, b_{k}$ belonging to $I G L_{q, r}(N)$. In fact one has the same formula as in (3.4.9) for $\omega_{m}{ }^{n}$, where all indices now are lower case. For $\omega_{0}{ }^{n}$ we find:

$$
\begin{equation*}
\omega_{0}^{n}=-\frac{q_{0 n}}{s r}\left[\kappa\left(T_{a}^{n}\right) d x^{a}+\kappa\left(x^{n}\right) d u\right] \tag{3.5.32}
\end{equation*}
$$

Finally, the two properties (2.1.3) and (2.1.4) hold also for $\operatorname{IG} L_{q, r}(N)$, because of the bi-invariance of $\tau=\omega_{a}{ }^{a}$. Thus all the axioms for a bicovariant first order differential calculus on $I G L_{q, r}(N)$ are satisfied.

The exterior product of left-invariant 1-forms is defined as

$$
\begin{equation*}
\omega^{i} \wedge \omega^{j} \equiv \omega^{i} \otimes \omega^{j}-\Lambda_{k l}^{i j} \omega^{k} \otimes \omega^{l} \tag{3.5.33}
\end{equation*}
$$

where

$$
\begin{equation*}
\Lambda^{i j}{ }_{k l}=f^{i}{ }_{l}\left(M_{k}{ }^{j}\right) \tag{3.5.34}
\end{equation*}
$$

This $\Lambda$ tensor can in fact be obtained from the one of $G L_{q, r}(N+1)$ by restricting its indices to the subset $a b, 0 b$. This is true because when $i, l=a b$ or $0 b$ we have $f^{i}{ }_{l}(\operatorname{Ker} P)=0$ so that $f^{i}{ }_{l}$ is well defined on $I G L_{q, r}(N)$, and we can write $f^{i}{ }_{l}\left(M_{k}{ }^{j}\right)=\bar{f}_{l}{ }_{l}\left[P\left(M_{k}{ }^{j}\right)\right]$ (see discussion after Theorem 3.5.1). The non-vanishing components of $\Lambda$ read:

$$
\begin{align*}
& \left.\Lambda_{a_{1} d_{1}}^{a_{2} d_{2}}\right|_{c_{2} b_{2}} ^{c_{1}} b_{1} b_{1} d^{f_{2}} d_{c_{2}}^{-1} R^{f_{2} b_{1}}{ }_{c_{2} g_{1}}\left(R^{-1}\right)^{c_{1} g_{1}}{ }_{e_{1} a_{1}}\left(R^{-1}\right)^{a_{2} e_{1}}{ }_{g_{2} d_{1}} R^{g_{2} d_{2}}{ }_{b_{2} f_{2}}^{g_{2}}  \tag{3.5.35}\\
& \left.\Lambda_{0}^{a}{ }_{d_{1}}^{a_{2}} d_{2}\right|_{c_{2} b_{2}} ^{c_{1} 0}=\frac{q_{0 c_{2}}}{q_{0 c_{1}}}\left(R^{-1}\right)^{a_{2} c_{1}}{ }_{g_{2} d_{1}} R_{b_{2} c_{2}}^{g_{2} d_{2}}  \tag{3.5.36}\\
& \left.\Lambda_{a_{1} 0}^{a_{2}} d_{2}^{d_{2}}\right|_{c_{2} b_{2}} ^{c_{1}}=-\left(r-r^{-1}\right) \frac{q_{0 c_{2}}}{q_{0 a_{2}}} \delta_{a_{1}}^{c_{1}} R^{a_{2} d_{2}}{ }_{b_{2} c_{2}}  \tag{3.5.37}\\
& \left.\Lambda_{a_{1}{ }_{0}}^{a_{2} d_{2}}\right|_{c_{2} b_{2}} ^{0 b_{1}}=\frac{q_{0 a_{1}}}{q_{0 a_{2}}} d^{f_{2}} d_{c_{2}}^{-1} R^{f_{2} b_{1}}{ }_{c_{2} a_{1}} R_{b_{b_{2} f_{2}}^{a_{2} d_{2}}}  \tag{3.5.38}\\
& \left.\Lambda_{0}{ }_{0}^{a_{2}} d_{2}\right|_{c_{2} b_{2}} ^{0}{ }_{c}^{0}=\frac{q_{0 c_{2}}}{q_{0 a_{2}}} r^{-1} R^{a_{2} d_{2}}{ }_{b_{2} c_{2}} \tag{3.5.39}
\end{align*}
$$

These components still satisfy the characteristic equation (2.2.40), because the $\Lambda$ tensor of $G L_{q, r}(N+1)$ does satisfy this equation, and if the free adjoint indices are taken as $a b, 0 b$, only the components in (3.5.35)-(3.5.39) enter in (2.2.40). To prove this, consider $\Lambda^{i j}{ }_{k l}$ with $k, l$ of the type $a b$ or $0 b$ and observe that it vanishes unless also $i, j$ are of the type $a b, 0 b$. (This can be checked directly via the formula (2.2.39)). Then equations (2.2.42) and (2.2.43) hold also for the $\omega$ 's of $I G L_{q, r}(N)$.

Note that $\Lambda^{-1}$ tensor of $I G L_{q, r}(N)$ can be obtained by specializing the indices in the $\Lambda^{-1}$ tensor of $G L_{q, r}(N+1)$ given in (2.2.37), as we did for $\Lambda$. The reader can convince himself of this by i) observing that the $\Lambda^{-1}{ }_{k l}{ }_{k l}$ tensor of (2.2.37) also vanishes when $k, l=a b$ or $0 b$ and $i, j$ are not of the type $a b, 0 b$; ii) considering the equation $\Lambda^{-1}{ }_{i j}{ }_{r s} \Lambda^{r s}{ }_{k l}=\delta_{k}^{i} \delta_{l}^{j}$ for $k, l=a b$ or $0 b$.

The exterior differential on $\Gamma^{\wedge n}$ can be defined as in Section 2.2 (eq. (2.2.44)), and satisfies all the properties (2.1.81)-(2.1.84). As for $G L_{q, r}(N+1)$ the last two hold because of the bi-invariance of $\tau$.

The Cartan-Maurer equations are

$$
\begin{equation*}
d \omega^{i}=\frac{1}{r-r^{-1}}\left(\tau \wedge \omega^{i}+\omega^{i} \wedge \tau\right)=-\frac{1}{2} C_{j k}{ }^{i} \omega^{j} \wedge \omega^{k} \tag{3.5.40}
\end{equation*}
$$

with

$$
\begin{align*}
& \left.C_{a_{2} b_{2}}^{a_{1}} b_{1}\right|_{c_{1}} ^{c_{2}}=\frac{2}{r^{2}+r^{-2}}\left[-\left(r-r^{-1}\right) \delta_{b_{2}}^{b_{1}} \delta_{c_{1}}^{a_{1}} \delta_{a_{2}}^{c_{2}}+\mathbf{C}_{a_{2} b_{2}}^{a_{1}} b_{1} \mid c_{c_{1}}^{c_{2}}\right]  \tag{3.5.41}\\
& \left.C_{a_{2} b_{2}}^{a_{1}} 0\right|_{0} ^{c_{2}}=\left.\frac{2}{r^{2}+r^{-2}} \mathbf{C}_{a_{2} b_{2}}^{a_{1}}\right|_{0} ^{c_{2}}  \tag{3.5.42}\\
& \left.C_{a_{2} b_{2}}^{0} b_{1}\right|_{0} ^{c_{2}}=\frac{2}{r^{2}+r^{-2}}\left[-\left(r-r^{-1}\right) \delta_{b_{2}}^{b_{1}} \delta_{a_{2}}^{c_{2}}+\left.\mathbf{C}_{a_{2} b_{2}}^{0} b_{1}\right|_{0} ^{c_{2}}\right] \tag{3.5.43}
\end{align*}
$$

The structure constants $\mathbf{C}$ (appearing in the $q$-Lie algebra of $I G L_{q, r}(N)$, see later) are given by

$$
\begin{align*}
\left.\mathbf{C}_{c_{2} b_{2}}^{c_{1}} b_{1}\right|_{d_{1}} ^{d_{2}} & =\frac{1}{r-r^{-1}}\left[-\delta_{b_{2}}^{b_{1}} \delta_{d_{1}}^{c_{1}} \delta_{c_{2}}^{d_{2}}+\left.\Lambda_{a d_{1}}^{a d_{2}}\right|_{c_{2}} ^{c_{1} b_{1} b_{2}}\right]  \tag{3.5.44}\\
& =\text { structure constants of } G L_{q, r}(N) \\
\left.\mathbf{C}_{c_{2} b_{2}}^{c_{1} 0}\right|_{0} ^{d_{2}} & =-\frac{q_{0 c_{2}}}{q_{0 c_{1}}} R_{b_{2} c_{2}}^{c_{1} d_{2}}  \tag{3.5.45}\\
\left.\mathbf{C}_{c_{2} b_{2}}^{0} b_{0}^{b_{1}}\right|_{0} ^{d_{2}} & =\frac{1}{r-r^{-1}}\left[-\delta_{b_{2}}^{b_{1}} \delta_{c_{2}}^{d_{2}}+d^{f_{2}} d_{c_{2}}^{-1} R_{c_{2} a}^{f_{2} b_{1}} R_{b_{2} f_{2}}^{a d_{2}}\right] \tag{3.5.46}
\end{align*}
$$

We conclude this section by observing that the functionals $f$ and $\chi$ in (3.5.1) and (3.5.24) close on the algebra (2.1.111), (2.1.112)-(2.1.114), where the product of functionals is defined by the coproduct $\Delta$ in $I G L_{q, r}(N)$. This result is expected, since the functionals in (3.5.1) and (3.5.24) correspond to a bicovariant differential calculus on $I G L_{q, r}(N)$. 2

[^6]Using the values of the $\Lambda$ and $\mathbf{C}$ tensors in (3.5.35)-(3.5.39) and (3.5.44)-(3.5.46), we can explicitly write the " $q$-Lie algebra" of $I G L_{q, r}(N)$ as:

$$
\begin{align*}
& \chi_{c_{2}}^{c_{1}} \chi_{b_{2}}^{b_{1}}-\left.\Lambda_{a_{1} d_{1}}^{a_{2}}\right|_{c_{2} b_{2}} ^{c_{1}}{ }_{c_{1} b_{1}}^{b_{1}} \chi_{a_{2}}^{a_{1}} \chi_{d_{2}}^{d_{1}}=\frac{1}{r-r^{-1}}\left[-\delta_{b_{2}}^{b_{1}} \delta_{d_{1}}^{c_{1}} \delta_{c_{2}}^{d_{2}}+\left.\Lambda_{a d_{1}}^{a d_{2}}\right|_{c_{2} b_{2}} ^{c_{1} b_{1}} \chi^{d_{d_{2}}}\right.  \tag{3.5.47}\\
& \chi_{c_{2}}^{c_{1}} \chi_{b_{2}}^{0}+\left(r-r^{-1}\right) \frac{q_{0 c_{2}}}{q_{0 a_{2}}} R_{b_{2} d_{2} d_{2}} \chi_{a_{2}}^{c_{1}} \chi_{d_{2}}^{0}- \\
& -\frac{q_{0 c_{2}}}{q_{0 c_{1}}}\left(R^{-1}\right)^{a_{2} c_{1}}{ }_{g_{2} d_{1}} R_{b_{2} c_{2}}^{g_{2} d_{2}} \chi_{a_{2}}^{0} \chi_{d_{2}}^{d_{1}}=-\frac{q_{0 c_{2}}}{q_{0 c_{1}}} R_{b_{2} c_{2}}^{c_{1} d_{2}} \chi_{d_{2}}^{0}  \tag{3.5.48}\\
& \chi_{c_{2}}^{0} \chi_{b_{2}}^{b_{1}}-\frac{q_{0 a_{1}}}{q_{0 a_{2}}} d^{f_{2}} d_{c_{2}}^{-1} R^{f_{2} b_{1}}{ }_{c_{2} a_{1}} R^{a_{2} d_{2}}{ }_{b_{2} f_{2}} \chi_{a_{2}}^{a_{1}} \chi_{d_{2}}^{0}= \\
& \frac{1}{r-r^{-1}}\left[-\delta_{b_{2}}^{b_{1}} \delta_{c_{2}}^{d_{2}}+d^{f_{2}} d_{c_{2}}^{-1} R_{c_{2} a}^{f_{2} b_{1}} R_{b_{2} f_{2}}^{a d_{2}}\right] \chi_{d_{2}}^{0}  \tag{3.5.49}\\
& \chi_{c_{2}}^{0} \chi_{b_{2}}^{0}-\frac{q_{0 c_{2}}}{q_{0 a_{2}}} r^{-1} R_{b_{2} c_{2}}^{a_{2} d_{2}} \chi_{a_{2}}^{0} \chi_{d_{2}}^{0}=0 \tag{3.5.50}
\end{align*}
$$

where $\left.\Lambda_{a_{1}}^{a_{2}} d_{1} d_{2}\right|_{c_{2}} ^{c_{1}} b_{1} b_{2}$ is the braiding matrix of $G L_{q}(n)$, given in (3.5.35), so that the commutations in (3.5.47) are those of the $q$-subalgebra $G L_{q}(n)$. Note that the $r \rightarrow 1$ limit on the right hand sides of (3.5.47) and (3.5.49) is finite, since the terms in square parentheses are a (finite) series in $r-r^{-1}$ whose $0-t h$ order part vanishes [see (2.2.55) and (2.2.57)].

### 3.6 The universal enveloping algebra of $I G L_{q, r}(N)$

In the previous section we have considered the Hopf algebra generated by the $f$ functionals in (3.5.1). This, togheter with $f_{0}{ }^{00}{ }_{0}$, is the universal enveloping algebra $U_{q, r}(i g l(N))$ of $I G L_{q, r}(N)$ [see later, after (3.6.66)]. We now briefly give an $L^{ \pm}$ description of $U_{q, r}(i g l(N))$. For all the details we refer to Section 4.3 where a similar construction is performed in the orthogonal case.

In the preceding section we have identified the $\bar{f}$ functionals on $I G L_{q, r}(N)$ with the corresponding $f$ functionals on $G L_{q, r}(N)$, in the same perspective, we construct $U_{q, r}(i g l(N))$ as a Hopf subalgebra of $U_{q, r}(g l(N+1))$. Let

$$
\begin{equation*}
I U \equiv\left[L^{+A}{ }_{B}, L^{-a}{ }_{b}, L^{-0}{ }_{0}, \Phi, \varepsilon\right] \tag{3.6.51}
\end{equation*}
$$

be the subalgebra of $U_{q, r}(g l(N+1))$ generated by $L^{+A}{ }_{B}, L^{-a}{ }_{b}, L^{-0}{ }_{0}, \Phi, \varepsilon$. ( $\Phi$ is the inverse of $\left.\operatorname{det} L^{+} \operatorname{det} L^{-}\right)$.

The remaining $U_{q, r}(g l(N+1))$ generators $L^{-b}{ }_{0}$ are the only ones that do not annihilate $T^{0}{ }_{a}$ (the generators of $H$ ) and are not included in (3.6.51): we construct the universal enveloping algebra of $I G L_{q, r}(N)$ as the Hopf subalgebra of $U_{q, r}(g l(N+$ 1)) that annihilates the ideal $H$.

Since $\Delta(I U) \subseteq I U \otimes I U$ and $\kappa^{\prime}(I U) \subseteq I U$ (as can be immediately seen at the generators level) we have that $I U$ is a Hopf subalgebra of $U_{q, r}(g l(N+1))$. Moreover one can also give the following $R$-marix formulation (cf. Theorem 4.4.2):

Theorem 3.6.1 The Hopf algebra $I U$ is generated by $\varepsilon, \Phi$ and the matrix entries:

$$
L^{-}=\left(L^{+A}{ }_{B}\right), \mathcal{L}^{-}=\left(\begin{array}{cc}
L^{-0}{ }_{0} & 0 \\
0 & L^{-a}{ }_{b}
\end{array}\right)
$$

these functionals satisfy the $q$-commutation relations:

$$
\begin{gather*}
R_{12} \mathcal{L}^{-}{ }_{2} \mathcal{L}^{-}{ }_{1}=\mathcal{L}^{-}{ }_{1} \mathcal{L}^{-}{ }_{2} R_{12}  \tag{3.6.52}\\
\text { or equivalently } \quad \mathcal{R}_{12} \mathcal{L}^{-}{ }_{2} \mathcal{L}^{-}{ }_{1}=\mathcal{L}^{-}{ }_{1} \mathcal{L}^{-}{ }_{2} \mathcal{R}_{12}  \tag{3.6.53}\\
R_{12} L_{2}^{+} L_{1}^{+}=L_{1}^{+} L_{2}^{+} R_{12}  \tag{3.6.54}\\
\mathcal{R}_{12} L_{2}^{+} \mathcal{L}^{-}{ }_{1}=\mathcal{L}^{-}{ }_{1} L_{2}^{+} \mathcal{R}_{12}
\end{gather*}
$$

where $\mathcal{R}_{12} \equiv c^{-}\left[\mathcal{L}^{-}{ }_{1}\left(T_{2}\right)\right]^{-1}$ that is $\mathcal{R}_{c d}^{a b}=R_{c d}^{a b}, \mathcal{R}_{A B}^{A B}=R_{A B}^{A B}$ and otherwise $\mathcal{R}_{C D}^{A B}=$ 0 .

Relations (3.6.52) and (3.6.53) explicitly read as in (3.3.24)-(3.3.34), just substitute $T$ with $L^{ \pm}$and "read from right to left"; this is due to $R_{12} L_{2}^{ \pm} L_{1}^{ \pm}=L_{1}^{ \pm} L_{2}^{ \pm} R_{12}$ while we have $R_{12} T_{1} T_{2}=T_{2} T_{1} R_{12}$. Relations (3.6.54) read

$$
\begin{align*}
& R^{a b} L^{+f}{ }_{d} L^{-e}{ }_{c}=L^{-a}{ }_{e} L^{+b}{ }_{f} R^{e f}{ }_{c d}  \tag{3.6.55}\\
& L^{+b}{ }_{d} L^{-0}{ }_{0}=\frac{q_{d 0}}{q_{b 0}} L^{-0}{ }_{0} L^{+b}{ }_{d}  \tag{3.6.56}\\
& L^{+0}{ }_{d} L^{-a}{ }_{c}=\frac{q_{a 0}}{r} R^{e f}{ }_{c d}^{-a} L^{-a} L^{+0}{ }_{f}  \tag{3.6.57}\\
& L^{+0}{ }_{d} L^{-0}{ }_{0}=\frac{q_{d 0}}{r^{2}} L^{-0}{ }_{0} L^{+0}{ }_{d}  \tag{3.6.58}\\
& L^{+0}{ }_{0} L^{-a}{ }_{c}=\frac{q_{a 0}}{q_{c 0}} L^{-a}{ }_{c} L^{+0}{ }_{0}  \tag{3.6.59}\\
& L^{+0}{ }_{0} L^{-0}{ }_{0}=L^{-0}{ }_{0} L^{+0}{ }_{0} \tag{3.6.60}
\end{align*}
$$

Note 3.6.1 Apply the second espression in (3.6.52) to $T^{A}{ }_{B}$ to obtain the quantum Yang-Baxter equation for the matrix $\mathcal{R}$. The need for a new $R$-matrix $\mathcal{R}$ can be seen as due to the impossibility of considering $I U$ as a quotient of the algebra $U_{q, r}(G L(N+1))$. The commutation relation that prevents $I U$ to be a quotient of $U_{q, r}(G L(N+1))$ with respect to the ideal generated by the $L^{-a}{ }_{0}$ elements is: $L^{+0}{ }_{d} L^{-a}{ }_{0}=\frac{q_{a o}}{q_{0 d}} L^{-a}{ }_{0} L^{+0}{ }_{d}+\left(1-r^{-2}\right) q_{a 0}\left(L^{-a}{ }_{d} L^{+0}{ }_{0}-L^{+a}{ }_{d} L^{-0}{ }_{0}\right)$.

We stress that $I U$ is a subalgebra of $U_{q, r}(N+1)$, so that (3.6.52), (3.6.53), (3.6.55)-(3.6.60) hold in $G L_{q, r}(N)$ as well. On the opposite side, the $R$-matrix of the $I G L_{q, r}(N) R T T$ relations is the same as the $R$-matrix of the $G L_{q, r}(N+1)$ $R T T$ relations, but this last set of $R T T$ relations does not contain as a subset the previous one.

We now briefly study the structure of $I U$ with respect to $U_{q, r}(g l(N))$, that is easily seen to be a Hopf subalgebra of $I U$. It is also a quotient of $I U$ via the Hopf algebra projection [well defined only if $q_{a 0}=$ const $\equiv q_{0} \forall a$ see (3.6.56) and (3.6.59)]:

$$
\pi\left(L^{-0}{ }_{a}\right)=0, \quad \pi\left(L^{-0}{ }_{0}\right)=I, \quad \pi\left(L^{ \pm a}{ }_{b}\right)=L^{ \pm a}{ }_{b}, \quad \pi\left(L^{+a}{ }_{0}\right)=L^{+a}{ }_{0}, \quad \pi\left(\varepsilon^{\prime}\right)=\varepsilon^{\prime} .
$$

Then the results of Theorem 3.3.6 apply to $I U$ as well, and we can write the Hopf algebra isomorhism $I U \cong B^{\prime} \rtimes U_{q, r}(g l(N))$ where $B^{\prime}$ is the algebra generated by $L^{+0}{ }_{0}$ and $L^{+0}{ }_{a}$. Also Theorem 3.3.4 hold for $I U$ since we can introduce the following $(\mathbf{Z}, \mathbf{N})$ grading: the elements $L^{ \pm a}{ }_{b}$ have grade ( 0,0 ), the elements $L^{+0}{ }_{a}$ have grade $(0,1)$, the elements $L^{ \pm 0}{ }_{0}$ have grade $( \pm 1,0)$. This grading is compatible with the $R L L$ commutation relations. Notice also that the elements $L^{+0}{ }_{0}$ and $L^{-0}{ }_{0}$ are not independent (see the text after (4.3.17) for a general discussion in the orthogonal case, the $G L_{q, r}(N)$ case is similar); here we give an easier argument that holds only if $q_{a 0}=$ const $=r \forall a$ : we fix the coefficient $c^{-}$defined in (2.2.3) and studied after (2.2.20), to be $c^{-}=\left(c^{+}\right)^{-1}$ (notice that the parameter $s=\left(c^{+}\right)^{-1} c^{-}$entering the differential calculus is still arbitrary, the parameter $c^{-}$is completely irrelevant). It follows that $L^{-0}{ }_{0}$ has a simple dependence from $L^{+0}{ }_{0}:\left(L^{-0}{ }_{0}\right)^{-1}=L^{+0}{ }_{0}$. [Proof: $\left.\forall A, B,\left(L^{-0}{ }_{0}\right)^{-1}\left(T^{A}{ }_{B}\right)=L^{+0}{ }_{0}\left(T^{A}{ }_{B}\right), \Delta^{\prime}\left(L^{ \pm 0}{ }_{0}\right)=L^{ \pm 0}{ }_{0} \otimes L^{ \pm 0}{ }_{0}\right]$.

From the $R L L$ relations a generic element of $I U$ can be written as $\eta^{i} a_{i}$ (or $\left.a_{i} \eta^{i}\right)$ where $a_{i} \in U_{q, r}(g l(N))$ and $\eta^{i}$ are ordered monomials in the $L^{+0}{ }_{0}$ and $L^{+0}{ }_{a}$ elements: $\eta^{i}=\left(L^{+0}{ }_{0}\right)^{i_{0}}\left(L^{+0}{ }_{1}\right)^{i_{1}} \ldots\left(L^{+0}{ }_{N}\right)^{i_{N}}$. As in Corollary 3.1.1, we have that $I U$, for $q_{a 0}=$ const $\forall a$, is a bicovariant bimodule over $G L_{q, r}(N)$ freely generated, as a right module, by the elements $\eta^{i}$; moreover

$$
\begin{equation*}
U_{q, r}(i g l(N))=\sum_{(h, k) \in(\mathbf{Z}, \mathbf{N})}^{\oplus} \Gamma^{\prime(h, k)} \tag{3.6.61}
\end{equation*}
$$

where $\Gamma^{\prime(0,0)}=U_{q, r}(g l(N))$

$$
\begin{align*}
& \Gamma^{\prime(0,1)}=\left\{L^{+0}{ }_{a} \varphi^{a} / \varphi^{a} \in U_{q, r}(g l(N))\right\}, \quad \Gamma^{\prime( \pm 1,0)}=\left\{\left(L^{+0}{ }_{0}\right)^{ \pm 1} \varphi / \varphi \in U_{q, r}(g l(N))\right\} \\
& \Gamma^{\prime(h, k)}=\left\{\left(L^{+0}{ }_{0}\right)^{h} L^{+0}{ }_{a_{1}} L^{+0}{ }_{a_{2}} \ldots L^{+0}{ }_{a_{k}} \varphi^{a_{1} a_{2} \ldots a_{k}} / \varphi^{a_{1} a_{2} \ldots a_{k}} \in U_{q, r}(g l(N))\right\} \tag{3.6.62}
\end{align*}
$$

Any submodule $\Gamma^{\prime(h, k)}$ is a bicovariant bimodule freely generated by the elements $\eta^{i}$ with degree $(h, k) \in(\mathbf{Z}, \mathbf{N})$. We leave to the reader to reformulate Note 3.3.5 and Note 3.3.6 in this context.

Duality $I U \leftrightarrow I G L_{q, r}(N)$
We now show that $I U$ is dually paired to $I G L_{q, r}(N)$. This is the fundamental step allowing to interpret $I U$ as the universal enveloping algebra of $I G L_{q, r}(N)$.

Theorem 3.6.2 $I U$ annihilates $H$.

Proof: $\quad$ This theorem has implicitly been proved in Theorem 3.5.1 and in the comments before (3.5.4). An explicit proof is given in Theorem 4.4.4.

In virtue of Theorem 3.6.2 the following bracket is well defined:

$$
\begin{align*}
\text { Definition. } & \langle,\rangle: I U \otimes I G L_{q, r}(N) \longrightarrow \boldsymbol{C} \\
& \left\langle a^{\prime}, P(a)\right\rangle \equiv a^{\prime}(a)  \tag{3.6.63}\\
& \forall a^{\prime} \in I U, \forall a \in I G L_{q, r}(N)
\end{align*}
$$

where $P: G L_{q, r}(N+1) \rightarrow G L_{q, r}(N+1) / H \equiv I G L_{q, r}(N)$ is the canonical projection, which is surjective. The bracket is well defined because two generic counterimages of $P(a)$ differ by an addend belonging to $H$.

Since $I U$ is a Hopf subalgebra of $U_{q, r}(g l(N+1))$ and $P$ is compatible with the structures and costructures of $G L_{q, r}(N+1)$ and $I G L_{q, r}(N)$, the following theorem is then easily shown [cf. (3.5.4), (3.5.8) and Theorem 4.4.5]

Theorem 3.6.3 The bracket (3.6.63) defines a pairing between $I U$ and $I G L_{q, r}(N)$ : $\forall a^{\prime}, b^{\prime} \in I U, \forall P(a), P(b) \in I G L_{q, r}(N)$

$$
\begin{aligned}
& \left\langle a^{\prime} b^{\prime}, P(a)\right\rangle=\left\langle a^{\prime} \otimes b^{\prime}, \Delta(P(a))\right\rangle \\
& \left\langle a^{\prime}, P(a) P(b)\right\rangle=\left\langle\Delta^{\prime}\left(a^{\prime}\right), P(a) \otimes P(b)\right\rangle \\
& \left\langle\kappa^{\prime}\left(a^{\prime}\right), P(a)\right\rangle=\left\langle a^{\prime}, \kappa(P(a))\right\rangle \\
& \langle I, P(a)\rangle=\varepsilon(a) ; \quad\left\langle a^{\prime}, P(I)\right\rangle=\varepsilon^{\prime}\left(a^{\prime}\right)
\end{aligned}
$$

We now recall that $I U$ and $I G L_{q, r}(N)$, besides being dually paired, are bicovariant algebras with the same graded structure (3.3.61) and (3.6.61), and can both be obtained as a cross-product cross-coproduct construction: $\operatorname{IG} L_{q, r}(N) \cong$ $B \rtimes G L_{q, r}(N), I U \cong B^{\prime} \rtimes U_{q, r}(g l(N))$. In particular $I G L_{q, r}(N)$ and $I U$ are freely generated (as modules) by $B$ and $B^{\prime}$ i.e. by the two isomorphic sets of the ordered monomials in the $q$-plane plus dilatation coordinates $L^{+0}{ }_{0}, L^{+0}{ }_{a}$ and $u, x^{a}$ respectively. We then conclude that $I U$ is the universal enveloping algebra of $I G L_{q, r}(N)$ :

$$
\begin{equation*}
U_{q, r}(i g l(N)) \equiv I U \tag{3.6.64}
\end{equation*}
$$

## Projected differential calculus

We have found the inhomogeneous quantum group $I G L_{q, r}(N)$ by means of a projection from $G L_{q, r}(N+1)$; dually, its universal enveloping algebra is a given Hopf subalgebra of $U_{q, r}(g l(N+1))$. Using the same techniques we conclude this section presenting another differential calculus on $\operatorname{IG} L_{q, r}(N)$, that is obtained from the previous one considering also the dilatation generator $\chi^{0}{ }_{0}$. To derive this calculus
one can follow the same steps of the Section 3.5, however the easiest way to derive it is to apply the results of Section 2.3.

From (2.3.4) and (2.3.5) it is immediate to see that $T^{\prime} \equiv T \cap U_{q, r}(i g l(N))$ satisfies

$$
\begin{gather*}
\Delta\left(T^{\prime}\right) \subset T^{\prime} \otimes \varepsilon+U_{q, r}(i g l(N)) \otimes T^{\prime}  \tag{3.6.65}\\
{\left[T^{\prime}, T^{\prime}\right] \subseteq T \cap I U=T^{\prime}} \tag{3.6.66}
\end{gather*}
$$

indeed $U_{q, r}(i g l(N))$ is a Hopf subalgebra of $U_{q, r}(g l(N+1))$. Also condition (2.3.3) is fulfilled since $T^{\prime}$ generates $U_{q, r}(\operatorname{igl}(N))$ in the same way $T$ generates $U_{q, r}(g l(N+1))$ 80], this is a consequence of the upper and lower triangularity of the $L^{+}$and $L^{-}$ matrices and of the dependence of the diagonal elements of $L^{+}$from the diagonal elements of $L^{-}$. We therefore obtain an $I G L_{q, r}(N)$ bicovariant differential calculus with $q$-Lie algebra generators:

$$
\begin{equation*}
\chi_{b}^{a}, \quad \chi_{b}^{0}, \quad \chi_{0}^{0} . \tag{3.6.67}
\end{equation*}
$$

Since these generators close on the subalgebra $T^{\prime} \subset T$, we have that the structure constants that appear in the $I G L_{q, r}(N)$ Lie algebra are a subset of the structure constants that appear in the $G L_{q, r}(N+1)$ Lie algebra [cf. the text after (3.5.34)].

The exterior differential reads

$$
\begin{equation*}
d a=\left(\chi^{a}{ }_{b} * a\right) \omega_{a}{ }^{b}+\left(\chi^{a}{ }_{0} * a\right) \omega_{a}{ }^{0}+\left(\chi_{0}^{0} * a\right) \omega_{0}{ }^{0} ; \tag{3.6.68}
\end{equation*}
$$

where $\omega_{a}{ }^{b}, \omega_{a}{ }^{0}$, and $\omega_{0}{ }^{0}$, following Section 2.3, are the 1 -forms dual to the tangent vectors (3.6.67).

### 3.7 The multiparametric quantum plane as a quantum coset space

In this section we derive the differential calculus on the quantum plane

$$
\begin{equation*}
F u n_{q, r}\left(\frac{I G L(N)}{G L(N)}\right) \tag{3.7.1}
\end{equation*}
$$

i.e. the subalgebra of $\operatorname{IG} L_{q, r}(N)$ generated by the coordinates $x^{a}$. These coordinates satisfy the commutations (3.3.4):

$$
\begin{equation*}
R_{e f}^{a b} x^{e} x^{f}=r x^{b} x^{a} \tag{3.7.2}
\end{equation*}
$$

The main difference with the more conventional approach to the quantum plane is that now the coordinates do not trivially commute with the $G L_{q, r}(N) q$-group elements, but $q$-commute according to relations (3.3.3):

$$
\begin{equation*}
R^{a b}{ }_{e f} T^{e}{ }_{c} x^{f}=\frac{q_{0 c}}{r} x^{b} T^{a}{ }_{c} \tag{3.7.3}
\end{equation*}
$$

From a more mathematical viewpoint the $q$-coset space Fun $_{q, r}(\operatorname{IGL}(N) / G L(N))$ is the algebra $B$ discussed in Theorem 3.3.6 and Note 3.3.5. $B$ is generated by $u$ and $x^{a}$. We then study the subalgebra of $B$ generated only by the elements $x^{a}$. Expression (3.3.70) is the translation in Hopf algebra language of the classical property: $\forall g \in \overline{I S O}(N), \forall h \in S O(N) \quad\{g h\}=\{g\}$, where $\{g\}$ is an element of the coset $I S O(N) / S O(N)$.

Lemma 3.7.1 $\chi_{c}^{b}(a)=0$ when a is a polynomial in $x^{a}$ and $u$ with all monomials containing at least one $x^{a}$. This is easily proved by observing that no tensor exists with the correct index structure. For $s=1$ we can extend this lemma even to $u \cdots u$, since for example

$$
\begin{equation*}
\chi_{c}^{b}(u)=\frac{s-1}{r-r^{-1}} \delta_{c}^{b} \tag{3.7.4}
\end{equation*}
$$

and using the coproduct rule (3.5.25) one finds that $\chi^{b}{ }_{c}(u \cdots u)$ is always proportional to $s-1$.

Theorem 3.7.1 $\chi^{b}{ }_{c} * a=0$ when $a$ is a polynomial in $x^{a}$ and $s=1$.
Proof: we have $\chi^{b}{ }_{c} * a=\left(i d \otimes \chi^{b}{ }_{c}\right)\left(a_{1} \otimes a_{2}\right)=a_{1} \chi^{b}{ }_{c}\left(a_{2}\right)$. (We use the notation $\Delta(a) \equiv a_{1} \otimes a_{2}$ ). Since $a_{2}$ is a polynomial in $x^{a}$ and $u$ (use the coproduct rule (3.3.11)), and $\chi^{b}{ }_{c}$ vanishes on such a polynomial when $s=1$ (previous Lemma), the theorem is proved.

Because of this theorem we will henceforth set $s=1$ : then we can write the exterior derivative of an element of the quantum plane as

$$
\begin{equation*}
d a=\left(\chi_{s} * a\right) V^{s} \tag{3.7.5}
\end{equation*}
$$

(with $\chi_{s} \equiv \chi^{0}{ }_{s}, V^{s} \equiv \omega_{0}{ }^{s}$ ), i.e. only in terms of the "q-vielbein" $V^{s}$. Notice also that $d u=0$.

The action and value of $\chi_{s}$ on the coordinates is easily computed [cf. the definition in (3.5.24)]:

$$
\begin{equation*}
\chi_{s} * x^{a}=-\frac{r}{q_{0 s}} T^{a}{ }_{s}, \quad \chi_{s}\left(x^{a}\right)=-\frac{r}{q_{0 s}} \delta_{s}^{a} \tag{3.7.6}
\end{equation*}
$$

so that the exterior derivative of $x^{a}$ is:

$$
\begin{equation*}
d x^{a}=-\frac{r}{q_{0 s}} T^{a}{ }_{s} V^{s} \tag{3.7.7}
\end{equation*}
$$

and gives the relation between the $q$-vielbein $V^{s}$ and the differentials $d x^{a}$.
Using (3.5.26), the Leibniz rule for the " $q$-partial derivatives" $\chi_{c}$ is given by :

$$
\begin{equation*}
\chi_{c} *(a b)=\left(\chi_{d} * a\right) f_{c}^{d} * b+a \chi_{c} * b \tag{3.7.8}
\end{equation*}
$$

where $f^{d}{ }_{c} \equiv f_{0}{ }^{d 0}{ }_{c}$.
The $x^{a}$ and $V^{b} q$-commute as (cf. (3.5.20)):

$$
\begin{equation*}
V^{a} x^{b}=\left(q_{0 a}\right)^{-1} x^{b} V^{a} \tag{3.7.9}
\end{equation*}
$$

and via eq. (3.7.7) and (3.7.3) we find the $d x^{a}, x^{b}$ commutations:

$$
\begin{equation*}
d x^{a} x^{b}=r^{-1}\left(R^{-1}\right)^{a b}{ }_{e f} x^{f} d x^{e} \tag{3.7.10}
\end{equation*}
$$

After acting on this equation with $d$ we obtain:

$$
\begin{equation*}
d x^{a} \wedge d x^{b}=-r^{-1}\left(R^{-1}\right)^{a b}{ }_{e f} d x^{f} \wedge d x^{e} \tag{3.7.11}
\end{equation*}
$$

which reproduce the known commutations between the differentials of the quantum plane, cf. ref. 48, 50.

The commutations between the partial derivatives are given in eq. (3.5.50).
All the relations of this section are covariant under the $I G L_{q, r}(N)$ action:

$$
\begin{equation*}
x^{a} \longrightarrow T^{a}{ }_{b} \otimes x^{b}+x^{a} \otimes u \tag{3.7.12}
\end{equation*}
$$

and in particular under the $G L_{q, r}(N)$ action $x^{a} \longrightarrow T^{a}{ }_{b} \otimes x^{b}$.
Note 3.7.1 The partial derivatives $\chi_{c}$, and in general all the tangent vectors $\chi$ of this chapter have "flat" indices. To compare them with the partial derivatives discussed in 48], which have "curved" indices, we need to define the operators $\overleftarrow{\partial}_{s}$ :

$$
\begin{equation*}
\overleftarrow{\partial}_{s}(a) \equiv-\frac{q_{0 a}}{r}\left(\chi_{a} * a\right) \kappa\left(T^{a}{ }_{s}\right) \tag{3.7.13}
\end{equation*}
$$

whose value and action on the coordinates is

$$
\begin{equation*}
\overleftarrow{\partial}_{s}\left(x^{a}\right)=\delta_{s}^{a} I \tag{3.7.14}
\end{equation*}
$$

so that

$$
\begin{equation*}
d a=\overleftarrow{\partial}_{s}(a) d x^{s} \tag{3.7.15}
\end{equation*}
$$

which is equation (3.7.5) in "curved" indices [Note: ref. 48] adopts a definition of $\overleftarrow{\partial}_{s}$ such that $\left.d a=d x^{s}\left(\partial_{s}(a)\right)\right]$.

Using the Lie derivarive and the contraction operator defined on the full inhomogeneous quantum group one can also study the Cartan calculus on the quantum plane; this should provide an alternative approach to 52].

The results of this section are applied to the multiparametric quantum plane $I G L_{q r}(2) / G L_{q r}(2)$ at the end of the Table. The usual relations of the uniparametric case [48] are recovered after setting $q=r$.

### 3.8 Table of $I G L_{q, r}(2)$

The quantum group $I G L_{q, r}(2)$ and its differential calculus

Parameters: $q\left(\equiv q_{12}\right), q_{01}, q_{02}, r$
$R$ and $D$-matrices of $G L_{q, r}(2)$ :

$$
R^{a b}{ }_{c d}=\left(\begin{array}{cccc}
r & 0 & 0 & 0 \\
0 & \frac{r}{q} & 0 & 0 \\
0 & r-r^{-1} & \frac{q}{r} & 0 \\
0 & 0 & 0 & r
\end{array}\right), \quad D^{a}{ }_{b}=\left(\begin{array}{cc}
r & 0 \\
0 & r^{3}
\end{array}\right)
$$

$T_{B}^{A}(A, B=0,1,2)$ : fundamental representation of $I G L_{q, r}(2)$

$$
T_{B}^{A}=\left(\begin{array}{ccc}
u & 0 & 0 \\
x^{1} & \alpha & \beta \\
x^{2} & \gamma & \delta
\end{array}\right)
$$

Determinant of $I G L_{q, r}(2)$ and definition of $\xi$

$$
\begin{gathered}
\operatorname{det} T_{B}^{A}=u \operatorname{det} T_{b}^{a}, \quad \text { where } \operatorname{det} T^{a}{ }_{b}=\alpha \delta-\frac{r^{2}}{q} \beta \gamma \\
\xi \operatorname{det} T_{B}^{A}=\operatorname{det} T_{B}^{A} \xi=I
\end{gathered}
$$

Basis elements generating $I G L_{q, r}(2)$

$$
\alpha, \beta, \gamma, \delta, x^{1}, x^{2}, u, \xi
$$

Commutations of the basis elements

$$
\begin{gathered}
\alpha \beta=\frac{r^{2}}{q} \beta \alpha, \quad \alpha \gamma=q \gamma \alpha, \quad \beta \delta=q \delta \beta, \quad \gamma \delta=\frac{r^{2}}{q} \delta \gamma \\
\beta \gamma=\frac{q^{2}}{r^{2}} \gamma \beta, \quad \alpha \delta-\delta \alpha=\frac{r}{q}\left(r-r^{-1}\right) \beta \gamma, \\
\alpha x^{1}=\frac{q_{01}}{r^{2}} x^{1} \alpha, \quad \beta x^{1}=\frac{q_{02}}{r^{2}} x^{1} \beta,
\end{gathered}
$$

$$
\begin{gathered}
\alpha x^{2}=q \frac{q_{01}}{r^{2}} x^{2} \alpha, \quad \beta x^{2}=q \frac{q_{02}}{r^{2}} x^{2} \beta, \\
\gamma x^{1}=\frac{q_{01}}{q} x^{1} \gamma-\frac{r}{q}\left(r-r^{-1}\right) \alpha x^{2}, \quad \delta x^{1}=\frac{q_{02}}{q} x^{1} \delta-\frac{r}{q}\left(r-r^{-1}\right) \beta x^{2}, \\
\gamma x^{2}=\frac{q_{01}}{r^{2}} x^{2} \gamma, \quad \delta x^{2}=\frac{q_{02}}{r^{2}} x^{2} \delta \\
x^{1} x^{2}=q x^{2} x^{1} \\
T^{a}{ }_{b} u=\frac{q_{0 b}}{q_{0 a}} u T^{a}{ }_{b}, \quad x^{a} u=\left(q_{0 a}\right)^{-1} u x^{a} \\
\left(\operatorname{det} T^{A}{ }_{B}\right) T_{B}^{A}=\frac{q_{0 A} q_{1 A} q_{2 A}}{q_{0 B} q_{1 B} q_{2 B}} T_{B}^{A}\left(\operatorname{det} T_{B}^{A}\right), q_{A A} \equiv r, q_{A B} \equiv \frac{r^{2}}{q_{B A}} \\

\end{aligned}
$$

## Chapter 4

## Geometry of the quantum Inhomogeneous Orthogonal and Symplectic Groups $I S O_{q, r}(N)$ and $I S p_{q, r}(N)$

In this chapter we study the inhomogeneous orthogonal and symplectic groups, their universal enveloping algebras and their differential calculi. We tush give a detailed analysis of the geometry of these inhomogeneous groups that are canonically associated (via a quotient procedure) to the orthogonal and symplectic quantum groups studied in (19].

