1 Introduction

Propagation and electron cyclotron resonance (ECR) damping of electron Bernstein waves (EBWs) in spherical tokamaks (ST) is usually analyzed assuming that absolute value of the tokamak magnetic field |B| increases inward the plasma. In this case the perpendicular index of refraction n_{\perp} grows as the wave approaches the ECR layer, where the wave is fully absorbed regardless of the resonance harmonic number [1]. However, in addition to traditional regimes with monotonously increasing |B|, regimes

Figure 1: Total magnetic field \boldsymbol{B} profile in NSTX tokamak mid-plane [2].

with "magnetic wells" also occur in STs [2]. The the magnetic field profile inversion modifies significantly the whole picture of the wave propagation and damping. Since the magnetic wells may become quite common with further improvement of ST performance (fig.1), analysis of such configurations is of interest for assessment of EBW plasma heating an CD perspectives.

Consider CMA diagram (fig.2) illustrating why this case was not considered in literature yet. In the conventional tokamaks EBWs produced via the linear conversion of the incident electromagnetic waves close to UHR are capable for propagating to the fundamental harmonic along dotted blue arrow. If the inequality $d[ln(n_e)]/dx > 2\omega_{ce}^2/\omega_{pe}^2 d[ln(|B|)]/dx$ is fulfilled (it's the case of STs) EBWs can propagate along solid red arrow to the nearest EC harmonic. In this paper we consider basic

Figure 2: CMA diagram. In the case of the conventional tokamak EBWs can propagate from UHR to the fundamental harmonic (dotted arrow). In the ST EBWs can propagate to the second EC harmonic (solid arrow). This case will be considered in this paper.

features of the EBWs propagation and damping for the second cyclotron harmonic, which is now the lowest possible resonance harmonic, in a slab model. This case is illustrated in fig.1 by solid red arrow.

2 Bernstein waves in electrostatic approximation

Assume all plasma parameters depending on the single dimensionless co-ordinate x scaled in units of c/ω with ω being the wave frequency. Suppose that the magnetic field \boldsymbol{B} is along the z - axis and both $v = \omega_{pe}^2/\omega^2$ and $q = \omega/\omega_{ce}$ grow inward the plasma.

We begin analysis of the EBW behavior assuming validity of the electrostatic approximation. Then the dispersion relation is

$$\varepsilon\left(n_{\perp}, n_{\parallel}, x\right) = 0,\tag{1}$$

where $\varepsilon \equiv (n_i \varepsilon_{ik} n_k) / n^2$ is the longitudinal dielectric function, ε_{ik} - the plasma dielectric tensor elements, $n_{\perp} = k_x c/\omega$ and $n_{\parallel} = k_{\parallel} c/\omega$. Since the UHR is known to be the cutoff for electrostatic EBWs, one expand the dielectric tensor components ε_{ij} , i, j = (x, y, z) in power of $\lambda = k_{\perp}^2 \rho_e^2 = (n_{\perp} q \beta)^2 / 2$, where ρ_e is the electron Larmor radius. As it will be seen, n_{\perp} remains within the limits $1 \ll n_{\perp} \leq \beta^{-1}$, where $\beta = \nu_{te}/c$, $\nu_{te} = \sqrt{2T_e/m_e}$, in the whole region between the UHR and the q = 2 resonance, so that $\lambda \leq 1$ here. For qualitative investigation we keep only zero- and first-order terms. Then

$$\varepsilon = \varepsilon^{(c)} - \frac{\upsilon\beta^2}{2n^2} \left(3n_{\parallel}^4 + \frac{6q^6 - 3q^4 + q^2}{(q^2 - 1)^3} n_{\parallel}^2 n_{\perp}^2 + \frac{3q^4}{(q^2 - 1)(q^2 - 4)} n_{\perp}^4 \right), \tag{2}$$

where $\varepsilon^{(c)} = \left(\varepsilon_{xx}^{(c)}n_{\perp}^2 + \varepsilon_{zz}^{(c)}n_{\parallel}^2\right)/n^2$ and

$$\varepsilon_{xx}^{(c)} = 1 - \frac{\upsilon q^2}{q^2 - 1}, \varepsilon_{zz}^{(c)} = 1 - \upsilon$$
 (3)

are the dielectric tensor elements in the cold plasma. The electron Bernstein waves are produced via the linear conversion of incident electromagnetic waves with $n_{\parallel} \leq 1$, while applicability of the electrostatic approximation requires that $n_{\perp} \gg 1$. This permits one to omit terms proportional to n_{\parallel}^2 and n_{\parallel}^4 in Eq.(2) reducing the dispersion relation (1) to

$$\varepsilon_{xx} = \varepsilon_{xx}^{(c)} - \frac{1}{2} \upsilon \beta^2 \frac{3q^4}{(q^2 - 1)(q^2 - 4)} n_{\perp}^2 = 0.$$
(4)

