

BOUNDEDLY SIMPLE GROUPS OF AUTOMORPHISMS OF TREES

JAKUB GISMATULLIN

ABSTRACT. A group is boundedly simple if for some constant N , every nontrivial conjugacy class generates the whole group in N steps (bounded simplicity implies simplicity). For a large class of colored trees, Tits proved simplicity of automorphism groups generated by stabilizers of edges. We determine for which colored trees such groups are boundedly simple. Namely, for (almost) bi-regular trees they are 32-boundedly simple. For all other colored trees in the class, such groups are not boundedly simple.

1. INTRODUCTION

A group G is called *N -boundedly simple* if for every two nontrivial elements $g, h \in G$, the element h is the product of N or fewer conjugates of $g^{\pm 1}$, i.e.

$$G = \left(g^G \cup g^{-1G} \right)^{\leq N}.$$

G is boundedly simple if it is N -boundedly simple, for some natural N .

Tits in [5] proved that if the full automorphism group of a tree leaves no nonempty proper subtree nor an end of the tree invariant, then a subgroup generated by stabilizers of edges is simple. We show (Corollary 3.4) that for (almost) bi-regular trees (see Definition 3.5) such groups are 32-boundedly simple. We prove the converse (Theorem 3.9): if the full automorphism group of a tree leaves no nonempty proper subtree invariant and the subgroup generated by stabilizers of edges is boundedly simple, then our tree is almost bi-regular and this group is 32-boundedly simple. Hence, almost bi-regular trees are distinguished in this sense. We do not expect that the bound 32 is sharp.

Our motivation for study bounded simplicity of automorphism groups of trees comes from Bruhat-Tits building for $\mathrm{PSL}_2(K)$, where K is a field with discrete valuation (see [4, Chapter II]). That is, $\mathrm{PSL}_2(K)$ acts faithfully on a n -regular tree, where n is the cardinality of the residue field. In fact, $\mathrm{PSL}_2(K)$ is a subgroup of an automorphism group of a regular tree generated by stabilizers of edges. On the other hand it is well known that for an arbitrary field K , group $\mathrm{PSL}_2(K)$ is boundedly simple (by [1, 6] $\mathrm{PSL}_2(K)$ is 5-boundedly simple).

In the last section we prove a version of Theorem 3.9 related to boundedly simple action on trees (Corollary 4.2). Namely, if a boundedly simple group G acts on a tree A in such a way, that some element of G stabilize some edge and G leaves no nonempty proper subtree invariant, then A is almost bi-regular (so, if A is not almost bi-regular, then G leaves invariant some nonempty proper subtree of A).

There are many examples and results related to boundedly simple groups (see e.g. [2, 3]). Bounded simplicity is a stronger property than usual simplicity (infinite alternating

group is simple but not boundedly simple). This property arises naturally in the study of the logic (model theoretic) nature of simple groups. For fixed N , N -bounded simplicity is a first order logic property, i.e. can be written as a sentence in the first order logic. Every ultraproduct (more generally every elementary extension) of boundedly simple group is boundedly simple. On the other hand,

(\otimes) if a non-principal ultrapower G^ω/\mathcal{U} (of a group G) is simple, then G itself is boundedly simple.

To see this, assume that for every natural N , there is $e \neq g_N \in G$ and $h_N \in G \setminus (g_N^G \cup g_N^{-1G})^{\leq N}$ (g^G is the conjugacy class of g in G). Consider $g = (g_N)_{N < \omega}/\mathcal{U}$ and $h = (h_N)_{N < \omega}/\mathcal{U}$ from G^ω/\mathcal{U} . Then the normal closure

$$H = \bigcup_{n < \omega} (g^{G^\omega/\mathcal{U}} \cup g^{-1G^\omega/\mathcal{U}})^n$$

of g in G^ω/\mathcal{U} is a nontrivial proper ($h \notin H$) subgroup of G^ω/\mathcal{U} , which is impossible. Using (\otimes) one can give an easy proof of bounded simplicity of e.g. projective special linear groups $\mathrm{PSL}_n(K)$ or projective symplectic groups $\mathrm{PSp}_n(K)$ ($n \geq 2$). Namely, let K be an arbitrary infinite field, then

$$\mathrm{PSL}_n(K)^\omega/\mathcal{U} \cong \mathrm{PSL}_n(K^\omega/\mathcal{U}), \quad \mathrm{PSp}_n(K)^\omega/\mathcal{U} \cong \mathrm{PSp}_n(K^\omega/\mathcal{U}).$$

Simplicity of $\mathrm{PSL}_n(K^\omega/\mathcal{U})$ and $\mathrm{PSp}_n(K^\omega/\mathcal{U})$ with (\otimes) implies bounded simplicity of $\mathrm{PSL}_n(K)$, $\mathrm{PSp}_n(K)$. In the model theoretic language we can translate above considerations as: if K is a saturated field and a group $G(K)$ is simple and definable in K , then $G(K)$ is boundedly simple.