The method used in the previous chapter to obtain $I G L_{q, r}(N)$, is here applied to obtain $I S O_{q, r}(N)$ and $I S p_{q, r}(N)$ and to give an $R$-matrix formulation of these $q$-groups. This method is based on a projection (consistent with respect to the Hopf structure) from the corresponding quantum groups of higher rank $A_{n+1}, B_{n+1}, C_{n+1}, D_{n+1}$.

In general the quantum inhomogeneous groups we analize do contain dilatations. There exists however a subclass of dilatation-free cases for special values of the deformation parameters. The important example of the $q$-Poincaré group is contained in our construction. In particular, we find a dilatation-free $q$-Poincaré group depending on one real parameter $q$.

We next present a detailed study of the universal enveloping algebra of the multiparametric homogeneous orthogonal and symplectic groups and find a suitable set of generators that can be ordered. This will clarify the structure of their inhomogeneous version. The projection procedure used to derive the $I S O_{q, r}(N)\left[I S p_{q, r}(N)\right]$ $q$-groups is then used to find their universal enveloping algebras as Hopf subalgebras of $U_{q, r}(s o(N+2))\left[U_{q, r}(s p(N+2))\right]$. An $R$-matrix formulation and the duality $I S O_{q, r}(N) \leftrightarrow U_{q, r}(i s o(N))\left[I S p_{q, r}(N) \leftrightarrow U_{q, r}(i s p(N))\right]$ are explicitly given.

The quantum Lie algebras of $I S O_{q, r}(N)\left[I S P_{q, r}(N)\right]$ are subspaces (adjoint submodules) of $U_{q, r}(i s o(N))$ [ $\left.U_{q, r}(i s p(N))\right]$, and in the second part of the chapter we study these deformed Lie algebras and their associated differential calculi. This is again done using the projection or quotient structure of $I S O_{q, r}(N)$ and $I S p_{q, r}(N)$. Contrary to the $I G L_{q, r}(N)$ case, only for $r=1$ we have a quantum differential calculus that is a continuous deformation of the commutative one. The necessity of taking $r=1$ is discussed. In Section 4.5 we briefly introduce the multiparametric bicovariant calculus on the homogeneous orthogonal and symplectyc $q$-groups. In Section 4.6 we examine the case $r=1$. We clarify some issues related to the classical limit and see how in this limit some tangent vectors become linearly dependent, thus providing the correct classical dimension of the tangent space. A similar mechanism occurs for the left-invariant 1-forms. In Section 4.7 the bicovariant calculi on $I S O_{q, r=1}(N)\left[I S p_{q, r=1}(N)\right]$ are studied. We first consider a calculus that has one more generator than in the classical case, this generator correspond to the dilatation $u$ of the quantum inhomogeneous group. Then we show how to restrict this calculus to one that has the same numbler of tangent vectors that appear in the classical case. All the quantities relevant to this differential calculus are explicitly constructed. The results are then directly applied to the $q$-Poincaré group $I S O_{q}(3,1)$.

## 4.1 $B_{n}, C_{n}, D_{n}$ multiparametric quantum groups

The $B_{n}, C_{n}, D_{n}$ multiparametric quantum groups are freely generated by the noncommuting matrix elements $T^{a}{ }_{b}$ (fundamental representation) and the identity $I$, modulo the quadratic $R T T$ and $C T T$ relations discussed below. The noncommutativity is controlled by the $R$ matrix:

$$
\begin{equation*}
R^{a b}{ }_{e f} T^{e}{ }_{c} T^{f}{ }_{d}=T^{b}{ }_{f} T^{a}{ }_{e} R^{e f}{ }_{c d} \tag{4.1.1}
\end{equation*}
$$

which satisfies the quantum Yang-Baxter equation (2.1.69)

$$
\begin{equation*}
R_{a_{2} b_{2}}^{a_{1} b_{1}} R_{a_{3} c_{2}}^{a_{2} c_{1}} R_{b_{3} c_{3}}^{b_{2} c_{2}}=R_{b_{2} c_{2}}^{b_{1} c_{1}} R_{a_{2} c_{3}}^{a_{1} c_{2}} R_{a_{3} b_{3}}^{a_{2} b_{2}}, \tag{4.1.2}
\end{equation*}
$$

a sufficient condition for the consistency of the " $R T T$ " relations (4.1.1). The $R$ matrix components $R^{a b}{ }_{c d}$ depend continuously on a (in general complex) set of parameters $q_{a b}, r$. For $q_{a b}=r$ we recover the uniparametric $q$-groups of ref. [19. Then $q_{a b} \rightarrow 1, r \rightarrow 1$ is the classical limit for which $R^{a b}{ }_{c d} \rightarrow \delta_{c}^{a} \delta_{d}^{b}$ : the matrix entries $T^{a}{ }_{b}$ commute and become the usual entries of the fundamental representation. The multiparametric $R$ matrices for the $A, B, C, D$ series can be found in (74] (other ref.s on multiparametric $q$-groups are given in [75, 76]). For the $B, C, D$ case they read:

$$
\begin{align*}
R^{a b}{ }_{c d}= & \delta_{c}^{a} \delta_{d}^{b}\left[\frac{r}{q_{a b}}+(r-1) \delta^{a b}+\left(r^{-1}-1\right) \delta^{a b^{\prime}}\right]\left(1-\delta^{a n_{2}}\right)+\delta_{n_{2}}^{a} \delta_{n_{2}}^{b} \delta_{c}^{n_{2}} \delta_{d}^{n_{2}} \\
& +\left(r-r^{-1}\right)\left[\theta^{a b} \delta_{c}^{b} \delta_{d}^{a}-\epsilon_{a} \epsilon_{c} \theta^{a c} r^{\rho_{a}-\rho_{c}} \delta^{a^{\prime} b} \delta_{c^{\prime} d}\right] \tag{4.1.3}
\end{align*}
$$

where $\theta^{a b}=1$ for $a>b$ and $\theta^{a b}=0$ for $a\left\langle b\right.$; we define $n_{2} \equiv \frac{N+1}{2}$ and primed indices as $a^{\prime} \equiv N+1-a$. The indices run on $N$ values ( $N=$ dimension of the fundamental representation $T^{a}{ }_{b}$ ), with $N=2 n+1$ for $B_{n}[S O(2 n+1)], N=2 n$ for $C_{n}[S p(2 n)]$, $D_{n}[S O(2 n)]$. The terms with the index $n_{2}$ are present only for the $B_{n}$ series. The $\epsilon_{a}$ and $\rho_{a}$ vectors are given by:

$$
\begin{gather*}
\epsilon_{a}= \begin{cases}+1 & \text { for } B_{n}, D_{n}, \\
+1 & \text { for } C_{n} \text { and } a<n, \\
-1 & \text { for } C_{n} \text { and } a>n .\end{cases}  \tag{4.1.4}\\
\left(\rho_{1}, \ldots \rho_{N}\right)= \begin{cases}\left(\frac{N}{2}-1, \frac{N}{2}-2, \ldots, \frac{1}{2}, 0,-\frac{1}{2}, \ldots,-\frac{N}{2}+1\right) & \text { for } B_{n} \\
\left(\frac{N}{2}, \frac{N}{2}-1, \ldots 1,-1, \ldots,-\frac{N}{2}\right) & \text { for } C_{n} \\
\left(\frac{N}{2}-1, \frac{N}{2}-2, \ldots, 1,0,-1, \ldots,-\frac{N}{2}+1\right) & \text { for } D_{n}\end{cases} \tag{4.1.5}
\end{gather*}
$$

Moreover the following relations reduce the number of independent $q_{a b}$ parameters (75), (74):

$$
\begin{gather*}
q_{a a}=r, \quad q_{b a}=\frac{r^{2}}{q_{a b}}  \tag{4.1.6}\\
q_{a b}=\frac{r^{2}}{q_{a b^{\prime}}}=\frac{r^{2}}{q_{a^{\prime} b}}=q_{a^{\prime} b^{\prime}} \tag{4.1.7}
\end{gather*}
$$

where (4.1.7) also implies $q_{a a^{\prime}}=r$. Therefore the $q_{a b}$ with $a<b<\frac{N}{2}$ give all the $q$ 's.

It is useful to list the nonzero complex components of the $R$ matrix (no sum on repeated indices):

$$
\begin{array}{ll}
R^{a a}{ }_{a a}=r, & a \neq n_{2} \\
R^{a a^{\prime}}{ }_{a a^{\prime}}=r^{-1}, & a \neq n_{2} \\
R^{n_{2} n_{2}}{ }_{n_{2} n_{2}}=1 & \\
R^{a b}{ }_{a b}=\frac{r}{q_{a b}}, & a \neq b, a^{\prime} \neq b  \tag{4.1.8}\\
R^{a b}{ }_{b}=r-r^{-1}, & a>b, a^{\prime} \neq b \\
R^{a a^{\prime}}{ }^{\prime}=\left(r-r^{-1}\right)\left(1-\epsilon r^{\rho_{a}-\rho_{a^{\prime}}}\right)=\left(r-r^{-1}\right)\left[1-C^{a^{\prime} a} C_{a^{\prime} a}\right], \quad a>a^{\prime} \\
R^{a a^{\prime}}{ }_{b b^{\prime}}=-\left(r-r^{-1}\right) \epsilon_{a} \epsilon_{b} r^{r_{a}-\rho_{b}}=-\left(r-r^{-1}\right) C^{a^{\prime} a} C_{b b^{\prime}}, \quad a>b, a^{\prime} \neq b
\end{array}
$$

where $\epsilon=\epsilon_{a} \epsilon_{a^{\prime}}$, i.e. $\epsilon=1$ for $B_{n}, D_{n}$ and $\epsilon=-1$ for $C_{n}$.
Note 4.1.1 The matrix $R$ is lower triangular, that is $R^{a b}{ }_{c d}=0$ if $[a=c$ and $b<d]$ or $a<c$, and has the following properties:

$$
\begin{equation*}
R_{q, r}^{-1}=R_{q^{-1}, r^{-1}} ; \quad\left(R_{q, r}\right)^{a b}{ }_{c d}=\left(R_{q, r}\right)^{c^{\prime} d^{\prime}}{ }_{a^{\prime} b^{\prime}} ; \quad\left(R_{q, r}\right)^{a b}{ }_{c d}=\left(R_{p, r}\right)^{d c}{ }_{b a} \tag{4.1.9}
\end{equation*}
$$

where $q, r$ denote the set of parameters $q_{a b}, r$, and $p_{a b} \equiv q_{b a}$.

The inverse $R^{-1}$ is defined by $\left(R^{-1}\right)^{a b}{ }_{c d} R^{c d}{ }_{e f}=\delta_{e}^{a} \delta_{f}^{b}=R^{a b}{ }_{c d}\left(R^{-1}\right)^{c d}{ }_{e f}$. Eq. (4.1.9) implies that for $|q|=|r|=1, \bar{R}=R^{-1}$.

Note 4.1.2 Let $R_{r}$ be the uniparametric $R$ matrix for the $B, C, D$ q-groups. The multiparametric $R_{q, r}$ matrix is obtained from $R_{r}$ via the transformation 75, 74)

$$
\begin{equation*}
R_{q, r}=F^{-1} R_{r} F^{-1} \tag{4.1.10}
\end{equation*}
$$

where $\left(F^{-1}\right)^{a b}{ }_{c d}$ is a diagonal matrix in the index couples $a b, c d$ :

$$
\begin{equation*}
F^{-1} \equiv \operatorname{diag}\left(\sqrt{\frac{r}{q_{11}}}, \sqrt{\frac{r}{q_{12}}}, \ldots \sqrt{\frac{r}{q_{N N}}}\right) \tag{4.1.11}
\end{equation*}
$$

and $a b, c d$ are ordered as in the $R$ matrix. Since $\sqrt{\frac{r}{q_{a b}}}=\left(\sqrt{\frac{r}{q_{b a}}}\right)^{-1}$ and $q_{a a^{\prime}}=q_{b b^{\prime}}$, the non diagonal elements of $R_{q, r}$ coincide with those of $R_{r}$. The matrix $F$ satisfies $F_{12} F_{21}=1$ i.e. $F^{a b}{ }_{e f} F^{f e}{ }_{d c}=\delta_{c}^{a} \delta_{d}^{b}$, the quantum Yang-Baxter equation $F_{12} F_{13} F_{23}=$ $F_{23} F_{13} F_{12}$ and the relations $\left(R_{r}\right)_{12} F_{13} F_{23}=F_{23} F_{13}\left(R_{r}\right)_{12}$. Note that for $r=1$ the multiparametric $R$ matrix reduces to $R=F^{-2}$.

Note 4.1.3 Let $\hat{R}$ the matrix defined by $\hat{R}^{a b}{ }_{c d} \equiv R^{b a}{ }_{c d}$. Then the multiparametric $\hat{R}_{q, r}$ is obtained from $\hat{R}_{r}$ via the similarity transformation

$$
\begin{equation*}
\hat{R}_{q, r}=F \hat{R}_{r} F^{-1} \tag{4.1.12}
\end{equation*}
$$

The characteristic equation and the projector decomposition of $\hat{R}_{q, r}$ are therefore the same as in the uniparametric case:

$$
\begin{gather*}
(\hat{R}-r I)\left(\hat{R}+r^{-1} I\right)\left(\hat{R}-\epsilon r^{\epsilon-N} I\right)=0  \tag{4.1.13}\\
\hat{R}-\hat{R}^{-1}=\left(r-r^{-1}\right)(I-K)  \tag{4.1.14}\\
\hat{R}=r P_{S}-r^{-1} P_{A}+\epsilon r^{\epsilon-N} P_{0} \tag{4.1.15}
\end{gather*}
$$

with

$$
\begin{align*}
& P_{S}=\frac{1}{r+r^{-1}}\left[\hat{R}+r^{-1} I-\left(r^{-1}+\epsilon r^{\epsilon-N}\right) P_{0}\right] \\
& P_{A}=\frac{1}{r+r^{-1}}\left[-\hat{R}+r I-\left(r-\epsilon r^{\epsilon-N}\right) P_{0}\right] \\
& P_{0}=Q_{N}(r) K  \tag{4.1.16}\\
& Q_{N}(r) \equiv\left(C_{a b} C^{a b}\right)^{-1}=\frac{1-r^{-2}}{\left(1-\epsilon r^{-N-1+\epsilon)\left(1+\epsilon r^{N-1-\epsilon}\right)}\right.}, \quad K_{c d}^{a b}=C^{a b} C_{c d} \\
& I=P_{S}+P_{A}+P_{0}
\end{align*}
$$

To prove (4.1.14) in the multiparametric case note that $F_{12} K_{12} F_{12}^{-1}=K_{12}$. Orthogonality (and symplecticity) conditions can be imposed on the elements $T^{a}{ }_{b}$, consistently with the $R T T$ relations (4.1.1):

$$
\begin{equation*}
C^{b c} T_{b}^{a} T_{c}^{d}=C^{a d} I, \quad C_{a c} T^{a}{ }_{b} T^{c}{ }_{d}=C_{b d} I \tag{4.1.17}
\end{equation*}
$$

where the (antidiagonal) metric is :

$$
\begin{equation*}
C_{a b}=\epsilon_{a} r^{-\rho_{a}} \delta_{a b^{\prime}} \tag{4.1.18}
\end{equation*}
$$

and its inverse $C^{a b}$ satisfies $C^{a b} C_{b c}=\delta_{c}^{a}=C_{c b} C^{b a}$. We see that for the orthogonal series, the matrix elements of the metric and the inverse metric coincide, while for the symplectic series there is a change of sign: $C^{a b}=\epsilon C_{a b}$. Notice also the symmetries $C_{a b}=C_{b^{\prime} a^{\prime}}$ and $C_{b a}(r)=\epsilon C_{a b}\left(r^{-1}\right)$.

The consistency of (4.1.17) with the $R T T$ relations is due to the identities:

$$
\begin{align*}
& C_{a b} \hat{R}_{d e}^{b c}=\left(\hat{R}^{-1}\right)^{c f}{ }_{a d} C_{f e},  \tag{4.1.19}\\
& \hat{R}^{b c}{ }_{d e} C^{e a}=C^{b f}\left(\hat{R}^{-1}\right)^{c a}{ }_{f d} . \tag{4.1.20}
\end{align*}
$$

These identities hold also for $\hat{R} \rightarrow \hat{R}^{-1}$ and can be proved using the explicit expression (4.1.8) of $R$.

We also note the useful relations, easily deduced from (4.1.15):

$$
\begin{equation*}
C_{a b} \hat{R}_{c d}^{a b}=\epsilon r^{\epsilon-N} C_{c d}, \quad C^{c d} \hat{R}_{c d}^{a b}=\epsilon r^{\epsilon-N} C^{a b} \tag{4.1.21}
\end{equation*}
$$

and, from (4.1.8),

$$
\begin{equation*}
R_{c c^{\prime}}^{a b}=-\left(r-r^{-1}\right) C^{b a} C_{c c^{\prime}}, R_{c d}^{a a^{\prime}}=-\left(r-r^{-1}\right) C^{a^{\prime} a} C_{c d} \text { for } a>c, a \neq c^{\prime} \tag{4.1.22}
\end{equation*}
$$

Notice also that $\kappa^{2}\left(T^{a}{ }_{b}\right)=D_{e}^{a} T^{e}{ }_{f} D^{-1}{ }_{b}^{f}$ where $D_{e}^{a}=C^{a s} C_{e s}$ and its inverse $D^{-1{ }_{b}^{f}}=$ $C^{s f} C_{s b}$ are diagonal.

The co-structures of the $B_{n}, C_{n}, D_{n}$ multiparametric quantum groups have the same form as in the uniparametric case: the coproduct $\Delta$, the counit $\varepsilon$ and the coinverse $\kappa$ are given by

$$
\begin{align*}
& \Delta\left(T^{a}{ }_{b}\right)=T^{a}{ }_{b} \otimes T^{b}{ }_{c}  \tag{4.1.23}\\
& \varepsilon\left(T^{a}{ }_{b}\right)=\delta_{b}^{a}  \tag{4.1.24}\\
& \kappa\left(T^{a}{ }_{b}\right)=C^{a c} T^{d}{ }_{c} C_{d b} \tag{4.1.25}
\end{align*}
$$

Note 4.1.4 Using formula (4.1.3) or (4.1.8), we find that the $R^{A B}{ }_{C D}$ matrix for the $S O_{q, r}(N+2)$ and $S p_{q, r}(N+2)$ quantum groups can be decomposed in terms of $S O_{q, r}(N)$ and $S p_{q, r}(N)$ quantities as follows (splitting the index A as $\mathrm{A}=(\circ, a, \bullet)$,
with $a=1, \ldots N)$ :

$$
R^{A B}{ }_{C D}=\left(\begin{array}{cccccccccc} 
& \circ \circ & \circ \bullet & \bullet \circ & \bullet \bullet & \circ d & \bullet d & c \circ & c \bullet & c d  \tag{4.1.26}\\
\circ & r & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\circ \bullet & 0 & r^{-1} & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\bullet \circ & 0 & f(r) & r^{-1} & 0 & 0 & 0 & 0 & 0 & -\epsilon C_{c d} \lambda r^{-\rho} \\
\bullet \bullet & 0 & 0 & 0 & r & 0 & 0 & 0 & 0 & 0 \\
\circ b & 0 & 0 & 0 & 0 & \frac{r}{q_{\circ}} \delta_{d}^{b} & 0 & 0 & 0 & 0 \\
\bullet b & 0 & 0 & 0 & 0 & 0 & \frac{r}{q_{\bullet}} \delta_{d}^{b} & 0 & \lambda \delta_{c}^{b} & 0 \\
a \circ & 0 & 0 & 0 & 0 & \lambda \delta_{d}^{a} & 0 & \frac{r}{q_{a o}} \delta_{c}^{a} & 0 & 0 \\
a \bullet & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \frac{r}{q_{a}} \delta_{c}^{a} & 0 \\
a b & 0 & -C^{b a} \lambda r^{-\rho} & 0 & 0 & 0 & 0 & 0 & 0 & R^{a b}{ }_{c d}
\end{array}\right)
$$

where $R^{a b}{ }_{c d}$ is the $R$ matrix for $S O_{q, r}(N)$ or $S p_{q, r}(N), C_{a b}$ is the corresponding metric, $\lambda \equiv r-r^{-1}, \rho=\frac{N+1-\epsilon}{2}\left(\epsilon r^{\rho}=C_{\bullet \circ}\right)$ and $f(r) \equiv \lambda\left(1-\epsilon r^{-2 \rho}\right)$. The sign $\epsilon$ has been defined after eq. s (4.1.8).

### 4.1.1 Real forms: $S O_{q, r}(N, \mathbf{R}), S O_{q, r}(N-1,1), S O_{q, r}(n, n)$, $S O_{q, r}(n+1, n-1), S O_{q, r}(n+1, n)$

Following [19], a conjugation -i.e. an algebra antiautomorphism, coalgebra automorphism and involution, satisfying $\kappa\left(\kappa\left(T^{*}\right)^{*}\right)=T$ - can be defined

- trivially as $T^{*}=T$. Compatibility with the $R T T$ relations (1.2.1) requires $\bar{R}_{q, r}=R_{q, r}^{-1}=R_{q^{-1}, r^{-1}}$, i.e. $|q|=|r|=1$. Then the CTT relations are invariant under $*$-conjugation. The corresponding real forms are $S O_{q, r}(n, n ; R), S O_{q, r}(n+$ $1, n ; R)$ (for N even and odd respectively) and $S p_{q, r}(2 n ; R)$. A conjugation on the quantum orthogonal (symplectic) plane (defined respectively by $P_{A}^{a b}{ }_{c d} x^{c} x^{d}=0$ and $x^{a} x^{b}=r^{-1} R_{c d}^{a b} x^{c} x^{d}$ ) that is compatible with the natural coaction $\delta$ of the $q$-group on the $q$-plane: $x^{a} \rightarrow T^{a}{ }_{b} \otimes x^{b}$ is given by $\left(x^{a}\right)^{*}=x^{a}$, indeed we have $\delta\left(x^{*}\right)=T^{*} \otimes x^{*} \equiv \delta^{*}(x)$.
- via the metric as $T^{\star}=(\kappa(T))^{t}$ i.e. $T^{\star}=C^{t} T C^{t}$. The condition on $R$ is $\bar{R}^{a b}{ }_{c d}=R^{d c}{ }_{b a}$, which happens for $q_{a b} \bar{q}_{a b}=r^{2}, r \in \mathbf{R}$. Again the $C T T$ relations are $\star$-invariant. The metric on a "real" basis has compact signature $(+,+, \ldots+)$ so that the real form is $S O_{q, r}(N ; R)$. The conjugation on the quantum orthogonal plane compatible with the coaction $x^{a} \rightarrow T^{a}{ }_{b} \otimes x^{b}$ is: $\left(x^{a}\right)^{\star}=C_{b a} x^{b}$, indeed $\delta\left(x^{\star}\right)=\delta^{\star}(x)$.

We now introduce two other conjugations that give the real forms $S O_{q, r}(N-1,1)$, $S O_{q, r}(n+1, n-1), S O_{q, r}(n+1, n)$. The real form $S O_{q, r}(n+1, n-1)$ has been found in [78]; the $*$-conjugation on the $T$ matrices that defines the real form $S O_{q, r}(2 n-1,1)$ appears here for the first time. Our study of real forms is based on the RTT relations and is complementary to the $\mathcal{U}_{q}(g) *$-structure classification of Twietmeyer [72], however, there, $g$ is an arbitrary semisimple Lie algebra. In [71] we explicitly
construct all $*$-structures of orthogonal quantum groups using the $R T T$ formalism, the result agrees with [72]. Other approaches to real forms can be found in [73].

In order to describe the $S O_{q, r}(N-1,1), S O_{q, r}(n+1, n-1), S O_{q, r}(n+1, n)$ conjugations we first notice that if we have an involution $\sharp$ that is a Hopf algebra automorphism (algebra and coalgebra morphism compatible with the antipode: $\left.\kappa\left(a^{\sharp}\right)=[\kappa(a)]^{\sharp}\right)$ and that commutes with a conjugation $*$, then the composition of these two involutions: ${ }^{* \sharp} \equiv \sharp \circ *=* \circ \sharp$ is again a conjugation. We now find an involution $\sharp$ that comutes with $*$ and $\star$ as defined above.

Define the map $\sharp$ on the generators as:

$$
\begin{equation*}
T^{\sharp}=\mathcal{D} T \mathcal{D}^{-1} \quad \text { i.e. } \quad\left(T^{a}{ }_{b}\right)^{\sharp}=\mathcal{D}^{a}{ }_{e} T^{e}{ }_{f} \mathcal{D}^{f}{ }_{b}{ }^{-1} \tag{4.1.27}
\end{equation*}
$$

and extend it by linearity and multiplicativity to all $S O_{q, r}(N)$. The entries of the $N$-dimensional $\mathcal{D}$ matrix are

$$
\mathcal{D}=\left(\begin{array}{ccccccccc}
1 & & & & & & &  \tag{4.1.28}\\
& \ldots & & & & & & \\
& & 1 & & & & & \\
& & & 0 & 1 & & & \\
& & & 1 & 0 & & & \\
& & & & & 1 & & \\
& & & & & & \cdots & \\
& & & & & \cdots & 1
\end{array}\right), \quad \mathcal{D}=\left(\begin{array}{ccccccc}
1 & & & & & & \\
& \ldots & & & & & \\
& & 1 & & & & \\
& & & -1 & & & \\
& & & & 1 & & \\
& & & & & \cdots & \\
& & & & & & \\
& & \text { for } N \text { even } N \text { odd } & & &
\end{array}\right)
$$

In the $N=2 n$ case the $\mathcal{D}$ matrix exchanges the index $n$ with the index $n+1$, in the $N=2 n+1$ case $\mathcal{D}$ change the sign of the entries of the $T$ matrix as many times as the index $n_{2}=(N+1) / 2$ appears. Since $\mathcal{D}^{2}=1$ we immediately see that $\sharp$ is an involution.

We now prove that $\sharp$ is compatible with the algebra structure, i.e. it is compatible with the $R T T$ and $C T T$ relations; in the $N=2 n$ case this is true if $q_{a b}=r$ when at least one of the indices $a, b$ is equal to $n$ or $n+1$.

Use relation (4.1.8) and, if $N=2 n$, the above restriction on the $q_{a b}$ parameters to prove that

$$
\begin{equation*}
\mathcal{D}_{1} \mathcal{D}_{2} R \mathcal{D}_{1} \mathcal{D}_{2}=R \tag{4.1.29}
\end{equation*}
$$

The compatibility with the $R T T$ relations is then esily seen to hold. [Hint: multiply $\left(R_{12} T_{1} T_{2}\right)^{\sharp}=\left(T_{2} T_{1} R_{12}\right)^{\sharp}$ by $\mathcal{D}_{1} \mathcal{D}_{2}$ from the left and from the right and use $\mathcal{D}^{2}=\mathbf{1}$ to prove the equivalence with $R_{12} T_{1} T_{2}=T_{2} T_{1} R_{12}$ ]. Similarly the compatibility of $\sharp$ with the orthogonality relations (4.1.17), that we rewite in matrix notation as:

$$
\begin{equation*}
T C T^{t}=C I, \quad T^{t} C T=C I \tag{4.1.30}
\end{equation*}
$$

is due to $\mathcal{D}^{2}=1, \mathcal{D}^{t}=\mathcal{D}$ and the commutativity of the $C$ matrix with the $\mathcal{D}$ matrix:

$$
\begin{equation*}
\mathcal{D} C \mathcal{D}=C \tag{4.1.31}
\end{equation*}
$$

For example we have: $\left(T C T^{t}\right)^{\sharp}=T^{\sharp} C\left(T^{t}\right)^{\sharp}=\mathcal{D} T \mathcal{D} C \mathcal{D} T^{t} \mathcal{D}=\mathcal{D}\left(T C T^{t}\right) \mathcal{D}$ and using $\mathcal{D}^{2}=1$ and again (4.1.31) we conclude that $\left(T C T^{t}\right)^{\sharp}=C I$ is equivalent to $T C T^{t}=C I$.

Next we prove that $\sharp$ is compatible with the coalgebra structure. Compatibility with the coproduct is trivial, compatibility with the antipode is easily verified:

$$
\begin{equation*}
\kappa\left(T^{\sharp}\right)=\kappa(\mathcal{D} T \mathcal{D})=\mathcal{D} \kappa(T) \mathcal{D}=\mathcal{D} C T^{t} C \mathcal{D}=C \mathcal{D} T^{t} \mathcal{D} C=[\kappa(T)]^{\sharp} . \tag{4.1.32}
\end{equation*}
$$

We now show that the two conjugations defined at the beginning of this subsection commutes with $\sharp$. For the second conjugation, defined by $T^{\star}=[\kappa(T)]^{t}=C^{t} T C^{t}$, we have, since $\overline{\mathcal{D}}=\mathcal{D}$ :

$$
\begin{align*}
\left(T^{\sharp}\right)^{\star} & =(\mathcal{D} T \mathcal{D})^{\star}=\mathcal{D} T^{\star} \mathcal{D}=\mathcal{D}[\kappa(T)]^{t} \mathcal{D} \\
& =\mathcal{D} C^{t} T C^{t} \mathcal{D}=C^{t} \mathcal{D} T \mathcal{D} C^{t}=\left(C^{t} T C^{t}\right)^{\sharp}=\left([\kappa(T)]^{t}\right)^{\sharp}  \tag{4.1.33}\\
& =\left(T^{\star}\right)^{\sharp}
\end{align*}
$$

The two maps $\star$ and $\sharp$ not only commute when applied to the $T^{a}{ }_{b}$ matrix entries, they also commute when applied to any element of the $q$-group because they are respectively multiplicative and antimultiplicative. The proof that $\sharp \circ *=* \circ \sharp$ for the first conjugation, defined by $T^{*}=T$, is straighforward.

We restate the above results as a theorem:
Theorem 4.1.1 The map $\sharp$ is an automorphism and an involution of the quantum group $S O_{q, r}(N)$; in the $N=2 n$ case this holds with the restriction $q_{a b}=r$ when at least one of the indices $a, b$ is equal to $n$ or $n+1$. The compositions ${ }^{* \sharp} \equiv \sharp \circ *$ and ${ }^{\star} \equiv \sharp \circ \star$ of the conjugations $*$ and $\star$ with the automorphism $\sharp$ is again a conjugation. The restrictions on the parameters $r, q_{a b}$ are obtained adding to the constraint imposed by $*$ ( $\star$ respectively) the constaints imposed by $\sharp$.

Associated to ${ }^{* \sharp}$ and ${ }^{\star^{\sharp}}$ we have the conjugations that act on the quantum orthogonal plane and are compatible with the coaction $x^{a} \rightarrow T^{a}{ }_{b} \otimes x^{b}$. These conjugations respectively are: $\left(x^{a}\right)^{*^{\sharp}}=\left(x^{a}\right)^{\sharp}$ and $\left(x^{a}\right)^{\star^{\sharp}}=C_{b a} \mathcal{D}^{b}{ }_{e} x^{e}$.

We now study the real forms related to the ${ }^{*^{\sharp}}$ and ${ }^{*^{\sharp}}$ conjugations.

- The conjugation ${ }^{* \sharp}$ for the $N$-dimensional orthogonal quantum groups with $N$ odd gives the real form $S O_{q, r}(n, n+1)$.
- The conjugation ${ }^{* \sharp}$ for the $N$-dimensional orthogonal quantum goups with $N$ even has been studied (in the uniparametric case) in [78], it gives the real form $S O_{q, r}(n+1, n-1 ; R)$ and in particular the quantum Lorentz group $S O_{r}(3,1)$ with $|r|=1$. For an explicit proof see formula (5.2.105).

If we require ${ }^{*^{\#}}$ to be a conjugaton but do not require $\#$ to be an automorphism and $*$ to be a conjugation, we can partially relax the constraints on the $r, q$
parameters. Compatibility of *" with the $R T T$ relations is indeed easily seen to require

$$
\begin{equation*}
(\bar{R})_{n \leftrightarrow n+1}=R^{-1}, \quad \text { i.e. } \quad \mathcal{D}_{1} \mathcal{D}_{2} R_{12} \mathcal{D}_{1} \mathcal{D}_{2}=\bar{R}_{12}^{-1} \tag{4.1.34}
\end{equation*}
$$

which implies
i) $\left|q_{a b}\right|=|r|=1$ for $a$ and $b$ both different from $n$ or $n+1$;
ii) $q_{a b} / r \in \mathbf{R}$ when at least one of the indices $a, b$ is equal to $n$ or $n+1$.

In the sequel we will denote simply by $*$ this conjugation. As discussed in ref.s [14, 67] and later in this chapter we will need this conjugation to obtain the inhomogeneous Lorentz group $I S O_{q, r}(3,1 ; R)$.

- The conjugation ${ }^{\star}$ for $N=2 n+1$ gives the real form $S O(2 n, 1)$ and has been introduced in (19.
- The conjugation ${ }^{\star}$ for $N=2 n$ as far as we know is not known in the literature, it gives the real form $S O_{q, r}(2 n-1,1)$. In particular we obtain another quantum Lorentz group $S O_{r}(3,1)$, notice that here $r \in \mathbf{R}$.

### 4.2 The quantum inhomogeneous groups $I S O_{q, r}(N)$ and $I S p_{q, r}(N)$

Following the projection procedure described in Section 3.3 we here introduce the quantum inhomogeneous groups $I S O_{q, r}(N)$ and $I S p_{q, r}(N)$ and give an $R$-matrix formulation. The $I S O_{q, r}(N)$ quantum group has been independently studied without an $R$-matrix formulation- in the first reference of [65]. The structure of $I S p_{q, r}(N)$ cannot be derived from $S p_{q, r}(N)$ and the symplectic $q$-plane relations as is the case for $I S O_{q, r}(N)$, however it can be easily defined via the projection procedure. $I S p_{q, r}(N)$ and its $R$-matrix formualtion where first introduced in [67].

We define $I S O_{q, r}(N)$ and $I S p_{q, r}(N)$ as the quotients:

$$
\begin{equation*}
I S O_{q, r}(N) \equiv \frac{S O_{q, r}(N+2)}{H}, \quad I S p_{q, r}(N) \equiv \frac{S p_{q, r}(N+2)}{H} \tag{4.2.1}
\end{equation*}
$$

where $H$ is the Hopf ideal in $S O_{q, r}(N+2)$ or $S p_{q, r}(N+2)$ of all sums of monomials containing at least an element of the kind $T^{a}{ }_{o}, T^{\bullet}{ }_{b}, T^{\bullet}{ }^{\circ}$. The Hopf structure of the groups in the numerators of (4.2.1) is naturally inherited by the quotient groups.

We introduce the following convenient notations: $\mathcal{T}$ stands for $T^{a}{ }_{o}, T^{\bullet}{ }_{b}$ or $T^{\bullet}{ }_{0}$, $S_{q, r}(N+2)$ stands for either $S O_{q, r}(N+2)$ or $S p_{q, r}(N+2)$, and we indicate by $\Delta_{N+2}$, $\varepsilon_{N+2}$ and $\kappa_{N+2}$ the corresponding co-structures.

We denote by $P$ the canonical projection

$$
\begin{equation*}
P: \quad S_{q, r}(N+2) \longrightarrow S_{q, r}(N+2) / H \tag{4.2.2}
\end{equation*}
$$

It is a Hopf algebra epimorphism because $H=\operatorname{Ker}(P)$ is a Hopf ideal. [The proof is as in Theorem 3.3.1, just use $\mathcal{T}$ instead of $T^{0}{ }_{b}$. In order to show that $\kappa_{N+2}(H) \subseteq H$, notice that $\kappa_{N+2}(\mathcal{T}) \propto \mathcal{T}$ and therefore, $\forall h \in H, \kappa_{N+2}(h)=$ $\left.\kappa_{N+2}(b \mathcal{T} c)=\kappa_{N+2}(c) \kappa_{N+2}(\mathcal{T}) \kappa_{N+2}(b) \in H\right]$. Then any element of $S_{q, r}(N+2) / H$ is of the form $P(a)$ and the Hopf algebra structure is given by:

$$
\begin{gather*}
P(a)+P(b) \equiv P(a+b) ; \quad P(a) P(b) \equiv P(a b) ; \quad \mu P(a) \equiv P(\mu a), \quad \mu \in \mathbf{C}(4.2 .  \tag{4.2.3}\\
\Delta(P(a)) \equiv(P \otimes P) \Delta_{N+2}(a) ; \quad \varepsilon(P(a)) \equiv \varepsilon_{N+2}(a) ; \quad \kappa(P(a)) \equiv P\left(\kappa_{N+2}(a)\right) . \tag{4.2.4}
\end{gather*}
$$

We can also give an $R$-matrix formulation of the inhomogeneous $I S O_{q, r}(N)$ and $I S p_{q, r}(N)$ q-groups. Indeed recall that $S_{q, r}(N+2)$ is the Hopf algebra freely generated by the non-commuting matrix elements $T^{A}{ }_{B}$ modulo the ideal generated by the $R T T$ and $C T T$ relations [ $R$ matrix and metric $C$ of $S_{q, r}(N+2)$ ]. This can be expressed as:

$$
\begin{equation*}
S_{q, r}(N+2) \equiv \frac{<T^{A}{ }_{B}>}{[R T T, C T T]} \tag{4.2.5}
\end{equation*}
$$

Therefore we have (recall that $H \equiv\left[T^{a}{ }_{o}, T^{\bullet}{ }_{b}, T^{\bullet}{ }_{0}\right] \equiv[\mathcal{T}]$ ) :

$$
\begin{equation*}
I S_{q, r}(N)=\frac{S_{q, r}(N+2)}{[\mathcal{T}]}=\frac{<T^{A}{ }_{B}>/[R T T, C T T]}{[\mathcal{T}]}=\frac{<T^{A}{ }_{B}>}{[R T T, C T T, \mathcal{T}]} \tag{4.2.6}
\end{equation*}
$$

so that we have shown the following:
Theorem 4.2.1 The quantum inhomogeneous groups $I S O_{q, r}(N)$ and $I S p_{q, r}(N)$ are freely generated by the non-commuting matrix elements $T_{B}^{A}[\mathrm{~A}=(\circ, a, \bullet)$, with $a=1, \ldots N)]$ and the identity $I$, modulo the relations:

$$
\begin{equation*}
T^{a}{ }_{\circ}=T_{b}^{\bullet}=T^{\bullet}{ }_{\circ}=0, \tag{4.2.7}
\end{equation*}
$$

the $R T T$ relations

$$
\begin{equation*}
R_{E F}^{A B} T_{C}^{E} T_{D}^{F}=T_{F}^{B} T_{E}^{A} R_{C D}^{E F} \tag{4.2.8}
\end{equation*}
$$

and the orthogonality (symplecticity) relations

$$
\begin{equation*}
C^{B C} T_{B}^{A} T_{C}^{D}=C^{A D}, \quad C_{A C} T_{B}^{A} T_{D}^{C}=C_{B D} \tag{4.2.9}
\end{equation*}
$$

The co-structures of $I S O_{q, r}(N)$ and $I S p_{q, r}(N)$ are simply given by:

$$
\begin{equation*}
\Delta\left(T_{B}^{A}\right)=T_{C}^{A} \otimes T_{B}^{C}, \quad \kappa\left(T_{B}^{A}\right)=C^{A C} T_{C}^{D} C_{D B}, \quad \varepsilon\left(T_{B}^{A}\right)=\delta_{B}^{A} . \tag{4.2.10}
\end{equation*}
$$

After decomposing the indices $\mathrm{A}=(\circ, a, \bullet)$, and defining:

$$
\begin{equation*}
u \equiv T_{\circ}^{\circ}, \quad v \equiv T_{\bullet}^{\bullet}, \quad z \equiv T_{\bullet}^{\circ}, \quad x^{a} \equiv T^{a} \bullet, \quad y_{a} \equiv T_{a}^{\circ} \tag{4.2.11}
\end{equation*}
$$

the relations (4.2.8) and (4.2.9) become 67):

$$
\begin{align*}
& R^{a b}{ }_{e f} T^{e}{ }_{c} T^{f}{ }_{d}=T^{b}{ }_{f} T^{a}{ }_{e} R^{e f}{ }_{c d}  \tag{4.2.12}\\
& T^{a}{ }_{b} C^{b c} T^{d}{ }_{c}=C^{a d} I  \tag{4.2.13}\\
& T^{a}{ }_{b} C_{a c} T^{c}{ }_{d}=C_{b d} I  \tag{4.2.14}\\
& T^{b}{ }_{d} x^{a}=\frac{r}{q_{d \bullet}} R^{a b}{ }_{e f} x^{e} T^{f}{ }_{d}  \tag{4.2.15}\\
& P_{A}^{a b}{ }_{c d} x^{c} x^{d}=0  \tag{4.2.16}\\
& T^{b}{ }_{d} v=\frac{q_{b \bullet}}{q_{d \bullet}} v T^{b}{ }_{d}  \tag{4.2.17}\\
& x^{b} v=q_{b \bullet} v x^{b}  \tag{4.2.18}\\
& u v=v u=I  \tag{4.2.19}\\
& u x^{b}=q_{b \bullet} x^{b} u  \tag{4.2.20}\\
& u T^{b}{ }_{d}=\frac{q_{b \bullet}}{q_{d \bullet}} T^{b}{ }_{d} u  \tag{4.2.21}\\
& y_{b}=-r^{\rho} T^{a}{ }_{b} C_{a c} x^{c} u  \tag{4.2.22}\\
& \left(r^{-\rho}+\epsilon r^{\rho-2}\right) z=-x^{b} C_{b a} x^{a} u \tag{4.2.23}
\end{align*}
$$

where $q_{a}$ are $N$ complex parameters related by $q_{a \bullet}=r^{2} / q_{a^{\prime}}$, with $a^{\prime}=N+1-a$. The matrix $P_{A}$ in eq. (4.2.16) is the $q$-antisymmetrizer for the $B, C, D$-groups given by (cf. (4.1.16)):

$$
\begin{equation*}
P_{A}^{a b}{ }_{c d}=-\frac{1}{r+r^{-1}}\left(\hat{R}_{c d}^{a b}-r \delta_{c}^{a} \delta_{d}^{b}+\frac{r-r^{-1}}{\epsilon r^{N-1-\epsilon}+1} C^{a b} C_{c d}\right) . \tag{4.2.24}
\end{equation*}
$$

The last two relations (4.2.22) - (4.2.23) are constraints, showing that the $T^{A}{ }_{B}$ matrix elements in eq. (4.2.8) are really a redundant set. This redundance is necessary if we want to express the $q$-commuations of the $I S O_{q, r}(N)$ and $I S p_{q, r}(N)$ basic group elements as $R T T=T T R$ (i.e. if we want an $R$-matrix formulation). Remark that, in the $R$-matrix formulation for $I G L_{q, r}(N)$, all the $T^{A}{ }_{B}$ are independent. Here we can take as independent generators the elements

$$
\begin{equation*}
T^{a}{ }_{b}, x^{a}, v, u \equiv v^{-1} \text { and the identity } I \quad(a=1, \ldots N) \tag{4.2.25}
\end{equation*}
$$

The co-structures on the $I S O_{q, r}(N)$ (or $\operatorname{ISp}_{q, r}(N)$ ) generators can be read from (4.2.10) after decomposing the indices $A=\circ, a, \bullet$ :

$$
\begin{align*}
& \Delta\left(T^{a}{ }_{b}\right)=T^{a}{ }_{c} \otimes T^{c}{ }_{b}, \quad \Delta\left(x^{a}\right)=T^{a}{ }_{c} \otimes x^{c}+x^{a} \otimes v,  \tag{4.2.26}\\
& \Delta(v)=v \otimes v, \quad \Delta(u)=u \otimes u,  \tag{4.2.27}\\
& \kappa\left(T^{a}{ }_{b}\right)=C^{a c} T^{d}{ }_{c} C_{d b}=\epsilon_{a} \epsilon_{b} r^{-\rho_{a}+\rho_{b}} T^{b^{\prime}}{ }_{a^{\prime}},  \tag{4.2.28}\\
& \kappa\left(x^{a}\right)=-\kappa\left(T^{a}{ }_{c}\right) x^{c} u, \quad \kappa(v)=u, \quad \kappa(u)=v, \tag{4.2.29}
\end{align*}
$$

$$
\begin{equation*}
\varepsilon\left(T^{a}{ }_{b}\right)=\delta_{b}^{a}, \quad \varepsilon\left(x^{a}\right)=0, \quad \varepsilon(u)=\varepsilon(v)=\varepsilon(I)=1 . \tag{4.2.30}
\end{equation*}
$$

In the commutative limit $q \rightarrow 1, r \rightarrow 1$ we recover the algebra of functions on $I S O(N)$ (plus the dilatation $v$ that can be set to the identity). In the $I S p(N)$ case, the $q \rightarrow 1, r \rightarrow 1$ limit of relation (4.2.23) implies $x^{b} C_{b a} x^{a}=0$ i.e. $P_{0}^{a b}{ }_{e f} x^{e} x^{f}=0$, that with (4.2.16) gives the commutativity of the coordinates $x^{a}$ (both $P_{A}$ and $P_{0}$ are antisymmetrizers in the symplectic case). We then recover the algebra of functions on $\operatorname{ISp}(N)$ plus the element $z$, that can be set to zero, and the dilatation $v$, that can be set to the identity (see also Note 4.2.4).

