# RECIPROCAL TRANSFORMATIONS AND DEFORMATIONS OF INTEGRABLE HIERARCHIES

#### A. SERGYEYEV

Abstract. We present changes of variables that transform new integrable hierarchies found by Szablikowski and Błaszak using the R-matrix deformation technique  $J$ . Math. Phys. 47 (2006), paper 043505] into known Harry-Dym-type and mKdV-type hierarchies.

#### **INTRODUCTION**

Recently, Szablikowski and Blaszak [\[6\]](#page-4-0) came up with a new class of integrable hierarchies which is constructed as follows. Consider the Lax operator

<span id="page-0-3"></span>
$$
L = \sum_{i=0}^{N} u_i D_x^i + D_x^{-1} \circ u_{-1}
$$
 (1)

and the related (formal) spectral problem

<span id="page-0-0"></span>
$$
L\psi = \lambda \psi. \tag{2}
$$

Here  $D_x = d/dx$  is the total x-derivative.

Following [\[6\]](#page-4-0) consider the following hierarchy of equations compatible with [\(2\)](#page-0-0):

<span id="page-0-1"></span>
$$
\psi_{t_q} = (P_{\geq 1}(L^q) + \epsilon [L^q]_0 D_x)(\psi), \qquad q = 1, 2, \dots
$$
\n(3)

where for any formal series  $K = \sum$ k j=−∞  $a_i D_x^i$  we have  $P_{\geq s}(K) \stackrel{\text{def}}{=} \sum_{i=1}^n$ k  $j = s$  $a_i D_x^i$  and  $[K]_i = a_i$ , and  $\epsilon$  is an

arbitrary constant.

The compatibility conditions for [\(2\)](#page-0-0) and [\(3\)](#page-0-1) read

<span id="page-0-2"></span>
$$
L_{t_q} = [P_{\geq 1}(L^q) + \epsilon [L^q]_0 D_x, L], \qquad q = 1, 2, \dots
$$
 (4)

Note that the hierarchy [\(4\)](#page-0-2) with  $\epsilon = 0$  was discovered by Kupershmidt [\[2\]](#page-4-1).

The goal of the present work is to show that, under a suitable change of dependent and independent variables  $x, t_i$ , and  $u_k$ , the "deformed" hierarchy [\(4\)](#page-0-2) can be transformed into the linear extension of the undeformed ( $\epsilon = 0$ ) hierarchy [\(4\)](#page-0-2) in the senses of [\[4\]](#page-4-2), i.e., into the said undeformed hierarchy plus a system of linear PDEs on the background of the latter. We also present a link among the deformed hierarchy [\(4\)](#page-0-2) and the Harry-Dym-type hierarchy [\(9\)](#page-1-0). Finally, we present the dispersionless limit of these results.

### 1. Main results

Let  $L$  be as above and suppose that we have

$$
[D_{t_i} - P_{\geq 1}(L^i) - \epsilon [L^i]_0 D_x, D_{t_j} - P_{\geq 1}(L^j) - \epsilon [L^j]_0 D_x] = 0, \quad i, j = 0, 1, 2, \dots
$$

Let  $\chi$  be an arbitrary (smooth) solution of the system

$$
\chi_{t_i} = (P_{\geq 1}(L^i) + \epsilon [L^i]_0 D_x) \chi, \quad i = 0, 1, 2, ...
$$

<sup>2000</sup> Mathematics Subject Classification. 37K10, 37K15.

Key words and phrases. Nonlinear evolution equations, integrability, Lax representation, R-matrix, reciprocal transformations.

such that  $\chi_x \neq 0$ .

Introduce new set of independent variables  $(z, \{\tau_i\})$ , where  $z = \chi$  and  $\tau_i = t_i$ , instead of  $(x, \{t_i\})$ . Define new dependent variables  $v_i$  by means of the formula

$$
\tilde{L} = L|_{D_x = \chi_x D_z} = \sum_{i=0}^{N} u_i (\chi_x D_z)^i + D_z^{-1} \circ \chi_x^{-1} u_{-1} \equiv v_N D_z^N + D_z^{-1} \circ v_{-1} + \sum_{i=0}^{N-1} v_i D_z^i \tag{5}
$$

We have the following generalization of Lemma 4, i) of [\[5\]](#page-4-3):

<span id="page-1-1"></span>**Theorem 1.** The transformation  $(x, \{t_i\}, \{u_j\}) \rightarrow (z, \{\tau_i\}, \{v_j\})$  sends the system