The solution to this equation

$$n_{\perp}^{2} = -\frac{2}{3\beta^{2}\upsilon}\varepsilon_{xx}^{(c)}\frac{(q^{2}-1)(4-q^{2})}{q^{4}},$$
(5)

where $\varepsilon_{xx}^{(c)} < 0$ and 1 < q < 2 shows that in the electrostatic approximation the EBW is confined between two cut-offs. One of them is the UHR, for which $\varepsilon_{xx}^{(c)}(x) = 0$, and the other one is the cyclotron resonance q = 2. The validity condition for the electrostatic approximation is $n^2 \gg |\varepsilon_{ik}|$. We consider here typical for STs high - density plasmas with $v \gg 1$, then the validity condition becomes

$$n_{\perp}^2 \gg v. \tag{6}$$

This condition breaks down close to the UHR and ECR. We do not consider first of these regions because analysis of wave behavior there is the subject of the mode coupling theory. In the dense plasma outside immediate UHR vicinity, Eq.(5) becomes

$$n_{\perp}^2 = \frac{2}{3\beta^2} \frac{(4-q^2)}{q^2} \tag{7}$$

so that the characteristic value of n_{\perp} is β^{-1} . In the 2^{nd} ECR vicinity, where the inequality (6) is broken down a full - wave treatment is required.

3 Full-wave equation near q = 2 resonance

To obtain a traceable full - wave hot plasma dispersion relation for EBWs with $n_{\perp} \sim n_{\parallel}$ and $n_{\perp} \ll \beta^{-1}$ near the q = 2 resonance we make some simplifications. Consider first the dielectric tensor elements ε_{ik} . It is well known that the elements can be presented as an infinite sums over cyclotron harmonic number $s, -\infty \ll s \ll \infty$ with each term of the sum related to the ECR q = s. Since parameter λ is small, we calculate the resonance (s = 2) terms of ε_{ik} up to the first order in λ using the zero order (cold plasma) approximation for non - resonant terms. In this approximation, the elements $\varepsilon_{xz}, \varepsilon_{zx}, \varepsilon_{yz}, \varepsilon_{zy}$ vanish, $\varepsilon_{xx} = \varepsilon_{yy} = \varepsilon_{\perp}, \varepsilon_{xy} = -\varepsilon_{yx} = -ig$ and

$$\varepsilon_{\perp} = \varepsilon_{\perp}^{(c)} + \frac{1}{2} \frac{\lambda \upsilon}{n_{\parallel} \beta} Z\left(\xi\right), \ g = g^{(c)} + \frac{1}{2} \frac{\lambda \upsilon}{n_{\parallel} \beta} Z\left(\xi\right), \tag{8}$$

here $g^{(c)} = -v|q|/(q^2-1)$, Z is the plasma dispersion function defined according to [3] with the argument $\xi = (q-2)/qn_{\parallel}\beta$. Consider now the wave equations

$$(n_{\parallel}^{2} - \varepsilon_{\perp}) E_{x} - igE_{y} - n_{\parallel}n_{\perp}E_{z} = 0 igE_{x} + (n^{2} - \varepsilon_{\perp}) E_{y} = 0 - n_{\parallel}n_{\perp}E_{x} + (n_{\parallel}^{2} - \varepsilon_{zz}) E_{z} = 0$$

$$(9)$$

Absolute values of dielectric tensor elements here are of order $v \gg 1$ and, therefore $E_z \ll E_x$. Omitting E_z in the first equation, that means neglecting terms of order n_{\perp}/v and 1/v compared to unity, obtain the dispersion relation

$$n_{\perp}^{2}\varepsilon_{\perp} - (\varepsilon_{\perp} - g)(\varepsilon_{\perp} + g) = 0.$$

Using Eq.(8), we obtain at $v \gg 1$

$$n_{\perp}^{2}\varepsilon_{\perp} - \frac{\upsilon^{2}q^{2}}{q^{2} - 1} \left(1 - \frac{n_{\perp}^{2}\beta^{2}(q-1)}{2q} \frac{Z}{n_{\parallel}\beta} \right) = 0.$$
(10)

Close to UHR, at large n_{\perp} , $n_{\perp}^2 \gg v$, the electrostatic approach is valid, the first term in (10) dominates and we returns to the electrostatic equation (5). In the ECR vicinity, at small n_{\perp} , $n_{\perp} \ll v$, this term can be omitted and the solution is found explicitly:

$$n_{\perp} = \frac{2}{\beta} \sqrt{\frac{n_{\parallel}\beta}{Z\left((q-2)/qn_{\parallel}\beta\right)}}.$$
(11)

Thus, in the vicinity of the q = 2 resonance, where $n_{\perp}(x)$ goes down with x, there is a spatial region $v^2 > n_{\perp}^2 > v$ where Eqs.(5) and (11) are valid simultaneously. The dispersion relation (10) can be also used in the "relativistic" case $n_{\parallel} \leq \beta$ if the "non-relativistic" plasma dispersion function Z is replaced by a proper relativistic dispersion function.