Note 4.2.1 In order to study the $I S O_{q, r}(N)$ and $I S p_{q, r}(N)$ differential calculus and universal enveloping algebras we will use the definition (4.2.1) rather then Theorem 4.2.1: $I S_{q, r}(N)=\frac{\left\langle T^{A}{ }_{B}\right\rangle}{[R T T, C T T, T]}$. With abuse of notations we therefore identify [cf. (4.2.11)]: $u=P\left(T^{\circ}{ }_{\circ}\right), v=P\left(T^{\bullet}\right.$ 。), $z=P\left(T^{\circ}{ }^{\circ}\right), x^{a}=P\left(T^{a} \bullet\right), y_{a}=$ $P\left(T^{\circ}{ }_{a}\right), T^{a}{ }_{b}=P\left(T^{a}{ }_{b}\right) ; \quad I=P(I)$ where $P \quad: \quad S_{q, r}(N+2) \rightarrow I S_{q, r}(N) \equiv$ $S_{q, r}(N+2) / H$.

Note 4.2.2 From the commutations (4.2.20) - (4.2.21) we see that one can set $u=I$ only when $q_{a \bullet}=1$ for all $a$. From $q_{a \bullet}=r^{2} / q_{a^{\prime} \bullet}$, cf. eq. (4.1.7), this implies also $r=1$.

Note 4.2..3 Eq.s (4.2.16) are the multiparametric orthogonal quantum plane commutations. They follow from the ( $\left.{ }^{a} \bullet^{b} \bullet\right) R T T$ components and (4.2.23).

Note 4.2.4 In the symplectic case eq.s (4.2.16) alone are not sufficient to order in an arbitrary given way a monomial in the $x$ elements; we can obtain an ordering only if we consider also the element $z v$ (or $z$ ) besides the $x$ elements. In other terms, the expression $x^{a} C_{a b} x^{b}$ appearing in 4.2.23) cannot be ordered as $\alpha_{a b} x^{a} x^{b}$ with $\alpha_{a b} \in \boldsymbol{C}$ and $\alpha_{a b}=0$ if $a>b$.

To recover the symplectic $q$-plane commutations relations described in [19] one has to impose also the condition

$$
\begin{equation*}
P_{0}{ }_{c d}^{a b} x^{c} x^{d}=0 \quad \text { i.e. } \quad x^{a} C_{a b} x^{b}=0, \quad z=0 \tag{4.2.31}
\end{equation*}
$$

that arises naturally from the characteristic equation and the projector decomposition of the $R$-matrix: in the symplectic case $P_{0}$ is an antisymmetrizer. As a consequence the $x x$ commutations (4.2.16) become

$$
\begin{equation*}
\hat{R}^{a b}{ }_{c d} x^{c} x^{d}-r x^{b} x^{a}=0 . \tag{4.2.32}
\end{equation*}
$$

Notice however that (4.2.31) is not compatible with a deformation of the whole symplectic group. Condition (4.2.31) amounts to consider the Hopf quotient $I S p_{q, r}(N) / K$ where $K$ is the Hopf ideal generated by $z$. From $\Delta(z)=y_{a} \otimes x^{a}+u \otimes z+z \otimes v$ $\in I S p_{q, r}(N) \otimes K+K \otimes I S p_{q, r}(N)$ we deduce that $y_{a} \otimes x^{a} \in I S p_{q, r}(N) \otimes K+$ $K \otimes I S p_{q, r}(N)$ and applying $(m \otimes i d)(i d \otimes \Delta)$ to $y_{a} \otimes x^{a}$ we obtain that $x^{b} C_{b d} \otimes x^{d}$
$\in I S p_{q, r}(N) \otimes K+K \otimes I S p_{q, r}(N)$. Projecting on $I S p_{q, r}(N) / K$ yields $x^{b} C_{b d} \otimes x^{d}=0$ since $K$ is the kernel of the projection. Now classically $x^{b} C_{b d} \otimes x^{d} \neq 0$. This proves that the classical limit of $I S p_{q, r}(N) / K$ is not the algebra of functions over $\operatorname{ISp}(N)$.

Note 4.2.5 We here briefly study the structure of $I S_{q, r}(N)$ with respect to $S_{q, r}(N)$, that is easily seen to be a Hopf subalgebra of $I S_{q, r}(N)$. It is also a quotient of $I S_{q, r}(N)$ via the Hopf algebra projection [well defined only if $q_{a} \bullet$ const $\forall a$ i.e. $q_{a \bullet}=r \forall a$ see 4.2.21)]:

$$
\pi\left(x^{a}\right)=0, \quad \pi(u)=I, \quad \pi\left(T_{b}^{a}\right)=T_{b}^{a}, \quad \pi(I)=I .
$$

Then the results of Theorem 3.3.6 apply to $I S_{q, r}(N)$ as well, and we can write the Hopf algebra isomorhism

$$
\begin{equation*}
I S_{q, r}(N) \cong B \rtimes S_{q, r}(N) \tag{4.2.33}
\end{equation*}
$$

where $B$ is the subalgebra of $I S_{q, r}(N)$ generated by $u$ and $x^{a}$ (in the orthogonal case $B$ is the quantum orthogonal plane with dilatation $u$ ). Also Theorem 3.3.4 hold for $I S_{q, r}(N)$. [This theorem, neglecting the graded structure, is a consequence of Theorem 3.3.6, an explicit proof for the $I S_{q, r}(N)$ case follows the same steps as for $\left.I G L_{q, r}(N)\right]$. The $(\mathbf{Z}, \mathbf{N})$ grading is introduced in the following way: the elements $T^{a}{ }_{b}$ have grade $(0,0)$, the elements $x^{a}$ have grade $(0,1)$, the elements $u$ and $v=u^{-1}$ have grade $(1,0)$ and $(-1,0)$. This grading is compatible with the $R T T$ commutation relations.

For $I S O_{q, r}(N)$, the generators $u$ and $x^{a}$ of $B$ can be ordered using (4.2.16) and (4.2.20), and the Poincaré series of the subalgebra $B$ is the same as that of the commutative algebra in the $N+1$ symbols $u, x^{a}$ 19. A linear basis of $B$ is therefore given by the ordered monomials: $\zeta^{i}=u^{i_{\circ}}\left(x^{1}\right)^{i_{1}} \ldots\left(x^{N}\right)^{i_{N}}$ with $i_{\circ} \in \boldsymbol{Z}, i_{1}, \ldots i_{N} \in$ $\boldsymbol{N} \cup\{0\}$. In the $I S p_{q, r}(N)$ case, if we also consider the elements $z$, a linear basis of $B \subset I S p_{q, r}(N)$ is given by the ordered monomials $\zeta^{i}=u^{i_{0}}\left(x^{1}\right)^{i_{1}} \ldots\left(x^{N}\right)^{i_{N}}(z v)^{i_{N+1}}$ with $i_{\circ} \in \boldsymbol{Z}, i_{1}, \ldots i_{N}, i_{N+1} \in \boldsymbol{N} \cup\{0\}\left(z v\right.$ commutes with the coordinates $\left.x^{a}\right)$.

Using (3.3.76), or (4.2.15) and (4.2.21), a generic element of $I S_{q, r}(N)$ can be written as $\zeta^{i} a_{i}$ (and also $a_{i} \zeta^{i}$ ) where $a_{i} \in S_{q, r}(N)$. As in Corollary 3.1.1, we have that $I S_{q, r}(N)$, for $q_{a}=r \forall a$, is a bicovariant bimodule over $S_{q, r}(N)$ freely generated, as a right module, by the elements $\zeta^{i}$; moreover

$$
\begin{equation*}
I S_{q, r}(N)=\sum_{(h, k) \in(\mathbf{Z}, \mathbf{N})}^{\oplus} \Gamma^{(h, k)} \tag{4.2.34}
\end{equation*}
$$

where $\Gamma^{(0,0)}=S_{q, r}(N)$

$$
\begin{array}{ll}
\Gamma^{(0,1)}=\left\{x^{a} b_{a} / b_{a} \in S_{q, r}(N)\right\}, \quad \Gamma^{( \pm 1,0)}=\left\{u^{ \pm 1} b / b \in S_{q, r}(N)\right\} \\
\Gamma^{(h, k)}=\left\{u^{h} x^{a_{1}} x^{a_{2}} \ldots x^{a_{k}} b_{a_{1} a_{2} \ldots a_{k}} /\right. & \left.b_{a_{1} a_{2} \ldots a_{k}} \in S_{q, r}(N)\right\} \tag{4.2.35}
\end{array}
$$

Any submodule $\Gamma^{(h, k)}$ is a bicovariant bimodule freely generated by the ordered monomials $\zeta^{i}$ with degree $(h, k) \in(\mathbf{Z}, \mathbf{N})$. We leave to the reader to reformulate Note 3.3.5 and Note 3.3.6 in this context.

Note 4.2.6 Among all the real forms of $S_{q, r}(N+2)$ mentioned in the previous section, only * and ${ }^{* \sharp}$ are inherited by $I S_{q, r}(N)$, indeed only these two conjugations are compatible with the ideal $H: H^{*} \subseteq H$ and $H^{* \sharp} \subseteq H$ [or, more easily, are compatible with (4.2.15)]. The conditions on the parameters are:

- $\left|q_{a b}\right|=\left|q_{a}\right|=|r|=1$ for $I S O_{q, r}(n, n ; \mathbf{R}), I S O_{q, r}(n, n+1 ; \mathbf{R})$ and $I S p_{q, r}(n ; \mathbf{R})$.
- For $I S O_{q, r}(n+1, n-1 ; \mathbf{R}):|r|=1 ;\left|q_{a \bullet}\right|=1$ for $a \neq n, n+1 ;\left|q_{a b}\right|=1$ for $a$ and $b$ both different from $n$ or $n+1 ; q_{a b} / r \in \mathbf{R}$ when at least one of the indices $a, b$ is equal to $n$ or $n+1 ; q_{a} / r \in \mathbf{R}$ for $a=n$ or $a=n+1$.

In particular, the quantum Poincaré group $I S O_{q, r}(3,1 ; \mathbf{R})$ is obtained by setting $\left|q_{1}\right|=|r|=1, q_{2 \bullet} / r \in \mathbf{R}, q_{12} / r \in \mathbf{R}$.

According to Note 4.2.2, a dilatation-free $q$-Poincaré group is found after the further restrictions $q_{1} \bullet=q_{2} \bullet=r=1$. The only free parameter remaining is then $q_{12} \in \mathbf{R}$.

### 4.3 Universal enveloping algebras $U_{q, r}(s o(N+2))$ and $U_{q, r}(s p(N+2))$

We construct the universal enveloping algebra $U_{q, r}(s(N+2))$ of $S_{q, r}(N+2)$ as the algebra of regular functionals [19] on $S_{q, r}(N+2)$ (recall that $S$ stands for $S O$ and $S p)$.
$U_{q, r}(s(N+2))$ is the algebra over $\boldsymbol{C}$ generated by the counit $\varepsilon$ and by the functionals $L^{ \pm}$defined by their value on the matrix elements $T^{A}{ }_{B}$ :

$$
\begin{gather*}
L_{B}^{ \pm A}\left(T_{D}^{C}\right)=\left(R^{ \pm}\right)_{B D}^{A C},  \tag{4.3.1}\\
L^{ \pm A}{ }_{B}(I)=\delta_{B}^{A} \tag{4.3.2}
\end{gather*}
$$

with

$$
\begin{equation*}
\left(R^{+}\right)^{A C}{ }_{B D} \equiv R_{D B}^{C A} ; \quad\left(R^{-}\right)^{A C}{ }_{B D} \equiv\left(R^{-1}\right)^{A C}{ }_{B D} . \tag{4.3.3}
\end{equation*}
$$

To extend the definition (4.3.1) to the whole algebra $S_{q, r}(N+2)$ we set

$$
\begin{equation*}
L^{ \pm A}{ }_{B}(a b)=L^{ \pm A}(a) L^{ \pm C}{ }_{B}(b) \quad \forall a, b \in S_{q, r}(N+2) . \tag{4.3.4}
\end{equation*}
$$

From (4.3.1), using the upper and lower triangularity of $R^{+}$and $R^{-}$, we see that $L^{+}$is upper triangular and $L^{-}$is lower triangular.

The commutations between $L^{ \pm A}{ }_{B}$ and $L^{ \pm C}{ }_{D}$ are induced by (4.1.2) :

$$
\begin{align*}
& R_{12} L_{2}^{ \pm} L_{1}^{ \pm}=L_{1}^{ \pm} L_{2}^{ \pm} R_{12}  \tag{4.3.5}\\
& R_{12} L_{2}^{+} L_{1}^{-}=L_{1}^{-} L_{2}^{+} R_{12} \tag{4.3.6}
\end{align*}
$$

where as usual the product $L_{2}^{ \pm} L_{1}^{ \pm}$is the convolution product $L_{2}^{ \pm} L_{1}^{ \pm} \equiv\left(L_{2}^{ \pm} \otimes L_{1}^{ \pm}\right) \Delta$.
The $L^{ \pm A}{ }_{B}$ elements satisfy orthogonality conditions analogous to (4.1.17):

$$
\begin{align*}
& C^{A B} L^{ \pm C}{ }_{B} L^{ \pm D}=C^{D C} \varepsilon  \tag{4.3.7}\\
& C_{A B} L^{ \pm B}{ }_{C} L^{ \pm A}=C_{D C} \varepsilon \tag{4.3.8}
\end{align*}
$$

as can be verified by applying them to the $q$-group generators and using (4.1.19), (4.1.20). They provide the inverse for the matrix $L^{ \pm}$:

$$
\begin{equation*}
\left[\left(L^{ \pm}\right)^{-1}\right]_{B}^{A}=C^{D A} L_{D}^{ \pm C} C_{B C} \tag{4.3.9}
\end{equation*}
$$

The co-structures of the algebra generated by the functionals $L^{ \pm}$and $\varepsilon$ are defined by the duality (4.3.4):

$$
\begin{gather*}
\Delta^{\prime}\left(L^{ \pm A}\right)(a \otimes b) \equiv L_{B}^{ \pm A}(a b)=L_{G}^{ \pm A}(a) L_{B}^{ \pm G_{B}}(b)  \tag{4.3.10}\\
\varepsilon^{\prime}\left(L^{ \pm A}\right)  \tag{4.3.11}\\
\kappa_{B}^{\prime}\left(L^{ \pm A}{ }_{B}\right)(a) \equiv L^{ \pm A}(I)  \tag{4.3.12}\\
L_{B}^{ \pm A}(\kappa(a))
\end{gather*}
$$

so that

$$
\begin{align*}
& \Delta^{\prime}\left(L^{ \pm A}{ }_{B}\right)=L^{ \pm A}{ }_{G} \otimes L^{ \pm G}  \tag{4.3.13}\\
& \varepsilon^{\prime}\left(L^{ \pm A}{ }_{B}\right)=\delta_{B}^{A}  \tag{4.3.14}\\
& \kappa^{\prime}\left(L^{ \pm A}{ }_{B}\right)=\left[\left(L^{ \pm}\right)^{-1}\right]^{A}{ }_{B}=C^{D A} L^{ \pm C}{ }_{D} C_{B C} \tag{4.3.15}
\end{align*}
$$

From (4.3.15) we have that $\kappa^{\prime}$ is an inner operation in the algebra generated by the functionals $L^{ \pm A}{ }_{B}$ and $\varepsilon$, it is then easy to see that these elements generate a Hopf algebra, the Hopf algebra $U_{q, r}(s(N+2))$ of regular functionals on the quantum group $S_{q, r}(N+2)$.

Note 4.3.1 From the $C L L$ relations $\kappa^{\prime}\left(L^{ \pm A}{ }_{B}\right) L^{ \pm B}{ }_{C}=L^{ \pm A}{ }_{B} \kappa^{\prime}\left(L^{ \pm B}{ }_{C}\right)=\delta_{C}^{A} \varepsilon$ we have, using upper-lower triangularity of $L^{ \pm}$:

$$
\begin{equation*}
L^{ \pm A}{ }_{A} \kappa^{\prime}\left(L^{ \pm A}\right)=\kappa^{\prime}\left(L^{ \pm A}{ }_{A}\right) L^{ \pm A}=\varepsilon \quad \text { i.e. } \quad L^{ \pm A}{ }_{A} L^{ \pm A^{\prime}}{ }_{A^{\prime}}=L^{ \pm A^{\prime}} L^{ \pm A}=\varepsilon \tag{4.3.16}
\end{equation*}
$$

As a consequence $\operatorname{det} L^{ \pm} \equiv L^{ \pm \circ}{ }_{0} L^{ \pm 1}{ }_{1} L^{ \pm 2}{ }_{2} \ldots L^{ \pm N}{ }_{N} L^{ \pm} \bullet \quad=\varepsilon$. In the $B_{n}$ case we also have $L^{ \pm n_{2}}=\varepsilon$.

Note 4.3.2 The $R L L$ relations imply that the subalgebra $U^{0}$ generated by the elements $L^{ \pm A} A$ and $\varepsilon$ is commutative (use upper triangularity of $R$ ). Moreover, from (4.3.13) the invertible elements $L^{ \pm A}{ }_{A}$ are also group like, and we conclude that $U^{0}$ is the group Hopf algebra of the abelian group generated by $L^{ \pm A}{ }_{A}$ and $\varepsilon$. In the classical limit $U^{0}$ is a maximal commutative subgroup of $S(N+2)$.

Note 4.3.3 When $q_{A B}=r$, the multiparametric $R$-matrix goes into the uniparametric $R$-matrix and we recover the standard uniparametric orthogonal (symplectic) quantum groups. Then the $L^{ \pm}$functionals satisfy the further relation:

$$
\begin{equation*}
\forall \mathrm{A}, \quad L^{+A}{ }_{A} L^{-A}=\varepsilon, \tag{4.3.17}
\end{equation*}
$$

indeed $L^{+A}{ }_{A} L^{-A}{ }_{A}(a)=\varepsilon(a)$ as can be easily seen when $a=T_{B}^{A}$ and generalized to any $a \in S_{q, r}(N+2)$ using (4.3.4). In this case [19] we can avoid to realize the Hopf algebra $U_{r}(s(N+2))$ as functionals on $S_{r}(N+2)$ and we can define it abstractly as the Hopf algebra generated by the symbols $L^{ \pm}$and the unit $\varepsilon$ modulo relations (4.3.5), (4.3.6), (4.3.7), (4.3.8), and (4.3.17).

As discussed in [19] in the uniparametric case, the Hopf algebra $U_{r}(s(N+2))$ of regular functionals is a Hopf subalgebra of the orthogonal (symplectic) DrinfeldJimbo universal enveloping algebra $U_{h}$, where $r=e^{h}$. In the general multiparametric case, relation (4.3.17) does not hold any more. Here we discuss the generalization of (4.3.17) and the relation between $U_{q, r}(s(N+2))$ and the multiparametric orthogonal (symplectic) Drinfeld-Jimbo universal enveloping algebra $U_{h}^{(\mathcal{F})}$. This latter is the quasitriangular Hopf algebra $U_{h}^{(\mathcal{F})}=\left(U_{h}, \Delta^{(\mathcal{F})}, S, \mathcal{R}^{(\mathcal{F})}\right)$ paired to the multiparametric $q$-group $S_{q, r}(N+2)$. It is obtained from $U_{h}=\left(U_{h}, \Delta, S, \mathcal{R}\right)$ via a twist [75]. $U_{h}^{(\mathcal{F})}$ has the same algebra structure of $U_{h}$ (and the same antipode $S$ ), while the coproduct $\Delta^{(\mathcal{F})}$ and the universal element $\mathcal{R}^{(\mathcal{F})}$ belonging to (a completion of) $U_{h} \otimes U_{h}$ are determined by the twisting element $\mathcal{F}$ that belongs to (a completion of) a maximal commutative subalgebra of $U_{h} \otimes U_{h}$. We have

$$
\begin{equation*}
\forall \phi \in U_{h}, \quad \Delta^{(\mathcal{F})}(\phi)=\mathcal{F} \Delta(\phi) \mathcal{F}^{-1} ; \quad \mathcal{R}^{(\mathcal{F})}=\mathcal{F}_{21} \mathcal{R} \mathcal{F}^{-1} ; \quad \mathcal{R}^{(\mathcal{F})}(T \otimes T)=R_{q, r} \tag{4.3.18}
\end{equation*}
$$

The element $\mathcal{F}$ satisfies: $\left(\Delta^{(\mathcal{F})} \otimes i d\right) \mathcal{F}=\mathcal{F}_{13} \mathcal{F}_{23},\left(i d \otimes \Delta^{(\mathcal{F})}\right) \mathcal{F}=\mathcal{F}_{13} \mathcal{F}_{12}, \mathcal{F}_{12} \mathcal{F}_{21}=$ $I, \mathcal{F}_{12} \mathcal{F}_{13} \mathcal{F}_{23}=\mathcal{F}_{23} \mathcal{F}_{13} \mathcal{F}_{12},(\varepsilon \otimes i d) \mathcal{F}=(i d \otimes \varepsilon) \mathcal{F}=\varepsilon,(S \otimes i d) \mathcal{F}=(i d \otimes S) \mathcal{F}=$ $\mathcal{F}^{-1}, \cdot(i d \otimes S) \mathcal{F}=\cdot(S \otimes i d) \mathcal{F}=\cdot(i d \otimes i d) \mathcal{F}=\varepsilon ;$ we explicitly have

$$
\begin{equation*}
\mathcal{F}\left(T_{B}^{A} \otimes T_{D}^{C}\right)=F_{B D}^{A C} \tag{4.3.19}
\end{equation*}
$$

where $F_{B D}^{A C}$ is the diagonal matrix

$$
\begin{equation*}
F=\operatorname{diag}\left(\sqrt{\frac{q_{11}}{r}}, \sqrt{\frac{q_{12}}{r}}, \ldots \sqrt{\frac{q_{N N}}{r}}\right) \tag{4.3.20}
\end{equation*}
$$

It is easy to see that the definition of the $L^{ \pm}$functionals given in the beginning of this section is equivalent to the following one: $L^{+A}{ }_{B}(a)=\mathcal{R}^{(\mathcal{F})}\left(a \otimes T_{B}^{A}\right)$ and $L^{-A}{ }_{B}(a)=$ $\mathcal{R}^{(\mathcal{F})^{-1}}\left(T^{A}{ }_{B} \otimes a\right)$. From $\left(\Delta^{(\mathcal{F})} \otimes i d\right) \mathcal{R}=\mathcal{R}_{13} \mathcal{R}_{23},\left(i d \otimes \Delta^{(\mathcal{F})}\right) \mathcal{R}=\mathcal{R}_{13} \mathcal{R}_{12}$, we have $\Delta^{(\mathcal{F})}\left(L^{ \pm A}{ }_{B}\right)=L^{ \pm A}{ }_{C} \otimes L^{ \pm C}{ }_{B}$ and therefore $\Delta^{(\mathcal{F})}=\Delta^{\prime}$ on $U_{q, r}(s(N+2))$. From $(i d \otimes S)(\mathcal{R})=(S \otimes i d)(\mathcal{R})=\mathcal{R}^{-1}$ it is also easy to see that $S=\kappa^{\prime}$ on $U_{q, r}(s(N+2))$ and we conclude that the algebra of regular functionals $U_{q, r}(s(N+2))$ is a realization [in terms of functionals on $S_{q, r}(N+2)$ ] of a Hopf subalgebra of $U_{h}^{(\mathcal{F})}$ with $r=e^{h}$.

The generalization of (4.3.17) lies in $U_{h}^{(\mathcal{F})}$ and not in $U_{q, r}(s(N+2))$, and it is given by

$$
\begin{equation*}
\forall A \quad L^{+A}{ }_{A} L^{-A}=f_{i}\left(T_{A}^{A}\right) f^{i} \quad \text { where } \mathcal{F}^{4}=f_{i} \otimes f^{i} \tag{4.3.21}
\end{equation*}
$$

This relation holds with $L^{ \pm}$considered as abstract symbols. It can easily be checked when $L^{ \pm}$are realized as functionals: indeed $L^{+A}{ }_{A} L^{-A_{A}}(a)=\mathcal{F}^{4}\left(T^{A}{ }_{A} \otimes a\right)$ as can be seen when $a=T_{B}^{A}\left[\right.$ use $\left.\mathcal{F}^{2}\left(T_{A}^{A} \otimes b\right)=\mathcal{F}\left(T_{A}^{A} \otimes b_{1}\right) \mathcal{F}\left(T_{A}^{A} \otimes b_{2}\right)\right]$ and generalized to any $a \in S_{q, r}(N+2)$ using $\mathcal{F}\left(T_{A}^{A} \otimes a b\right)=\mathcal{F}\left(T_{A}^{A} \otimes a\right) \mathcal{F}\left(T_{A}^{A} \otimes b\right)$.

In order to characterize the relation between the Hopf algebra of regular functionals $U_{q, r}(s(N+2))$ and $U_{h}^{(\mathcal{F})}$, following [19], we extend the group Hopf algebra $U^{0}$ described in Note 4.3.2 to $\hat{U}^{0}$ by means of the elements $\square \ell^{ \pm A}{ }_{A}=\ln L^{ \pm A}{ }_{A}$. Otherwise stated this means that in $\hat{U}^{0}$ we can write $L^{ \pm A}{ }_{A}=\exp \left(\ell^{ \pm A}{ }_{A}\right)$ where $\ell^{ \pm}{ }_{A} \in \hat{U}^{0}$. [Explicitly $\ell^{ \pm A}{ }_{A}\left(T^{C}{ }_{D}\right)=\ln \left(R^{ \pm A C}{ }_{A C}\right) \delta_{D}^{C}, \ell^{ \pm A_{A}}{ }_{A}(I)=0, \ell^{ \pm A}{ }_{A}(a b)=$ $\ell^{ \pm}{ }_{A}(a) \varepsilon(b)+\varepsilon(a) \ell^{ \pm} A_{A}(b)$ and $\left.\kappa^{\prime}\left(\ell^{ \pm A}{ }_{A}\right)=-\ell^{ \pm A}{ }_{A}\right]$. It then follows that $\mathcal{F}$ belongs to (a completion of) $\hat{U}^{0} \otimes \hat{U}^{0}$. The corresponding extension $\hat{U}_{q, r}(s(N+2))$ of $U_{q, r}\left(s(N+2)\right.$ ), defined as the Hopf algebra generated by the symbols $L^{ \pm}$and $\ell^{ \pm}$modulo relations (4.3.5)-(4.3.8) and (4.3.21), is isomorphic - when $r=e^{h}$ - to $U_{h}^{(\mathcal{F})}: \hat{U}_{q, r}(s(N+2)) \cong U_{h}^{(\mathcal{F})}$. This relation holds because it is the twisted version of the known uniparametric analogue $\hat{U}_{r}(s(N+2)) \cong U_{h}$ (19, (79).

The elements $L^{ \pm}\left[\right.$or $\left.\frac{1}{r-r^{-1}}\left(L_{B}^{ \pm A}-\delta_{B}^{A} \varepsilon\right)\right]$ may be seen as the quantum analogue of the tangent vectors; then the $R L L$ relations are the quantum analogue of the Lie algebra relations, and we can use the orthogonal (symplectic) $C L L$ conditions to reduce the number of the $L^{ \pm}$generators to $(N+2)(N+1) / 2$, (orthogonal case) or $(N+2)(N+3) / 2$ (symplectic case) i.e. the dimension of the classical group manifold.

This we proceed to do for $U_{q, r}(s o(N+2))$, for $U_{q, r}(s p(N+2))$ one can proceed in a similar way $\|$; we next study the $R L^{ \pm} L^{ \pm}$commutation relations restricted to these $(N+2)(N+1) / 2$ generators and find a set of ordered monomials in the reduced $L^{ \pm}$that linearly span all $\hat{U}_{q, r}(s o(N+2))$.

We first observe that the commutative subalgebra $\hat{U}^{0}$ is generated by $(N+2) / 2$ elements ( $N$ even, $N=2 n$ ) or $(N+1) / 2$ elements ( $N$ odd, $N=2 n+1$ ), for example $\ell^{-0}{ }_{0}, \ell^{-1}{ }_{1} \ldots \ell^{-n}{ }_{n}$. For the off-diagonal $L^{ \pm}$elements, we can choose as free indices $(C, D)=(c, \circ)$ in relation (4.3.8), and using $L^{-\circ}{ }_{0} L^{-\bullet} \bullet=\varepsilon$, we find:

$$
\begin{equation*}
L^{-\bullet}{ }_{c}=-\left(C_{0 \bullet}\right)^{-1} C_{a b} L^{-b}{ }_{c} L^{-a}{ }_{o} L^{-\bullet} \bullet \tag{4.3.22}
\end{equation*}
$$

[^7]If we choose $(C, D)=(\circ, \circ)$ we obtain

$$
\begin{equation*}
L^{-\bullet}{ }_{\circ}=-\left(r^{-2} C_{\bullet}+C_{\circ}\right)^{-1} C_{a b} L^{-b}{ }_{\circ} L^{-a}{ }_{\circ} L^{-\bullet} \bullet \tag{4.3.23}
\end{equation*}
$$

Similar results hold for $L^{+\circ}{ }_{d}$ and $L^{+\circ}$. Iterating this procedure, from $C_{a b} L^{-b}{ }_{c} L^{-a}{ }_{d}=$ $C_{d c} \varepsilon$ we find that $L^{-N_{i}}$ (with $i=2, \ldots N-1$ ) and $L^{-N}{ }_{1}$ are functionally dependent on $L^{-i}{ }_{1}$ and $L^{-N}{ }_{N}$. Similarly for $L^{+1}{ }_{i}$ and $L^{+1}{ }_{N}$. The final result is that the elements $L^{-a}{ }_{J}$ with $J<a<J^{\prime}$ and $L^{+a}{ }_{J}$ with $J^{\prime}<a<J-$ whose number in both $\pm$ cases is $\frac{1}{4} N(N+2)$ for $N$ even and $\frac{1}{4}(N+1)^{2}$ for $N$ odd - and the elements $\ell^{-\circ}{ }_{\circ}$, $\ell^{-1}{ }_{1} \ldots \ell^{-n}{ }_{n}$ generate all $\hat{U}_{q, r}(s o(N+2))$. The total number of generators is therefore $(N+2)(N+1) / 2$.

Notice that in this derivation we have not used the $R L L$ relations (i.e. the quantum analogue of the Lie algebra relations) to further reduce the number of generators. We therefore expect that, as in the classical case, monomials in the $(N+2)(N+1) / 2$ generators can be ordered (in any arbitrary way). We begin by proving this for polynomials in $L^{+A}{ }_{A}, L^{+\alpha}{ }_{J}$ with $J^{\prime}<\alpha<J$, and for polynomials in $L^{-A}{ }_{A}, L^{-\alpha}{ }_{J}$ with $J<\alpha<J^{\prime}$.

Lemma 4.3.1 Consider the $R L^{ \pm} L^{ \pm}$commutation relations

$$
\begin{equation*}
R_{E F}^{A B} L_{D}^{ \pm F} L_{C}^{ \pm E}{ }_{C}=L_{E}^{ \pm A} L_{F}^{ \pm B}{ }_{F} R_{C D}^{E F} . \tag{4.3.24}
\end{equation*}
$$

For $C \neq D$ they close respectively on the subset of the $L^{+\alpha}{ }_{J}$ with $J^{\prime}<\alpha \leq J$ and on the subset of the $L^{-\alpha}{ }_{J}$ with $J \leq \alpha<J^{\prime}$. For $C=D$ they are equivalent to the $q^{-1}$-plane commutation relations:

$$
\begin{equation*}
\left[P_{A}\left(J^{\prime}-J+1\right)\right]_{\gamma \delta}^{\alpha \beta} L^{ \pm \delta}{ }_{J} L^{ \pm \gamma}{ }_{J}=0 \tag{4.3.25}
\end{equation*}
$$

where $P_{A}\left(J^{\prime}-J+1\right)$ is the antisymmetrizer in dimension $J-J^{\prime}+1$ [compare with (4.1.16)]. In particular

$$
\begin{equation*}
P_{A}^{a b}{ }_{c d} L^{-d}{ }_{0} L^{-c}{ }_{o}=0 \tag{4.3.26}
\end{equation*}
$$

or equivalently $\left[\left(P_{A}\right)_{q^{-1, r-r}}\right]^{a b}{ }_{c d} L^{-c}{ }_{\circ} L^{-d}{ }_{\circ}=0$ which coincide, for $r \rightarrow r^{-1}$ and $q \rightarrow$ $q^{-1}$, with the $N$-dimensional quantum orthogonal plane relations (4.2.16).
Proof: The proof is a straightforward calculation based on (4.1.22) and on upper or lower triangularity of the $R$ matrix and of the $L^{ \pm}$functionals.

Lemma 4.3.2 $U_{q, r}(s o(N))$ is a Hopf subalgebra of $U_{q, r}(s o(N+2))$.
Proof: Choosing $S O_{q, r}(N)$ indices as free indices in (4.3.24) and using upper or lower triangularity of the $L^{ \pm}$matrices, and (4.1.8) or (4.1.26), we find that only $S O_{q, r}(N)$ indices appear in (4.3.24); similarly for relations (4.3.6)-4.3.8), and for the costructures (4.3.13)-(4.3.15).

Now we observe that in virtue of the $R L^{+} L^{+}$relations the $L^{+}$elements can be ordered; similarly we can order the $L^{-}$using the $R L^{-} L^{-}$relations. This statement
can be proved by induction using that $U_{q, r}(s o(N))$ is a subalgebra of $U_{q, r}(s o(N+2))$, and splitting the $S O_{q, r}(N+2)$ index in the usual way [some of the resulting formulas are given in (4.4.9)-(4.4.12)].

It is then straightforward to prove that the elements $L^{+\alpha}{ }_{J}$ with $J^{\prime}<\alpha \leq J$ can be ordered; indeed we can always order the $L^{+\alpha}{ }_{J} L^{+\beta}{ }_{K}$ with $J^{\prime}<\alpha \leq J, K^{\prime}<\beta \leq K$ and $J \neq K$ since their commutation relations are a closed subset of (4.3.24) [see Lemma 4.3.1]. Then there is no difficulty in ordering substrings composed by $L^{+\alpha}{ }_{J}$ and $L^{+\beta}{ }_{J}$ elements because (4.3.25) are $q^{-1}$-plane commutation relations, that allow for any ordering of the quantum plane coordinates [19]. More in general the $L^{+A}{ }_{A}$ and $L^{+\alpha}{ }_{J}$ with $J^{\prime}<\alpha<J$ can be ordered because of $L^{+A}{ }_{A} L^{+B}{ }_{C}=\left(q_{B A} / q_{C A}\right) L^{+B}{ }_{C} L^{+A}{ }_{A}$. Similarly we can order the $L^{-A}{ }_{A}$ and $L^{-\alpha}{ }_{J}$ with $J<\alpha<J^{\prime}$. It is now easy to prove the following

Theorem 4.3.1 A set of elements spanning $\hat{U}_{q, r}(s o(N+2))$ is given by the ordered monomials

$$
\begin{equation*}
\operatorname{Mon}\left(L^{+\alpha}{ }_{J} ; J^{\prime}<\alpha<J\right)\left(\ell_{\circ}^{-\circ}\right)^{p_{\circ}}\left(\ell_{1}^{-1}\right)^{p_{1}} \ldots\left(\ell_{n}^{-n}\right)^{p_{n}} \operatorname{Mon}\left(L_{J}^{-\alpha} ; J<\alpha<J^{\prime}\right) \tag{4.3.27}
\end{equation*}
$$

where $p_{\circ}, p_{1}, \ldots p_{n} \in \boldsymbol{N} \cup\{0\}, n=N / 2(N$ even $), n=(N-1) / 2(N$ odd $)$ and $\operatorname{Mon}\left(L^{+\alpha}{ }_{J} ; J^{\prime}<\alpha<J\right),\left[\operatorname{Mon}\left(L^{-\alpha}{ }_{J} ; J<\alpha<J^{\prime}\right)\right]$ is a monomial in the off-diagonal elements $L^{+\alpha}{ }_{J}$ with $J^{\prime}<\alpha<J\left[L^{-\alpha}{ }_{J}\right.$ with $\left.J<\alpha<J^{\prime}\right]$ where an ordering has been chosen.

Note 4.3.4 Conjecture: the above monomials are linearly independent and therefore form a basis of $\hat{U}_{q, r}(s o(N+2))$.