<span id="page-1-2"></span>
$$
L\psi = \lambda \psi
$$
,  $\psi_{t_i} = (P_{\geq 1}(L^i) + \epsilon [L^i]_0 D_x) \psi$ ,  $i = 0, 1, 2, ...$  (6)

into

<span id="page-1-3"></span>
$$
\tilde{L}\psi = \lambda\psi, \qquad \psi_{\tau_i} = (P'_{\geq 2}(\tilde{L}^i))\psi, \quad i = 0, 1, 2, \dots,
$$
\n<sup>(7)</sup>

and hence sends the hierarchy

<span id="page-1-4"></span>
$$
L_{t_i} = [P_{\geq 1}(L^i) + \epsilon [L^i]_0 D_x, L], \quad i = 0, 1, 2, \dots
$$
\n(8)

into the Harry-Dym-type hierarchy

<span id="page-1-0"></span>
$$
\tilde{L}_{\tau_i} = [P'_{\geq 2}(\tilde{L}^i), \tilde{L}], \quad i = 0, 1, 2, \dots
$$
\n(9)

Here and below for any formal series  $M = \sum$ k j=−∞  $b_i D_z^i$  we set  $P'_{\geq s}(M) = \sum$ k  $j = s$  $b_i D_z^i$ .

In the undeformed case  $(\epsilon = 0)$  we just recover Lemma 4, i) of [\[5\]](#page-4-3). The proof of Theorem [1](#page-1-1) amounts to performing the change of variables  $(x, \{t_i\}, \{u_j\}) \rightarrow (z, \{\tau_i\}, \{v_j\})$  in [\(6\)](#page-1-2) and using the identity (see Lemma 3, i) of [\[5\]](#page-4-3))

$$
P'_{\geq 2}(\tilde{A}) = P_{\geq 1}(A) - (P_{\geq 1}(A)\chi)D_z
$$

where  $z = \chi$  and  $\tilde{A} = A|_{D_x = \chi_x D_z}$ , valid for any pseudodifferential operator A. With this in mind, we readily see that the transformation in question indeed sends [\(6\)](#page-1-2) into [\(7\)](#page-1-3). Finally, as [\(8\)](#page-1-4) (resp. [\(9\)](#page-1-0)) are compatibility conditions for  $(6)$  (resp.  $(7)$ ),  $(6)$  goes into  $(7)$ , as desired.

Note that for  $N = 1$  a transformation relating the *hierarchies* [\(8\)](#page-1-4) and [\(9\)](#page-1-0) was found in [\[1\]](#page-4-4).

<span id="page-1-7"></span>**Theorem 2.** Consider the reciprocal transformation from x and  $t_i$ ,  $i = 1, 2, \ldots$  to new independent variables z and  $\tau_i$ ,  $i = 1, 2, \ldots$ , where  $\tau_i = t_i$ ,  $i = 1, 2, \ldots$ , and z is defined by the formula

$$
dz = (u_N)^{-1/N} dx + \epsilon \sum_{q=1}^{\infty} (u_N)^{-1/N} [L^q]_0 dt_q,
$$
\n(10)

and introduce new dependent variables  $v_i$  related to  $u_i$  by means of the formulas

<span id="page-1-5"></span>
$$
\tilde{L} = L|_{D_x = (u_N)^{-1/N} D_z} = \sum_{i=0}^{N} u_i ((u_N)^{-1/N} D_z)^i + D_z^{-1} \circ (u_N)^{-1/N} u_{-1} \equiv D_z^N + D_z \circ v_{-1} + \sum_{i=0}^{N-1} v_i D_z^i \tag{11}
$$

and

$$
v_N = (u_N)^{1/N}.
$$
\n(12)

Then the hierarchy  $(4)$  goes into the mKdV-type hierarchy of nonlinear PDEs for  $v_i$ ,

<span id="page-1-6"></span>
$$
\tilde{L}_{\tau_q} = [P'_{\geq 1}(\tilde{L}^q), \tilde{L}], \quad q = 1, 2, ...,
$$
\n(13)

along with a separate hierarchy for  $v_N$ :

$$
(v_N)_{\tau_q} = -\epsilon([\tilde{L}^q]_0)_z, \quad q = 1, 2, \dots
$$
\n(14)

*Proof.* First of all notice that [\[6\]](#page-4-0) by virtue of [\(4\)](#page-0-2) we have  $(u_N)_{t_q} = \epsilon D_x(u_N) [L^q]_0 - \epsilon Nu_N D_x([L^q]_0)$ , which is equivalent to

<span id="page-2-2"></span>
$$
(u_N^{-1/N})_{t_q} = \epsilon D_x(u_N[L^q]_0). \tag{15}
$$

From this equality it is immediate that the variable z above is well defined.