4 Wave behavior in the 2^{nd} ECR layer

Close to the 2^{nd} ECR layer we consider, for simplicity, as x dependent only the resonant factor (q-2)/q in the argument of the Z function, putting (q-2)/q = x/l, where l is the dimensionless characteristic scale-length of the magnetic field variation. Using the asymptotic expression $Z \sim -1/\xi$, where $\xi = x/L$ and $L = l\beta n_{\parallel}$, at $|\xi| \gg 1$, one find that at negative x outside the resonance layer Eq.(11) differs from the electrostatic equation (5) only by a constant factor in the right-hand side. Inside the EC layer at $|\xi| \sim 1$ the function Z is a complex function with $|Z| \sim 1$ and $Re(Z) \sim Im(Z)$. Solution to Eq.(11) is also complex with $|n_{\perp}| \sim (n_{\parallel}/\beta)^{1/2}$, so that the applicability condition for the WKB theory in the resonance region takes the form

$$n_{\perp}L = ln_{\parallel}^{3/2}\beta^{1/2} \gg 1,$$
 (12)

The estimation for the relativistic case can be obtained from this equation by putting $n_{\parallel} \sim \beta$. We assume that the WKB approximation is applicable in the region outside the resonance layer where $|n_{\perp}|$ grows. Suppose now that inequality (12) is satisfied and consider solution to Eq.(11) inside the resonance layer. This solution in a parameter free form

$$N = \pm Z^{-1/2}, N = n_{\perp} \left(\beta/(4n_{\parallel})\right)^{1/2}$$
(13)

is shown in fig.3 on the plane (Re(N), Im(N)). Brunches located in the upper

Figure 3: Plane (Re(N), Im(N)). Left branch corresponds to incident wave, right one - to reflected. In WKB approximation branches are not intersected. Reflection is the result of WKB approximation breaking.

and lower complex N-plane correspond to the signs (-) and (+) in Eq.(13), respectively. Consider first the brunch $N = -Z^{-1/2}$. The fragment of the curve with Re(N) < 0, $Re(N) \gg Im(N)$ belongs to the region x < 0, $|x| \gg L$ when the asymptotic expression for Z can be used and $n_{\perp} \rightarrow -(4|x|n_{\parallel}/(\beta l))^{1/2}$. Since $(Im(Z))^{-1/2} < 0$, the whole curve lies in the upper complex N plane. At $|x| \gg L$ we have $n_{\perp} \to i \left(4|x|n_{\parallel}/(\beta l)\right)^{1/2}$. The second curve describes transition from $n_{\perp} \rightarrow \left(4|x|n_{\parallel}/(\beta l)\right)^{1/2}$ to $n_{\perp} \rightarrow -i\left(4|x|n_{\parallel}/(\beta l)\right)^{1/2}$ via the lower complex N plane. Note that the waves under consideration have their phase and group velocities directed oppositely. Therefore, the incident wave has asymptotically a negative n_{\perp} in the propagation region x < 0. This wave is described by the $N = -Z^{-1/2}$ dispersion curve. At large positive x this mode vanishes exponentially. The second brunch describes the wave reflected from the ECR. This mode grows exponentially in the non propagation region $|x| \gg L$. Three important conclusions can be drawn from this analysis. First, incoming waves incident on the ECR layer from the high-field side are not converted in the resonance region into outgoing EBWs with large n_{\perp} propagating on the low field side of the ECR. Instead, the incident waves become non-propagating beyond the resonance layer. Second, two effects are simultaneously responsible for $Im(n_{\perp})$: the

ECR damping and the wave transition into the non-propagation region. These two contribution can not be separated. Finally, since the function $|Z(\xi)^{-1}|$ has no zeros at finite $|\xi|$, two brunches of the dispersion curves are separated in the whole complex x plane. As a result, reflection from the ECR layer can only be due to approximate nature of the WKB theory.