## Conjugation

The canonical $*$-conjugation on $U_{q, r}(s(N+2))$ induced by the $*$-conjugation on $S_{q, r}(N+2)$ is given by:

$$
\begin{equation*}
\psi^{*}(a) \equiv \overline{\psi\left(\kappa^{-1}\left(a^{*}\right)\right)} \tag{4.3.28}
\end{equation*}
$$

where $\psi \in U_{q, r}(s(N+2)), a \in S_{q, r}(N+2)$, and the overline denotes the usual complex conjugation. It is not difficult to determine the action on the basis elements $L^{ \pm A}{ }_{B}$. The two $S_{q, r}(N+2) *$-conjugations that are compatible with $I S O_{q, r} N$ induce respectively the following conjugations on the $L^{ \pm A}{ }_{B}$ (we denote ${ }^{* \sharp}$ simply by ${ }^{*}$ ):

$$
\begin{align*}
& \left(L^{ \pm A}\right)^{*}=\kappa^{\prime 2}\left(L^{ \pm A}{ }_{B}\right)  \tag{4.3.29}\\
& \left(L_{B}^{ \pm A}\right)^{*}=\mathcal{D}_{C}^{A} \kappa^{\prime 2}\left(L^{ \pm C}{ }_{D}\right) \mathcal{D}_{B}^{D} \tag{4.3.30}
\end{align*}
$$

Notice that $\kappa^{\prime 2}\left(L^{ \pm A}{ }_{B}\right)=D_{E}^{-1 A} L^{ \pm E}{ }_{F} D_{B}^{F}$ where $D_{e}^{a}=C^{a s} C_{e s}$ and its inverse is $D_{b}^{-1}=C^{s f} C_{s b}$.

### 4.4 Universal enveloping algebras $U_{q, r}(i s o(N))$ and $U_{q, r}(i s p(N))$

Consider a generic functional $f \in U_{q, r}(s(N+2))$. It is well defined on the quotient $I S_{q, r}(N)=S_{q, r}(N+2) / H$ if and only if $f(H)=0$. It is easy to see that the set $H^{\perp}$ of all these functionals is a subalgebra of $U_{q, r}(s(N+2))$ : if $f(H)=0$ and $g(H)=0$ then $f g(H)=0$ because $\Delta(H) \subseteq H \otimes S_{q, r}(N+2)+S_{q, r}(N+2) \otimes H$. Moreover [83] $H^{\perp}$ is a Hopf subalgebra of $U_{q, r}(s(N+2))$ since $H$ is a Hopf ideal, cf. sections 3.5-6. In agreement with these observations we will find the Hopf algebra $U_{q, r}(i s o(N))$ [dually paired to $I S_{q, r}(N)$ ] as a subalgebra of $U_{q, r}(s(N+2))$ vanishing on the ideal $H$.

Let

$$
\begin{equation*}
I U \equiv\left[L^{-A}{ }_{B}, L^{+a}{ }_{b}, L^{+{ }^{\circ}}{ }_{\circ}, L^{+\bullet} \bullet, \varepsilon\right] \subseteq U_{q, r}(s(N+2)) \tag{4.4.1}
\end{equation*}
$$

be the subalgebra of $U_{q, r}(s(N+2))$ generated by $L^{-A}{ }_{B}, L^{+a}{ }_{b}, L^{+{ }^{\circ}}{ }_{0}, L^{+\bullet}, ~, \varepsilon$.
Note 4.4.1 These are all and only the functionals annihilating the generators of $H$ : $T^{a}{ }_{\circ}, T^{\bullet}{ }_{b}$ and $T^{\bullet}{ }_{\circ}$. The remaining $U_{q, r}(s(N+2))$ generators $L^{+{ }_{0}}{ }_{b}, L^{+a} \bullet, L^{+{ }^{+}}{ }^{\bullet}$ do not annihilate the generators of $H$ and are not included in (4.4.1).

We now proceed to study this algebra $I U$. We will show that it is a Hopf algebra and that $I U \subseteq H^{\perp}$; we will give an $R$-matrix formulation, and prove that $I U$ is the semidirect product of $U_{q, r}(s(N))$ and the algebra $B^{\prime}$ generated by the elements $L^{-\circ}{ }_{\circ}$ and $L^{-a}{ }_{\circ}$. This is the analogue of $I S_{q, r}(N)$ being the semidirect product of $S_{q, r}(N)$ and the algebra $B$ generated by the elements $u$ and $x^{a}$, cf. Note 4.2.5.

We then show that $I U$ is dually paired with $I S_{q, r}(N)$. These results lead to the conclusion that $I U$ is the universal enveloping algebra of $I S_{q, r}(N)$.

Theorem 4.4.1 $I U$ is a Hopf subalgebra of $U_{q, r}(s(N+2))$.
Proof: $\quad I U$ is by definition a subalgebra. The sub-coalgebra property $\Delta^{\prime}(I U) \subseteq$ $I U \otimes I U$ follows immediately from the upper triangularity of $L^{+A_{B}}$ :

$$
\begin{equation*}
\Delta^{\prime}\left(L^{+a}{ }_{b}\right)=L^{+a}{ }_{c} \otimes L^{+c}{ }_{b} ; \Delta^{\prime}\left(L^{+{ }_{0}}{ }_{o}\right)=L^{+{ }_{0}}{ }_{\circ} \otimes L^{+{ }_{0}}{ }_{\circ} ; \Delta^{\prime}\left(L^{+\bullet} \bullet\right)=L^{+\bullet} \bullet \otimes L^{+\bullet} . \tag{4.4.2}
\end{equation*}
$$

and the compatibility of $\Delta^{\prime}$ with the product. We conclude that $I U$ is a Hopfsubalgebra because $\kappa^{\prime}(I U) \subseteq I U$ as is easily seen using (4.3.15) and antimultiplicativity of $\kappa^{\prime}$.

We may wonder whether the $R L L$ and $C L L$ relations of $U_{q, r}(s(N+2))$ close in $I U$. In this case $I U$ will be given by all and only the polynomials in the functionals $L^{-A}{ }_{B}, L^{+a}{ }_{b}, L^{+\circ}{ }_{0}, L^{+\bullet}$, , $\varepsilon$. This check is done by writing explicitly all $q$-commutations between the generators of $I U$ : they do not involve the functionals $L^{+o}{ }_{b}, L^{+a} \bullet, L^{+o}$ • . Moreover one can also write them in a compact form using a new $R$-matrix $\mathcal{R}_{12} \equiv \mathcal{L}^{+}{ }_{2}\left(t_{1}\right)$, where $\mathcal{L}^{+}$is defined below. Similarly the orthog-
onality (symplecticity) conditions (4.3.7)-(4.3.8) do not relate elements of $I U$ with elements not belonging to $I U$. We therefore conclude

Theorem 4.4.2 The Hopf algebra $I U$ is generated by the unit $\varepsilon$ and the matrix entries:

$$
L^{-}=\left(L^{-A}{ }_{B}\right) ; \quad \mathcal{L}^{+}=\left(\begin{array}{ccc}
L^{+0}{ }_{\circ} & 0 & 0  \tag{4.4.3}\\
0 & L^{+a}{ }_{b} & 0 \\
0 & 0 & L^{+\bullet}
\end{array}\right) ;
$$

these functionals satisfy the $q$-commutation relations:

$$
\begin{gather*}
R_{12} \mathcal{L}^{+}{ }_{2} \mathcal{L}^{+}{ }_{1}=\mathcal{L}^{+}{ }_{1} \mathcal{L}^{+}{ }_{2} R_{12} \text { or equivalently } \mathcal{R}_{12} \mathcal{L}^{+}{ }_{2} \mathcal{L}^{+}{ }_{1}=\mathcal{L}^{+}{ }_{1} \mathcal{L}^{+}{ }_{2} \mathcal{R}_{12}  \tag{4.4.4}\\
R_{12} L_{2}^{-} L_{1}^{-}=L_{1}^{-} L_{2}^{-} R_{12}  \tag{4.4.5}\\
\mathcal{R}_{12} \mathcal{L}^{+}{ }_{2} L_{1}^{-}=L_{1}^{-} \mathcal{L}^{+}{ }_{2} \mathcal{R}_{12} \tag{4.4.6}
\end{gather*}
$$

where

$$
\mathcal{R}_{12} \equiv \mathcal{L}^{+}{ }_{2}\left(t_{1}\right) \quad \text { that is } \quad \mathcal{R}_{c d}^{a b}=R_{c d}^{a b} ; \quad \mathcal{R}_{A B}^{A B}=R_{A B}^{A B} \quad \text { and otherwise } \quad \mathcal{R}_{C D}^{A B}=0
$$

and the orthogonality (symplecticity) conditions :

$$
\begin{gather*}
C^{A B} \mathcal{L}^{+C}{ }_{B} \mathcal{L}^{+D}{ }_{A}=C^{D C} \varepsilon ; \quad C_{A B} \mathcal{L}^{+B}{ }_{C} \mathcal{L}^{+A}{ }_{D}=C_{D C} \varepsilon  \tag{4.4.7}\\
C^{A B} L^{-C}{ }_{B} L^{-D}{ }_{A}=C^{D C} \varepsilon ; \quad C_{A B} L^{-B}{ }_{C} L^{-A}{ }_{D}=C_{D C} \varepsilon \tag{4.4.8}
\end{gather*}
$$

The costructures are the ones given in (4.3.13)-(4.3.15) with $L^{+}$replaced by $\mathcal{L}^{+}$.

Note 4.4.2 We can consider the extension $\hat{I} \subset \hat{U}_{q, r}(s(N+2))$ obtained by including the elements $\ell^{ \pm A} A\left(\ell^{ \pm}{ }_{A}=\ln L^{ \pm A}{ }_{A}\right.$, see the previous section). Then $\hat{U}$ is generated by the symbols $L^{-A}{ }_{B}, \mathcal{L}^{+A}{ }_{B}, \ell^{ \pm A}{ }_{A}$ modulo the relations (4.4.4)(4.4.8) and (4.3.21) [(4.3.17) in the uniparametric case]. Equivalently, from (4.3.22)(4.3.23), we have that $\hat{I U}$ is generated by $\hat{U}_{q, r}(s(N))$, the dilatation $\ell^{-\circ} \circ$ and the $N$ elements $L^{-a}{ }_{\circ}$ (satisfying, in the orthogonal case, the quantum plane relations). All the relations are then given by those between the generators of $\hat{U}_{q, r}(s(N))$-listed in (4.3.5)-(4.3.8), 4.3.21) with lower case indices- and by the following ones

$$
\begin{align*}
& L^{-\circ}{ }_{o} L^{-a}{ }_{\circ}=q_{o a}^{-1} L^{-a}{ }_{o} L^{-\circ}{ }_{\circ}  \tag{4.4.9}\\
& P_{A}^{a b}{ }_{f e} L^{-e}{ }_{o} L^{-f}{ }_{o}=0  \tag{4.4.10}\\
& L^{-\circ}{ }_{\circ} L^{ \pm b}{ }_{d}=\frac{q_{b o}}{q_{d \circ}} L^{ \pm b}{ }_{d} L^{-\circ}{ }_{\circ}  \tag{4.4.11}\\
& L^{-a}{ }_{o} L^{ \pm b}{ }_{d}=\frac{r}{q_{d o}}\left(R^{ \pm}\right)^{b a}{ }_{e f} L^{ \pm e}{ }_{d} L^{-f}{ }_{\circ} \tag{4.4.12}
\end{align*}
$$

where $R^{ \pm}$is defined in (4.3.3). The number of generators is $N(N-1) / 2+N+1$ in the orthogonal case and $N(N+1) / 2+N+2$ in the symplectic case because we
consider also the element $L^{-\bullet}$ 。 so that the $L^{-a}{ }_{\circ}$ elements can be ordered (cf. last footnote).
 analogy to (4.2.25), $I U$ is generated by $U_{q, r}(s(N)), L^{-a}{ }_{o}, L^{-\circ}{ }_{\circ}$ and $L^{-\bullet} \bullet=\left(L^{-\circ}{ }_{\circ}\right)^{-1}$. With abuse of notations we will consider $I U$ generated by these elements also for arbitrary values of the parameters $q_{a} \bullet$ this is what actually happens in $I \hat{U}$.

Note 4.4.4 From the second equation in (4.4.4) applied to $t$ we obtain the quantum Yang-Baxter equation for the matrix $\mathcal{R}$.

The results of Note 4.2 .5 holds also for $U_{q, r}(i s(N))$ with the obvious changes in notation. The projection $\pi$ [well defined only if $q_{a}=r \forall a$ see (4.4.11)] is given by:

$$
\pi\left(L^{-a}{ }_{o}\right)=0, \quad \pi\left(L^{-{ }^{\circ}}{ }_{o}\right)=I, \quad \pi\left(L^{ \pm a}{ }_{b}\right)=L^{ \pm a}{ }_{b}, \quad \pi(\varepsilon)=\varepsilon .
$$

The semidirect product structure is:

$$
\begin{equation*}
U_{q, r}(i s(N)) \cong B^{\prime} \rtimes U_{q, r}(s(N)) \tag{4.4.13}
\end{equation*}
$$

where $B^{\prime}$ is the subalgebra of $U_{q, r}(i s(N))$ generated by $L^{-\circ}{ }_{\circ}$ and $L^{-a}{ }_{0}$. Moreover $B^{\prime}=I U_{\mathrm{inv}}$, the space of all right invariant elements of the $U_{q, r}(s(N))$-bicovariant algebra $U_{q, r}(i s(N))$. The ordered monomials that form a basis of $B^{\prime}$ and that freely generate $I U$ as a right module, in the orthogonal case are:

$$
\eta^{i}=\left(L^{-\circ}{ }_{\circ}\right)^{i_{\circ}}\left(L^{-1}{ }_{\circ}\right)^{i_{1}} \ldots\left(L^{-N}{ }_{\circ}\right)^{i_{N}} \quad \text { with } i_{\circ} \in \boldsymbol{Z}, \quad i_{1}, \ldots i_{N} \in \boldsymbol{N} \cup\{0\}
$$

In the symplectic case, if we also consider the element $z$, a linear basis of $B^{\prime}$ is given by the ordered monomials
$\eta^{i}=\left(L^{-\circ}{ }_{\circ}\right)^{i_{0}}\left(L^{-1}{ }_{\circ}\right)^{i_{1}} \ldots\left(L^{-N}{ }_{\circ}\right)^{i_{N}}\left(L^{-\bullet}{ }_{\circ} L^{-\odot}{ }_{\circ}\right)^{i_{N+1}}$ with $i_{\circ} \in \boldsymbol{Z}, i_{1}, \ldots i_{N}, i_{N+1} \in \boldsymbol{N} \cup\{0\}$
[ $L^{-\bullet}{ }_{\circ} L^{-\circ}{ }_{\circ}$ commutes with the elements $L^{-a}{ }_{\mathrm{o}}$. Use (4.4.9), (4.4.10) and then (4.4.11) and (4.4.12), to exlicitly write a generic element of $I U$ as $\eta^{i} a_{i}$ where $\left.a_{i} \in U_{q, r}(s(N))\right]$.

The $(\mathbf{Z}, \mathbf{N})$ grading is: $\operatorname{grade}\left(T^{a}{ }_{b}\right)=(0,0), \operatorname{grade}\left(L^{-a}{ }_{o}\right)=(0,1), \operatorname{grade}\left(L^{-}{ }_{o}{ }_{o}\right)=$ $(1,0)$, so that:

$$
\begin{equation*}
U_{q, r}(i s(N))=\sum_{(h, k) \in(\mathbf{Z}, \mathbf{N})}^{\oplus} \Gamma^{\prime(h, k)} \tag{4.4.14}
\end{equation*}
$$

where $\Gamma^{\prime(0,0)}=U_{q, r}(s(N))$
$\Gamma^{\prime(0,1)}=\left\{L^{-a}{ }_{o} \varphi^{a} \quad / \quad \varphi^{a} \in U_{q, r}(s(N))\right\} \quad, \quad \Gamma^{\prime( \pm 1,0)}=\left\{\left(L^{-\circ}{ }_{o}\right)^{ \pm 1} \varphi / \varphi \in U_{q, r}(s(N))\right\}$ $\Gamma^{\prime(h, k)}=\left\{\left(L^{-\circ}{ }_{\circ}\right)^{h} L^{-a_{1}} L^{-\circ}{ }_{a_{2}} \ldots L^{-\circ}{ }_{a_{k}} \varphi^{a_{1} a_{2} \ldots a_{k}} / \varphi^{a_{1} a_{2} \ldots a_{k}} \in U_{q, r}(s(N))\right\}$

Any submodule $\Gamma^{\prime(h, k)}$ is a $U_{q, r}(s(N))$-bicovariant bimodule freely generated by the elements $\eta^{i}$ with degree $(h, k) \in(\mathbf{Z}, \mathbf{N})$. Also the analogue of Note 3.3.5 and Note 3.3.6 still holds for $I U$.

## Duality $U_{q, r}(i s o(N)) \leftrightarrow I S_{q, r}(N)$

We now show that $I U$ is dually paired to $S_{q, r}(N+2)$. This is the fundamental step allowing to interpret $I U$ as the algebra of regular functionals on $I S_{q, r}(N)$.

Theorem 4.4.4 $I U$ annihilates $H$.
Proof: Let $\mathcal{L}$ and $\mathcal{T}$ be generic generators of $I U$ and $H$ respectively. As discussed in Note 4.4.1, $\mathcal{L}(\mathcal{T})=0$. A generic element of the ideal is given by $a \mathcal{T} b$ where sum of polynomials is understood; we have (using Sweedler's notation for the coproduct): $\mathcal{L}(a \mathcal{T} b)=\mathcal{L}_{(1)}(a) \mathcal{L}_{(2)}(\mathcal{T}) \mathcal{L}_{(3)}(b)=0$ because $\mathcal{L}_{(2)}(\mathcal{T})=0$. Indeed $\mathcal{L}_{(2)}$ is still a generator of $I U$ since $I U$ is a sub-coalgebra of $U_{q, r}(s(N+2))$. Thus $\mathcal{L}(H)=0$. Recalling that a product of functionals annihilating $H$ still annihilates the co-ideal $H$, we also have $I U(H)=0$.

In virtue of Theorem 4.4.4 the following bracket is well defined:

$$
\begin{align*}
\text { Definition }\langle,\rangle: \quad & I U \otimes I S_{q, r}(N) \longrightarrow \boldsymbol{C} \\
& \left\langle a^{\prime}, P(a)\right\rangle \equiv a^{\prime}(a) \quad \forall a^{\prime} \in I U, \forall a \in S_{q, r}(N+2) \tag{4.4.15}
\end{align*}
$$

where $P: S_{q, r}(N+2) \rightarrow S_{q, r}(N+2) / H \equiv I S_{q, r}(N)$ is the canonical projection, which is surjective. The bracket is well defined because two generic counterimages of $P(a)$ differ by an addend belonging to $H$.

Note that when we use the bracket $\langle\rangle,, a^{\prime}$ is seen as an element of $I U$, while in the expression $a^{\prime}(a), a^{\prime}$ is seen as an element of $U_{q, r}(s(N+2)$ ) (vanishing on $H$ ).

Theorem 4.4.5 The bracket (4.4.15) defines a pairing between $I U$ and $I S_{q, r}(N)$ : $\forall a^{\prime}, b^{\prime} \in I U, \forall P(a), P(b) \in I S_{q, r}(N)$

$$
\begin{align*}
& \left\langle a^{\prime} b^{\prime}, P(a)\right\rangle=\left\langle a^{\prime} \otimes b^{\prime}, \Delta(P(a))\right\rangle  \tag{4.4.16}\\
& \left\langle a^{\prime}, P(a) P(b)\right\rangle=\left\langle\Delta^{\prime}\left(a^{\prime}\right), P(a) \otimes P(b)\right\rangle  \tag{4.4.17}\\
& \left\langle\kappa^{\prime}\left(a^{\prime}\right), P(a)\right\rangle=\left\langle a^{\prime}, \kappa(P(a))\right\rangle  \tag{4.4.18}\\
& \langle I, P(a)\rangle=\varepsilon(P(a)) ; \quad\left\langle a^{\prime}, P(I)\right\rangle=\varepsilon^{\prime}\left(a^{\prime}\right) \tag{4.4.19}
\end{align*}
$$

Proof: The proof is easy since $I U$ is a Hopf subalgebra of $U_{q, r}(s(N+2))$ and $P$ is compatible with the structures and costructures of $S_{q, r}(N+2)$ and $I S_{q, r}(N)$. Indeed we have

$$
\begin{gathered}
\left\langle a^{\prime}, P(a) P(b)\right\rangle=\left\langle a^{\prime}, P(a b)\right\rangle=a^{\prime}(a b)=\Delta^{\prime}\left(a^{\prime}\right)(a \otimes b)=\left\langle\Delta^{\prime}\left(a^{\prime}\right), P(a) \otimes P(b)\right\rangle \\
\left\langle a^{\prime} b^{\prime}, P(a)\right\rangle=a^{\prime} b^{\prime}(a)=\left(a^{\prime} \otimes b^{\prime}\right) \Delta_{N+2}(a)=\left\langle a^{\prime} \otimes b^{\prime},(P \otimes P) \Delta_{N+2}(a)\right\rangle=\left\langle a^{\prime} \otimes b^{\prime}, \Delta(P(a))\right\rangle \\
\left\langle\kappa^{\prime}\left(a^{\prime}\right), P(a)\right\rangle=\kappa^{\prime}\left(a^{\prime}\right)(a)=a^{\prime}\left(\kappa_{N+2}(a)\right)=\left\langle a^{\prime}, P\left(\kappa_{N+2}(a)\right)\right\rangle=\left\langle a^{\prime}, \kappa(P(a))\right\rangle
\end{gathered}
$$

We now recall that $I U$ and $I S_{q, r}(N)$, besides being dually paired, are bicovariant algebras with the same graded structure (4.2.34) and (4.4.14), and can both be
obtained as a cross-product cross-coproduct construction: $I S_{q, r}(N) \cong B \rtimes S_{q, r}(N)$, $I U \cong B^{\prime} \rtimes U_{q, r}(s(N))$. In particular $I S_{q, r}(N)$ and $I U$ are freely generated (as modules) by $B$ and $B^{\prime}$ i.e. by the two isomorphic sets of the monomials in the $q$-plane plus dilatation coordinates $L^{-\circ}{ }_{\circ}, L^{-a}{ }_{\circ}$ and $u, x^{a}$ respectively. We then conclude that $I U$ is the universal enveloping algebra of $I S_{q, r}(N)$ :

$$
\begin{equation*}
U_{q, r}(i s(N)) \equiv I U \tag{4.4.20}
\end{equation*}
$$

Note 4.4.5 Given a $*$-structure on $I S_{q, r}(N)$, the duality $I S_{q, r}(N) \leftrightarrow U_{q, r}(i s(N))$ induces a $*$-structure on $U_{q, r}(i s(N))$. If in particular the $*$-conjugation on $I S_{q, r}(N)$ is found by projecting a $*$-conjugation on $S_{q, r}(N+2)$, then the induced $*$ on $U_{q, r}(i s o(N))$ is simply the restriction to $U_{q, r}(i s(N))$ of the $*$ on $U_{q, r}(s(N+2))$. This is the case for the $*$-structures that lead to the real forms $I S_{q, r}(N, \boldsymbol{R})$ and $I S O_{q, r}(n+1, n-1)$ and in particular to the quantum Poincaré group.

### 4.5 Bicovariant calculus on $S O_{q, r}(N+2)$ and $S p_{q, r}(N+2)$

The bicovariant differential calculus on the multiparametric $q$-groups of the $B, C, D$ series can be formulated following Section 2.2. We list here some formulae and comments that do not appear in that section.

The commutations between the generators $T_{S}^{R}$ and the 1-forms $\omega_{A_{1}}^{A_{2}}$ are explicitly given by

$$
\begin{equation*}
\omega_{A_{1}}^{A_{2}} T^{R}{ }_{S}=\left(R^{-1}\right)^{T B_{1}}{ }_{C A_{1}}\left(R^{-1}\right)^{A_{2} C}{ }_{B_{2} S} T^{R}{ }_{T} \omega_{B_{1}}^{B_{2}} \tag{4.5.1}
\end{equation*}
$$

Using (2.2.45) we compute the exterior derivative on the basis elements of $S_{q, r}(N+$ $2)$ :

$$
\begin{equation*}
d T_{B}^{A}=\frac{1}{r-r^{-1}}\left[\left(R^{-1}\right)^{C R}{ }_{E T}\left(R^{-1}\right)^{T E}{ }_{S B} T_{C}^{A}-\delta_{S}^{R} T_{B}^{A}\right] \omega_{R}^{S} \equiv T_{C}^{A} X_{B S}^{C R} \omega_{R}^{S} \tag{4.5.2}
\end{equation*}
$$

where we have

$$
\begin{equation*}
X_{A_{2} B_{2}}^{A_{1} B_{1}} \equiv \frac{1}{r-r^{-1}}\left[\left(R^{-1}\right)^{A_{1} B_{1}}\left(R^{-1}\right)^{T E}{ }_{B_{2} A_{2}}-\delta_{B_{2}}^{B_{1}} \delta_{A_{2}}^{A_{1}}\right]=z K_{A_{2} B_{2}}^{A_{1} B_{1}}-\left(\hat{R}^{-1}\right)_{A_{2} B_{2}}^{A_{1} B_{1}} \tag{4.5.3}
\end{equation*}
$$

with $z \equiv \epsilon r^{N-\epsilon}, K_{A_{2} B_{2}}^{A_{1} B_{1}}=C^{A_{1} B_{1}} C_{A_{2} B_{2}} .[$ From (4.1.14) and 4.1.21), the second equality in (4.5.3) is easily proven.] Notice also that from (4.5.2) and (2.1.85), $X_{A_{2} B_{2}}^{A_{1} B_{1}}$ is the fundamental representation of the $q$-Lie algebra generators $\chi_{B_{2}}^{B_{1}}$ :

$$
X_{A_{2} B_{2}}^{A_{1} B_{1}}=\chi_{B_{2}}^{B_{1}}\left(T_{A_{2}}^{A_{1}}\right)
$$

Every element $\rho$ of $\Gamma$, which by definition is written in a unique way as $\rho=$ $a^{A_{1}}{ }_{A_{2}} \omega_{A_{1}}^{A_{2}}$, can also be written as

$$
\begin{equation*}
\rho=\sum_{k} a_{k} d b_{k} \tag{4.5.4}
\end{equation*}
$$

for some $a_{k}, b_{k}$ belonging to $A$. This can be proven directly by inverting the relation (4.5.2). The result is an expression of the $\omega$ in terms of a linear combination of $\kappa(T) d T$, as in the classical case:

$$
\begin{equation*}
\omega_{A_{1}}^{A_{2}}=Y_{A_{1} B_{1}}{ }_{2}^{A_{2} B_{2}} \kappa\left(T_{C}^{B_{1}}\right) d T_{B_{2}}^{C} \tag{4.5.5}
\end{equation*}
$$

where $Y$ satisfies $X_{A_{2} B_{2}}^{A_{1} B_{1}} Y_{B_{1} C_{1}}^{B_{2} C_{2}}=\delta_{C_{1}}^{A_{1}} \delta_{A_{2}}^{C_{2}}, Y_{A_{1} B_{1}}{ }_{A_{2} B_{2}}^{B_{2}} X^{B_{1} C_{1}}{ }_{B_{2} C_{2}}=\delta_{A_{1}}^{C_{1}} \delta_{C_{2}}^{A_{2}}$ and is given explicitly by

$$
\begin{equation*}
Y_{A_{1} B_{1}}^{A_{2} B_{2}}=\alpha\left[(z-\lambda) C_{A_{1} B_{1}} C^{A_{2} B_{2}}+C_{A_{1} D} R_{C B_{1}}^{D A_{2}} C^{C B_{2}}-\frac{\lambda}{z\left(z-z^{-1}\right)} D_{A_{1}}^{A_{2}}\left(D^{-1}\right)_{B_{1}}^{B_{2}}\right] \tag{4.5.6}
\end{equation*}
$$

with $\alpha=\frac{1}{z\left(z-z^{-1}-\lambda\right)}$ and $D_{C}^{E} \equiv C^{E F} C_{C F}$. The $r=1$ limit of (4.5.2) is discussed in the next section.

The braiding matrix $\Lambda$ that defines the exterior product of forms is given by (2.2.3.5). It satisfies the characteristic equation:

$$
\begin{gather*}
\left(\Lambda+r^{2} I\right)\left(\Lambda+r^{-2} I\right)\left(\Lambda+\epsilon r^{\epsilon+1-N} I\right)\left(\Lambda+\epsilon r^{-\epsilon-1+N} I\right) \times  \tag{4.5.7}\\
\left(\Lambda-\epsilon r^{-\epsilon+1+N} I\right)\left(\Lambda-\epsilon r^{\epsilon-1-N} I\right)(\Lambda-I)=0
\end{gather*}
$$

due to the characteristic equation (4.1.13). For simplicity we will at times use the adjoint indices $i, j, k, \ldots$ with ${ }^{i}={ }_{A}^{B},{ }_{i}={ }_{B}$. Define

$$
\begin{equation*}
\left.\left.\left(P_{I}, P_{J}\right)_{a_{1} d_{1}}^{a_{2}}\right|_{c_{2}} ^{d_{2}}\right|_{c_{2}} ^{c_{1}} b_{2} \equiv d^{f_{2}} d_{c_{2}}^{-1} \hat{R}_{c_{2} g_{1}}^{b_{1} f_{2}}\left(P_{I}\right)^{c_{1} g_{1}}{ }_{a_{1} e_{1}}\left(\hat{R}^{-1}\right)_{d_{1} g_{2}}^{a_{2} e_{1}}\left(P_{J}\right)^{d_{2} g_{2}}{ }_{b_{2} f_{2}} \tag{4.5.8}
\end{equation*}
$$

where $P_{I}=P_{S}, P_{A}, P_{0}$ are given in (4.1.16) and $d^{f_{2}} \equiv D_{f_{2}}^{f_{2}}, d_{c_{2}}^{-1} \equiv\left(D^{-1}\right)_{c_{2}}^{c_{2}}$. The $\left(P_{I}, P_{J}\right)$ are themselves projectors, i.e.:

$$
\begin{equation*}
\left(P_{I}, P_{J}\right)\left(P_{K}, P_{L}\right)=\delta_{I K} \delta_{J L}\left(P_{I}, P_{J}\right) \tag{4.5.9}
\end{equation*}
$$

Moreover

$$
\begin{equation*}
(I, I)=I \tag{4.5.10}
\end{equation*}
$$

From $\omega^{i} \wedge \omega^{j} \equiv \omega^{i} \otimes \omega^{j}-\Lambda_{k l}^{i j} \omega^{k} \otimes \omega^{l}$ we find

$$
\begin{equation*}
\omega^{i} \wedge \omega^{j}=-Z_{k l}^{i j} \omega^{k} \wedge \omega^{l} \tag{4.5.11}
\end{equation*}
$$

with

$$
\begin{equation*}
Z=\left(P_{S}, P_{S}\right)+\left(P_{A}, P_{A}\right)+\left(P_{0}, P_{0}\right)-I \tag{4.5.12}
\end{equation*}
$$

see ref. [30]. The inverse of $\Lambda$ always exists, and is given by

$$
\begin{align*}
\left.\left(\Lambda^{-1}\right)_{A_{1} D_{1}}^{A_{2} D_{2}}\right|_{B_{2} C_{2}} ^{B_{1}} C_{C_{2}} & =f_{D_{1}}^{D_{2} B_{1}}\left(T_{C_{2}}^{A_{2}} \kappa^{-1}\left(T_{A_{1}}^{C_{1}}\right)\right)= \\
& =R_{A_{1}}^{F_{1} B_{1}}\left(R_{1} R^{-1}\right)^{A_{2} G_{1}}{ }_{E_{2} D_{1}}\left(R^{-1}\right)^{D_{2} E_{2}}{ }_{G_{2} C_{2}} R_{B_{2}}^{G_{2} C_{1}}{ }^{G_{2} C_{1}}\left(d^{-1}\right)^{C_{1}} d_{F_{1}} \tag{4.5.13}
\end{align*}
$$

Note that for $r=1, \Lambda^{2}=I$ and $(\Lambda+I)(\Lambda-I)=0$ replaces the seventh-order spectral equation (4.5.7). In this special case, one finds the simple formula:

$$
\begin{equation*}
\omega^{i} \wedge \omega^{j}=-\Lambda_{k l}^{i j} \omega^{k} \wedge \omega^{l} \quad \text { i.e. } Z=\Lambda . \tag{4.5.14}
\end{equation*}
$$

The $\boldsymbol{q}$-Cartan-Maurer equations are given by:

$$
\begin{equation*}
d \omega_{C_{1}}^{C_{2}}=\frac{1}{r-r^{-1}}\left(\omega_{B}^{B} \wedge \omega_{C_{1}}^{C_{2}}+\omega_{C_{1}}^{C_{2}} \wedge \omega_{B}^{B}\right) \equiv-\left.\frac{1}{2} C_{A_{2} B_{2}}^{A_{1} B_{1}}\right|_{C_{1}} ^{C_{2}} \omega_{A_{1}}^{A_{2}} \wedge \omega_{B_{1}}^{B_{2}} \tag{4.5.15}
\end{equation*}
$$

with:

$$
\begin{equation*}
\left.C_{A_{2}}^{A_{1}} B_{B_{2}}^{B_{1}}\right|_{C_{1}} ^{C_{2}}=-\frac{2}{\left(r-r^{-1}\right)}\left[\left.Z_{B}^{B} C_{1}^{C_{2}}\right|_{A_{2}} ^{A_{1}} B_{1} B_{2}+\delta_{C_{1}}^{A_{1}} \delta_{A_{2}}^{C_{2}} \delta_{B_{2}}^{B_{1}}\right] \tag{4.5.16}
\end{equation*}
$$

To derive this formula we have used the flip operator $Z$ on $\omega_{B}^{B} \wedge \omega_{C_{1}}^{C_{2}}$.
Finally, we recall that the $\chi$ operators close on the $q$-Lie algebra :

$$
\begin{equation*}
\chi_{i} \chi_{j}-\Lambda^{k l}{ }_{i j} \chi_{k} \chi_{l}=\mathbf{C}_{i j}{ }^{k} \chi_{k} \tag{4.5.17}
\end{equation*}
$$

where the $q$-structure constants are given by

$$
\begin{equation*}
\mathbf{C}_{j k}{ }^{i}=\chi_{k}\left(M_{j}{ }^{i}\right) \quad \text { explicitly : }\left.\quad \mathbf{C}_{A_{2}}^{A_{1}} B_{1} B_{2}\right|_{C_{1}} ^{C_{2}}=\frac{1}{r-r^{-1}}\left[-\delta_{B_{2}}^{B_{1}} \delta_{C_{1}}^{A_{1}} \delta_{A_{2}}^{C_{2}}+\left.\Lambda_{B}^{B} C_{1} C_{C_{2}}^{C_{2}}\right|_{A_{2}} ^{A_{1}} B_{B_{2}}\right] . \tag{4.5.18}
\end{equation*}
$$

The $C$ structure constants appearing in the Cartan-Maurer equations are related to the $\mathbf{C}$ constants of the $q$-Lie algebra by:

$$
\begin{equation*}
\mathbf{C}_{j k}{ }^{i}=\frac{1}{2}\left[C_{j k}{ }^{i}-\Lambda^{r s}{ }_{j k} C_{r s}{ }^{i}\right] \tag{4.5.19}
\end{equation*}
$$

In the particular case $\Lambda^{2}=I$ (i.e. for $r=1$ ) it is not difficult to see that in fact $C=\mathbf{C}$, and that the $q$-structure constants are $\Lambda$-antisymmetric:

$$
\begin{equation*}
\mathbf{C}_{j k}{ }^{i}=-\Lambda^{r s}{ }_{j k} \mathbf{C}_{r s}{ }^{i} \tag{4.5.20}
\end{equation*}
$$

Note 4.5.1 The formulae characterizing the bicovariant calculus have been written in the basis $\left\{\chi_{B}^{A}\right\},\left\{\omega_{C}^{D}\right\}$ because of the particularly simple expression of the $f_{A}^{B C}{ }_{D}$ and $\chi_{B}^{A}$ functionals in terms of $L^{ \pm A}{ }_{B}$, see (2.2.32) and (2.2.52). Obviously the calculus is independent from the basis chosen. If we consider the linear transformation

$$
\omega^{i} \rightarrow \omega^{\prime i}=X^{i}{ }_{j} \omega^{j}
$$

(where we use adjoint indices ${ }^{i}={ }_{A_{1}}{ }^{A_{2}},{ }_{j}={ }^{B_{1}}{ }_{B_{2}}$ ), from the exterior differential

$$
\begin{equation*}
d a=\left(\chi_{i} * a\right) \omega^{i}=\left(\chi_{i}^{\prime} * a\right) \omega^{\prime i} \tag{4.5.21}
\end{equation*}
$$

we find

$$
\chi_{i} \rightarrow \chi_{i}^{\prime}=\chi_{j}\left(X^{-1}\right)^{j}{ }_{i}
$$

and from the coproduct rule (2.1.35) of the $\chi_{i}$ we find $f^{i}{ }_{j} \rightarrow f^{\prime i}{ }_{j}=X^{i}{ }_{l} f^{l}{ }_{m}\left(X^{-1}\right)^{m}{ }_{j}$; while from (2.1.38) we have $M_{i}{ }^{j} \rightarrow M_{i}^{\prime j}=\left(X^{-1}\right)^{l}{ }_{i} M_{l}{ }^{m} X^{j}{ }_{m}$.

A useful change of basis is obtained via the following transformation:

$$
\begin{align*}
\omega_{A_{1}}^{A_{2}} \rightarrow \vartheta_{A_{2}}^{A_{1}} & =X^{A_{1} B_{1}}{ }_{A_{2} B_{2}}^{\omega_{D_{2}}} \omega_{B_{1}}^{B_{2}}  \tag{4.5.22}\\
\chi_{A_{2}}^{A_{1}} \rightarrow \psi_{A_{1}}^{A_{2}} & =\chi_{B_{2}}^{B_{1}} Y_{B_{1} A_{1} A_{2}}
\end{align*}
$$

where $X$ and its (second) inverse $Y$ are defined in (4.5.3) and (4.5.6). Using (4.5.5) it is immediate to see that

$$
\begin{equation*}
\vartheta_{A_{2}}^{A_{1}}=\kappa\left(T_{C}^{A_{1}}\right) d T_{A_{2}}^{C} \tag{4.5.23}
\end{equation*}
$$

We also have:

$$
\begin{equation*}
\psi_{A_{1}}^{A_{2}}\left(T_{B_{2}}^{B_{1}}\right)=\psi_{A_{1}}^{A_{2}}\left(\widetilde{T}_{B_{2}}^{B_{1}}\right)=\delta_{A_{1}}^{B_{1}} \delta_{B_{2}}^{A_{2}} \quad \text { where } \quad \widetilde{T}_{B_{2}}^{B_{1}} \equiv T_{B_{2}}^{B_{1}}-\delta_{B_{2}}^{B_{1}} I \tag{4.5.24}
\end{equation*}
$$

Formula (4.5.24) follows from $\psi_{A_{1}}^{A_{2}}(I)=0$ and:

$$
\begin{align*}
\vartheta_{A_{2}}^{A_{1}} & =\kappa\left(T^{A_{1}}\right) d T^{C}{ }_{A_{2}}=\kappa\left(T_{C}^{A_{1}}\right)\left(\psi_{B_{1}}^{B_{2}} * T^{C}{ }_{A}^{A_{2}}\right) \vartheta^{B_{1}}{ }_{B_{2}} \\
& =\kappa\left(T_{C}^{A_{1}}\right) T^{C}{ }_{D} \psi_{B_{1}}^{B_{2}}\left(T^{D}{ }_{A_{2}}\right) \vartheta_{B_{2}}^{B_{1}}=\psi_{B_{1}}^{B_{2}}\left(T_{A_{2}}^{A_{1}}\right) \vartheta_{B_{2}}^{B_{1}} . \tag{4.5.25}
\end{align*}
$$

The analogue of the coordinates $\widetilde{T}_{B_{2}}^{B_{1}}$ in the old basis is given by

$$
\begin{equation*}
x_{B_{1}}^{B_{2}} \equiv Y_{B_{1} C_{1}}^{B_{2} C_{2}} \widetilde{T}_{C_{2}}^{C_{1}} \quad, \quad \chi_{A_{2}}^{A_{1}}\left(x_{B_{1}}^{B_{2}}\right)=\delta_{B_{1}}^{A_{1}} \delta_{A_{2}}^{B_{2}} \tag{4.5.26}
\end{equation*}
$$

The set of coordinates $x_{B_{1}}^{B_{2}}$ and $\widetilde{T}_{C_{2}}^{C_{1}}$ span the space $X$ described in (2.1.89) and dual to the $q$-Lie algebra of $S_{q, r}(N+2)$.