Next, pass in [\(2\)](#page-0-0) and [\(3\)](#page-0-1) from the independent variables  $(x, \{t_q\})$  to  $(z, \{\tau_q\})$ . Then (2) takes the form

<span id="page-2-0"></span>
$$
\tilde{L}\psi = \lambda\psi,\tag{16}
$$

where  $\tilde{L}$  is defined by the first part of [\(11\)](#page-1-5), that is,

$$
\tilde{L} = L|_{D_x = (u_N)^{-1/N} D_z} = \sum_{i=0}^{N} u_i ((u_N)^{-1/N} D_z)^i + D_z^{-1} \circ (u_N)^{-1/N} u_{-1}
$$

while [\(3\)](#page-0-1) becomes

<span id="page-2-1"></span>
$$
\psi_{\tau_q} = P_{\geq 1}(L^q)(\psi), \qquad q = 1, 2, \dots \tag{17}
$$

Moreover, if we now introduce new dependent variables  $v_i$  using [\(11\)](#page-1-5) then we have (see e.g. [\[5\]](#page-4-3))  $P_{\geq 1}(L^q) = P'_{\geq 1}(\tilde{L}^q)$ , so the compatibility conditions for [\(16\)](#page-2-0) and [\(17\)](#page-2-1) are precisely [\(13\)](#page-1-6).

On the other hand, if we pass from  $(x, \{t_q\})$  to  $(z, \{\tau_q\})$  in [\(15\)](#page-2-2) and set  $v_N = u_N^{1/N}$ , we obtain

<span id="page-2-3"></span>
$$
(v_N)_{\tau_q} = -\epsilon D_z([L^q]_0), \quad q = 1, 2, \dots,
$$
\n(18)

and as  $P_{\geq 1}(L^q) = P'_{\geq 1}(\tilde{L}^q)$  implies [\[5\]](#page-4-3)  $[L^q]_0 = [\tilde{L}^q]_0$ , we see that [\(18\)](#page-2-3) becomes [\(13\)](#page-1-6), as desired. Therefore, the hierarchy [\(4\)](#page-0-2) goes into [\(13\)](#page-1-6) plus the equations [\(35\)](#page-4-5), q.e.d.  $\square$ 

Thus, the hierarchy [\(4\)](#page-0-2) does not produce any substantially new integrable systems: its contents is formed by the linear extensions [\(35\)](#page-4-5) of the undeformed mKdV-type hierarchy [\(13\)](#page-1-6).

To show how the above transformation works, set  $N = 1$  and consider the so-called extended Broer– Kaup system (see Example 4 in [\[6\]](#page-4-0)) with  $L = uD_x + v + D_x^{-1} \circ w$ . From  $L_{t_i} = [P_{\geq 1}(L^i) + \epsilon[L^i]_0 D_x, L]$ with  $i = 1, 2$  we obtain

<span id="page-2-4"></span>
$$
\begin{pmatrix} u \\ v \\ w \end{pmatrix}_{t_1} = \begin{pmatrix} \epsilon u_x v - \epsilon u v_x \\ u v_x + \epsilon v v_x \\ u_x w + u w_x + \epsilon v_x w + \epsilon v w_x \end{pmatrix}
$$
\n(19)

$$
u_{t_2} = \epsilon u_x v^2 - 2\epsilon u v v_x - 2\epsilon u^2 w_x - \epsilon u^2 v_{xx}
$$
  
\n
$$
v_{t_2} = 2u u_x w + 2u v v_x + 2u^2 w_x + u u_x v_x + u^2 v_{xx} + \epsilon v^2 v_x + 2\epsilon u v_x w + \epsilon u v_x^2
$$
  
\n
$$
w_{t_2} = 2u_x v w + 2u v_x w + 2u v w_x - u_x^2 w - 3u u_x w_x - u u_{xx} w - u^2 w_{xx} + 2\epsilon u_x w^2
$$
  
\n
$$
+2\epsilon v v_x w + \epsilon u_x v_x w + \epsilon v^2 w_x + 4\epsilon u w w_x + \epsilon u v_x w_x + \epsilon u v_x w_x.
$$

Upon setting  $\epsilon = 0$  and  $u = 1$  we recover [\[6\]](#page-4-0) from the second  $(t_2)$  flow the standard Kaup–Broer system.