5 Reflection from ECR layer

We analyze reflection of EBWs from the q = 2 cyclotron resonance with the use of the model wave equation obtained from the dispersion relation (13) by replacement $n_{\perp} \rightarrow -id/dx$:

$$U''(x) + n_{\perp}(x)^2 U(x) = 0.$$
(14)

Here n_{\perp}^2 is given by the right - hand side of Eq.(11) and we assume that function U is related linearly to the wave field components. More definite interpretation of this function is not required. In the WKB approximation Eq.(14) has two linearly independent solutions

$$U_{1} = \frac{1}{n_{\perp}^{1/2}} \exp\left(-i \int_{a}^{x} n_{\perp} dx\right), \ U_{2} = \frac{1}{n_{\perp}^{1/2}} \exp\left(i \int_{a}^{x} n_{\perp} dx\right)$$
(15)

where a is an arbitrary constant. As it has been mentioned before, U_1 and U_2 represent incoming and outgoing waves, respectively. The solution to Eq.(14) describing the ECR damping and reflection of the wave incident from the high-field side vanishes at $|x| \gg L$ and has the asymptotic form

$$U = U_1 + RU_2 \tag{16}$$

at $x < 0, |x| \gg L$. Here R is a constant and the quantity $|R|^2$ is the energy reflection coefficient. Presenting Eq.(14) in the form

$$U''(x) + (V_0 + V_1) U(x) = 0, (17)$$

where $V_0 = n_{\perp}^2 - V_1$, $V_1 = (n_{\perp}^{-1/2})'' n_{\perp}^{1/2}$. One can easily see that functions $U_{1,2}$ are exact solutions to the equation $U''_{1,2} + V_0 U_{1,2} = 0$ and V_1 is small, of order $(|n_{\perp}L|)^{-2}$ compared to V_0 , if the WKB method applicability condition $|n_{\perp}| L \gg 1$ is satisfied. In this case the reflection coefficient R can be calculating by treating the term in Eq.(17) as a small perturbation and using U_1 as a zero order solution:

$$R = \frac{1}{2} \int_{-\infty}^{\infty} V_1 U_0^2 dx$$
 (18)

or explicitly,

$$R = \frac{1}{\Gamma_0} \int_{-\infty}^{\infty} \left(Z^{1/4} \right)'' Z^{1/4} \exp\left(-i\Gamma_0 \int_{-\infty}^{\xi} Z^{-1/2} \left(\zeta \right) d\zeta \right) d\xi, \tag{19}$$

where the prime denotes differentiation with respect to ξ and $\Gamma_0 = 2l\beta^{1/2}n_{\parallel}^{3/2}$. For Eq.(19) validity, Γ_0 must be large compared to unity. Since the integrand has no

saddle points at finite $|\xi|$, and contribution to the integral is spread over the whole $|\xi| \leq 1$, the possibility of obtaining an accurate analytical estimation of the integral seems rather doubtful. Numerical evaluation shows that $|R|^2$ is negligibly small at $\Gamma_0 \geq 1$.

In the limiting case $|k_{\perp}| L < 1$ opposite to the WKB one, the reflection coefficient can be found by presenting $Z^{-1}(\xi) \simeq -\xi + V$ and treating V as a perturbation. Substituting these expressions into Eq.(14) and introducing the new independent variable $\tau = k_0 x \left(\beta^2 l/4\right)^{-1/3}$, obtain

$$U'' - (\tau - \gamma V(\tau/\gamma)) U = 0, \qquad (20)$$

where $\gamma = \Gamma_0^{2/3}$ is a small parameter. In the present case the reflection coefficient is close to unity. Calculating the correction to it in the lowest order in γ yields

$$|R| \simeq 1 - \frac{\Gamma_0^2}{\xi^2},$$
 (21)

where $\xi^{-1} = \pi Ai(0) = 1.12$. The comparison of the reflection coefficient, R, calculated

Figure 4: Absolute value of the reflection coefficient |R| for the non-relativistic $(n_{\parallel} \gg \beta)$ case.

numerically and its analytical estimation (21) is presented in fig.4. The reasonable agreement is demonstrated. Note in conclusion that standard ray tracing method using the full wave dispersion relation or the approximate dispersion relation (11) can be used for high-field side propagation only if the wave is damped in the periphery of the ECR, where $Im(n_{\perp}) \ll Re(n_{\perp})$. Otherwise the wave penetrates into the region of strong cyclotron damping where the ray tracing method is inapplicable.

6 Summary

Existence of EBWs in the region between the UHR and ECR requires inhomogeneous plasma density.

Waves in this region are adequately described by the approximate full-wave dispersion relation (10). Incoming waves incident on the ECR layer from the high-field side are not converted in the resonance region into outgoing EBWs propagating on the low field side of the ECR. Instead, the incident waves become non-propagating beyond the resonance layer.

Decreasing of the wave amplitude within ECR layer is due to combine effect of the ECR damping and non-propagation.

In the WKB approximation, the waves are fully damped in the ECR layer. Reflection from the ECR layer is only due to approximate nature of the WKB theory.

Standard ray tracing method can be used for high-field side propagation only if the wave is damped in the periphery of the ECR layer. Otherwise the wave penetrates into the region of strong cyclotron damping where the ray tracing method is inapplicable.