## Conjugation

From the $*$-structures (4.3.29), (4.3.30) and the definition (2.2.52) it is straightforward to find how the $*$-conjugation acts on the tangent vectors $\chi$. Both conjugations (4.3.29) and (4.3.30) are compatibile with the differential calculus. Indeed they respectively yield [use (2.2.52), (4.3.15), (4.3.5), (4.1.19), (4.1.20) and (4.1.21) with $N \rightarrow N+2$ since we have capital indices]:

$$
\begin{align*}
& \left(\chi_{B}^{A}\right)^{*}=-r^{-N-1} \chi_{D}^{C} \mathcal{D}^{F}{ }_{B} \mathcal{D}^{A}{ }_{G} R^{E G}{ }_{F C} D_{E}^{D} \quad \text { for } S O_{q, r}(n+2, n ; \mathbf{R}) ; 2 n+2=N+2 \\
& \left(\chi_{B}^{A}\right)^{*}=-\epsilon r^{\epsilon-(N+2)} \chi_{D}^{C} R^{E A}{ }_{B C} D_{E}^{D} \text { for } S O_{q, r}(n+1, n+1 ; \mathbf{R}) \text { or } S p_{q, r}(n+1, n+1 ; \mathbf{R})  \tag{4.5.27}\\
& \text { with } D_{C}^{E} \equiv C^{E F} C_{C F} \text {. As for the } L \text { matrices (and similarly to the } T \text { matrices) we } \\
& \text { have } \kappa^{2}\left(\chi_{B}^{A}\right)=D^{-1}{ }_{E}^{A} \chi_{F}^{E} D_{B}^{F} .
\end{align*}
$$

In a basis $\left\{\chi_{B}^{A}\right\}$ relation（2．3．52）reads

$$
\begin{equation*}
\left(\chi_{B}^{A}\right)^{*}=V_{B P}^{A}{ }^{Q} \chi_{Q}^{P} \quad \text { if and only if } \quad \omega_{C}^{D}=-\omega_{E}^{F} \overline{V_{F C}^{E}{ }^{D}} \tag{4.5.28}
\end{equation*}
$$

where $V$ is a matrix with complex entries and $\bar{V}$ is its complex conjugate ．Using this espression［or the inversion formulae（4．5．5）］one finds the induced conjugation on the left invariant 1－forms（use $\overline{D_{B}^{A}}=D^{-1 A}{ }_{B}$ ）：

$$
\begin{gather*}
\left(\omega_{A}^{B}\right)^{*}=r^{N+1} \mathcal{D}_{D}^{F} \mathcal{D}_{G}^{C} D^{-1 B}{ }_{E} R^{-1}{ }_{F A}^{E G} \omega_{C}^{D} \quad \text { for } S O_{q, r}(n+2, n ; \mathbf{R}) ; 2 n+2=N+2  \tag{4.5.29}\\
\left(\omega_{A}^{B}\right)^{*}=\epsilon r^{N+2-\epsilon} D^{-1 B}{ }_{E} R^{-1 E C}{ }_{D A} \omega_{C}^{D} \quad \text { for } S O_{q, r}(n+1, n+1 ; \mathbf{R}) \text { or } S p_{q, r}(n+1, n+1 ; \mathbf{R}) .
\end{gather*}
$$

## 4．6 Differential calculus on $S O_{q, r=1}(N+2)$ and $S p_{q, r=1}(N+2)$

As discussed in Section 4．2，we have obtained the quantum inhomogeneous groups $I S_{q, r}(N)$ via the projection

$$
\begin{equation*}
P: \quad S_{q, r}(N+2) \longrightarrow \frac{S_{q, r}(N+2)}{H}=I S_{q, r}(N) \tag{4.6.1}
\end{equation*}
$$

with $H=$ Hopf ideal in $S_{q, r}(N+2)$ defined after（4．2．1）．As a consequence，the universal enveloping algebra $U\left(i s_{q, r}(N)\right)$ is a Hopf subalgebra of $U\left(s_{q, r}(N+2)\right)$ and contains all the functionals that annihilate $H=\operatorname{Ker}(P)$ ．

Let us consider now the $\chi$ functionals in the differential calculus on $S_{q, r}(N+2)$ ． Decomposing the indices we find：

$$
\begin{align*}
& \chi^{a}{ }_{b}=\frac{1}{r-r^{-1}}\left[f_{c}{ }^{c a}{ }_{b}-\delta_{b}^{a} \varepsilon\right] \quad+\frac{1}{r-r^{-1}} f_{\bullet}^{\bullet a}{ }_{b}  \tag{4.6.2}\\
& \chi^{a}{ }_{\circ}=\frac{1}{r-r^{-1}} f_{c}{ }^{c a}{ }^{\circ} \quad+\frac{1}{r-r^{-1}} f_{\bullet}{ }^{\bullet}{ }^{\circ} \text { 。 }  \tag{4.6.3}\\
& \chi^{\circ}{ }_{b}=  \tag{4.6.4}\\
& +\frac{1}{r-r^{-1}}\left[f_{c}{ }^{c \circ}{ }_{b}+f_{\bullet}{ }^{\bullet \circ}{ }_{b}\right] \\
& \chi^{a} .=  \tag{4.6.5}\\
& +\frac{1}{r-r^{-1}} f_{\bullet}^{\bullet} \text {. } \\
& \chi_{b}^{\bullet}=\frac{1}{r-r^{-1}} f_{\bullet}^{\bullet \bullet}{ }_{b}  \tag{4.6.6}\\
& \chi^{\circ}{ }_{\circ}=\frac{1}{r-r^{-1}}\left[f_{\circ}{ }^{\circ \circ}{ }_{\circ}-\varepsilon\right] \quad+\frac{1}{r-r^{-1}}\left[f_{c}{ }^{c \circ}{ }_{\circ}+f_{\bullet}{ }^{\bullet \circ}{ }_{\circ}\right]  \tag{4.6.7}\\
& \chi_{\bullet}^{\circ}=\quad+\frac{1}{r-r^{-1}} f_{\bullet} \bullet  \tag{4.6.8}\\
& \chi_{\bullet}=\frac{1}{r-r^{-1}} f_{\bullet}{ }^{\bullet \bullet} \text { 。 }  \tag{4.6.9}\\
& \chi_{\bullet}^{\bullet}=\frac{1}{r-r^{-1}}\left[f_{\bullet}^{\bullet} \bullet-\varepsilon\right]  \tag{4.6.10}\\
& \text { terms annihilating } H
\end{align*}
$$

where we have indicated the terms that do and do not annihilate the Hopf ideal $H$, i.e. that belong or do not belong to $U_{q, r}(i s(N))$. We see that only the functionals $\chi^{\bullet}{ }_{b}, \chi^{\bullet}$ 。and $\chi^{\bullet}$ 。 do annihilate $H$, and therefore belong to $U\left(i s_{q, r}(N)\right)$. The resulting bicovariant differential calculus, see Chapter 5, contains dilatations and translations, but does not contain the tangent vectors of $S_{q, r}(N)$, i.e. the functionals $\chi^{a}{ }_{b}$. Indeed these contain $f_{\bullet}{ }^{\bullet a}{ }_{b}$, in general not vanishing on $H$. We can, however, try to find restrictions on the parameters $q, r$ such that $f_{\bullet}{ }^{\bullet a}{ }_{b}(H)=0$. As we will see, this happens for $r=1$. For this reason we consider in the following the particular multiparametric deformations called "minimal deformations" or twistings, corresponding to $r=1$.

We first examine what happens to the bicovariant calculus on $S_{q, r}(N+2)$ in the $r=1$ limit ${ }^{\prime}$. The $R$ matrix is given by, cf. (4.1.8):

$$
\begin{array}{ll}
R_{A B}^{A B}=q_{A B}^{-1}+O(\lambda) & \\
R^{A B}{ }_{B A}=\lambda & A>B, A^{\prime} \neq B \\
R^{A A_{A}^{\prime}}=\lambda\left(1-\epsilon r^{\rho_{A}-\rho_{A^{\prime}}}\right) & A>A^{\prime} \\
R^{A A_{B B^{\prime}}^{\prime}}=-\lambda \epsilon_{A} \epsilon_{B}+O\left(\lambda^{2}\right) & A>B, A^{\prime} \neq B \tag{4.6.14}
\end{array}
$$

where $O\left(\lambda^{n}\right)$ indicates an infinitesimal of order $\geq \lambda^{n}$; the $q_{A B}$ parameters satisfy:

$$
\begin{equation*}
q_{A B}=q_{A B^{\prime}}^{-1}=q_{A^{\prime} B}^{-1}=q_{B A}^{-1} ; \quad q_{A A}=q_{A A^{\prime}}=1 \tag{4.6.15}
\end{equation*}
$$

up to order $O(\lambda)$. Note that the components $R^{A A_{A^{\prime} A}^{\prime}}$ are of order $O\left(\lambda^{2}\right)$ for the orthogonal case $(\epsilon=1)$ and of order $O(\lambda)$ for the symplectic case $(\epsilon=-1)$. The $R T T$ relations simply become:

$$
\begin{equation*}
T_{A_{1}}^{B_{1}} T_{A_{2}}^{B_{2}}=\frac{q_{B_{1} B_{2}}}{q_{A_{1} A_{2}}} T_{A_{2}}^{B_{2}} T_{A_{1}}^{B_{1}} \tag{4.6.16}
\end{equation*}
$$

For $r=1$ the metric is $C_{A B}=\epsilon_{A} \delta_{A B^{\prime}}$ and therefore we have $C_{A B}=\epsilon C_{B A}$. Using the definition (4.3.1), it is easy to see that

$$
\begin{align*}
& L^{ \pm A} A_{A}\left(T_{D}^{C}\right)=\delta_{D}^{C} q_{A C}+O(\lambda)  \tag{4.6.17}\\
& L^{ \pm A}\left(T_{B}^{B}\right)= \pm \lambda \quad A \neq B, A^{\prime} \neq B ; A<B \text { for } L^{+}, A>B \text { for } L^{-}  \tag{4.6.18}\\
& L^{ \pm A}{ }_{A^{\prime}}\left(T^{A^{\prime}}\right)= \pm \lambda\left[1-\epsilon r^{ \pm\left(\rho_{A}-\rho_{A^{\prime}}\right)}\right] \quad A<A^{\prime} \text { for } L^{+}, A>A^{\prime} \text { for } L^{-}  \tag{4.6.19}\\
& L^{ \pm A}{ }_{B}\left(T_{A^{\prime}}^{A^{\prime}}\right)=\mp \lambda \epsilon_{A} \epsilon_{B}+O\left(\lambda^{2}\right) \quad A \neq B, A^{\prime} \neq B ; A<B \text { for } L^{+}, A>B \text { for } L \tag{4.6.20}
\end{align*}
$$

[^8]all other $L^{ \pm}(T)$ vanishing. Relations (4.6.18) and (4.6.20) imply that for any generator $T^{C}{ }_{D}$ we have $L^{ \pm A}{ }_{B}\left(T^{C}{ }_{D}\right)=-\epsilon_{A} \epsilon_{B} L^{ \pm B^{\prime}}{ }_{A^{\prime}}\left(T^{C}{ }_{D}\right)+O\left(\lambda^{2}\right)$ with $A \neq B, A \neq B^{\prime}$. In general, since
$\Delta\left(L^{ \pm A}{ }_{A}\right)=L^{ \pm A}{ }_{A} \otimes L^{ \pm A}{ }_{A} ; \quad \Delta\left(L^{ \pm A}{ }_{B}\right)=L^{ \pm A}{ }_{A} \otimes L^{ \pm A}{ }_{B}+L^{ \pm A}{ }_{B} \otimes L^{ \pm B}{ }_{B}+O\left(\lambda^{2}\right), \quad A \neq B$
we find that
\[

$$
\begin{align*}
& L^{ \pm A}{ }_{A}=O(1)  \tag{4.6.21}\\
& L^{ \pm A}=O(\lambda), \quad A \neq B, A \neq B^{\prime}  \tag{4.6.22}\\
& L^{ \pm A}{ }_{A^{\prime}}=O\left(\lambda^{2}\right) \text { for } S O_{q}, \quad O(\lambda) \text { for } S p_{q} \tag{4.6.23}
\end{align*}
$$
\]

where, by definition, $\phi=O\left(\lambda^{n}\right)$ ( $\phi$ being a functional) means that for any element $a \in S_{q, r}(N+2)$ with well-defined classical limit, we have $\phi(a)=O\left(\lambda^{n}\right)$. Moreover the following relations hold:

$$
\begin{align*}
& L_{A}^{ \pm A}=L^{\mp A}+O(\lambda)  \tag{4.6.24}\\
& \kappa\left(L^{ \pm A}{ }_{B}\right)=\epsilon_{A} \epsilon_{B} L_{A^{\prime}}^{ \pm B^{\prime}}+O(\lambda) \text { and therefore, } \kappa^{2}=i d+O(\lambda) . \tag{4.6.25}
\end{align*}
$$

Similarly one can prove the relations involving the $f$ functionals (no sum on repeated indices):

$$
\begin{align*}
& f_{A}^{A A}{ }_{A}=\varepsilon+O(\lambda)  \tag{4.6.26}\\
& f_{A}{ }^{B A}{ }_{B}=O(1) \quad \text { and } f_{A}^{B A}{ }_{B}=f_{B^{\prime}}^{A^{\prime} B^{\prime}}{ }_{A^{\prime}}+O(\lambda)  \tag{4.6.27}\\
& f_{C}^{C A}=O\left(\lambda^{2}\right) \quad C \neq A  \tag{4.6.28}\\
& f_{C}^{C A}{ }_{B}=O\left(\lambda^{2}\right) \quad[A<B, C \neq B] \text { or }[A>B, C \neq A] \tag{4.6.29}
\end{align*}
$$

[hint: check (4.6.27)-(4.6.29) first on the generators, then use the coproduct in (2.1.35)]. From the last relation we deduce

$$
\begin{array}{lll}
\chi_{B}^{A} & =\frac{1}{\lambda} f_{B}{ }^{B A}{ }_{B}+O(\lambda), & \\
& A<B  \tag{4.6.31}\\
\chi_{B}^{A} & =\frac{1}{\lambda} f_{A}^{A A}{ }_{B}+O(\lambda), & \\
& A>B
\end{array}
$$

and from (4.6.26) and (4.6.28) one has

$$
\begin{equation*}
\chi_{A}^{A}=\frac{1}{\lambda}\left[f_{A}^{A A}{ }_{A}-\varepsilon\right] \tag{4.6.32}
\end{equation*}
$$

Next one can verify that

$$
\left.\begin{array}{l}
\chi_{B}^{A}\left(T^{B}{ }_{A}^{A}\right)=-q_{B A}+O(\lambda)  \tag{4.6.33}\\
\chi_{B}^{A}\left(T^{A^{\prime}}\right)=\epsilon_{A} \epsilon_{B}+O(\lambda) \\
\chi_{B}^{A}\left(T_{D}^{C}\right)=0 \text { otherwise }
\end{array}\right\} A \neq B, A \neq B^{\prime}
$$

$$
\begin{equation*}
\forall T_{D}^{C}, \quad \chi_{A}^{A}\left(T_{D}^{C}\right)=-\chi_{A^{\prime}}^{A^{\prime}}\left(T_{D}^{C}\right)+O(\lambda) . \tag{4.6.34}
\end{equation*}
$$

Eq.s (4.6.33) yield the relation between $\chi$ functionals:

$$
\begin{equation*}
\forall T_{D}^{C}, \quad \chi_{A^{\prime}}^{B^{\prime}}\left(T_{D}^{C}\right)=-\frac{\epsilon_{A} \epsilon_{B}}{q_{B A}} \chi_{B}^{A}\left(T_{D}^{C}\right)+O(\lambda), A \neq B, A \neq B^{\prime} \tag{4.6.35}
\end{equation*}
$$

It is not difficult to prove that the coproduct rule in (2.1.35) is compatible with (4.6.35) and (4.6.34) making them valid on arbitrary polynomials in the $T^{A}{ }_{B}$ elements:

$$
\begin{equation*}
\chi_{A^{\prime}}^{B^{\prime}}=-\frac{\epsilon_{A} \epsilon_{B}}{q_{B A}} \chi_{B}^{A}+O(\lambda), A \neq B, A \neq B^{\prime} \quad ; \quad \chi_{A}^{A}=-\chi_{A^{\prime}}^{A^{\prime}}+O(\lambda) . \tag{4.6.36}
\end{equation*}
$$

Finally:

$$
\begin{equation*}
\chi_{A^{\prime}}^{A}=O(\lambda) \text { for } S O_{q}, \quad O(1) \text { for } S p_{q}, \quad A \neq A^{\prime} . \tag{4.6.37}
\end{equation*}
$$

Summarizing, in the $r \rightarrow 1$ limit, only the following $\chi$ functionals survive:

$$
\begin{align*}
\chi_{A}^{A} & \equiv \lim _{r \rightarrow 1} \frac{1}{\lambda}\left[f_{A}^{A A}{ }_{A}-\varepsilon\right]  \tag{4.6.38}\\
\chi_{B}^{A} & \equiv \lim _{r \rightarrow 1} \frac{1}{\lambda} f_{A}^{A A}{ }_{B}, \quad A>B, A \neq B^{\prime}  \tag{4.6.39}\\
\chi_{B}^{A} & \equiv \lim _{r \rightarrow 1} \frac{1}{\lambda} f_{B}{ }^{B A}{ }_{B}, \quad A<B, A \neq B^{\prime}  \tag{4.6.40}\\
\chi_{A^{\prime}}^{A} & \equiv \lim _{r \rightarrow 1} \frac{1}{\lambda} \sum_{C} f_{C}{ }^{C A}{ }_{A^{\prime}}=0 \text { for } S O_{q}, \quad \neq 0 \text { for } S p_{q} \tag{4.6.41}
\end{align*}
$$

Notice that (4.6.36) and (4.6.37) are all contained in the formula:

$$
\begin{equation*}
\chi_{A^{\prime}}^{B^{\prime}}=-\frac{\epsilon_{A} \epsilon_{B}}{q_{B A}} \chi_{B}^{A}+O(\lambda) \tag{4.6.42}
\end{equation*}
$$

thus in the $r \rightarrow 1$ limit there are $(N+2)(N+1) / 2$ tangent vectors for $S O_{q}(N+2)$ and $(N+2)(N+3) / 2$ tangent vectors for $S p_{q}(N+2)$, exactly as in the classical case.

The $r=1$ limit of (4.5.2) reads:

$$
\begin{equation*}
d T_{B}^{A}=-\sum_{C} T_{C}^{A} q_{C B}\left(\omega_{B}^{C}-\epsilon_{B} \epsilon_{C} q_{B C} \omega_{C^{\prime}}^{B^{\prime}}\right), \tag{4.6.43}
\end{equation*}
$$

and therefore, for $r=1, \omega$ appears only in the combination

$$
\begin{equation*}
\Omega_{A}^{B} \equiv \omega_{A}^{B}-\epsilon_{A} \epsilon_{B} q_{A B} \omega_{B^{\prime}}^{A^{\prime}} \tag{4.6.44}
\end{equation*}
$$

Only $(N+2)(N+1) / 2\left[(N+2)(N+3) / 2\right.$ for $\left.S p_{q}(N+2)\right]$ of the $(N+2)^{2}$ one forms $\Omega_{A}^{B}$ are linearly independent because [compare with (4.6.42)]:

$$
\begin{equation*}
\Omega_{B^{\prime}}^{A^{\prime}}=-\frac{\epsilon_{A} \epsilon_{B}}{q_{A B}} \Omega_{A}^{B} . \tag{4.6.45}
\end{equation*}
$$

In the sequel, instead of considering the left module of 1 -forms freely generated by $\omega_{A}^{B}$, we consider the submodule $\Gamma$ freely generated by $\Omega_{A}{ }^{B}$ with $A^{\prime}<B$ for $S O_{q}$ and $A^{\prime} \leq B$ for $S p_{q}$. In fact only this submodule will be relevant for the $r=1$ differential calculus. As in the classical case 生, in order to simplify notations in sums we often $^{\text {a }}$ use $\chi_{B}^{A}$ and $\Omega_{A}^{B}$ without the restriction $A^{\prime} \leq B$ see for ex. (4.6.50) below. The bimodule structure on $\Gamma$, see Theorem 4.5.1, is given by the $r \rightarrow 1$ limit of the $f^{i}{ }_{j}$ functionals. These are diagonal in the $i, j$ indices [i.e. they vanish for $i \neq j$, see (4.6.26)-(4.6.29)] and still satisfy the property (2.1.32). We have:

$$
\begin{align*}
\Omega_{A}^{B} a & =\left(\omega_{A}^{B}-\epsilon_{A} \epsilon_{B} q_{A B} \omega_{B^{\prime}}^{A^{\prime}}\right) a \\
& =\left(f_{A}^{B C}{ }^{B} * a\right) \omega_{C}^{D}-\epsilon_{A} \epsilon_{B} q_{A B}\left(f_{B^{\prime}}^{A^{\prime} D^{\prime}}{ }_{C^{\prime}} * a\right) \omega_{D^{\prime}}^{C^{\prime}}  \tag{4.6.46}\\
& =\left(f_{A}^{B A}{ }_{B} * a\right) \Omega_{A}^{B}
\end{align*}
$$

where in the last equality we have used (4.6.27) and no sum is understood. We see that the bimodule structure is very simple since it does not mix different $\Omega$ 's. Moreover, relation (4.6.43) is invertible and yields:

$$
\begin{equation*}
\Omega_{A}^{B}=-q_{A B} \kappa\left(T_{C}^{B}\right) d T_{A}^{C} ; \tag{4.6.47}
\end{equation*}
$$

in the limit $q_{A B}=1$, the $\Omega_{A}^{B}$ are to be identified with the classical 1-forms, and indeed for $q_{A B}=1$ eq. (4.6.47) reproduces the correct classical limit $\Omega=-g^{-1} d g$ for the left-invariant 1 -forms on the group manifold.

The bimodule commutation rule (4.6.46) yields a formula similar to (4.5.1), replacing the values of the $R$ matrix for $r=1$ we find the commutations:

$$
\begin{equation*}
\Omega_{A_{1}}^{A_{2}} T_{S}^{R}=\frac{q_{A_{2} S}}{q_{A_{1} S}} T_{S}^{R} \Omega_{A_{1}}^{A_{2}} \tag{4.6.48}
\end{equation*}
$$

For $r=1$ the coproduct on the $\chi$ functionals reads

$$
\begin{equation*}
\Delta^{\prime}\left(\chi_{B}^{A}\right)=\chi_{B}^{A} \otimes f_{A}^{B A}{ }_{B}+\varepsilon \otimes \chi_{B}^{A} \quad \text { no sum on repeated indices. } \tag{4.6.49}
\end{equation*}
$$

We then consider the $r=1$ limit of (2.3.30): $d a=\left(\chi_{i} * a\right) \omega^{i}$ and therefore obtain the following definition of the exterior differential:

$$
\begin{equation*}
d a \equiv \frac{1}{2}\left(\chi_{B}^{A} * a\right) \Omega_{A}^{B}=\sum_{A^{\prime} \leq B}\left(\chi_{B}^{A} * a\right) \Omega_{A}^{B}, \quad \forall a \in A \tag{4.6.50}
\end{equation*}
$$

${ }^{4}$ To make closer contact with the classical case one may define:

$$
\Omega^{A B} \equiv \Omega_{C}^{B} C^{C A}=\epsilon_{A} \Omega_{A^{\prime}}^{B} ; \quad \chi_{A B} \equiv C_{A C} \chi_{B}^{C}=\epsilon_{A} \chi_{B}^{A^{\prime}}
$$

and retrieve the more familiar $q$-antisymmetry:

$$
\Omega^{A B}=-\epsilon q_{B A} \Omega^{B A} ; \quad \chi_{A B}=-\epsilon q_{A B} \chi_{B A}
$$

where in the second expression we have used the basis of linear independent tangent vectors $\left\{\chi_{B}^{A}\right\}_{A^{\prime} \leq B}$ and dual 1-forms $\left\{\Omega_{A}^{B}\right\}_{A^{\prime} \leq B}$ (notice that in the $S O_{q}$ case we have $A^{\prime}<B$ because $\chi_{A}^{A}=\Omega_{A}^{A}=0$ ). The Leibniz rule is satisfied for $d$ defined in (4.6.50) because of (4.6.49) and (4.6.46). Moreover any $\rho=a^{A}{ }_{B} \Omega_{A}{ }^{B} \in \Gamma$ can be written as $\rho=\sum_{k} a_{k} d b_{k}$, [use (4.6.47)].

We now introduce a left and a right action on the bimodule $\Gamma$ of 1-forms:

$$
\begin{align*}
\Delta_{L}\left(a \Omega_{A}^{B}\right) & \equiv \Delta(a) I \otimes \Omega_{A}^{B}  \tag{4.6.51}\\
\Delta_{R}\left(a \Omega_{A}^{B}\right) & \equiv \Delta(a)\left(\Omega_{C}^{D} \otimes M_{D A}^{C}\right) . \tag{4.6.52}
\end{align*}
$$

where $M_{D A}^{C}{ }^{B}=T^{C}{ }_{A} \kappa\left(T^{B}{ }_{D}\right)$. [Using (4.6.44) one can check that this is the $r=1$ limit of $\Delta_{L}\left(a \omega_{A_{1}}^{A_{2}}\right)=\Delta(a)\left(I \otimes \omega_{A_{1}}^{A_{2}}\right)$ and $\left.\Delta_{R}\left(a \omega_{A_{1}}^{A_{2}}\right)=\Delta(a)\left(\omega_{B_{1}}^{B_{2}} \otimes M_{B_{2} A_{1}}^{B_{1}} A_{2}\right)\right]$. Relation (4.6.52) is well defined i.e. $\Delta_{R}\left(\Omega_{B^{\prime}}^{A^{\prime}}\right)=\Delta_{R}\left(-\frac{\epsilon_{A} \epsilon_{B}}{q_{A B}} \Omega_{A}^{B}\right)$ because $\epsilon_{F} \epsilon_{E} q_{F E} M_{E^{\prime} A}^{F^{\prime}}$ $=\epsilon_{A} \epsilon_{B} q_{A B} M_{F B^{\prime}}^{E} A^{\prime}$. Since in the $r=1$ case the bicovariant bimodule conditions (2.1.32), (2.1.44) and (2.1.51) are still satisfied, it is easy to deduce that $\Delta_{L}$ and $\Delta_{R}$ give a bicovariant bimodule structure to $\Gamma$.

The differential (4.6.50) gives a bicovariant differential calculus if it is compatible with $\Delta_{L}$ and $\Delta_{R}$, i.e. if:

$$
\begin{align*}
& \Delta_{L}(a d b)=\Delta(a)(i d \otimes d) \Delta(b)  \tag{4.6.53}\\
& \Delta_{R}(a d b)=\Delta(a)(d \otimes i d) \Delta(b) \tag{4.6.54}
\end{align*}
$$

The proof of the compatibility of $d$ with $\Delta_{L}$ is straightforward, just use (4.6.50) and the coassociativity of the coproduct $\Delta$. In order to prove (4.6.54) we recall, from Proposition 2.3.1, that in the case $r \neq 1$ property (4.6.54) holds if and only if

$$
\begin{equation*}
b_{1} \omega^{j} \otimes b_{2} \chi_{i}\left(b_{3}\right) M_{j}^{i}=b_{1} \omega^{j} \otimes \chi_{j}\left(b_{2}\right) b_{3} \tag{4.6.55}
\end{equation*}
$$

and this last relation is equivalent to

$$
\begin{equation*}
b_{1} \chi_{i}\left(b_{2}\right) M_{j}^{i}=\chi_{j}\left(b_{1}\right) b_{2}, \quad \text { i.e. } \quad \chi_{i} * b=\left(b * \chi_{j}\right) \kappa\left(M_{i}{ }^{j}\right) \tag{4.6.56}
\end{equation*}
$$

as one can verify by applying $m(\kappa \otimes i d) \Delta_{L} \otimes i d$ ( $m$ denotes multiplication) to 4.6.55), and using the linear independence of the $\omega^{i}$. Now formula (4.6.56) holds also in the limit $r=1$. Indeed if we consider $b$ to be a polynomial in the $T_{B}^{A}$ with well behaved coefficents in the $r \rightarrow 1$ limit, then $\lim _{r \rightarrow 1}\left[b_{1} \chi_{i}\left(b_{2}\right) M_{j}{ }^{i}\right]=\lim _{r \rightarrow 1}\left[\chi_{j}\left(b_{1}\right) b_{2}\right]$ i.e. $b_{1}\left[\lim _{r \rightarrow 1} \chi_{i}\left(b_{2}\right)\right] M_{j}{ }^{i}=\left[\lim _{r \rightarrow 1} \chi_{j}\left(b_{1}\right)\right] b_{2}$ so that relation (4.6.56) remains valid for $r=1$, cf . 4.6.38)-(4.6.41). At this point one can prove (4.6.54) in the $r=1$ case simply by substituting $\Omega$ to $\omega$ in (2.3.37), (2.3.38) and (4.6.55). Since (4.6.56) holds for $r=1$, then also (4.6.55) holds in this limit and the theorem is proved.

We conclude that (4.6.50) defines a bicovariant differential calculus on $S_{q}(N+2)$.

Note 4.6.1 We have found the $S_{q, r=1}(N)$ differential calculus studying the $r=1$ limit of the $\chi$ functionals and of the bicovariant bimodule of 1-forms [see (4.6.51), (4.6.52), (4.6.53), (4.6.54)]. This has given a comprehensive analysis of the $r \rightarrow 1$ limit. The classical limit $r \rightarrow 1, q \rightarrow 1$ and the classical differential calculus are now easily recovered. From a slightly different perspective, since the calculus can be defined from the $q$-Lie algebra alone, we could just have studied only the limit of the $q$-Lie algebra. It is immediate to see that (2.3.3), (2.3.4), (2.3.5) or (2.3.18) still hold. This is another proof of the bicovariance of the $S_{q, r=1}(N)$ calculus.

We have chosen to study the $r \rightarrow 1$ limit of the quantum Lie algebra in the $\chi$ basis because this gives the classical Lie algebra. Another possiblity is to perform the limit in the $\psi$ basis. In this case the $\psi$ are linearly independent also when $r=1$, see (4.5.24) and the classical differential calculus is contained in this calculus.

Note 4.6.2 In (4.6.56) the sum on the indices $j=(C, D)$ can be restricted to $C^{\prime} \leq D$, thus using the basis $\left\{\chi_{D}^{C}\right\}_{C^{\prime} \leq D}$, provided one replaces $M$ by

$$
\begin{align*}
& M_{-}^{C}{ }_{D A}{ }^{B} \equiv M_{D A}^{C}{ }_{D}^{B}-\epsilon_{A} \epsilon_{B} q_{A B} M_{D B^{\prime}}^{C A^{\prime}} \quad \text { for } C^{\prime} \neq D, A^{\prime} \neq B \\
& M_{-}^{C}{ }_{C}{ }^{\prime}{ }^{B}{ }_{B}^{B} \equiv 0 \quad, \quad M_{-}^{C}{ }_{D A}{ }^{A^{\prime}} \equiv 0 \quad \text { for } S O_{q}  \tag{4.6.57}\\
& M_{-}^{C}{ }_{C^{\prime} A}{ }^{B} \equiv M_{C^{\prime}}^{C}{ }_{A}^{B}, \quad M_{-}^{C}{ }_{D A}{ }^{A^{\prime}} \equiv M_{D A}^{C}{ }^{A^{\prime}} \quad \text { for } S p_{q}
\end{align*}
$$

This is easily seen from (4.6.42). We have thus obtained the fundamental relation (2.3.23): $\left(\chi_{B_{2}}^{B_{1}} * b\right) M_{-}^{A_{1} B_{1}} B_{2}=\left(b * \chi_{A_{2}}^{A_{1}}\right)$, with $A_{1}^{\prime} \leq A_{2}, B_{1}^{\prime} \leq B_{2}$ for the $I S_{q, r=1}(N)$ differential calculus. Notice that $M_{-}^{C}{ }_{D A}{ }^{B}=M_{D A}^{C}{ }_{D}{ }^{B}-\epsilon_{C} \epsilon_{D} q_{D C} M_{C^{\prime} A}^{D^{\prime}}{ }^{B}$, this equality is due to the $R T T$ relations (4.6.16). We can also write $\Delta_{R}\left(a \Omega_{A}^{B}\right)=$ $\sum_{C^{\prime} \leq D} \Delta(a)\left(\Omega_{C}^{D} \otimes M_{-}^{C}{ }_{D A}{ }^{B}\right)$ cf.(4.6.52), thus using the basis $\left\{\Omega_{C}^{D}\right\}_{C^{\prime} \leq D}$. According to the general theory the elements $M_{-}^{C}{ }_{D A}{ }^{B}$ with $C^{\prime} \leq D, A^{\prime} \leq B$ are the adjoint representation for the differential calculus on $S_{q, r=1}(N+2)$. Since the calculus is bicovariant [cf.(4.6.53), (4.6.54)] we know a priori that the $M_{-}^{C}{ }_{D A}{ }^{B}$ with $C^{\prime} \leq D, A^{\prime} \leq B$ satisfy the properties (2.1.44) and (2.1.51). ${ }^{\text {p }}$

It is useful to express the bicovariant algebra (4.5.17), (2.1.112)-(2.1.114) in

[^9]the $r \rightarrow 1$ limit. Due to the $R$ matrix being diagonal for $r=1$, the $\Lambda$ tensor $\left.\left.\Lambda_{A_{1}}^{A_{2} D_{1}}\right|_{C_{2}}\right|_{B_{2}} ^{C_{1}} B_{1}{ }^{2} f_{A_{1}}^{A_{2} B_{B_{2}}}\left(M_{C_{2} D_{1}}^{C_{1} D_{2}}\right)$ takes the simple form:
\[

$$
\begin{equation*}
\left.\Lambda_{A_{1} B_{1}}^{A_{2} B_{2}}\right|_{B_{2} A_{2}} ^{B_{1}} A_{1}=q_{A_{1} B_{2}} q_{A_{2} B_{1}} q_{B_{1} A_{1}} q_{B_{2} A_{2}}, \quad 0 \text { otherwise } \tag{4.6.58}
\end{equation*}
$$

\]

Therefore (2.1.112)-(2.1.114) read (no sum on repeated indices):

$$
\begin{gather*}
f_{i}^{i} f_{j}^{j}=f_{j}^{j} f_{i}^{i}  \tag{4.6.59}\\
\mathbf{C}_{j k}{ }^{i} f_{j}^{j}{ }_{j} f_{k}^{k}+f^{i}{ }_{j} \chi_{k}=\Lambda^{k j}{ }_{j k} \chi_{k} f^{i}{ }_{j}+\mathbf{C}_{j k}{ }^{i} f^{i}{ }_{i}  \tag{4.6.60}\\
\chi_{k} f^{i}{ }_{i}=\Lambda^{i k}{ }_{k i} f^{i}{ }_{i} \chi_{k} . \tag{4.6.61}
\end{gather*}
$$

Explicitly the $q$-Lie algebra (4.5.17) reads:

$$
\begin{align*}
& \chi_{C_{2}}^{C_{1}} \chi_{B_{2}}^{B_{1}}-q_{B_{1} C_{2}} q_{C_{1} B_{1}} q_{B_{2} C_{1}} q_{C_{2} B_{2}} \chi_{B_{2}}^{B_{1}} \chi_{C_{2}}^{C_{1}}= \\
& \quad-q_{B_{1} C_{2}} q_{C_{2} B_{2}} q_{B_{2} B_{1}} \delta_{B_{2}}^{C_{1}} \chi_{C_{2}}^{B_{1}}+q_{C_{1} B_{1}} q_{B_{2} B_{1}} C_{B_{2} C_{2}} \chi_{C_{1}^{\prime}}^{B_{1}}+ \\
& \quad+q_{C_{2} B_{2}} q_{B_{1} C_{2}} C^{C_{1} B_{1}} \chi_{C_{2}}^{B_{2}^{\prime}}-q_{B_{2} C_{1}} \delta_{C_{2}}^{B_{1}} \chi_{C_{1}^{\prime}}^{B_{2}^{\prime}} . \tag{4.6.62}
\end{align*}
$$

The Cartan-Maurer equations are obtained by differentiating (4.6.47):

$$
\begin{equation*}
d \Omega_{A}^{B}=q_{A B} q_{B C} q_{C A} C_{C D} \Omega_{C}^{B} \wedge \Omega_{A}^{D} \tag{4.6.63}
\end{equation*}
$$

The commutations between $\Omega$ 's are easy to find using (4.5.14):

$$
\begin{equation*}
\Omega_{A_{1}}^{A_{2}} \wedge \Omega_{D_{1}}^{D_{2}}=-q_{A_{1} D_{2}} q_{D_{1} A_{1}} q_{A_{2} D_{1}} q_{D_{2} A_{2}} \Omega_{D_{1}}^{D_{2}} \wedge \Omega_{A_{1}}^{A_{2}} \tag{4.6.64}
\end{equation*}
$$

Finally, we turn to the $*$-conjugations given by equations (4.5.27) and 4.5.29). Their $r \rightarrow 1$ limit yields, for (4.3.30)

$$
\begin{equation*}
\left(\Omega_{A}^{B}\right)^{*}=q_{B A} \mathcal{D}_{A}^{C} \Omega_{C}^{D} \mathcal{D}_{D}^{B} \quad ; \quad\left(\chi_{B}^{A}\right)^{*}=-q_{C D} \mathcal{D}_{C}^{A} \chi^{C}{ }_{D} \mathcal{D}_{B}^{D}=-\overline{q_{B A}} \mathcal{D}_{E}^{A} \chi_{F}^{E} \mathcal{D}_{B}^{F}, \tag{4.6.65}
\end{equation*}
$$

while for the conjugation (4.3.29)

$$
\begin{equation*}
\left(\Omega_{A}^{B}\right)^{*}=\epsilon q_{B A} \Omega_{A}^{B} \quad ; \quad\left(\chi_{B}^{A}\right)^{*}=-\epsilon q_{A B} \chi_{B}^{A} \tag{4.6.66}
\end{equation*}
$$

This shows that we have a bicovariant *-differential calculus.

### 4.7 Differential calculus on $I S O_{q, r=1}(N)$ and $I S p_{q, r=1}(N)$

We have found the inhomogeneous quantum group $I S_{q, r}(N)$ by means of a projection from $S_{q, r}(N+2)$; dually, its universal enveloping algebra is a given Hopf
subalgebra of $U_{q, r}(s(N+2))$. Using the same techniques and the results of Section 2.3 we here derive the differential calculus on $I S_{q, r=1}(N)$.

From (2.3.4), (2.3.5) and (2.3.18) it is immediate to see that $T^{\prime} \equiv T \cap U_{q, r=1}(i s(N))$ satisfies

$$
\begin{gather*}
\Delta\left(T^{\prime}\right) \subset T^{\prime} \otimes \varepsilon+U_{q, r=1}(i s(N)) \otimes T^{\prime}  \tag{4.7.1}\\
{\left[T^{\prime}, T^{\prime}\right] \subseteq T \cap U_{q, r=1}(i s(N))=T^{\prime}}  \tag{4.7.2}\\
\forall \psi \in U_{q, r}(i s(N)), \quad a d_{\psi} T^{\prime} \subseteq T^{\prime} \tag{4.7.3}
\end{gather*}
$$

indeed $U_{q, r}(i s(N))$ is a Hopf subalgebra of $U_{q, r}(s(N+2))$. Also condition (2.3.3) is fulfilled since $T^{\prime}$ generates $U_{q, r}(i s(N))$ in the same way $T$ generates $U_{q, r}(s(N+2))$ [80, this is a consequence of the upper and lower triangularity of the $L^{+}$and $L^{-}$ matrices and of the dependence of the diagonal elements of $L^{+}$from the diagonal elements of $L^{-}$; this is true for $r \neq 1$ and therefore also for $r=1$. From this last statement, (4.7.1) and (4.7.2)-or just from (4.7.1) and (4.7.3)- we obtain that $T^{\prime}$ generates an $I S_{q, r=1}(N)$ bicovariant differential calculus.

We reconsider now, in the $r \rightarrow 1$ limit, the functionals given in eq.s (4.6.2)(4.6.10). We list below the functionals among these that belong to $T^{\prime}$ :

$$
\begin{align*}
\chi^{a}{ }_{b} & =\frac{1}{r-r^{-1}}\left[f_{c}{ }_{c}{ }^{c a}{ }_{b}-\delta_{b}^{a} \varepsilon\right] \\
\chi^{a}{ }_{\circ} & =\frac{1}{r-r^{-1}} f_{c}{ }^{c a}{ }^{\circ}{ }^{\circ} \\
\chi^{\bullet} & =\frac{1}{r-r^{-1}} f_{\bullet}{ }^{\bullet}{ }_{b} \\
\chi^{\circ} & =\frac{1}{r-r^{-1}}\left[f_{\circ}{ }^{\circ \circ}{ }_{\circ}-\varepsilon\right] \\
\chi_{\bullet}^{\bullet} & =\frac{1}{r-r^{-1}}\left[f_{\bullet}^{\bullet \bullet} \bullet-\varepsilon\right] \\
\chi^{\bullet} & =\frac{1}{r-r^{-1}} f_{\bullet}^{\bullet \bullet}{ }^{\bullet} \tag{4.7.4}
\end{align*}
$$

Note that in the $r \rightarrow 1$ limit $\chi^{\bullet}$ 。 vanishes for $S O_{q, r=1}(N+2)$, and does not vanish in the case $S p_{q, r=1}(N+2)$.