However, using the transformation from Theorem [2](#page-1-7) we can reduce the system [\(19\)](#page-2-4) to the standard Broer–Kaup system plus a linear equation for u. Indeed, let us pass from the independent variables x and  $t_1$  to z and  $\tau_1$  defined by the formulas  $\tau_1 = t_1$ ,  $\tau_2 = t_2$ , and

$$
dz = (1/u)dx + \epsilon(v/u)dt_1 + (\epsilon/u)(2wu + uv_x + v^2)dt_2
$$

(we ignored here the times  $t_i$  with  $i \neq 1, 2$ ).

We have  $D_x = (1/u)D_z$ , so L becomes

$$
L = uD_x + v + D_x^{-1} \circ w = D_z + v + D_z^{-1} \circ r,
$$

where  $r = wu$ .

#### 4 A. SERGYEYEV

Upon passing from the variables  $(x, t_1, t_2, u, v, w)$  to  $(z, \tau_1, \tau_2, u, v, r)$  the system [\(19\)](#page-2-4) takes the form

<span id="page-3-0"></span>
$$
\begin{pmatrix} u \\ v \\ r \end{pmatrix}_{\tau_1} = \begin{pmatrix} -\epsilon v_z \\ v_z \\ r_z \end{pmatrix}
$$
\n(20)

$$
u_{\tau_2} = -\epsilon (2r + v_z + v^2)_z
$$
  
\n
$$
v_{\tau_2} = 2uu_xw + 2uvv_x + 2u^2w_x + uu_xv_x + u^2v_{xx} + \epsilon v^2v_x + 2\epsilon uv_xw + \epsilon uv_x^2
$$
  
\n
$$
r_{\tau_2} = 2u_xvw + 2uv_xw + 2uvw_x - u_x^2w - 3uu_xw_x - uu_{xx}w - u^2w_{xx} + 2\epsilon u_xw^2
$$
  
\n
$$
+2\epsilon vv_xw + \epsilon u_xv_xw + \epsilon v^2w_x + 4\epsilon uww_x + \epsilon uv_xw_x + \epsilon uv_{xx}w.
$$

It is immediate that the last two equations of [\(20\)](#page-3-0), namely those for  $v_{\tau_2}$  and  $r_{\tau_2}$ , form the standard (non-extended) Broer–Kaup system for v and r, while the equation determining  $u_{\tau_2}$  is a linear equation that can be readily solved for given  $v$  and  $r$ .

As a final remark note that the result of Theorem [2](#page-1-7) remains valid for the operators L of more general form than  $(1)$ . Namely, Theorem [2](#page-1-7) still holds if we replace  $L(1)$  by

$$
L = \sum_{i = -\infty}^{N} u_i D_x^i \tag{21}
$$

and define new dependent variables  $v_i$  using the following modification of the formula [\(11\)](#page-1-5):

$$
\tilde{L} = L|_{D_x = (u_N)^{-1/N} D_z} = \sum_{i = -\infty}^{N} u_i ((u_N)^{-1/N} D_z)^i \equiv D_z^N + \sum_{i = -\infty}^{N-1} v_i D_z^i.
$$
\n(22)

## 2. Dispersionless case

Analogs of Theorems [1](#page-1-1) and [2](#page-1-7) hold in the dispersionless case when  $D_x$  is replaced by a formal parameter  $p$  and the commutator  $\left[\right]$  is replaced by the Poisson bracket

$$
\{f,g\} = \partial f/\partial p D_x(g) - \partial g/\partial p D_x(f),
$$

see e.g. the discussion in [\[6\]](#page-4-0) and references therein for further details.