For $r=1$ the $\chi$ 's in (4.7.4) are not linearly independent, cf. relation (4.6.42) of previous section, and we have:

$$
\begin{equation*}
\chi_{a^{\prime}}^{b^{\prime}}=-q_{a b} \chi^{a}{ }_{b}, \quad \chi_{\circ}^{b^{\prime}}=-\frac{1}{q_{b \bullet}} \chi_{b}^{\bullet}, \quad \chi_{\circ}^{\circ}=-\chi^{\bullet} \tag{4.7.5}
\end{equation*}
$$

A basis of tangent vectors for $T^{\prime}$, in the orthogonal case, is therefore given by

$$
\begin{equation*}
\chi^{a}{ }_{b}=\lim _{r \rightarrow 1} \frac{1}{\lambda}\left[f_{c}{ }^{c a}{ }_{b}-\delta_{b}^{a} \varepsilon\right], \quad \text { with } a+b>N+1 \quad \text { i.e. } \quad a^{\prime}<b ; \tag{4.7.6}
\end{equation*}
$$

$$
\begin{equation*}
\chi_{b}^{\bullet}=\lim _{r \rightarrow 1} \frac{1}{\lambda} f_{\bullet} \bullet_{b} \quad ; \quad \chi_{\bullet}^{\bullet}=\lim _{r \rightarrow 1} \frac{1}{\lambda}\left[f_{\bullet} \bullet \bullet-\varepsilon\right], \tag{4.7.7}
\end{equation*}
$$

The $q$-Lie algebra commutations are a subset of (4.6.62) obtained specializing the capital indices of (4.6.62) to the indices ${ }^{a}{ }_{b},{ }^{\bullet}{ }_{b}$ and $\bullet \cdot$. We have the $S O_{q, r=1}(N)$ $q$-Lie algebra that reads as in eq. (4.6.62) with lower case indices; the remaining commutations are:

$$
\begin{align*}
& \chi_{c_{2}}^{c_{1}} \chi_{b_{2}}-\frac{q_{c_{1} \bullet}}{q_{c_{2} \bullet}} q_{b_{2} c_{1}} q_{c_{2} b_{2}} \chi_{b_{2}} \chi_{c_{2}}^{c_{1}}=\frac{q_{c_{1} \bullet}}{q_{c_{2} \bullet}}\left[C_{b_{2} c_{2}} \chi_{c_{1}^{\prime}}-\delta_{b_{2}}^{c_{1}} q_{c_{2} c_{1}} \chi_{c_{2}}\right],  \tag{4.7.8}\\
& \chi_{c_{2}} \chi_{b_{2}}-\frac{q_{b_{2} \bullet}}{q_{c_{2}}} q_{c_{2} b_{2}} \chi_{b_{2}} \chi_{c_{2}}=0,  \tag{4.7.9}\\
& \chi_{c_{2}}^{c_{1}} \chi_{\bullet}^{\bullet}-\chi^{\bullet} \cdot \chi_{c_{2}}^{c_{1}}=0 \quad, \quad \chi_{c_{2}} \chi^{\bullet} \bullet-\chi_{\bullet}^{\bullet} \bullet \chi_{c_{2}}=-\chi_{c_{2}} \tag{4.7.10}
\end{align*}
$$

where we have defined $\chi_{a} \equiv \chi_{a}^{\bullet}$. The exterior differential reads, $\forall a \in I S O_{q, r=1}(N)$

$$
\begin{equation*}
d a=\sum_{a^{\prime}<b}\left(\chi_{b}^{a} * a\right) \Omega_{a}{ }^{b}+\left(\chi_{b}^{\bullet} * a\right) \Omega_{\bullet}{ }^{b}+\left(\chi_{\bullet}^{\bullet} * a\right) \Omega_{\bullet}^{\bullet} \tag{4.7.11}
\end{equation*}
$$

where $\Omega_{a}{ }^{b}, \Omega_{\bullet}{ }^{b}$, and $\Omega_{\bullet}{ }^{\bullet}$ are the 1 -forms dual to the tangent vectors (4.7.6) and (4.7.7). As discussed in 69], these 1-forms can be seen as the projection of the $S_{q, r=1}(N+2)$ 1-forms : $P\left(\Omega_{A}{ }^{B}\right)=-q_{A B} P\left[\kappa\left(T_{C}^{B}\right)\right] d P\left(T_{A}^{C}\right)$.

The adjoint representation, defined by (2.3.18): $a d_{\psi}=M_{i}{ }^{j}(\psi) \chi_{j}$, is given by the elements $P\left(M_{-}^{C}{ }_{D A}{ }^{B}\right) \in I S O_{q, r=1}(N)$ with $C^{\prime} \leq D, A^{\prime} \leq B$ obtained by projecting with $P$ those of $S O_{q, r=1}(N+2)$.
Proof: In $S O_{q, r}(N+2)$ we have $a d_{\psi} \chi^{C}{ }_{D}=M_{-}^{C}{ }_{D A}{ }^{B}(\psi) \chi^{C}{ }_{D}$ with $C^{\prime} \leq D, A^{\prime} \leq B$, since $M_{-}^{C}{ }_{D A}^{B}$ is the adjoint representation of the $S O_{q, r}(N+2)$ calculus (see Note 4.6.2). Now $M_{-}^{C}{ }_{D A}{ }^{B}(\psi)=\psi\left(M_{-}^{C}{ }_{D A}{ }^{B}\right)=\left\langle\psi, P\left(M_{-}^{C}{ }_{D A}{ }^{B}\right)\right\rangle$ where the last bracket is the duality bracket between $I S O_{q, r}(N)$ and $U_{q, r}(i s o(N))$ [cf. (4.4.15)]. We then obtain:

$$
a d_{\psi} \chi^{C}{ }_{D}=\left\langle\psi, P\left(M_{D A}^{C}{ }_{D A}^{B}\right)\right\rangle \chi_{D}^{C} \quad \text { with } C^{\prime} \leq D, A^{\prime} \leq B,
$$

this is the defining formula for the adjoint representation associated to the quantum Lie algebra $T^{\prime}$. The nonvanishing elements are:

$$
\left.\begin{array}{l}
P\left(M_{-}^{b_{1}}{ }_{b_{2} a_{1}}^{a_{2}}\right)=T_{a_{1}}^{b_{1}} \kappa\left(T_{b_{2}}^{a_{2}}\right)-q_{b_{2} b_{1}} T_{a_{1}}^{b_{2}^{\prime}} \kappa\left(T_{b_{1}^{\prime}}^{a_{2}}\right) \\
P\left(M_{-}^{b_{1}}{ }_{b_{2} \bullet}^{a_{2}}\right)=x^{b_{1}} \kappa\left(T_{b_{2}}^{a_{2}}\right)-q_{b_{2} b_{1}} x^{b_{2}^{\prime}} \kappa\left(T_{b_{1}^{\prime}}^{a_{2}}\right) \\
P\left(M_{-}^{\bullet}{ }_{b_{2} \bullet}^{a_{2}}\right)=v \kappa\left(T_{b_{2}}^{a_{2}}\right) \\
P\left(M_{\bullet}^{\bullet} \bullet a_{2}\right.
\end{array}\right)=v \kappa\left(x^{a_{2}}\right), \begin{aligned}
& \text { a }
\end{aligned}
$$

We will later use the relation between left invariant and right invariant vectorfields; in our case (2.3.23) reads:

$$
\begin{equation*}
\left(\chi_{A_{2}}^{A_{1}} * b\right) P\left(M_{-}^{B_{1}} B_{B_{1}}^{A_{1}}\right)=b * \chi_{B_{2}}^{B_{1}} \quad \text { with } A_{1}^{\prime}<A_{2}, B_{1}^{\prime}<B_{2} . \tag{4.7.13}
\end{equation*}
$$

The $I S p_{q, r=1}(N)$ differential calculus has the same structure as the $I S O_{q, r=1}(N)$ one, provided one considers $a^{\prime} \leq b$ in (4.7.6) and (4.7.11), and includes the extra generator $\chi^{\bullet}$ 。in (4.7.7) and his dual form $\Omega_{0}{ }^{\bullet}$ in the definition of the exterior differential. The adjoint representation is obtained by projecting with $P$ the adjoint representation of the $S p_{q, r}(N+2)$ differential calculus.

We now show that it is possible to exclude the generator $\chi^{\bullet}$. (and $\chi^{\circ}{ }_{0}$ ) and obtain a dilatation-free bicovariant differential calculus on $I S O_{q, r=1}(N)$.

We study the $I S O_{q, r=1}(N)$ subspace $g$ linearly spanned by the functionals $\chi^{a}{ }_{b}, \chi_{b}$ :

$$
\begin{equation*}
g \equiv \operatorname{span}\left\{\chi_{b}^{a}, \chi_{b}\right\} . \tag{4.7.14}
\end{equation*}
$$

The space $g$ is our candidate $q$-Lie algebra. A basis of $g$ is $\left\{\chi_{\alpha}\right\}=\left\{\chi^{a}{ }_{b}\left(a^{\prime}<b\right), \chi^{\bullet}{ }_{b}\right\}$. In the sequel greek letters will denote adjoint indices $\alpha=\left(a_{1}, a_{2}\right)$ with $a_{1}^{\prime}<$ $a_{2}$, and $\alpha=\left(\bullet, a_{2}\right)$. The coproduct on the elements $\chi_{\alpha}$ reads $\Delta^{\prime} \chi_{\alpha}=\chi_{\alpha} \otimes f^{\alpha}{ }_{\alpha}+\varepsilon \otimes$ $\chi_{\alpha}$; this shows that $g$ satisfies condition (2.3.4). We also have $\Delta^{\prime} f^{\alpha}{ }_{\alpha}=f^{\alpha}{ }_{\alpha} \otimes f^{\alpha}{ }_{\alpha}$. To prove that $g$ defines a bicovariant differential calculus we can proceed as in Section 3.5. We here give an alternative proof based on the results of Section 2.3. Recalling Theorem 2.3.1, $g$ defines a bicovariant differential calculus if there exists a set of elements $M_{i}{ }^{j} \in I S O_{q, r=1}(N)$ that satysfy (2.3.4) and(2.3.23): $\left(\chi_{j} * b\right) M_{i}{ }^{j}=b * \chi_{i}$. It is immediate to verify that the subset of (4.7.12) given by

$$
\begin{align*}
& P\left(M_{-}^{b_{1}}{ }_{b_{2} a_{1}}^{a_{2}}\right)=T^{b_{1}}{ }_{a_{1}} \kappa\left(T_{b_{2}}^{a_{2}}\right)-q_{b_{2} b_{1}} T_{a_{1}}^{b_{2}^{\prime}} \kappa\left(T_{b_{1}^{\prime}}^{a_{2}}\right) \\
& P\left(M_{-}^{b_{1}}{ }_{b_{2} \bullet}^{a_{2}}\right)=x^{b_{1}} \kappa\left(T_{b_{2}}^{a_{2}}\right)-q_{b_{2} b_{1}} x^{b_{2}^{\prime}} \kappa\left(T_{b_{1}^{\prime}}^{a_{2}}\right) \\
& P\left(M_{-}^{\bullet}{ }_{b_{2} \bullet}^{a_{2}}\right)=v \kappa\left(T_{b_{2}}^{a_{2}}\right) \tag{4.7.15}
\end{align*}
$$

satisfies

$$
\begin{equation*}
\left(\chi_{\beta} * a\right) M_{\alpha}{ }^{\beta}=a * \chi_{\alpha} \tag{4.7.16}
\end{equation*}
$$

indeed $P\left(M_{-}^{b_{1}}{ }_{b_{2} \bullet}{ }^{\bullet}\right)=P\left(M_{-}^{\bullet}{ }_{b_{2} \bullet} \bullet\right)=0$ and therefore (4.7.13) closes also on the subset of $\chi$ and $M_{-}$with greek indices. We have therefore shown:

Theorem 4.7.1 $g$ is a quantum Lie algebra and defines a bicovariant differential calculus on $I S O_{q, r=1}(N)$ that has the same dimension as in the commutative case.

We now analize this differential calculus. The exterior derivative is

$$
\begin{equation*}
d a=\left(\chi_{\alpha} * a\right) \Omega^{\alpha} \tag{4.7.17}
\end{equation*}
$$

The left $I S O_{q, r=1}(N)$-module $\Gamma$ freely generated by the 1 -forms $\Omega^{\alpha}$ dual to the tangent vectors $\chi_{\alpha}$ is a bicovariant bimodule over $I S O_{q, r=1}(N)$ with the right multiplication (no sum on repeated indices):

$$
\begin{equation*}
\Omega^{\alpha} a=\left(f_{\alpha}^{\alpha} * a\right) \Omega^{\alpha}, \quad a \in I S O_{q, r=1}(N) \tag{4.7.18}
\end{equation*}
$$

and with the left and right actions of $\operatorname{ISO}_{q, r=1}(N)$ on $\Gamma$ given by:

$$
\begin{align*}
\Delta_{L}\left(a_{\alpha} \Omega^{\alpha}\right) & \equiv \Delta\left(a_{\alpha}\right) I \otimes \Omega^{\alpha}  \tag{4.7.19}\\
\Delta_{R}\left(a_{\alpha} \Omega^{\alpha}\right) & \equiv \Delta\left(a_{\alpha}\right) \Omega^{\beta} \otimes P\left(M_{-\beta}^{\alpha}\right) \tag{4.7.20}
\end{align*}
$$

Using the general formula (4.7.18) we can deduce the $\Omega, T$ commutations:

$$
\begin{align*}
& \Omega_{a_{1}}^{a_{2}} T^{r}{ }_{s}=\frac{q_{a_{2} s}}{q_{a_{1} s}} T^{r}{ }_{s} \Omega_{a_{1}}^{a_{2}}  \tag{4.7.21}\\
& \Omega_{a_{1}}^{a_{2}} x^{r}=\frac{q_{a_{2}}}{q_{a_{1}} \bullet} x^{r} \Omega_{a_{1}}^{a_{2}}  \tag{4.7.22}\\
& \Omega_{a_{1}}^{a_{2}} u=\frac{q_{a_{\bullet} \bullet}}{q_{a_{2} \bullet}^{\bullet}} u \Omega_{a_{1}}^{a_{2}}  \tag{4.7.23}\\
& \Omega_{\bullet}^{a_{2}} T^{r}{ }_{s}=q_{\bullet \bullet} q_{a_{2} s} T^{r}{ }_{s} \Omega_{\bullet}^{a_{2}}  \tag{4.7.24}\\
& \Omega_{\bullet}^{a_{2}} x^{r}=q_{a_{2} \bullet} x^{r} \Omega_{\bullet}^{a_{2}}  \tag{4.7.25}\\
& \Omega_{\bullet}^{a_{2}} u=\frac{1}{q_{a_{2} \bullet}} u \Omega_{\bullet}^{a_{2}} \tag{4.7.26}
\end{align*}
$$

Note 4.7.1 $u$ commutes with all $\Omega$ 's only if $q_{a} \bullet=1$ (cf. Note 4.2.2). This means that $u=I$ is consistent with the differential calculus on $I S O_{q_{a b}, r=1, q_{a}=1}(N)$.

The exterior derivative on the generators $T^{A}{ }_{B}$ is given by:

$$
\begin{align*}
& d T^{a}{ }_{b}=-\sum_{c} T^{a}{ }_{c} q_{c b} \Omega_{b}{ }^{c} \\
& d x^{a}=-\sum_{c} T^{a}{ }_{c} q_{c \bullet} V^{c}  \tag{4.7.27}\\
& d u=d v=0
\end{align*}
$$

where we have defined $V^{a} \equiv \Omega_{\bullet}{ }^{a}$. Again, for $q_{a \bullet}=1, u=v=I$ is a consistent choice.

Inverting (4.7.27) yields:

$$
\begin{align*}
& \Omega_{a}^{b}=-q_{a b} \kappa\left(T_{c}^{b}\right) d T_{a}^{c}  \tag{4.7.28}\\
& V^{b}=-\frac{1}{q_{b \bullet}} \kappa\left(T_{c}^{b}\right) d x^{c} \tag{4.7.29}
\end{align*}
$$

The exterior product of the left-invariant 1-forms is defined as

$$
\begin{equation*}
\Omega^{\alpha} \wedge \Omega^{\beta} \equiv \Omega^{\alpha} \otimes \Omega^{\beta}-\Lambda_{\gamma \delta}^{\alpha \beta} \Omega^{\gamma} \otimes \Omega^{\delta} \tag{4.7.30}
\end{equation*}
$$

where

$$
\begin{equation*}
\Lambda^{\alpha \beta}{ }_{\gamma \delta} \equiv\left\langle f^{\alpha}{ }_{\delta}, P\left(M_{\gamma}^{\beta}\right)\right\rangle=f_{\delta}^{\alpha}\left(M_{-}^{\beta}\right) \tag{4.7.31}
\end{equation*}
$$

[cf. (4.4.15)]; so that this $\Lambda$ tensor is obtained from the one of $S O_{q, r=1}(N+2)$ by restricting its indices to the subset $a b, \bullet b$. We therefore just specialize the indices in equation (4.6.64) to deduce the $q$-commutations for the 1 -forms $\Omega$ and $V$ :

$$
\begin{gather*}
\Omega_{a_{1}}^{a_{2}} \wedge \Omega_{d_{1}}^{d_{2}}=-q_{a_{1} d_{2}} q_{d_{1} a_{1}} q_{a_{2} d_{1}} q_{d_{2} a_{2}} \Omega_{d_{1}}^{d_{2}} \wedge \Omega_{a_{1}}^{a_{2}}  \tag{4.7.32}\\
\Omega_{a_{1}}^{a_{2}} \wedge V^{d_{2}}=-\frac{q_{a_{2} \bullet}}{q_{a_{1} \bullet}} q_{a_{1} d_{2}} q_{d_{2} a_{2}} V^{d_{2}} \wedge \Omega_{a_{1}}^{a_{2}}  \tag{4.7.33}\\
V^{a_{2}} \wedge V^{d_{2}}=-\frac{q_{a_{2} \bullet}}{q_{d_{2} \bullet} \bullet} q_{d_{2} a_{2}} V^{d_{2}} \wedge V^{a_{2}} \tag{4.7.34}
\end{gather*}
$$

The Cartan-Maurer equations

$$
\begin{equation*}
d \Omega^{\alpha}=-\frac{1}{2} C_{\beta \gamma}^{\alpha} \Omega^{\beta} \wedge \Omega^{\gamma} \tag{4.7.35}
\end{equation*}
$$

can be explicitly written for the $\Omega$ and $V$ by differentiating eq.s (4.7.28) and (4.7.29) [or again secializing the indices in (4.6.63)]:

$$
\begin{align*}
& d \Omega_{a}^{b}=q_{a b} q_{b c} q_{c a} \Omega_{c}^{b} \wedge \Omega_{a}^{c}  \tag{4.7.36}\\
& d V^{b}=\frac{q_{a \bullet}}{q_{b \bullet}} q_{b a} \Omega_{a}^{b} \wedge V^{a} \tag{4.7.37}
\end{align*}
$$

where the 1 -forms $\Omega_{a}{ }^{b}$ with $a^{\prime}>b$ are given by $\Omega_{a}{ }^{b}=-q_{a b} \Omega_{b^{\prime}}{ }^{{ }^{\prime}}$; i.e. we consider (as it is usually done in the classical limit), the 1 -forms $\Omega_{a}^{b}$ to be " $q$-antisymmetric" $\Omega_{a}{ }^{b}=-q_{a b} \Omega_{b^{\prime}}^{a^{\prime}}$, cf. eq. (4.6.45).

The $*$-conjugation on the $\chi$ functionals and on the 1 -forms $\Omega$ can be deduced from (4.6.65):

$$
\begin{gather*}
\left(\chi_{b}^{a}\right)^{*}=-q_{c d} \mathcal{D}^{a}{ }_{c} \chi^{c}{ }_{d} \mathcal{D}^{d}{ }_{b}, \quad\left(\chi_{b}\right)^{*}=-\left(q_{d \bullet}\right)^{-1} \chi_{d} \mathcal{D}^{d}{ }_{b}=-\overline{q_{\bullet \bullet}} \chi_{d} \mathcal{D}^{d}{ }_{b}  \tag{4.7.38}\\
\left(\Omega_{a}^{b}\right)^{*}=q_{b a} \mathcal{D}_{a}^{c} \Omega_{c}{ }^{d} \mathcal{D}^{b}{ }_{d}, \quad\left(V^{b}\right)^{*}=q_{b \bullet} V^{d} \mathcal{D}^{b}{ }_{d} \tag{4.7.39}
\end{gather*}
$$

Note 4.7.2 As discussed at the end of Section 4.2, a $q$-Poincaré group without dilatations (i.e. $u=I$ ) has only one free real parameter $q_{12}$, which is the real parameter related to the $q$-Lorentz subalgebra. Then the formulas of this section can be specialized to describe a bicovariant calculus on the dilatation-free $I S O_{q, r=1}(3,1)$ provided $q_{a \bullet}=1$ and $q_{12} \in \mathbf{R}$. It is however possible to have a bicovariant calculus without the dilatation generator $\chi^{\bullet}$. even on $\operatorname{ISO}_{q, r=1}(3,1)$ with $u \neq I$. The $q$ Poincaré algebra presented in [14] corresponds to the case $q \equiv q_{1 \bullet}, q_{\bullet \bullet}=q_{12}=1$, for which the Lorentz subalgebra is undeformed and the $q$-Poincaré group contains $u \neq$ $I$. The possibility of having a dilatation-free $q$-Lie algebra describing a bicovariant calculus on a $q$-group containing dilatations $u$ was already observed in the case of $I G L q$-groups (see Section 3.5).

Note 4.7.3 We here study a differential calculus on $I S p_{q, r=1}(N)$ that has the same number of tangent vectors as in the classical case. Following the same arguments given after (4.7.14) we have an $I S p_{q, r=1}(N)$ differential calculus with quantum Lie algebra generators $\chi^{a}{ }_{b}$ with $a^{\prime} \leq b, \chi_{b}$ and $\chi_{0}^{\bullet}$. To further restrict the quantum Lie algebra to the one spanned by the basis $\left\{\chi^{a}{ }_{b}\left(a^{\prime} \leq b\right), \chi_{b}\right\}$, observe that from (4.6.19),

$$
\begin{equation*}
\chi_{\circ}^{\bullet}=\lim _{r \rightarrow 1} \frac{1}{\lambda} \kappa^{\prime}\left(L^{+\bullet}\right) L^{-\bullet} \tag{4.7.40}
\end{equation*}
$$

is different from zero only on monomials that contain the element $z$. However in the $q, r \rightarrow 1$ limit, as noticed after (4.2.30), $z$ can be set to zero since there is no more any constraint between $z$ and the generators $T^{a}{ }_{b}, x^{a}, u, v=u^{-1}$. Then $\chi^{\bullet}$ 。is zero as well and we have an $[N(N+1) / 2+N]$-dimensional bicovariant differential calculus on the twisted inhomogeneous symplectic group generated by $T^{a}{ }_{b}, x^{a}, u, v=u^{-1}$. The adjoint representation is given by the elements $P\left(M_{-\alpha}{ }^{\beta}\right) \in I S p_{q, r}(N)$ obtained by projecting with $P$ those of $S p_{q, r=1}(N+2)$. The explicit formulae carachterizing this differential calculus are as in (4.7.17)-(4.7.35), where now greek letters denote adjoint indices $\alpha=\left(a_{1}, a_{2}\right)$ with $a_{1}^{\prime} \leq a_{2}$, and $\alpha=\left(\bullet, a_{2}\right)$.

## Chapter 5

## Geometry of the quantum orthogonal plane

We present here a bicovariant calculus on the full multiparametric $I S O_{q, r}(N)$ without the restriction $r=1$. This calculus, however, is trivial on the $S O_{q, r}(N)$ quantum subgroup: it can really be seen as a non-trivial calculus only on the coset Fun $_{q, r}[\operatorname{ISO}(N) / S O(N)]$, i.e. on the quantum orthogonal plane. We therefore call this calculus on the quantum plane $I S O_{q, r}(N)$-bicovariant. We find that in the $r \neq 1$ case this $I S O_{q, r}(N)$-bicovariant calculus necessarily contains dilatations.

If we break $I S O_{q, r}(N)$ bicovariance and require right covariance under $I S O_{q, r}(N)$ and left covariance only under $S O_{q, r}(N)$, i.e. compatibility of the exterior differential on the quantum plane with the right $I S O_{q, r}(N)$-coaction and the left $S O_{q, r}(N)$ coaction, the calculus can be expressed in terms of coordinates $x$, differentials $d x$ and partial derivatives $\partial$, without the need of dilatations. In this case $q$-commutations between $x, d x$ and $\partial$ close by themselves, and in fact generalize to the multiparametric case the known results of ref.s 51, 53, 54. Here these results emerge from the broader setting of the bicovariant calculus on $\operatorname{ISO}_{q, r}(N)$.

The two $*$-conjugations of the previous sections, consistent with the $q$-group structure, lead to a $I S O_{q, r}(n+1, n-1)$, and a $I S O_{q, r}(n, n)$ or $I S O_{q, r}(n, n+1)$ bicovariant calculus on the quantum orthogonal plane respectively with $(n+1, n-1)$, $(n, n)$ or $(n, n+1)$ signature. We will be concerned with the conjugation that gives the $I S O_{q, r}(n-1, n+1)$ calculus. [To retrieve the other conjugations, both for $N=$ even and $N=$ odd, just take $\mathcal{D}_{B}^{A}=\delta_{B}^{A}$ in the formulae where $\mathcal{D}_{B}^{A}$ appears].

Using this conjugation one can define real coordinates $X$ and hermitian partial derivative operators $P$ i.e. momenta. This is achieved by a canonical procedure, using the compatibility of the $*$-structure with the bicovariant calculus on $I S O_{q, r}(N)$, i.e. the property that $*$ is a linear operation on the $q$-Lie algebra. The $q$-commutations of the momenta $P$ with the coordinates $X$ define a deformed version of the Heisenberg $X, P$ commutation relations (with no extra operator as in ref.s (9]). In the same spirit as in ref.s [9] it would be interesting to investigate the Hilbert space representations of this deformed phase-space algebra.

In Section 5.1 we present the $I S O_{q, r}(N)$ bicovariant differential calculus with $r \neq 1$ ，then，in Section 5.2 we restrict this calculus to the quantum orthogonal plane． We find that in order to obtain a space of 1 －forms that has the same dimension as in classical case we have to break $I S O_{q, r}(N)$－bicovariance．This naturally leads to a right $I S O_{q, r}(N)$－covariant and $S O_{q, r}(N)$－bicovariant calculus．The commutation relations caracterizing this calculus are explicitly given in the tables at the end of the chapter．

## 5．1 Bicovariant calculus on $I S O_{q, r}(N)$ with $r \neq 1$

In this section we study，with projection techniques，a differential calculus on $I S O_{q, r}(N)$ with $r \neq 1$ ，a similar calculus exists also for $I S p_{q, r}(N)$ ；for physical reasons we here treat in detail the orthogonal case．

As discussed at the beginning of Section 4．6，in the $r \neq 1$ case，the quantum tan－ gent space $T^{\prime} \equiv T \cup U_{q, r}(i s(N))$ contains dilatations and translations，but does not contain the tangent vectors of $S_{q, r}(N)$ ，i．e．the functionals $\chi^{a}{ }_{b}$ ．However $T^{\prime}$ defines a bicovariant differential calculus on $I S O_{q, r}(N)$ or $I S p_{q, r}(N)$ because conditions （2．3．4）and（2．3．18）are satisfied．The proof is as in（4．7．1）and（4．7．3）．

The $q$－Lie algebra in the orthogonal case is explicitly given by

$$
\begin{align*}
& \chi^{\bullet}{ }^{\bullet} \chi^{\bullet}{ }_{b}-\left(q_{\bullet b}\right)^{-2} \chi^{\bullet}{ }_{b} \chi^{\bullet} \text { 。 }=0  \tag{5.1.1}\\
& \chi^{\bullet} \chi^{\bullet} \bullet-r^{-2} \chi^{\bullet} \cdot \chi_{c}^{\bullet}=-r^{-1} \chi^{\bullet}{ }_{c}  \tag{5.1.2}\\
& \chi^{\bullet} \circ \chi^{\bullet} \bullet-r^{-4} \chi^{\bullet} \cdot \chi^{\bullet} \circ=\frac{-\left(1+r^{2}\right)}{r^{3}} \chi^{\bullet} \text { 。 }  \tag{5.1.3}\\
& q_{\bullet a} P_{A}^{a b}{ }_{c d} \chi^{\bullet}{ }_{b} \chi^{\bullet}{ }_{a}=0 \tag{5.1.4}
\end{align*}
$$

Relation（5．1．4）is equivalent to $q_{b \bullet} P_{A}^{a b}{ }_{c d} \chi^{\bullet}{ }_{b} \chi^{\bullet}{ }_{a}=0$ and $q_{a \bullet}\left[\left(P_{A}\right)_{q^{-1}, r^{-1}}\right]_{c d}^{a b} \chi^{\bullet} \chi^{\bullet}{ }_{b}=0$ ． A combination of（5．1．1）－（5．1．4）yields：

$$
\begin{equation*}
\chi_{\bullet}^{\bullet}+\lambda \chi_{\bullet}^{\bullet} \chi_{\bullet}^{\bullet}=\lambda \frac{-r^{\frac{N}{2}}}{r^{2}+r^{N}} \frac{1}{q_{d \bullet}} \chi_{\bullet}^{\bullet} C^{d b} \chi_{{ }^{\bullet}} \tag{5.1.5}
\end{equation*}
$$

Notice the similar structure of eq．s（4．2．23），（4．3．23）and（5．1．5）．
Following the same arguments as in（4．7．12），the adjoint representation is given by the elements

$$
\begin{equation*}
P\left(M_{B \bullet}^{\bullet}{ }^{D}\right)=P\left(T^{\bullet}{ }^{\bullet} \kappa_{N+2}\left(T_{B}^{D}\right)\right)=v P\left(\kappa_{N+2}\left(T_{B}^{D}\right)\right) \tag{5.1.6}
\end{equation*}
$$

that explicitly read

$$
\begin{array}{lll}
P\left(M_{\bullet \bullet}^{\bullet} \bullet^{\circ}\right)=v^{2} & P\left(M_{\bullet}^{\bullet}{ }^{d}\right)=0 & P\left(M_{\bullet \bullet \bullet}^{\bullet}\right)=0 \\
P\left(M_{b \bullet}^{\bullet}{ }^{\circ}\right)=v r^{-\frac{N}{2}} x^{e} C_{e b} & P\left(M_{\bullet \bullet}^{\bullet}\right)=v \kappa\left(T^{d}{ }_{b}\right) & P\left(M_{b \bullet}^{\bullet} \bullet\right)=0 \\
P\left(M_{\bullet \bullet}^{\bullet}\right)=-\frac{1}{r^{N}\left(r^{\frac{N}{2}}+r^{-\frac{N}{2}+2}\right)} x^{e} C_{e f} x^{f} & P\left(M_{\bullet \bullet}^{\bullet}\right)=v \kappa\left(x^{d}\right) & P\left(M_{\bullet \bullet}^{\bullet}\right)=I \tag{5.1.7}
\end{array}
$$

The differential related to this calculus is given by

$$
\begin{equation*}
\forall a \in I S O_{q, r}(N) \quad d a=\left(\chi_{b}^{\bullet} * a\right) \omega_{\bullet}^{b}+\left(\chi_{\bullet}^{\bullet} * a\right) \omega_{\bullet}^{\bullet}+\left(\chi_{\bullet}^{\bullet} * a\right) \omega_{\bullet}^{\circ} \tag{5.1.8}
\end{equation*}
$$

where $\omega_{\bullet}{ }^{b}, \omega_{\bullet}^{\bullet}$ and $\omega_{\bullet}{ }^{\circ}$ are the 1 -forms dual to the tangent vectors $\chi^{\bullet}, \chi_{\bullet}$ 。and $\chi^{\bullet}$. The left and right actions $\Delta_{L}: \Gamma \rightarrow I S O_{q, r}(N) \otimes \Gamma$ and $\Delta_{R}: \Gamma \rightarrow \Gamma \otimes I S O_{q, r}(N)$ are defined by:

$$
\begin{equation*}
\Delta_{L}\left(\omega_{\bullet}^{A}\right)=I \otimes \omega_{\bullet}^{A} \quad, \quad \Delta_{R}\left(\omega_{\bullet}^{A}\right)=\omega_{\bullet}^{B} \otimes P\left(M_{B \bullet}^{\bullet}{ }^{A}\right) \tag{5.1.9}
\end{equation*}
$$

We now explicitly give the relation characterizing this differential calculus. These formulae will be needed in the next chapter.

To simplify notations, we write the composite indices as follows:

$$
\begin{equation*}
\bullet^{a} \rightarrow^{a}, \bullet^{\bullet} \rightarrow^{\bullet}, \bullet^{\circ} \rightarrow^{\circ} ; \quad{ }_{a} \rightarrow_{a}, \bullet \rightarrow \bullet,{ }_{\bullet} \rightarrow_{\circ} \tag{5.1.10}
\end{equation*}
$$

Similarly we'll write $q_{b}$ instead of $q_{b}$. The explicit expression for the tangent vectors then reads:

$$
\begin{align*}
\chi_{b} & =\frac{1}{r-r^{-1}} f_{b}^{\bullet} \\
\chi_{\circ} & =\frac{1}{r-r^{-1}} f_{\bullet}^{\bullet} \\
\chi_{\bullet} & =\frac{1}{r-r^{-1}}\left[f^{\bullet} \bullet-\varepsilon\right] \tag{5.1.11}
\end{align*}
$$

and their coproduct is given by

$$
\begin{align*}
& \Delta\left(\chi_{b}\right)=\chi_{\bullet} \otimes f^{\bullet}{ }_{b}+\chi_{c} \otimes f^{c}{ }_{b}+\varepsilon \otimes \chi_{b}  \tag{5.1.12}\\
& \Delta\left(\chi_{\bullet}\right)=\chi_{\bullet} \otimes f_{\bullet}^{\bullet}+\varepsilon \otimes \chi_{\bullet}  \tag{5.1.13}\\
& \Delta\left(\chi_{\circ}\right)=\chi_{\circ} \otimes f_{\circ}^{\circ}+\chi_{\bullet} \otimes f_{\circ}^{\bullet}+\chi_{c} \otimes f^{c}{ }_{\circ}+\varepsilon \otimes \chi_{\circ} \tag{5.1.14}
\end{align*}
$$

Using the general formula (4.7.18) we can deduce the $\omega, T$ commutations for $I S O_{q, r}(N)$ :

$$
\begin{align*}
& \omega^{b} T^{c}{ }_{d}=\frac{q_{f}}{r}\left(R^{-1}\right)^{b f}{ }_{e d} T^{c}{ }_{f} \omega^{e}  \tag{5.1.15}\\
& \omega^{b} x^{c}=\frac{q_{b}}{r^{2}} x^{c} \omega^{b}+\lambda r^{\frac{N}{2}-1} q_{d} C^{b d} T^{c}{ }_{d} \omega^{\circ}  \tag{5.1.16}\\
& \omega^{b} u=\frac{r^{2}}{q_{b}} u \omega^{b}  \tag{5.1.17}\\
& \omega^{b} v=\frac{q_{b}}{r^{2}} v \omega^{b}  \tag{5.1.18}\\
& \omega^{\bullet} T^{c}{ }_{d}=T^{c}{ }_{d} \omega^{\bullet}  \tag{5.1.19}\\
& \omega^{\bullet} x^{c}=\frac{1}{r^{2}} x^{c} \omega^{\bullet}-\lambda \frac{q_{b}}{r} T^{c}{ }_{b} \omega^{b} \tag{5.1.20}
\end{align*}
$$

$$
\begin{align*}
& \omega^{\bullet} u=r^{2} u \omega^{\bullet}  \tag{5.1.21}\\
& \omega^{\bullet} v=r^{-2} v \omega^{\bullet}  \tag{5.1.22}\\
& \omega^{\circ} T_{d}^{c}=q_{d}^{2} r^{-2} T_{d}^{c} \omega^{\circ}  \tag{5.1.23}\\
& \omega^{\circ} x^{c}=x^{c} \omega^{\circ}  \tag{5.1.24}\\
& \omega^{\circ} u=u \omega^{\circ}  \tag{5.1.25}\\
& \omega^{\circ} v=v \omega^{\circ} \tag{5.1.26}
\end{align*}
$$

The 1-form $\tau \equiv \omega^{\bullet} \equiv \omega_{\bullet}^{\bullet}$ is bi-invariant, and one can check that $\forall a \in A, \quad d a=$ $\frac{1}{\lambda}[\tau a-a \tau]$. The exterior derivative on the generators of $I S O_{q, r}(N)$ reads:

$$
\begin{align*}
& d T^{c}{ }_{d}=0  \tag{5.1.27}\\
& d x^{c}=-q_{b} r^{-1} T^{c}{ }_{b} \omega^{b}-r^{-1} x^{c} \omega^{\bullet}  \tag{5.1.28}\\
& d u=r u \omega^{\bullet}  \tag{5.1.29}\\
& d v=-r^{-1} v \omega^{\bullet}  \tag{5.1.30}\\
& d z=-q_{b} r^{-1} y_{b} \omega^{b}-r\left(1-r^{N}\right) u \omega^{\circ}-r^{-1} z \omega^{\bullet} \tag{5.1.31}
\end{align*}
$$

where we have included the exterior derivative on $z$ for convenience. Note that the calculus is trivial on the $S O_{q, r}(N)$ subgroup of $I S O_{q, r}(N)$, as is evident from (5.1.27). Thus effectively we are discussing a bicovariant calculus on the orthogonal $q$-plane generated by the coordinates $x^{a}$ and the "dilatations" $u, v$.

Every element $\rho$ of $\Gamma$ can be written as $\rho=\sum_{k} a_{k} d b_{k}$ for some $a_{k}, b_{k}$ belonging to $I S O_{q, r}(N)$. Indeed inverting the relations (5.1.28)-(5.1.31) yields:

$$
\begin{align*}
\omega^{a} & =-\frac{r}{q_{a}} \kappa\left(T^{a}{ }_{c}\right)\left[d x^{c}-x^{c} u d v\right]=\frac{r}{q_{a}}\left[d \kappa\left(x^{a}\right)\right] v=r^{-1} v d \kappa\left(x^{a}\right)  \tag{5.1.32}\\
\omega^{\bullet} & =-r u d v=r^{-1} v d u  \tag{5.1.33}\\
\omega^{\circ} & =-\frac{v d z+r^{-N} z d v+r^{-\frac{N}{2}} C_{a b} x^{a} d x^{b}}{r\left(1-r^{N}\right)} \tag{5.1.34}
\end{align*}
$$

The exterior product of left-invariant 1-forms is as usual defined by

$$
\begin{equation*}
\omega^{i} \wedge \omega^{j} \equiv \omega^{i} \otimes \omega^{j}-\Lambda_{k l}^{i j} \omega^{k} \otimes \omega^{l} \tag{5.1.35}
\end{equation*}
$$

where

$$
\begin{equation*}
\Lambda_{k l}^{i j}=f^{i}{ }_{l}\left(M_{k}{ }^{j}{ }^{\prime}\right) \tag{5.1.36}
\end{equation*}
$$

As in (4.7.31) this $\Lambda$ tensor is obtained from the one of $S O_{q, r}(N+2)$ by restricting its indices to the subset $\bullet b, \bullet \bullet, \bullet$. The non-vanishing components of $\Lambda$ read:

$$
\begin{aligned}
& \Lambda^{a d}{ }_{c b}=\frac{q_{a}}{q_{c}} r^{-1} R^{a d}{ }_{b c} \quad \Lambda^{\bullet \bullet}{ }_{c b}=-\frac{r^{-\frac{N}{2}-1}}{q_{c}} \lambda C_{b c} \quad \Lambda^{\bullet d}{ }_{c \bullet}=r^{-2} \delta_{c}^{d} \\
& \Lambda^{a \circ}{ }_{c \circ}=r^{-1} \lambda \delta_{c}^{a} \quad \Lambda^{\circ d}{ }_{c \circ}=\left(\frac{r}{q_{c}}\right)^{2} \delta_{c}^{d} \quad \Lambda^{a \bullet}{ }_{\bullet b}=\delta_{b}^{a} \\
& \Lambda^{\bullet d}{ }_{\bullet b}=r^{-1} \lambda \delta_{b}^{d} \quad \quad \Lambda^{a \circ}{ }_{o b}=r^{-4}\left(q_{a}\right)^{2} \delta_{b}^{a} \quad \Lambda^{\bullet \bullet} \bullet \bullet=1 \\
& \Lambda^{a d}{ }_{\bullet \circ}=-q_{a} r^{-\frac{N}{2}-1} \lambda C^{d a} \quad \Lambda^{\bullet \circ} \quad \bullet=\lambda r^{-1}\left(1-r^{-N}\right) \quad \Lambda^{\bullet \bullet} \quad \bullet=1 \\
& \Lambda^{\bullet \circ}{ }_{\circ}=r^{-4} \quad \Lambda^{\circ \circ}{ }_{\circ}=1
\end{aligned}
$$

From (5.1.35) it is not difficult to deduce the commutations between the $\omega$ 's:

$$
\begin{align*}
& \frac{1}{q_{c}} P_{S c d}^{a b} \omega^{d} \wedge \omega^{c}=0  \tag{5.1.37}\\
& \omega^{a} \wedge \omega^{\bullet}=-r^{2} \omega^{\bullet} \wedge \omega^{a}  \tag{5.1.38}\\
& \omega^{a} \wedge \omega^{\circ}=-r^{-4}\left(q_{a}\right)^{2} \omega^{\circ} \wedge \omega^{a}  \tag{5.1.39}\\
& \omega^{\bullet} \wedge \omega^{\bullet}=\omega^{\circ} \wedge \omega^{\circ}=0  \tag{5.1.40}\\
& \omega^{\bullet} \wedge \omega^{\circ}=-r^{-4} \omega^{\circ} \wedge \omega^{\bullet}+\frac{\lambda r^{-\frac{N}{2}-1}}{q_{a}\left(1-r^{-N}\right)} C_{b a} \omega^{a} \wedge \omega^{b} \tag{5.1.41}
\end{align*}
$$

Notice that the dimension of the space of 2-forms generated by $\omega^{a} \wedge \omega^{b}$ is larger than in the commutative case since $P_{S}$ project into an $N(N+1) / 2-1$ (and not into an $N(N+1) / 2$ ) dimensional space. This is not surprising since the exterior algebra of homogeneous orthogonal quantum groups is known to be larger than its classical counterpart.

The Cartan-Maurer equations

$$
\begin{equation*}
d \omega^{i}=\frac{1}{r-r^{-1}}\left(\tau \wedge \omega^{i}+\omega^{i} \wedge \tau\right) \tag{5.1.42}
\end{equation*}
$$

can be explicitly found after use of the commutations (5.1.37)- (5.1.41):

$$
\begin{align*}
& d \omega^{a}=r^{-1} \omega^{a} \wedge \omega^{\bullet}  \tag{5.1.43}\\
& d \omega^{\bullet}=0  \tag{5.1.44}\\
& d \omega^{\circ}=-r\left(1+r^{2}\right) \omega^{\bullet} \wedge \omega^{\circ}+\frac{r^{3}}{r^{\frac{N}{2}}-r^{-\frac{N}{2}}} \frac{C_{b a}}{q_{a}} \omega^{a} \wedge \omega^{b} \tag{5.1.45}
\end{align*}
$$

Finally, the nonvanishing structure constants $\boldsymbol{C}$, given by $\boldsymbol{C}_{j k}{ }^{i}=\chi_{k}\left(M_{j}{ }^{i}\right)$, read:

$$
\begin{array}{lll}
\boldsymbol{C}_{a b}{ }^{\circ}=-q_{a}^{-1} r^{-\frac{N}{2}-1} C_{b a} & \boldsymbol{C}_{a \bullet}{ }^{c}=-r^{-1} \delta_{a}^{c} & \boldsymbol{C}_{\bullet}{ }^{c}=r^{-1} \delta_{b}^{c} \\
\boldsymbol{C}_{\circ}{ }^{\circ}=-r^{-3}\left(1+r^{2}\right) & \boldsymbol{C}_{\bullet}{ }^{\circ}=r^{-1}\left(1-r^{-N}\right) &
\end{array}
$$

These structure constants can be obtained from those of $S O_{q, r}(N+2)$ by specializing indices, for the same reason as for the $\Lambda$ components.

The $*$-conjugation on the $\chi$ functionals can be deduced from (4.5.27) [use $\left(q_{f}\right)^{-1} \mathcal{D}^{f}{ }_{b}$ $\left.=\bar{q}_{b} \mathcal{D}^{f}{ }_{b}\right]$

$$
\begin{align*}
& \left(\chi_{b}\right)^{*}=-r^{-N} \mathcal{D}^{f}{ }_{b} \frac{1}{q_{f}} D_{f}^{d} \chi_{d}=-r^{-N} \bar{q}_{b} \mathcal{D}_{b}^{f} D_{f}^{d} \chi_{d}=-r^{-N} \bar{q}_{b} D_{b}^{f} \mathcal{D}^{d}{ }_{f} \chi_{d}  \tag{5.1.46}\\
& \left(\chi_{\bullet}\right)^{*}=-\chi_{\bullet}  \tag{5.1.47}\\
& \left(\chi_{\circ}\right)^{*}=-r^{-2 N-2} \chi_{\bullet} \tag{5.1.48}
\end{align*}
$$

whereas the conjugation on the $\omega$ 1-forms can be deduced from (2.3.52) and (5.1.46)(5.1.48) or directly from their expression in terms of $d x, d u, d v$ differentials (5.1.32)(5.1.34) remembering that $(d a)^{*}=d\left(a^{*}\right)$ :

$$
\begin{align*}
& \left(\omega^{a}\right)^{*}=\bar{q}_{a}{ }^{-1} r^{N}\left(D^{-1}\right)^{a}{ }_{b} \mathcal{D}_{c}^{b}=\bar{q}_{a}{ }^{-1} r^{N} \mathcal{D}^{a}{ }_{b}\left(D^{-1}\right)^{b}{ }_{c} \omega^{c}  \tag{5.1.49}\\
& \left(\omega^{\bullet}\right)^{*}=\omega^{\bullet}  \tag{5.1.50}\\
& \left(\omega^{\circ}\right)^{*}=r^{2 N+2} \omega^{\circ} \tag{5.1.51}
\end{align*}
$$

### 5.2 Calculus on the multiparametric orthogonal quantum plane

In this section we concentrate on the orthogonal quantum plane

$$
\begin{equation*}
M \equiv F u n_{q, r}\left(\frac{I S O(N)}{S O(N)}\right), \tag{5.2.52}
\end{equation*}
$$

i.e. the $I S O_{q, r}(N)$ subalgebra generated by the coordinates $x^{a}$ and the dilatations $u, v$. This is the algebra we called $B$ in the study of the cross-product crosscoproduct construction $\operatorname{ISO}_{q, r}(N) \cong B \rtimes S O_{q, r}(N)$ of Section 4.2.

We study the action of the exterior differential $d$ on $M$ and the corresponding space $\Gamma_{M}$ of 1-forms. $\Gamma_{M}$ is the sub-bimodule of $\Gamma$ formed by all the elements $a d b$ or $\left(d a^{\prime}\right) b^{\prime}$ where $a, b, a^{\prime}, b^{\prime}$ are polynomials in $x^{a}, u$ and $v$ [of course $\left.a d b=d(a b)-(d a) b\right]$.

We will see that a generic element $\rho$ of $\Gamma_{M}$ cannot be generated, as a left module, only by the differentials $d x, d v$, i.e. it cannot be written as $\rho=a_{i} d x^{i}+a d v$. We need also to introduce the differential $d z$ (or equivalently $d L \equiv d\left(x^{a} C_{a b} x^{b}\right)$ ). Thus the basis of differentials is given by $d x^{a}, d v, d z$ and corresponds to the intrinsic basis of independent 1 -forms $\omega^{a}, \omega^{\bullet}$ and $\omega^{\circ}$. Note that $d u$ can be expressed in terms of $d v$ since $d u=-u(d v) u=-r^{2} u^{2} d v=-r^{-2}(d v) u^{2}$ [ see (5.3.124) below].

In Subsection 5.2.1 we consistently impose an extra conditon in order to relate $d z$ to $d x$ and $d v$. This is done in two different ways: checking explicilty the consistency of the extra condition as in 48] [3] and also deriving it using $I S O_{q, r}(N)$ symmetry principles.

## Commutations

The commutations between the coordinates $x^{a}, u$ and $v$ have been given in Section 4.2. The commutations between coordinates and differentials are found by expressing the differentials in terms of the 1 -forms $\omega$ as in (5.1.28)-(5.1.31), and using then the $x, u, v$ commutations with the $\omega$ 's given in (5.1.15)-(5.1.26). The resulting $q$-commutations between $x$ and $d x$ are found to be:

$$
\begin{equation*}
\left(r^{-2} P_{S}-P_{A}\right)(x \otimes d x)=\left(P_{S}+P_{A}\right)(d x \otimes x) \tag{5.2.53}
\end{equation*}
$$

where we have used the tensor notation $A^{a b}{ }_{c d} x^{c} d x^{d} \equiv A(x \otimes d x)$ etc. The remaining commutations are given in formulae (5.3.121) -(5.3.132) in Table 1.

Let us consider the above formula, giving the $x, d x$ commutations. If we multiply it by $P_{0}$ we find $0=0$. Thus from this equation we have no information on $P_{0}(x \otimes d x)$. Applying instead the projectors $P_{S}$ and $P_{A}$ yields

$$
\begin{equation*}
P_{S}(x \otimes d x)=r^{2} P_{S}(d x \otimes x) ; \quad P_{A}(x \otimes d x)=-P_{A}(d x \otimes x) \tag{5.2.54}
\end{equation*}
$$

which does not allow to express $x^{a} d x^{b}$ only in terms of linear combinations of $(d x) x$ since no linear combination of $P_{S}$ and $P_{A}$ is invertible. The space of 1-forms has therefore one more dimension than his classical analogue because we are missing a condition involving the one dimensional projector $P_{0 \text { ef }}^{a b}=\left(C^{l m} C_{l m}\right)^{-1} C^{a b} C_{e f}$, see (4.1.16).

However, if we consider the 1-form $d L \equiv d\left(x^{e} C_{e f} x^{f}\right)$ - an exterior derivative of polynomials in the basic elements - we can write the commutations between the $x$ and $d x$ elements as follows:

$$
\begin{align*}
d x \otimes x & =-\left(P_{S}+P_{A}+P_{0}\right) x \otimes d x+\left(P_{S}+P_{A}\right) d(x \otimes x)+P_{0} d(x \otimes x) \\
& =P_{S} d x \otimes x+P_{A} d x \otimes x-P_{0} x \otimes d x+P_{0} d(x \otimes x) \\
& =\left(r^{-2} P_{S}-P_{A}-P_{0}\right) x \otimes d x+P_{0} d(x \otimes x) \tag{5.2.55}
\end{align*}
$$

where we have used the Leibniz rule, the commutations (5.2.54) and $P_{S}+P_{A}+P_{0}=$ I. Equivalently we have

$$
\begin{equation*}
d x \otimes x=\left(r^{-2} P_{S}-P_{A}-P_{0}\right) x \otimes d x-C \frac{r^{\frac{N}{2}-2}\left(1-r^{2}\right)}{1-r^{N}}(v d z+z d v) \tag{5.2.56}
\end{equation*}
$$

involving the $d v$ and $d z$ differentials.
The presence of $d z$ can also be explained within the general theory by recalling that $\Gamma$ is a free right module [see paragraph following (2.1.47)]. A basis of right invariant 1-forms is given by (2.1.47): $\eta^{A} \equiv \kappa^{-1}\left(M_{B}{ }^{A}\right) \omega^{B}$, we explicitly have:

$$
\begin{align*}
\eta^{a} & =-r^{-1} d x^{a} u=-r^{-1} d T^{a} \bullet \kappa\left(T_{\bullet}^{\bullet}\right)  \tag{5.2.57}\\
\eta^{\bullet} & =-r^{-1} d v u=-r^{-1} d T^{\bullet} \bullet \kappa\left(T^{\bullet} \bullet\right)  \tag{5.2.58}\\
\eta^{\circ} & =\frac{r^{\frac{N}{2}-1}}{\left(1-r^{N}\right)\left(1+r^{N-2}\right)}\left[d x^{e} C_{e f} x^{f}-r^{N-2} x^{e} C_{e f} d x^{f}\right] u^{2}  \tag{5.2.59}\\
& =\frac{-r^{N-1}}{r^{N}-1}\left[d z u+d y_{b} \kappa\left(x^{b}\right)+d u \kappa(z)\right]=\frac{-r^{N-1}}{r^{N}-1} d T^{\circ}{ }_{B} \kappa\left(T^{B}{ }_{\bullet}\right) \tag{5.2.60}
\end{align*}
$$

To derive the expressions for $\eta^{\circ}$ use: $y_{b}=-r^{-\frac{N}{2}} u x^{e} C_{e f} T^{f}{ }_{b} ; d y_{b} \kappa\left(x^{b}\right)=r^{-\frac{N}{2}} d u x x u+$ $r^{-\frac{N}{2}} d x x u^{2} ; d z=d\left(\frac{-r^{-\frac{N}{2}}}{1+r^{2-N}} u x x\right)=\frac{-r^{-\frac{N}{2}}}{1+r^{2-N}}(d u x x+d x x u+x d x u) ; \kappa(z)=\kappa\left(T^{\circ}\right.$ 。)= $r^{-N} z ; u x x=r^{2} x x u ; u d x x=d x x u$, where $x x \equiv L \equiv x^{e} C_{e f} x^{f}$.

The 1-forms (5.2.58)-(5.2.59) in $\Gamma$ do not contain any $T^{a}{ }_{b}$ element and therefore belong to $\Gamma_{M}$ as well; they are linearly independent and freely generate $\Gamma_{M}$ as a right module because they freely generate the full $\Gamma$ as a right module. The extra 1-form $\eta^{\circ}$ (or $d z$ ) is therefore a natural consequence of the right module structure of $\Gamma$.

In summary: either $d L$ or $d z$ or $\eta^{\circ}$ are necessary in order to close the commutation algebra between coordinates and differentials. Thus the commutations involving $z$ and $d z$ appear in Table 1.

We have seen that $d v u ; d x^{a} u$ and $\eta^{\circ}$ freely generate $\Gamma_{M}$ as a right module; recalling that $\Gamma$ is also a free left module, we have the :

Proposition 5.1 The $M$-bimodule $\Gamma_{M}$, as a left module (or as a right module), is freely generated by the differentials $d x, d L$ (or $d z$ ) and $d v$. Proof: to show that $a_{i} d x^{i}+a d L+a_{\bullet} d v=0 \Rightarrow a_{i}=0, a=0, a_{\bullet}=0$ express $d x^{i}, d L, d v$ in terms of $\omega^{a}, \omega^{\circ} \omega^{\bullet}$, see (5.1.28)-(5.1.31), and recall that $\Gamma$ is a free left module.

Note 5.2.1 From (5.3.121), (5.3.122) and the commutations of $L$ with $x$ and $u$ we have $x^{c} d L=d L x^{c}, u d L=d L u$ and $v d L=d L v$. These relations and (5.3.120) show that inside $\Gamma_{M}$ there is the smaller bimodule generated by the differentials $d x^{a}$ and $d L$.

We now examine the space of 2 -forms. By simply applying the exterior derivative $d$ to the relations (5.3.120)-(5.3.132) we deduce the commutations between the differentials given in Table 1. As with the $\omega^{a}$ 's in eq. (5.1.37), the relations in (5.3.133) are not sufficient to order the differentials $d x^{a}$.
$I S O_{q, r}(N)$ - coactions
All the relations we have been deriving have many symmetry properties because they are covariant, under the actions on $M$ and $\Gamma$, of the full $I S O_{q, r}(N) q$-group. In fact we have the following three $I S O_{q, r}(N)$ actions:

1) the coproduct of $I S O_{q, r}(N)$ can be seen as a left-coaction $\Delta: M \rightarrow$ $I S O_{q, r}(N) \otimes M:$

$$
\begin{equation*}
\Delta x^{a}=T_{b}^{a} \otimes x^{b}+x^{a} \otimes v, \quad \Delta(u)=u \otimes u, \quad \Delta(v)=v \otimes v \tag{5.2.61}
\end{equation*}
$$

2) the left coaction $\Delta_{L}: \Gamma \rightarrow I S O_{q, r}(N) \otimes \Gamma$, when restricted to $\Gamma_{M}$ gives

$$
\begin{equation*}
\left.\Delta_{L}\right|_{\Gamma_{M}}: \Gamma_{M} \rightarrow I S O_{q, r}(N) \otimes \Gamma_{M} \tag{5.2.62}
\end{equation*}
$$

and defines a left coaction of $I S O_{q, r}(N)$ on $\Gamma_{M}$ compatible with the bimodule structure of $\Gamma_{M}$ and the exterior differential: $\left.\Delta_{L}\right|_{\Gamma_{M}}(a d b)=\Delta(a)(i d \otimes d) \Delta(b)$.
3) the right coaction $\Delta_{R}: \Gamma \rightarrow \Gamma \otimes I S O_{q, r}(N)$, does not become a right coaction of $I S O_{q, r}(N)$ on $\Gamma_{M}$; however we have

$$
\begin{equation*}
\left.\Delta_{R}\right|_{\Gamma_{M}}: \Gamma_{M} \rightarrow \Gamma \otimes M \subset \Gamma \otimes I S O_{q, r}(N) \tag{5.2.63}
\end{equation*}
$$

this map is obviously well defined and satisfies $\left.\Delta_{R}\right|_{\Gamma_{M}}(a d b)=\Delta(a)(d \otimes i d) \Delta(b)$ $\forall a, b \in M$ since $M \subset I S O_{q, r}(N)$.

We call this calculus $I S O_{q, r}(N)$-bicovariant because $\left.\Delta_{L}\right|_{\Gamma_{M}}$ and $\left.\Delta_{R}\right|_{\Gamma_{M}}$ are compatible with the bimodule structure of $\Gamma_{M}$ and with the exterior differential.

### 5.2.1 $I S O_{q, r}(N)$-covariant and $S O_{q, r}(N)$-bicovariant calculus

## Commutations

Since the $P_{A}^{a b}{ }_{c d} x^{c} x^{d}=0$ commutation relations allow for an ordering of the coordinates (moreover the Poincaré series of the polynomials on the quantum orthogonal plane is the same as the classical one), it is tempting to impose extra conditions on the differential algebra of the $q$-Minkowski plane, so that the space of 1 -forms has the same dimension as in the classical case. We require that the commutation relations between $x$ and $d x$ close on the algebra generated by $x$ and $d x$ :

$$
\begin{equation*}
d x^{a} x^{b}=\alpha^{a b}{ }_{e f} x^{e} d x^{f} \tag{5.2.64}
\end{equation*}
$$

where $\alpha$ is an unknown matrix whose entries are complex numbers. Any matrix can be expanded as $\alpha=a P_{S}+b P_{A}+c P_{0}$ with $a, b, c=$ const. From (5.2.54) we have $\alpha=r^{-2} P_{S}-P_{A}+c P_{0}$; therefore condition (5.2.64) is equivalent to

$$
\begin{equation*}
P_{0}(d x \otimes x)=c P_{0}(x \otimes d x) \tag{5.2.65}
\end{equation*}
$$

and supplements eq.s (5.2.54). Taking its exterior derivative leads to a supplementary condition on the $d x, d x$ products (for $c \neq-1$ ):

$$
\begin{equation*}
P_{0}(d x \wedge d x)=0 \tag{5.2.66}
\end{equation*}
$$

From (5.3.133) and (5.2.66) it follows that $d x \wedge d x=\left(P_{S}+P_{A}+P_{0}\right)(d x \wedge d x)=$ $P_{A}(d x \wedge d x)$, or [see the definition of $P_{A}$ in (4.1.16)] :

$$
\begin{equation*}
d x \wedge d x=-r \hat{R} d x \wedge d x \tag{5.2.67}
\end{equation*}
$$

which allows the ordering of $d x, d x$ products.
Using (5.2.55), (5.2.65) and (4.1.15), we find

$$
\begin{align*}
d x \otimes x & =\left(r^{-2} P_{S}-P_{A}\right)(x \otimes d x)+P_{0}(d x \otimes x)  \tag{5.2.68}\\
& =\left(r^{-2} P_{S}-P_{A}\right)(x \otimes d x)+c P_{0}(x \otimes d x)  \tag{5.2.69}\\
& =\left(r^{-2} P_{S}-P_{A}+r^{N-2} P_{0}\right)(x \otimes d x)+\left(c-r^{N-2}\right) P_{0}(x \otimes d x)  \tag{5.2.70}\\
& =r^{-1} \hat{R}^{-1}(x \otimes d x)+\left(c-r^{N-2}\right) P_{0}(x \otimes d x) \tag{5.2.71}
\end{align*}
$$

The consistency of the commutation relations (5.2.67) and (5.2.71) with the associativity condition on the triple $d x^{i} d x^{j} x^{k}$ fixes $c=r^{N-2}$ i.e.:

$$
\begin{equation*}
P_{0}(d x \otimes x)=r^{N-2} P_{0}(x \otimes d x) \tag{5.2.72}
\end{equation*}
$$

the $x, d x$ commutations (5.2.71) then become:

$$
\begin{equation*}
x \otimes d x=r \hat{R}(d x \otimes x) \tag{5.2.73}
\end{equation*}
$$

and reproduce (in the uniparametric case) the known $x, d x$ commutations of the quantum orthogonal plane (54.

## Coactions

This calculus is no more bicovariant under the $I S O_{q, r}(N)$ action,

$$
\begin{equation*}
x^{a} \longrightarrow T^{a}{ }_{b} \otimes x^{b}+x^{a} \otimes v, \quad u \longrightarrow u \otimes u, \quad v \longrightarrow v \otimes v \tag{5.2.74}
\end{equation*}
$$

but we are left with bicovariance under the $S O_{q, r}(N)$ action

$$
\begin{equation*}
x^{a} \longrightarrow T^{a}{ }_{b} \otimes x^{b} . \tag{5.2.75}
\end{equation*}
$$

In other words, $\delta_{L}: \Gamma_{M}^{\prime} \rightarrow S O_{q, r} \otimes \Gamma_{M}^{\prime}$ defined by $\delta_{L}(a d b)=\delta(c)(i d \otimes d) \delta(b)$ with $\delta\left(x^{a}\right)=T^{a}{ }_{b} \otimes x^{b}$ is a left coaction of $S O_{q, r}(N)$ on the bimodule $\Gamma_{M}^{\prime}$ where $\Gamma_{M}^{\prime}$ is $\Gamma_{M}$ with the extra condition (5.2.65) [cf. (5.2.62)]. Similarly, the map $\delta_{R}(a d b)=$ $\delta(a)(d \otimes i d) \delta(b)$ is well defined [cf. (5.2.63)].

Left covariance under (5.2.74) is broken only by (5.2.65). Indeed, while relations (5.2.54) are left and right $I S O_{q, r}(N)$-covariant, the extra condition (5.2.65) is not left $I S O_{q, r}(N)$-covariant : $\Delta_{L}\left[P_{0}(d x \otimes x)-c P_{0}(x \otimes d x)\right] \neq 0, \forall c$. It is right $I S O_{q, r}(N)$-covariant, $\Delta_{R}\left[P_{0}(d x \otimes x)-c P_{0}(x \otimes d x)\right]=0$, only for $c=r^{N-2}$, as can be seen using $T^{b}{ }_{d} d x^{a}=d\left(T^{b}{ }_{d} x^{a}\right)=\frac{r}{q_{d}} R^{a b}{ }_{e f} d x^{e} T^{f}{ }_{d}$ and (4.1.21). Therefore the choice $c=r^{N-2}$ preserves the right coaction $\Delta_{R}$ i.e. the right $I S O_{q, r}(N)$-covariance.

Note 5.2.2 We can reformulate the quotient procedure $\Gamma_{M} \rightarrow \Gamma_{M}^{\prime}$ in a more abstact setting by considering that $\Gamma_{M}$ is a subbimodule of the bicovariant bimodule $\Gamma$. In (5.2.59) we have expressed the $x^{e} C_{e f} d x^{f} \leftrightarrow d x^{e} C_{e f} x^{f}$ commutation via the right invariant 1-form $\eta^{\circ}$. A condition on $\Gamma$ (and therefore on $\Gamma_{M}$ ) that preserves right $I S O_{q, r}(N)$ covariance, i.e. compatible with $\Delta_{R}$, is: $\eta^{\circ}$ linearly dependent from the remaining right invariant 1 -forms: $d v u$ and $d x^{a} u$. It is easily seen that since $\eta^{\circ}$ is quadratic in the basis elements $x^{a}$ the only possible linear condition is $\eta^{\circ}=0$, and this gives exactly (5.2.72). The $M$-bimodule $\Gamma_{M}^{\prime}$ is therefore generated by the differentials $d x^{b}$ and $d v$. Since left $I S O_{q, r}(N)$ covariance, contrary to right $I S O_{q, r}(N)$ covariance, is broken, the relations between the left invariants 1-forms is nonlinear. Explicitly we have

$$
\begin{equation*}
\omega^{\circ}=-\frac{q_{a}}{r^{2}} v y_{a} \omega^{a}+\frac{r^{\frac{N}{2}-2}}{r^{N}+r^{2}} C_{a b} x^{a} x^{b} \omega^{\bullet} \tag{5.2.76}
\end{equation*}
$$

[express $d z$ in terms of $d x^{i}, d v$ in (5.1.34) and use the expansion of $d x^{b}$ and $d v$ on $\omega^{a}$ and $\omega^{\bullet}$ as given in (5.1.28), (5.1.30)].

## Partial derivatives

The tangent vectors $\chi$ in (5.1.11) and the corresponding vector fields $\chi *$ have "flat" indices. To compare $\chi *$ with partial derivative operators with "curved" indices, we need to define the operators $\overleftarrow{\partial}$ such that

$$
\begin{equation*}
d a=\overleftarrow{\partial}_{c}(a) d x^{c}+\overleftarrow{\partial}_{\bullet}(a) d v \equiv \overleftarrow{\partial}_{C}(a) d x^{C} \tag{5.2.77}
\end{equation*}
$$

$\left[C=(c, \bullet), d x^{C}=\left(d x^{c}, d v\right)\right]$. The action of $\overleftarrow{\partial_{C}}$ on the coordinates $x^{C}=\left(x^{c}, v\right)$ is given by

$$
\begin{equation*}
\overleftarrow{\partial_{C}}\left(x^{A}\right)=\delta_{C}^{A} I \tag{5.2.78}
\end{equation*}
$$

From the Leibniz rule $d(a b)=(d a) b+a(d b)$, using (5.2.77) and the fact that $d x^{C}=$ $\left(d x^{c}, d v\right)$ is a basis for 1 -forms, we find

$$
\begin{gather*}
\overleftarrow{\partial}_{c}\left(a x^{b}\right)=a \delta_{c}^{b}+\overleftarrow{\partial}_{d}(a) r^{-1}\left(\hat{R}^{-1}\right)^{d b}{ }_{e c} x^{e}-\left(1-r^{2}\right) \overleftarrow{\partial} \bullet \delta_{c}^{b} v  \tag{5.2.79}\\
\overleftarrow{\partial}_{\bullet}\left(a x^{b}\right)=q_{b}^{-1} \overleftarrow{\partial}_{\bullet}(a) x^{b}  \tag{5.2.80}\\
\overleftarrow{\partial}_{c}(a v)=r^{-2} q_{c} \overleftarrow{\partial}_{c}(a) v  \tag{5.2.81}\\
\overleftarrow{\partial} \cdot(a v)=r^{-2} \overleftarrow{\partial}_{\bullet}(a) v+a \tag{5.2.82}
\end{gather*}
$$

Note the dilatation operator $\overleftarrow{\partial}$. appearing on the right-hand side of (5.2.79).
From $d^{2}(a)=0=d\left(\overleftarrow{\partial}_{C}(a) d x^{C}\right)=\overleftarrow{\partial}_{B}\left(\overleftarrow{\partial}_{C}(a)\right) d x^{B} \wedge d x^{C}$ and the $q$-commutations of the differentials (5.3.133)-(5.3.139) one finds the commutations between the "curved" partial derivatives:

$$
\begin{align*}
& \left(P_{A}\right)^{a b}{ }_{c d} \overleftarrow{\partial}_{\partial} \overleftarrow{\partial}_{b}=0  \tag{5.2.83}\\
& \overleftarrow{\partial}_{b} \overleftarrow{\overleftarrow{H}_{\bullet}}-\frac{q_{b}}{r^{2}} \overleftarrow{\partial}_{\partial} \overleftarrow{\partial}_{b}=0 \tag{5.2.84}
\end{align*}
$$

We can also define the partial derivatives $\partial_{C}$ so that 48], [53],

$$
\begin{equation*}
d a=d x^{C} \partial_{C}(a) ; \tag{5.2.85}
\end{equation*}
$$

again the action of $\partial_{C}$ on the coordinates is

$$
\begin{equation*}
\partial_{C}\left(x^{A}\right)=\delta_{C}^{A} I \tag{5.2.86}
\end{equation*}
$$

We now give an explicit relation between the $\partial_{C}$ and the $q$-Lie algebra generators $\chi_{C}$ (a similar expression holds also for the $\overleftarrow{\partial}$ derivatives). From (2.3.32) we have:

$$
\begin{equation*}
d a=-\eta^{C}\left(a * \kappa^{\prime}\left(\chi_{C}\right)\right) \tag{5.2.87}
\end{equation*}
$$

where $C=(c, \bullet)$ because we have set $\eta^{\circ}=0$. Relations (5.2.85) and (5.2.87) give, $\forall a \in I S O_{q, r}(N):$

$$
\begin{equation*}
\partial_{c}(a)=r^{-1} u\left(a * \kappa^{\prime}\left(\chi_{c}\right)\right) \quad, \quad \partial_{\bullet}(a)=r^{-1} u\left(a * \kappa^{\prime}\left(\chi_{\bullet}\right)\right) \tag{5.2.88}
\end{equation*}
$$

The commutations between the partial derivatives can be derived as done above for $\stackrel{\overleftarrow{\partial}}{\partial}$, or via (5.2.88) and the $q$-Lie algebra (5.1.1)-(5.1.4). They are given in Table 2. Similarly we can introduce the right invariant vectorfields

$$
\begin{equation*}
\tilde{h}_{C} \equiv \tilde{h}_{\kappa^{\prime}}\left(\chi_{C}\right) \equiv\left[\kappa^{\prime}\left(\chi_{C}\right) \otimes i d\right] \Delta \tag{5.2.89}
\end{equation*}
$$

and use their Leibniz rule [it follows from $\Delta\left(\kappa^{\prime}\left(\chi_{C}\right)\right)=\kappa^{\prime}\left(\chi_{C}\right) \otimes \varepsilon+\kappa^{\prime}\left(f^{D}{ }_{C}\right) \otimes \kappa^{\prime}\left(\chi_{D}\right)$ ]:

$$
\begin{equation*}
\tilde{h}_{C}(a b)=\tilde{h}_{C}(a) b+\kappa^{\prime}\left(f_{C}^{D}\right)\left(a_{1}\right) a_{2} \tilde{h}_{D}(b) \tag{5.2.90}
\end{equation*}
$$

to derive the $\partial, x, u$ commutations. For example we have $\tilde{h}_{a} x^{b}=r v \delta_{a}^{b}+\left(r / q_{b}\right) R_{a c}^{l b} c^{c} \tilde{h}_{l}$ $+r \lambda \tilde{h} \bullet$ that togheter with $\partial_{C}=r^{-1} u \tilde{h}_{C}$ gives

$$
\partial_{a} x^{b}=\delta_{j}^{i}\left[I+\left(r^{2}-1\right) v \partial_{\bullet}\right]+r R_{a c}^{l b} x^{c} \partial_{l} .
$$

Similarly for the the other relations, see Table 2.

## Conjugation

The commutations in Table 2 are consistent under the conjugation (already defined for $x^{a}$ and $d x^{a}$ )

$$
\begin{gather*}
\left(x^{a}\right)^{*}=\mathcal{D}^{a}{ }_{b} x^{b},\left(d x^{a}\right)^{*}=\mathcal{D}^{a}{ }_{b} d x^{b},\left(\partial_{a}\right)^{*}=-r^{N} d_{b}^{-1} \mathcal{D}^{b}{ }_{a} \partial_{b}  \tag{5.2.91}\\
v^{*}=v,(d v)^{*}=d v,\left(\partial_{\bullet}\right)^{*}=u-\partial_{\bullet} \tag{5.2.92}
\end{gather*}
$$

where we have used the notation $D_{a}^{a}=d^{a}, D_{a}^{-1 a}=d_{a}^{-1}\left(D_{b}^{a}=C^{a e} C_{b e}\right.$ is diagonal $)$. This consistency can be checked directly by taking the $*$-conjugates of the relations in Table 2, and by using the identity (4.1.34) and:

$$
\begin{gather*}
\bar{C}=C^{T} ;\left[Q_{N}(r)\right]^{*}=Q_{N}(r) ;  \tag{5.2.93}\\
d^{c} d_{h}^{-1} R^{c g}{ }_{h a}\left(R^{-1}\right)^{e a}{ }_{c d}=\delta_{h}^{e} \delta_{d}^{g} ; \quad R^{a b}{ }_{c d} d^{a} d^{b}=R^{a b}{ }_{c d} d^{c} d^{d} \\
d^{c} R^{c g}{ }_{h c}=r^{N-1} \delta_{h}^{g} ; \quad R^{a b}{ }_{c d} d_{a}^{-1} d_{b}^{-1}=R^{a b}{ }_{c d} d_{c}^{-1} d_{d}^{-1}  \tag{5.2.94}\\
\overline{q_{a}}=\frac{1}{q_{a}} \text { for } a \neq n, n+1, \quad \overline{q_{n}}=\frac{1}{q_{n+1}} \tag{5.2.95}
\end{gather*}
$$

We now derive the conjugation on the partial derivatives from the differential calculus on $I S O_{q, r}(N)$. This is achieved by studying the conjugation on the right invariant vectorfields $\tilde{h}$.

For a general Hopf algebra, with tangent vectors $\chi_{i}$, we deduce the conjugation on $\tilde{h}$ from the commutation relations between $\tilde{h}$ and a generic element of the Hopf algebra:

$$
\begin{equation*}
\tilde{h}_{j} b=\tilde{h}_{j}(b)+\left\langle\kappa^{\prime}\left(f^{s}{ }_{j}\right), b_{1}\right\rangle b_{2} \tilde{h}_{s}=\left\langle\kappa^{\prime}\left(\chi_{j}\right), b_{1}\right\rangle b_{2}+\left\langle\kappa^{\prime}\left(f^{s}{ }_{j}\right), b_{1}\right\rangle b_{2} \tilde{h}_{s} \tag{5.2.96}
\end{equation*}
$$

We multiply this expression by $\left\langle\kappa^{\prime 2}\left(f^{j}{ }_{i}\right), b_{0}\right\rangle$ [where we have used the notation $\left.(i d \otimes \Delta) \Delta(b)=b_{0} \otimes b_{1} \otimes b_{2}\right]$ to obtain

$$
\begin{equation*}
\left\langle\kappa^{\prime 2}\left(f^{j}{ }_{i}\right), b_{1}\right\rangle \tilde{h}_{j} b_{2}+\left\langle\kappa^{\prime 2}\left(\chi_{i}\right), b_{1}\right\rangle b_{2}=b \tilde{h}_{i} \tag{5.2.97}
\end{equation*}
$$

Now, using $\langle\psi, b\rangle=\overline{\left\langle\left[\kappa^{\prime}(\psi)\right]^{*}, b^{*}\right\rangle}$ and then applying * we obtain (here $a=b^{*}$ )

$$
\begin{equation*}
\tilde{h}_{j}^{*} a=\left\langle\left[\kappa^{\prime 3}\left(\chi_{j}\right)\right]^{*}, a_{1}\right\rangle a_{2}+\left\langle\left[\kappa^{\prime 3}\left(f_{j}^{s}\right)\right]^{*}, a_{1}\right\rangle a_{2} \tilde{h}_{s} . \tag{5.2.98}
\end{equation*}
$$

This last relation implies

$$
\begin{equation*}
\tilde{h}_{i}^{*} \equiv\left[\tilde{h}_{\kappa^{\prime}\left(\chi_{i}\right)}\right]^{*}=\tilde{h}_{\left[\kappa^{\prime 3}\left(\chi_{i}\right)\right]^{*}} \tag{5.2.99}
\end{equation*}
$$

notice that $* \circ \kappa^{\prime 2}$ is a well defined conjugation since $\left(* \circ \kappa^{\prime 2}\right)^{2}=i d$.
We now apply formula (5.2.99), valid for a generic Hopf algebra, to the *conjugation and the right invariant vectorfields of this section; we have:

$$
\begin{align*}
{\left[\tilde{h}_{\kappa^{\prime}\left(\chi_{a}\right)}\right]^{*} } & =-r^{N} \bar{q}_{a} d_{a}^{-1} \mathcal{D}_{a}^{b} \tilde{h}_{\kappa^{\prime}}\left(\chi_{b}\right)  \tag{5.2.100}\\
{\left[\tilde{h}_{\kappa^{\prime}}\left(\chi_{\bullet}\right)\right]^{*} } & =-\tilde{h}_{\kappa^{\prime}}\left(\chi_{\bullet}\right) \tag{5.2.101}
\end{align*}
$$

From these last relations and (5.2.88) we then finally deduce $\left(\partial_{a}\right)^{*}=-d_{b}^{-1} \mathcal{D}^{b}{ }_{a} r^{N} \partial_{b}$ and $\left(\partial_{\bullet}\right)^{*}=u-\partial_{\bullet}$.

### 5.2.2 The reduced $x^{a}, d x^{a}, \partial_{a}$ algebra and the quantum Minkowski phase-space.

Note that the algebra in Table 2 actually contains a subalgebra generated only by $x^{a}, d x^{a}, \partial_{a}$, indeed $\partial_{\bullet}$ vanishes when acting on monomials containing only the coordinates $x^{b}$, as can be seen from (5.4.149). This calculus is $I S O_{q, r}(N)$-right covariant because it can also be obtained imposing the conditions $\eta^{\bullet}=0$ and $\chi_{\bullet}=0$ that are compatible with the right coaction $\Delta_{R}$ and the bimodule structure given by the $f_{j}^{i}$ functionals.

Table 3 contains the multiparametric orthogonal quantum plane algebra of coordinates, differentials and partial derivatives, together with a consistent conjugation for any even dimension. We emphasize here that this conjugation does not require an additional scaling operator as in ref. (9]. Thus the algebra in Table 3
can be taken as starting point for a deformed Heisenberg algebra (i.e. a deformed phase-space).

## Real coordinates and hermitean momenta

We note that the transformation

$$
\begin{align*}
& X^{a}=\frac{1}{\sqrt{2}}\left(x^{a}+x^{a^{\prime}}\right), \quad a \leq n  \tag{5.2.102}\\
& X^{n+1}=\frac{i}{\sqrt{2}}\left(x^{n}-x^{n+1}\right)  \tag{5.2.103}\\
& X^{a}=\frac{1}{\sqrt{2}}\left(x^{a}-x^{a^{\prime}}\right), \quad a>n+1 \tag{5.2.104}
\end{align*}
$$

defines real coordinates $X^{a}$. On this basis the metric becomes $C^{\prime}=\left(M^{-1}\right)^{T} C M^{-1}$ (where $M$ is the transformation matrix $X=M x$ ):

$$
C^{\prime}=\frac{1}{2}\left(\begin{array}{cccc}
r^{\frac{N}{2}-1}+r^{-\frac{N}{2}+1} & 0 & 0 & -\left(r^{\frac{N}{2}-1}-r^{-\frac{N}{2}+1}\right)  \tag{5.2.105}\\
0 & r^{\frac{N}{2}-2}+r^{-\frac{N}{2}+2} & -\left(r^{\frac{N}{2}-2}-r^{-\frac{N}{2}+2}\right) & 0 \\
\vdots & \vdots & & \vdots \\
\vdots & 0 & 2 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0 & 2 \\
\vdots & \vdots & \vdots & \vdots \\
0 & r^{\frac{N}{2}-2}-r^{-\frac{N}{2}+2} & -\left(r^{\frac{N}{2}-2}+r^{-\frac{N}{2}+2}\right) & 0 \\
r^{\frac{N}{2}-1}-r^{-\frac{N}{2}+1} & 0 & 0 & -\left(r^{\frac{N}{2}-1}+r^{-\frac{N}{2}+1}\right)
\end{array}\right)
$$

and reduces for $r \rightarrow 1$ to the usual $S O(n+1, n-1)$ diagonal metric with $n+1$ plus signs and $n-1$ minus signs. Notice that the diagonal elements of $C^{\prime}$ are real while the off diagonal ones are pure imaginary, moreover $C^{\prime}$ is hermitian (and can therefore be diagonalized via a unitary matrix).

As for the coordinates $X$, it is possible to define antihermitian $\chi$ and $\partial$, and real $\omega$ and $d x$. To define hermitian momenta we first notice that the partial derivatives

$$
\begin{equation*}
\tilde{\partial}_{a} \equiv r^{\frac{N}{2}} d_{a}^{-\frac{1}{2}} \partial_{a} \tag{5.2.106}
\end{equation*}
$$

behave, under the hermitian conjugation $*$, similarly to the coordinates $x^{a}$ :

$$
\begin{align*}
& \left(\tilde{\partial}_{a}\right)^{*}=-\tilde{\partial}_{a} \quad a \neq n, n+1  \tag{5.2.107}\\
& \left(\tilde{\partial}_{n}\right)^{*}=-\tilde{\partial}_{n+1} . \tag{5.2.108}
\end{align*}
$$

As in (5.2.102)-(5.2.104) we then define:

$$
\begin{equation*}
P_{a}=\frac{-i \hbar}{\sqrt{2}}\left(\tilde{\partial}_{a}+\tilde{\partial}_{a^{\prime}}\right), \quad a \leq n \tag{5.2.109}
\end{equation*}
$$

$$
\begin{align*}
& P_{n+1}=\frac{-\hbar}{\sqrt{2}}\left(\tilde{\partial}_{n}-\tilde{\partial}_{n+1}\right)  \tag{5.2.110}\\
& P_{a}=\frac{-i \hbar}{\sqrt{2}}\left(\tilde{\partial}_{a}-\tilde{\partial}_{a^{\prime}}\right), \quad a>n+1 \tag{5.2.111}
\end{align*}
$$

It is easy to see that the $P_{a}$ are hermitian: $P_{a}{ }^{*}=P_{a}$ and that in the classical limit are the momenta conjugated to the coordinates $X^{a}: P_{a}\left(X^{b}\right)=-i \hbar \delta_{a}^{b}$. In the $r \neq 1$ case we explicitly have (use $d_{a^{\prime}}=d_{a}^{-1}, d_{n}=d_{n+1}=1$ ):

$$
\begin{aligned}
& P_{a}\left(X^{a}\right)=\frac{-i}{2} r^{\frac{N}{2}} \hbar\left(d_{a}^{\frac{1}{2}}+d_{a}^{-\frac{1}{2}}\right) \\
& P_{a}\left(X^{a^{\prime}}\right)=\epsilon_{a} \frac{-i}{2} r^{\frac{N}{2}} \hbar\left(d_{a}^{\frac{1}{2}}-d_{a}^{-\frac{1}{2}}\right) \quad \text { where } \epsilon_{a}=1 \text { if } a<n \text { and } \epsilon_{a}=-1 \text { if } a>n+1
\end{aligned}
$$

while the other entries of the $P_{a}\left(X^{b}\right)$ matrix are zero.
By defining the transformation matrix $N_{a}{ }^{b}$ as:

$$
\begin{equation*}
P_{a} \equiv-i \hbar N_{a}{ }^{b} \partial_{b} \tag{5.2.112}
\end{equation*}
$$

we find the deformed canonical commutation relations:

$$
\begin{equation*}
P_{a} X^{b}-r S^{b c}{ }_{a d} X^{d} P_{c}=-i \hbar E_{a}^{b} I \tag{5.2.113}
\end{equation*}
$$

where

$$
\begin{equation*}
S_{a d}^{b c}=N_{a}^{e} M_{f}^{b} \hat{R}_{e g}^{f h}{ }_{e g}\left(M^{-1}\right)_{d}^{g}\left(N^{-1}\right)_{h}^{c}, \quad E_{a}^{b} \equiv \frac{i}{\hbar} P_{a}\left(X^{b}\right)=N_{a}^{c} M_{c}^{b} \tag{5.2.114}
\end{equation*}
$$

Similarly one finds all the remaining commutations of the $P, X$ and $d X$ algebra. Notice that no unitary operator appears on the right-hand side of (5.2.113). Our conjugation is consistent with ( 5.2 .113 ) without the need of the extra operator of ref. (9] .

For $n=2$ the results of this section immediately yield the bicovariant calculus on the quantum Minkowski space, i.e. on the multiparametric orthogonal quantum plane Fun $_{q, r}(I S O(3,1) / S O(3,1))$.