The differential operator  $L(1)$  $L(1)$  is now replaced by a function

$$
\mathcal{L} = \sum_{i=0}^{N} u_i p^i + p^{-1} u_{-1},\tag{23}
$$

and instead of the spectral problem [\(2\)](#page-0-0) we have

$$
\mathcal{L}|_{p=\psi_x} = \lambda,\tag{24}
$$

while [\(3\)](#page-0-1) is replaced by

$$
\psi_{t_q} = (P_{\geq 1}(\mathcal{L}^q)|_{p=\psi_x} + \epsilon [\mathcal{L}^q]_0|_{p=\psi_x}\psi_x, \qquad q = 1, 2, \dots,
$$
\n(25)

where the projection  $P_{\geq s}$  is now now defined as follows:

$$
P_{\geq s}\left(\sum_{j=-\infty}^N a_i p^i\right) = \sum_{j=s}^N a_i p^i.
$$

Finally, the associated hierarchy, the counterpart of [\(4\)](#page-0-2), has the form

<span id="page-3-1"></span>
$$
\mathcal{L}_{t_q} = \{ P_{\geq 1}(\mathcal{L}^q) + \epsilon(\mathcal{L}^q)_{p=0} D_x, \mathcal{L} \}, \qquad q = 1, 2, \dots \tag{26}
$$

We have the following results:

**Theorem 3.** The transformation  $(x, \{t_i\}, \{u_j\}) \rightarrow (z, \{\tau_i\}, \{v_j\})$  sends the system

$$
\mathcal{L}|_{p=\psi_x} = \lambda, \qquad \psi_{t_i} = (P_{\geq 1}(\mathcal{L}^i) + \epsilon[\mathcal{L}^i]_0 p)_{p=\psi_x}, \quad i = 0, 1, 2, \dots
$$
\n
$$
(27)
$$

into

$$
\tilde{\mathcal{L}}|_{\tilde{p}=\psi_z} = \lambda, \qquad \psi_{\tau_i} = (P'_{\geq 2}(\tilde{\mathcal{L}}^i))_{\tilde{p}=\psi_z}, \quad i = 0, 1, 2, \dots,
$$
\n(28)

and hence sends the hierarchy

$$
\mathcal{L}_{t_i} = \{ P_{\geq 1}(\mathcal{L}^i) + \epsilon [\mathcal{L}^i]_0 p, \mathcal{L} \}, \quad i = 0, 1, 2, \dots
$$
\n
$$
(29)
$$

into the dispersionless Harry-Dym-type hierarchy

$$
\tilde{\mathcal{L}}_{\tau_i} = \{ P'_{\geq 2}(\tilde{\mathcal{L}}^i), \tilde{\mathcal{L}} \}, \quad i = 0, 1, 2, \dots
$$
\n(30)

**Theorem 4.** Consider the reciprocal transformation from x and  $t_i$ ,  $i = 1, 2, \ldots$  to new independent variables z and  $\tau_i$ ,  $i = 1, 2, \ldots$ , where  $\tau_i = t_i$ ,  $i = 1, 2, \ldots$ , and z is defined by the formula

$$
dz = (u_N)^{-1/N} dx + \epsilon \sum_{q=1}^{\infty} (u_N)^{-1/N} (\mathcal{L}^q)_{p=0} dt_q,
$$
\n(31)

and introduce new dependent variables  $v_i$  related to  $u_i$  by means of the formulas

$$
\tilde{\mathcal{L}} = \mathcal{L}|_{p=(u_N)^{-1/N}\bar{p}} = \sum_{i=0}^{N} u_i((u_N)^{-1/N}\bar{p})^i + \bar{p}^{-1}(u_N)^{-1/N}u_{-1} \equiv \bar{p}^N + \bar{p}v_{-1} + \sum_{i=0}^{N-1} v_i \bar{p}^i
$$
(32)

and

$$
v_N = (u_N)^{1/N}.
$$
\n(33)

Then the hierarchy [\(26\)](#page-3-1) goes into the hierarchy of nonlinear PDEs for  $v_i$ :

<span id="page-4-6"></span>
$$
\tilde{\mathcal{L}}_{\tau_q} = \{ P'_{\geq 1}(\tilde{\mathcal{L}}^q), \tilde{\mathcal{L}} \}, \quad q = 1, 2, \dots \tag{34}
$$

and

<span id="page-4-5"></span>
$$
(v_N)_{\tau_q} = -\epsilon([\tilde{\mathcal{L}}^q]_0)_z, \quad q = 1, 2, \dots
$$
\n
$$
(35)
$$

Note that equations [\(34\)](#page-4-6) are the compatibility conditions for the system

$$
\tilde{\mathcal{L}}|_{\tilde{p}=\psi_z}=\lambda
$$

with

$$
\psi_{\tau_q} = \left(P_{\geq 1}(\tilde{\mathcal{L}}^q)\right)_{\tilde{p} = \psi_z}, \qquad q = 1, 2, \dots
$$
\n(36)