Note 5.2.3 In the $r \rightarrow 1$ limit the reduced differential calculus on the coordinates $x^{a}$ coincides with the $r=1$ bicovariant differential calculus on $\operatorname{ISO}_{q, r=1}(N)$ of Section 4.7 [see (4.7.17)]. This is so because the $I S O_{q, r=1}(N)$ bicovariant differential can be written $d a=\left(\chi^{a}{ }_{b} * a\right) \omega_{a}{ }^{b}+\left(\chi^{\bullet}{ }_{c} * a\right) \omega_{\bullet}{ }^{c}=-\eta_{a}{ }^{b}\left(a * \kappa^{\prime}\left(\chi^{a}{ }_{b}\right)\right)-\eta_{\bullet}{ }^{c}\left(a * \kappa^{\prime}\left(\chi^{\bullet}{ }_{c}\right)\right)$. Similarly to Theorem 3.7.1, we have that $\left(a * \kappa^{\prime}\left(\chi^{a}{ }_{b}\right)\right)=0$ when $a$ is a polynomial in $x^{a}$. Then the exterior differential on such polynomials reads $d a=-\eta_{\bullet}{ }^{c}\left(a * \kappa^{\prime}\left(\chi^{\bullet}{ }_{c}\right)\right)$ as in the reduced differential calculus on the coordinates $x^{a}$.

### 5.3 Table 1: the $I S O_{q, r}(N)$-bicovariant algebra

$$
\begin{align*}
& P_{A}^{a b}{ }_{c d} x^{c} x^{d}=0  \tag{5.3.115}\\
& x^{b} v=q_{b} v x^{b} ; \quad x^{b} u=q_{b}^{-1} u x^{b}  \tag{5.3.116}\\
& z=-\frac{1}{\left(r^{-\frac{N}{2}}+r^{\frac{N}{2}-2}\right)} x^{b} C_{b a} x^{a} u  \tag{5.3.117}\\
& z v=r^{2} v z ; \quad z u=r^{-2} u z  \tag{5.3.118}\\
& q_{a} x^{a} z=z x^{a}  \tag{5.3.119}\\
& (x \otimes d x)=\left(r^{2} P_{S}-P_{A}-P_{0}\right)(d x \otimes x)+P_{0} d(x \otimes x)  \tag{5.3.120}\\
& x^{c} d u=\frac{1}{q_{c}}(d u) x^{c}-\frac{\lambda}{r}\left(d x^{c}\right) u ; \quad x^{c} d v=q_{c}(d v) x^{c}+\lambda r\left(d x^{c}\right) v  \tag{5.3.121}\\
& x^{c} d z=\frac{1}{q_{c}}(d z) x^{c}  \tag{5.3.122}\\
& u d x^{c}=\frac{q_{c}}{r^{2}}\left(d x^{c}\right) u  \tag{5.3.123}\\
& u d u=r^{-2}(d u) u ; \quad u d v=r^{-2}(d v) u  \tag{5.3.124}\\
& u d z=(d z) u  \tag{5.3.125}\\
& v d x^{c}=\frac{r^{2}}{q_{c}}\left(d x^{c}\right) v  \tag{5.3.126}\\
& v d u=r^{2}(d u) v ; \quad v d v=r^{2}(d v) v  \tag{5.3.127}\\
& v d z=(d z) v  \tag{5.3.128}\\
& z d x^{c}=q_{c}\left(d x^{c}\right) z  \tag{5.3.129}\\
& z d u=r^{-2}(d u) z+\left(r^{-2}-1\right)(d z) u  \tag{5.3.130}\\
& z d v=r^{2}(d v) z+\left(r^{2}-1\right)(d z) v  \tag{5.3.131}\\
& z d z=r^{-2}(d z) z  \tag{5.3.132}\\
& P_{S}(d x \wedge d x)=0  \tag{5.3.133}\\
& d x^{c} \wedge d u=-\frac{r^{2}}{q_{c}} d u \wedge d x^{c} ; \quad d x^{c} \wedge d v=-\frac{q_{c}}{r^{2}} d v \wedge d x^{c}  \tag{5.3.134}\\
& d x^{c} \wedge d z=-\frac{1}{q_{c}} d z \wedge d x^{c}  \tag{5.3.135}\\
& d u \wedge d u=d v \wedge d v=0 \tag{5.3.136}
\end{align*}
$$

$$
\begin{align*}
& d u \wedge d v=-r^{-2} d v \wedge d u  \tag{5.3.137}\\
& d z \wedge d u=-d u \wedge d z ; \quad d z \wedge d v=-d v \wedge d z  \tag{5.3.138}\\
& d z \wedge d z=0 \tag{5.3.139}
\end{align*}
$$

### 5.4 Table 2: the $I S O_{q, r}(N)$-covariant $x^{a}, v, \partial_{a}, \partial_{\bullet}, d x^{a}, d v$ algebra

$$
\begin{align*}
& P_{A}^{a b}{ }_{c d} x^{c} x^{d}=0  \tag{5.4.140}\\
& x^{b} v=q_{b} v x^{b} \tag{5.4.141}
\end{align*}
$$

$$
\begin{align*}
& x \otimes d x=r \hat{R}(d x \otimes x)  \tag{5.4.142}\\
& x^{c} d v=q_{c}(d v) x^{c}+\lambda r\left(d x^{c}\right) v  \tag{5.4.143}\\
& v d x^{c}=\frac{r^{2}}{q_{c}}\left(d x^{c}\right) v \tag{5.4.144}
\end{align*}
$$

$$
\begin{equation*}
d x \wedge d x=-r \hat{R} d x \wedge d x \tag{5.4.145}
\end{equation*}
$$

$$
\begin{equation*}
d x^{c} \wedge d v=-\frac{q_{c}}{r^{2}} d v \wedge d x^{c} \tag{5.4.146}
\end{equation*}
$$

$$
\begin{equation*}
d v \wedge d v=0 \tag{5.4.147}
\end{equation*}
$$

$$
\begin{align*}
& \left(P_{A}\right)^{a b}{ }_{c d} \partial_{b} \partial_{a}=0  \tag{5.4.151}\\
& \partial_{b} \partial_{\bullet}-\frac{q_{b}}{r^{2}} \partial_{\bullet} \partial_{b}=0 \tag{5.4.152}
\end{align*}
$$

## Conjugation:

$$
\begin{gather*}
\left(x^{a}\right)^{*}=\mathcal{D}^{a}{ }_{b} x^{b},\left(d x^{a}\right)^{*}=\mathcal{D}_{b}^{a} d x^{b},\left(\partial_{a}\right)^{*}=-r^{N} d_{a}^{-1} \mathcal{D}_{a}^{b} \partial_{b}  \tag{5.4.153}\\
v^{*}=v,(d v)^{*}=d v,\left(\partial_{\bullet}\right)^{*}=u-\partial_{\bullet}  \tag{5.4.154}\\
r^{*}=r^{-1}, \quad q_{a}^{*}=\frac{1}{q_{a}} \text { for } a \neq n, n+1, \quad q_{n}^{*}=\frac{1}{q_{n+1}} \tag{5.4.155}
\end{gather*}
$$

### 5.5 Table 3: the reduced $I S O_{q, r}(N)$-covariant $x^{a}, \partial_{a}, d x^{a}$ algebra

$$
\begin{gather*}
P_{A}^{a b}{ }_{c d} x^{c} x^{d}=0  \tag{5.5.156}\\
x \otimes d x=r \hat{R}(d x \otimes x)  \tag{5.5.157}\\
d x \wedge d x=-r \hat{R}(d x \wedge d x)  \tag{5.5.158}\\
\partial_{c} x^{b}=r \hat{R}^{b e}{ }_{c d} x^{d} \partial_{e}+\delta_{c}^{b} I  \tag{5.5.159}\\
P_{A}^{a b}{ }_{c d} \partial_{b} \partial_{a}=0 \tag{5.5.160}
\end{gather*}
$$

Conjugation:

$$
\begin{equation*}
\left(x^{a}\right)^{*}=\mathcal{D}^{a}{ }_{b} x^{b},\left(d x^{a}\right)^{*}=\mathcal{D}^{a}{ }_{b} d x^{b},\left(\partial_{a}\right)^{*}=-r^{N} d_{a}^{-1} \mathcal{D}^{b}{ }_{a} \partial_{b} \tag{5.5.161}
\end{equation*}
$$

## Chapter 6

## Appendix

## A The Hopf algebra axioms

A Hopf algebra over the field $K$ is a unital algebra over $K$ endowed with the linear maps:

$$
\begin{equation*}
\Delta: A \rightarrow A \otimes A, \varepsilon: A \rightarrow K, \kappa: A \rightarrow A \tag{A.1}
\end{equation*}
$$

satisfying the following properties $\forall a, b \in A$ :

$$
\begin{gather*}
(\Delta \otimes i d) \Delta(a)=(i d \otimes \Delta) \Delta(a)  \tag{A.2}\\
(\varepsilon \otimes i d) \Delta(a)=(i d \otimes \varepsilon) \Delta(a)=a  \tag{A.3}\\
m(\kappa \otimes i d) \Delta(a)=m(i d \otimes \kappa) \Delta(a)=\varepsilon(a) I  \tag{A.4}\\
\Delta(a b)=\Delta(a) \Delta(b) ; \quad \Delta(I)=I \otimes I  \tag{A.5}\\
\varepsilon(a b)=\varepsilon(a) \varepsilon(b) ; \quad \varepsilon(I)=1 \tag{A.6}
\end{gather*}
$$

where $m$ is the multiplication map $m(a \otimes b)=a b$. From these axioms we deduce:

$$
\begin{equation*}
\kappa(a b)=\kappa(b) \kappa(a) ; \quad \Delta[\kappa(a)]=\tau(\kappa \otimes \kappa) \Delta(a) ; \quad \varepsilon[\kappa(a)]=\varepsilon(a) ; \quad \kappa(I)=I \tag{A.7}
\end{equation*}
$$

where $\tau(a \otimes b)=b \otimes a$ is the twist map.

## B The derivation of two equations

In this Appendix we derive the two equations (2.1.108) and (2.1.110). Consider the exterior derivative of eq. (2.1.30):

$$
\begin{equation*}
d\left(\omega^{i} a\right)=d\left[\left(f_{j}^{i} * a\right) \omega^{j}\right] . \tag{B.1}
\end{equation*}
$$

The left-hand side is equal to:

$$
\begin{align*}
& d\left(\omega^{i} a\right)= \\
& \quad=d \omega^{i} \wedge a-\omega^{i} \wedge d a=-\boldsymbol{C}_{j k}{ }^{i} \omega^{j} \otimes \omega^{k} a-\omega^{i} \wedge\left(\chi_{j} * a\right) \omega^{j}= \\
& \quad=-\boldsymbol{C}_{j k}{ }^{i} \omega^{j} \otimes \omega^{k} a-\left(f^{i}{ }_{s} * \chi_{j} * a\right) \omega^{s} \wedge \omega^{j}= \\
& \quad=-\boldsymbol{C}_{j k}{ }^{i}\left(f^{j}{ }_{p} * f^{k}{ }_{q} * a\right) \omega^{p} \otimes \omega^{q}-\left(f^{i}{ }_{s} * \chi_{j} * a\right)\left(\omega^{s} \otimes \omega^{j}-\Lambda^{s j}{ }_{p q} \omega^{p} \otimes \omega^{q}\right)= \\
& \quad=\left[\left(-\boldsymbol{C}_{j k}{ }^{i} f^{j}{ }_{p} f^{k}{ }_{q}-f^{i}{ }_{p} \chi_{q}+\Lambda^{s j}{ }_{p q} f^{i}{ }_{s} \chi_{j}\right) * a\right]\left(\omega^{p} \otimes \omega^{q}\right) \tag{B.2}
\end{align*}
$$

The right-hand side reads:

$$
\begin{align*}
& d\left[\left(f_{j}^{i} * a\right) \omega^{j}\right]= \\
& \quad=d\left(f^{i}{ }_{j} * a\right) \omega^{j}+\left(f^{i}{ }_{j} * a\right) d \omega^{j}= \\
& \quad=\left(\chi_{k} * f^{i}{ }_{j} * a\right) \omega^{k} \wedge \omega^{j}-\left(f^{i}{ }_{j} * a\right) \boldsymbol{C}_{p q}{ }^{j} \omega^{p} \otimes \omega^{q}= \\
& \quad=\left(\chi_{k} * f^{i}{ }_{j} * a\right)\left(\omega^{k} \otimes \omega^{j}-\Lambda^{k j} \omega^{p} \otimes \omega^{q}\right)-\left(f^{i}{ }_{j} * a\right) \boldsymbol{C}_{p q}{ }^{j} \omega^{p} \otimes \omega^{q}= \\
& \quad=\left[\left(\chi_{p} f^{i}{ }_{q}-\Lambda^{k j}{ }_{p q} \chi_{k} f^{i}{ }_{j}-\boldsymbol{C}_{p q}{ }^{j} f^{i}{ }_{j}\right) * a\right]\left(\omega^{p} \otimes \omega^{q}\right), \tag{B.3}
\end{align*}
$$

so that we deduce the equation

$$
\begin{align*}
& -\boldsymbol{C}_{j k}{ }^{i} f^{j}{ }_{p} f^{k}{ }_{q}-f^{i}{ }_{p} \chi_{q}+\Lambda^{s j}{ }_{p q} f^{i}{ }_{s} \chi_{j}= \\
& =\chi_{p} f^{i}{ }_{q}-\Lambda^{k j} p q \chi_{k} f^{i}{ }_{j}-C_{p q}{ }^{j} f^{i}{ }_{j} . \tag{B.4}
\end{align*}
$$

We now need two lemmas.

## Lemma 1

$$
\begin{equation*}
f_{l}^{n} * a \theta=\left(f_{r}^{n} * a\right)\left(f^{r}{ }_{l} * \theta\right), \quad a \in A, \quad \theta \in \Gamma^{\otimes n} . \tag{B.5}
\end{equation*}
$$

Proof

$$
\begin{align*}
& f_{l}^{n} * a \theta= \\
& \quad\left(i d \otimes f^{n}{ }_{l}\right) \Delta(a) \Delta_{R}(\theta)=a_{1} \theta_{1} f^{n}{ }_{l}\left(a_{2} \theta_{2}\right)= \\
& a_{1} \theta_{1} f^{n}{ }_{r}\left(a_{2}\right) f^{r}{ }_{l}\left(\theta_{2}\right)=a_{1} f^{n}{ }_{r}\left(a_{2}\right) \theta_{1} f^{r}{ }_{l}\left(\theta_{2}\right)= \\
&  \tag{B.6}\\
& \left(f^{n}{ }_{r} * a\right) \theta_{1} f^{r}{ }_{l}\left(\theta_{2}\right)=\left(f^{n}{ }_{r} * a\right)\left(f^{r}{ }_{l} * \theta\right) .
\end{align*}
$$

Lemma 2

$$
\begin{equation*}
f^{r}{ }_{l} * \omega^{j}=\Lambda_{k l}^{r j} \omega^{k} . \tag{B.7}
\end{equation*}
$$

Proof

$$
\begin{align*}
& f_{l}^{r}{ }_{l} * \omega^{j}= \\
& \quad\left(i d \otimes f^{r}{ }_{l}\right) \Delta_{R}\left(\omega^{j}\right)=\left(i d \otimes f^{r}{ }_{l}\right)\left[\omega^{k} \otimes M_{k}^{j}\right]= \\
& \quad=\omega^{k} f^{r}{ }_{l}\left(M_{k}{ }^{j}\right)=\Lambda_{k l}^{r j} . \tag{B.8}
\end{align*}
$$

Consider now eq. (2.1.107) with $h=f^{n}{ }_{l}$ :

$$
\begin{equation*}
d\left(f^{n}{ }_{l} * a\right)=f^{n}{ }_{l} * d a . \tag{B.9}
\end{equation*}
$$

The first member is equal to $\left(\chi_{k} * f^{n}{ }_{l} * a\right) \omega^{k}$, while the second member is:

$$
\begin{align*}
f^{n}{ }_{l} * d a & =f^{n}{ }_{l} *\left[\left(\chi_{j} * a\right) \omega^{j}\right]=\left(f^{n}{ }_{r} * \chi_{j} * a\right)\left(f^{r}{ }_{l} * \omega^{j}\right) \\
& =\left(f^{n}{ }_{r} * \chi_{j} * a\right)\left(\Lambda_{k l}^{r j} \omega^{k}\right) \tag{B.10}
\end{align*}
$$

We have used here the two lemmas (B.5) and (B.7). Therefore the following equation holds:

$$
\begin{equation*}
\chi_{k} * f^{n}{ }_{l}=\Lambda_{k l}^{r j} f_{r}^{n} * \chi_{j}, \tag{B.11}
\end{equation*}
$$

which is just eq. (2.1.108). Equation (2.1.110) is obtained simply by subtracting (B.11) from eq. (B.4).

## C Two theorems on $i_{t}$ and $\ell_{t}$

Theorem 2.4.11

$$
\ell_{t_{i}}=i_{t_{i}} d+d i_{t_{i}}
$$

that is

$$
\begin{align*}
\forall a_{i_{1} \ldots i_{n}} \omega^{i_{1}} \wedge \ldots \omega^{i_{n}} \in \Gamma^{\wedge n} \\
\ell_{t_{i}}\left(a_{i_{1} \ldots i_{n}} \omega^{i_{1}} \wedge \ldots \omega^{i_{n}}\right)=\left(i_{t_{i}} d+d i_{t_{i}}\right)\left(a_{i_{1} \ldots i_{n}} \omega^{i_{1}} \wedge \ldots \omega^{i_{n}}\right) . \tag{C.1}
\end{align*}
$$

We will show this theorem by induction on the integer $n$. To do this, we need the following:

Lemma
If $n=1$, the theorem is true, i.e.

$$
\begin{equation*}
\ell_{t_{i}}\left(b_{k} \omega^{k}\right)=\left(i_{t_{i}} d+d i_{t_{i}}\right)\left(b_{k} \omega^{k}\right) . \tag{C.2}
\end{equation*}
$$

First we show that:

$$
\begin{equation*}
\ell_{t_{i}}\left(\omega^{k}\right)=\left(i_{t_{i}} d+d i_{t_{i}}\right) \omega^{k} . \tag{C.3}
\end{equation*}
$$

We already know that $\ell_{t_{i}}\left(\omega^{k}\right)=\omega^{j} \boldsymbol{C}_{j i}{ }^{k}$. The right-hand side of (C.3) yields:

$$
\begin{aligned}
\left(i_{t_{i}} d+d i_{t_{i}}\right)\left(\omega^{k}\right) & =i_{t_{i}} d \omega^{k}+d\left(i_{t_{i}} \omega^{k}\right)= \\
& =-\frac{1}{2} C_{n j}{ }^{k} i_{t_{i}}\left(\omega^{n} \wedge \omega^{j}\right)= \\
& =-\frac{1}{2} C_{n j}{ }^{k}\left(f^{n}{ }_{i} * \omega^{j}-\omega^{n} \delta_{i}^{j}\right)= \\
& =-\frac{1}{2} C_{n j}{ }^{k}\left[\left(i d \otimes f^{n}{ }_{i}\right)\left(\omega^{\ell} \otimes M_{\ell}{ }^{j}\right)-\delta_{i}^{j} \omega^{n}\right]= \\
& \left.\left.=-\frac{1}{2} C_{n j}{ }^{k}\right] \omega^{\ell} \Lambda_{\ell i}^{n j}-\delta_{i}^{j} \omega^{n}\right]= \\
& =+\frac{1}{2} C_{n j}{ }^{k}\left[\delta_{\ell}^{n} \delta_{i}^{j}-\Lambda_{\ell i}^{n j}\right] \omega^{\ell}= \\
& =\boldsymbol{C}_{\ell i}{ }^{k} \omega^{\ell}
\end{aligned}
$$

and (C.3) is thus proved.
The right-hand side of (C.2) gives:

$$
\begin{aligned}
\left(i_{t_{i}} d+d i_{t_{i}}\right)\left(b_{k} \omega^{k}\right)= & i_{t_{i}}\left(d b_{k} \wedge \omega^{k}+b_{k} d \omega^{k}\right)+d\left(b_{k} i_{t_{i}}\left(\omega^{k}\right)\right)= \\
= & i_{t_{j}}\left(d b_{k}\right) f^{j}{ }_{i} * \omega^{k}-\left(d b_{k}\right) i_{t_{i}}\left(\omega^{k}\right)+ \\
& +b_{k} i_{t_{i}}\left(d \omega^{k}\right)+\left(d b_{k}\right) i_{t_{i}}\left(\omega^{k}\right)= \\
= & i_{t_{j}}\left(\left(\chi_{n} * b_{k}\right) \omega^{n}\right) f^{j}{ }_{i} * \omega^{k}+b_{k} i_{t_{i}}\left(d \omega^{k}\right)= \\
= & \left(\chi_{n} * b_{k}\right) \delta_{j}^{n} f_{j}^{j}{ }_{i} * \omega^{k}+b_{k}\left(i_{t_{i}} d+d i_{t_{i}}\right) \omega^{k}= \\
= & \left(\chi_{n} * b_{k}\right) f^{n}{ }_{i} * \omega^{k}+b_{k} \ell_{t_{i}}\left(\omega^{k}\right)= \\
= & \ell_{t_{n}}\left(b_{k}\right) f^{n}{ }_{i} * \omega^{k}+b_{k} \ell_{t_{i}}\left(\omega^{k}\right)= \\
= & \ell_{t_{i}}\left(b_{k} \omega^{k}\right),
\end{aligned}
$$

and the lemma is proved. We now finally prove the theorem.
Let us suppose it to be true for a $(n-1)$-form:

$$
\begin{equation*}
\ell_{t_{a}}\left(a_{i_{2} \ldots i_{n}} \omega^{i_{2}} \wedge \ldots \omega^{i_{n}}\right)=\left(i_{t_{i}} d+d i_{t_{i}}\right)\left(a_{i_{2} \ldots i_{n}} \omega^{i_{2}} \wedge \ldots \omega^{i_{n}}\right) . \tag{C.4}
\end{equation*}
$$

Then it holds also for an $n$-form. Indeed, the left-hand side of (C.1) yields

$$
\begin{aligned}
& \ell_{t_{i}}\left(a_{i_{1} \ldots i_{n}} \omega^{i_{1}} \wedge \ldots \omega^{i_{n}}\right)= \\
& =\ell_{t_{j}}\left(a_{i_{1} \ldots i_{n}} \omega^{i_{1}}\right) \wedge f^{j}{ }_{i} *\left(\omega^{i_{2}} \wedge \ldots \omega^{i_{n}}\right)+a_{i_{1} \ldots i_{n}} \omega^{i_{1}} \wedge \ell_{t_{i}}\left(\omega^{i_{2}} \wedge \ldots \omega^{i_{n}}\right)
\end{aligned}
$$

while the right-hand side of (C.1) is given by :

$$
\begin{aligned}
& \left(i_{t_{i}} d+d i_{t_{i}}\right)\left(a_{i_{1} \ldots i_{n}} \omega^{i_{1}} \wedge \ldots \omega^{i_{n}}\right)= \\
=\quad & i_{t_{i}}\left[d\left(a_{i_{1} \ldots i_{n}} \omega^{i_{1}}\right) \wedge \omega^{i_{2}} \wedge \ldots \omega^{i_{n}}-\left(a_{i_{1} \ldots i_{n}} \omega^{i_{1}}\right) \wedge d\left(\omega^{i_{2}} \wedge \ldots \omega^{i_{n}}\right)\right]+ \\
& d\left[i_{t_{j}}\left(a_{i_{1} \ldots i_{n}} \omega^{i_{1}}\right) f^{j}{ }_{i} *\left(\omega^{i_{2}} \wedge \ldots \omega^{i_{n}}\right)-\left(a_{i_{1} \ldots i_{n}} \omega^{i_{1}}\right) \wedge i_{t_{i}}\left(\omega^{i_{2}} \wedge \ldots \omega^{i_{n}}\right)\right]= \\
=\quad & i_{t_{j}}\left(d a_{i_{1} \ldots i_{n}} \omega^{i_{1}}\right) \wedge f^{j}{ }_{i} *\left(\omega^{i_{2}} \wedge \ldots \omega^{i_{n}}\right)+d\left(a_{i_{1} \ldots i_{n}} \omega^{i_{1}}\right) \wedge i_{t_{i}}\left(\omega^{i_{2}} \wedge \ldots \omega^{i_{n}}\right)+ \\
& -i_{t_{j}}\left(a_{i_{1} \ldots i_{n}} \omega^{i_{1}}\right) f^{j}{ }_{i} * d\left(\omega^{i_{2}} \wedge \ldots \omega^{i_{n}}\right)+a_{i_{1} \ldots i_{n}} \omega^{i_{1}} \wedge i_{t_{i}} d\left(\omega^{i_{2}} \wedge \ldots \omega^{i_{n}}\right)+ \\
& +d i_{t_{j}}\left(a_{i_{1} \ldots i_{n}} \omega^{i_{1}}\right) f^{j}{ }_{i} *\left(\omega^{i_{2}} \wedge \ldots \omega^{i_{n}}\right)+i_{t_{j}}\left(a_{i_{1} \ldots i_{n}} \omega^{i_{1}}\right) \wedge f^{j}{ }_{i} * d\left(\omega^{i_{2}} \wedge \ldots \omega^{i_{n}}\right)+ \\
& -d\left(a_{i_{1} \ldots i_{n}} \omega^{i_{1}}\right) \wedge i_{t_{i}}\left(\omega^{i_{2}} \wedge \ldots \omega^{i_{n}}\right)+a_{i_{1} \ldots i_{n}} \omega^{i_{1}} \wedge d i_{t_{i}}\left(\omega^{i_{2}} \wedge \ldots \omega^{i_{n}}\right)= \\
=\quad & {\left[\left(i_{t_{j}} d+d i_{t_{j}}\right)\left(a_{i_{1} \ldots i_{n}} \omega^{i_{1}}\right)\right] \wedge f^{j}{ }_{i} *\left(\omega^{i_{2}} \wedge \ldots \omega^{i_{n}}\right)+} \\
& +a_{i_{1} \ldots i_{n}} \omega^{i_{1}}\left(i_{t_{i}} d+d i_{t_{i}}\right)\left(\omega^{i_{2}} \wedge \ldots \omega^{i_{n}}\right)= \\
=\quad & \ell_{t_{j}}\left(a_{i_{1} \ldots i_{n}} \omega^{i_{1}}\right) \wedge f^{j}{ }_{i} *\left(\omega^{i_{2}} \wedge \ldots \omega^{i_{n}}\right)+a_{i_{1} \ldots i_{n}} \omega^{i_{1}} \wedge \ell_{t_{i}}\left(\omega^{i_{2}} \wedge \ldots \omega^{i_{n}}\right) \ldots
\end{aligned}
$$

and the theorem is proved.
Lemma $\left[i_{t_{i}}, \ell_{t_{k}}\right]=i_{t_{i}} \circ \ell_{t_{k}}-\Lambda_{i k}^{e f} \ell_{t_{e}} \circ i_{t_{f}}$
Proof By definition we have

$$
\begin{equation*}
\left[i_{t_{i}}, \ell_{t_{k}},\right](\vartheta) \equiv \ell_{\kappa^{\prime}\left(\chi_{k 1}\right) *} i_{t_{i}} \circ \ell_{\chi_{k 2^{*}}}(\vartheta)=\kappa^{\prime}\left(\chi_{j}\right) *\left(i_{t_{i}}\left(f^{j}{ }_{k} * \vartheta\right)\right)+i_{t_{i}}\left(\ell_{t_{k}}(\vartheta)\right) \tag{C.5}
\end{equation*}
$$

we therefore have to prove that

$$
\begin{equation*}
\kappa^{\prime}\left(\chi_{j}\right) *\left(i_{t_{i}}\left(f^{j}{ }_{k} * \vartheta\right)\right)=-\Lambda_{i k}^{e f} \ell_{t_{e}} \circ i_{t_{f}} \tag{C.6}
\end{equation*}
$$

First notice that on a generic covariant tensor $\tau \in \Gamma^{\otimes}$

$$
\begin{equation*}
i_{t_{i}}\left(f^{j}{ }_{k} * \tau\right)=\Lambda_{i k}^{e f} f^{j}{ }_{e} * i_{t_{f}}(\tau) \tag{C.7}
\end{equation*}
$$

as can be easily proved by induction with $\tau=\tau^{\prime} \otimes \omega^{\ell}, \tau^{\prime} \in \Gamma^{\otimes}$. To complete the proof recall that $\kappa\left(\chi_{j}\right) f^{j}{ }_{e}=-\chi_{e}$ [apply $m\left(\kappa^{\prime} \otimes i d\right)$ to $\left.\Delta^{\prime}\left(\chi_{e}\right)\right]$.

Theorem $\left[i_{t_{i}}, \ell_{t_{k}}\right]=i_{\left[t_{i}, t_{k}\right]}=\boldsymbol{C}_{i k}{ }^{l} i_{t_{l}}$
Proof
The proof is by induction, it holds on 1 -forms, let assume it holds for a generic $\vartheta$ form of order $n$, we prove it holds also for the generic $n+1$ form $\omega^{a} \wedge \vartheta$. Use the previous lemma to rewrite $\left[i_{t_{i}}, \ell_{t_{k}}\right]$ as (1)+(2):

$$
\begin{align*}
& i_{t_{i}} \ell_{t_{j}}\left(\omega^{a} \wedge \vartheta\right)=i_{t_{i}}\left[\left(\omega^{b} \boldsymbol{C}_{b p}{ }^{a} \wedge f^{p}{ }_{j} * \vartheta+\omega^{a} \wedge \ell_{t_{j}}(\vartheta)\right]\right.  \tag{1}\\
& \quad=\left[\boldsymbol{C}_{b p}{ }^{a} f^{b}{ }_{i} f^{p}{ }_{j}+f^{a}{ }_{i} \chi_{j}\right] * \vartheta-\omega^{b} \wedge \boldsymbol{C}_{b p}{ }^{a} i_{t_{i}}\left(f^{p}{ }_{j} * \vartheta\right)-\omega^{a} \wedge i_{t_{i}} \ell_{t_{j}}(\vartheta) \\
& -\Lambda^{k l}{ }_{i j} \ell_{t_{k}} i_{t_{l}}\left(\omega^{a} \wedge \vartheta\right)=-\Lambda^{k l}{ }_{i j} \ell_{t_{k}}\left[f^{a}{ }_{l} * \vartheta-\omega^{a} i_{t_{l}}(\vartheta)\right]  \tag{2}\\
& \quad=\left[-\Lambda^{k}{ }_{i j} \chi_{k} f^{a}{ }_{l}\right] * \vartheta+\Lambda^{k l}{ }_{i j} \omega^{b} \wedge \boldsymbol{C}_{b p}{ }^{a} f^{p}{ }_{k} * i_{t_{l}}(\vartheta)-\omega^{a} \wedge(-1) \Lambda^{k l}{ }_{i j} \ell_{t_{k}} i_{t_{l}}(\vartheta)
\end{align*}
$$

$$
\begin{equation*}
\boldsymbol{C}_{i j}{ }^{k} i_{t_{k}}\left(\omega^{a} \wedge \vartheta\right)=\boldsymbol{C}_{i j}{ }^{k} f^{a}{ }_{k} * \vartheta-\boldsymbol{C}_{i j}{ }^{k} \omega^{a} \wedge i_{t_{k}}(\vartheta) \tag{3}
\end{equation*}
$$

We then have

$$
\begin{align*}
(1)+(2)-(3)= & {\left[\boldsymbol{C}_{b p}{ }^{a} f^{b}{ }_{i} f^{p}{ }_{j}+f^{a}{ }_{i} \chi_{j}-\Lambda_{i j}^{k l} \chi_{k} f^{a}{ }_{l}-\boldsymbol{C}_{i j}{ }^{k} f^{a}{ }_{k}\right] * \vartheta }  \tag{C.9}\\
& -\omega^{b} \wedge \boldsymbol{C}_{b p}{ }^{a}\left[i_{t_{i}}\left(f^{p}{ }_{j} * \vartheta\right)-\Lambda^{k l}{ }_{i j} f^{p}{ }_{k} * i_{t_{l}}(\vartheta)\right]  \tag{C.10}\\
& -\omega^{a} \wedge\left[i_{t_{i}} \ell_{t_{j}}-\Lambda_{i j}^{k l}{ }_{t_{k}} i_{t_{l}}-\boldsymbol{C}_{i j}{ }^{k} i_{t_{k}}\right](\vartheta)  \tag{C.11}\\
= & 0 \tag{C.12}
\end{align*}
$$

Where the first addend is zero because of (2.1.113), the second is zero because of (C.7), the third because of the inductive hypothesis.

[^0]:    ${ }^{1}$ For example, in relativistic quantum mechanics the position of a particle can be detected with a precision at most of the order of its Compton wave length $\lambda_{C}=\hbar / m c$. Probing spacetime at infinitesimal distances implies an extremely heavy particle that in turn curves spacetime itself. When $\lambda_{C}$ is of the order of the Planck length, the spacetime curvature radius due to the particle has the same order of magnitude and the attempt to measure spacetime structure beyond Planck scale fails.

[^1]:    ${ }^{1}$ To be precise, $\operatorname{Fun}(G)$ is a Hopf algebra when $\operatorname{Fun}(G \times G)$ can be identified with $\operatorname{Fun}(G) \otimes$ Fun $(G)$, since only then can one define a coproduct as in (1.1.1).

[^2]:    ${ }^{1}$ Recall the $q=1$ definition of the adjoint representation $x^{-1} T_{j} x \equiv M_{j}{ }^{i}(x) T_{i}$.

[^3]:    ${ }^{2}$ The pairing between these two Hopf algebras is nondegenerate, indeed $U_{q}(g l((n))$ as a Hopf algebra is isomorphic 79, 19] to $\mathcal{U}_{q}(g l(n))$ (as defined by Jimbo 18]) then the Hopf isomorphism $\mathcal{U}_{h}^{0}(s l(n)) \cong S U_{q}(n)$ (where $\mathcal{U}_{h}^{0}(s l(n))$ is the Hopf dual of Drinfeld universal enveloping algebra $\mathcal{U}_{h}(s l(n))$ 16] allows to conclude that the pairing between $G L_{q}(n)$ and $U_{q}(g l(n))$ is nondegenerate.

[^4]:    ${ }^{3} \Delta M_{i}{ }^{j}=\chi_{i}\left(x_{2}^{j}\right) \Delta\left(\kappa\left(x_{1}^{j}\right) x_{3}^{j}\right)=\kappa\left(x_{1}^{j}\right) \chi_{i}\left(x_{2}^{j}\right) x_{3}^{j} \otimes \kappa\left(x_{0}^{j}\right) x_{4}^{j}$
    $=\kappa\left(x_{1}^{j}\right) x_{2}^{j} \chi_{n}\left(x_{3}^{j}\right) M_{i}{ }^{n} \otimes \kappa\left(x_{0}^{j}\right) x_{4}^{j}=M_{i}^{n} \otimes \chi_{n}\left(x_{3}^{j}\right) \kappa\left(x_{1}^{j}\right) \varepsilon\left(x_{2}^{j}\right) x_{4}^{j}$
    $=M_{i}{ }^{n} \otimes M_{n}{ }^{j}$.

[^5]:    ${ }^{1}$ We disregard the solutions $\forall A \in a, Q_{A}=\sqrt[N]{1}$ because we want a continuous deformation of the classical limit.

[^6]:    ${ }^{2}$ An explicit proof is also instructive. We first note that in $G L_{q, r}(N+1)$ the subset in (3.5.1) and (3.5.24) closes by itself on the bicovariant algebra (2.1.111), (2.1.112)-(2.1.114). This is due to the particular index structure of the tensors $\mathbf{C}$ and $\Lambda$, and to the vanishing of the $f$ components in (3.5.7). The nonvanishing components of $\mathbf{C}$ and $\Lambda$ that enter the operatorial bicovariance conditions (where the free adjoint indices are taken as $a b, 0 b$ ), are given in (3.5.44)-(3.5.46) and (3.5.35)-(3.5.39). Finally, we know that the $f$ functionals vanish on $\operatorname{Ker} \bar{P}$, and so do the $\chi$ functionals (as can be deduced from their definition in terms of the $f$ functionals, eq. (2.2.52)). From the discussion after Theorem 3.5.1 it follows that they are well defined on $I G L_{q, r}(N)$, and that their products involve the $I G L_{q, r}(N)$ coproduct $\Delta$.

    Thus the relations (2.1.111), (2.1.112)-(2.1.114) hold for the functionals (3.5.1) and (3.5.24) on $I G L_{q, r}(N)$. They are the bicovariance conditions corresponding to a consistent differential calculus on $I G L_{q, r}(N)$.

[^7]:    ${ }^{1}$ In the classical limit $\ell^{ \pm}{ }_{A}^{A}$ are the tangent vectors to a maximal commutative subgroup of $S(N+2)$. They generate a Cartan subalgebra of the Lie algebra $s(N+2)$.
    ${ }^{2}$ In the $U_{q, r}(\operatorname{sp}(N+2))$ case relations 4.3.26) [and more in general (4.3.25)] do not allow to order the $L^{-a}{ }_{o}$ (and more in general the $L^{ \pm \alpha}{ }_{J}$ ) elements because we are missing the relation with the $P_{0}$ projector, cf. Note 4.2.4. However we can still order the $L^{-a}{ }_{\circ}$ (or $L^{ \pm \alpha}{ }_{J}$ ) elements if we consider also $L^{-\bullet}$ 。 (or $\left.L_{J}^{ \pm J^{\prime}}\right)$. This leads to the $(N+2)(N+3) / 2$ generators of the symplectic case. Notice that Lemma 4.3.1 and 4.3.2 still hold; Theorem 4.3.1 holds as well provided that $\alpha$ can also be equal to $J^{\prime}: J^{\prime}<\alpha \leq J$.

[^8]:    ${ }^{3} \mathrm{By} \lim _{r \rightarrow 1} a$, where the generic element $a \in S_{q, r}(N+2)$ is a polynomial in the matrix elements $T_{B}^{A}$ with complex coefficients $f(r)$ depending on $r$, we understand the element of $S_{q, r=1}(N+2)$ with coefficients given by $\lim _{r \rightarrow 1} f(r)$. The expression $\lim _{r \rightarrow 1} \phi=\varphi$, where $\phi \in U\left(s_{q, r}(N+2)\right)$ and $\varphi \in U\left(S_{q, r=1}(N+2)\right)$ means that $\lim _{r \rightarrow 1} \phi(a)=\varphi\left(\lim _{r \rightarrow 1} a\right)$ for any $a \in S_{q, r}(N+2)$ such that $\lim _{r \rightarrow 1} a$ exists. Finally, the left invariant 1-forms $\omega^{i}$ are symbols, and therefore $\lim _{r \rightarrow 1} a_{i} \omega^{i} \equiv$ $\left(\lim _{r \rightarrow 1} a_{i}\right) \omega^{i}$.

[^9]:    ${ }^{5}$ A direct proof in the $S O_{q}$ case is also instructive. We call $P_{-}$the " q -antisymmetric" projector defined by:

    $$
    P_{-}{ }_{B C}^{A} \equiv \frac{1}{2}\left(\delta_{C}^{A} \delta_{B}^{D}-q_{B A} \delta_{C}^{B^{\prime}} \delta_{A^{\prime}}^{D}\right)=\frac{1}{2}\left(\delta_{C}^{A} \delta_{B}^{D}-q_{C D} \delta_{C}^{B^{\prime}} \delta_{A^{\prime}}^{D}\right) .
    $$

    Then one easily shows that $P_{-}{ }_{B C}{ }^{D}=-q_{B A} P_{-} B_{A^{\prime} D}^{\prime}{ }^{C}, \quad P_{-}{ }_{B C}{ }^{D}=-q_{C D} P_{-}{ }_{B D^{\prime}}{ }^{C^{\prime}}$ and

    $$
    \begin{gathered}
    \Omega^{j} P_{-j}{ }^{i}=\Omega^{i}, \quad P_{-i}{ }^{j} \chi_{j}=\chi_{i}, \quad P_{-k}{ }^{i} f^{k}{ }_{j}=f^{i}{ }_{k} P_{-j}{ }^{k}=P_{-k}{ }^{i} f^{k}{ }_{n} P_{-j}{ }^{n}, \\
    M_{-i}{ }^{j}=2 P_{-i}{ }^{l} M_{l}^{j}=2 M_{i}^{l} P_{-l}^{j}, \quad M_{-i}{ }^{j}=P_{-i}{ }^{l} M_{-l}{ }^{j}=M_{-i}{ }^{l} P_{-l}^{j}=2 P_{-i}{ }^{\alpha} M_{-\alpha}{ }^{j}=2 M_{-i}{ }^{\beta} P_{-\beta}{ }^{j},
    \end{gathered}
    $$

    where greek letters $\alpha, \beta$ represent adjoint indices $\left(A_{1}, A_{2}\right)$, $\left(B_{1}, B_{2}\right)$ with the restriction $A_{1}^{\prime}<A_{2}, B_{1}^{\prime}<B_{2}$. It is then straightforward to show that $\Delta\left(M_{-i}^{j}\right)=M_{-i}{ }^{\alpha} \otimes M_{-\alpha}{ }^{j}$ and $\varepsilon\left(M_{-\alpha}{ }^{\beta}\right)=\delta_{\alpha}^{\beta}$. Applying $P_{-}$to (2.1.51) and using $f^{i}{ }_{j}=0$ unless $i=j$ cf. (4.6.26)-(4.6.29) one also proves $M_{-\alpha}{ }^{j}\left(a * f^{\alpha}{ }_{k}\right)=\left(f^{j}{ }_{\beta} * a\right) M_{-k}{ }^{\beta}$. These formulae hold in particular if all indices are greek, thus proving (2.1.44) and (2.1.51) for $S O_{q, r=1}(N+2)$.