2. BASIC NOTATION AND PREREQUISITES

We use the notation and basic facts from [5]. A tree is a connected graph without cycles. In this paper A always denotes a tree. By $S(A)$ we denote the set of vertices of A . The set of edges $\mathrm{Ar}(A)$ is a collection of some 2-element subsets of $S(A)$. Let $\mathrm{Ch}(A)$ be the set of all infinite paths starting in some vertex of A . *Ends* $\mathrm{Bout}(A)$ are equivalence classes of the following relation defined on $\mathrm{Ch}(A)$:

$$C \sim C' \iff C \cap C' \in \mathrm{Ch}(A).$$

By $\mathrm{Aut}(A)$ we denote the group of all automorphisms of A , i.e. bijections of $S(A)$ preserving all edges. An automorphism $\alpha \in \mathrm{Aut}(A)$ is called a *rotation* if it stabilizes some vertex $s \in S(A)$, i.e. $\alpha(s) = s$. α is a *symmetry* if for some edge $\{s, s'\} \in \mathrm{Ar}(A)$, $\alpha(s) = s'$ and $\alpha(s') = s$. If for some double-infinite path C in A , an automorphism α fixes C setwise and is not a rotation, then we call α a *translation* (in this case C is the unique double-infinite path with above properties and α restricted to C is nontrivial translation). By [5, Proposition 3.2] the group $\mathrm{Aut}(A)$ splits into rotations, symmetries and translations. The subtree of A consisting of vertices fixing pointwise by α is called a *fixed tree of α* and denoted by $\mathrm{Fix}(\alpha)$. The subgroup of $\mathrm{Aut}(A)$ stabilizing pointwise a given subtree A' of A is denoted by $\mathrm{Stab}(A')$. For $G < \mathrm{Aut}(A)$, by $G_{A'}$ or $\mathrm{Stab}^G(A')$ we denote $\mathrm{Stab}(A') \cap G$.

$\mathrm{Aut}(A)$ acts naturally on ends $\mathrm{Bout}(A)$. We say that $\alpha \in \mathrm{Aut}(A)$ *stabilizes an end* $b \in \mathrm{Bout}(A)$ if α fixes pointwise some infinite path C from b (this implies that in the action of $\mathrm{Aut}(A)$ on $\mathrm{Bout}(A)$, $f(b) = b$, but is not equivalent).

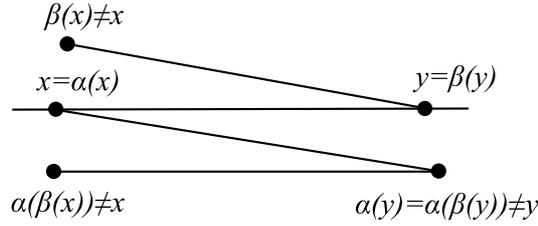

FIGURE 2.1. Composition of two rotations

It is proved in [5, Proposition 3.4] that if a subgroup $G < \text{Aut}(A)$ does not contain translations, then G stabilize some vertex, an edge or an end of A . The proof of this uses the assumption that G is a group in a very limited way, so a slightly general fact is true (Remark 2.2). We use this generalization in the proof of Theorem 2.6.

Lemma 2.1. *Let $\alpha, \beta \in \text{Aut}(A)$, and for some $x, y \in S(A)$*

$$\alpha(x) = x, \quad \beta(y) = y, \quad \alpha(y) \neq y \text{ and } \beta(x) \neq x.$$

Then $\alpha \circ \beta$ is a translation by an even distance.

Proof. Let $\gamma = \alpha \circ \beta$. We use the following criterion ([5, Lemma 3.1]) for an automorphism $\gamma \in \text{Aut}(A)$ to be a translation:

- (♠) if for some edge $\{x, y\} \in \text{Ar}(A)$, x is on the shortest path from y to $\gamma(y)$ and $\gamma(y)$ is on the shortest path from x to $\gamma(x)$, then γ is a translation along a double infinite path containing $y, x, \gamma(y)$ and $\gamma(x)$ by $\text{dist}(x, \gamma(x)) = \text{dist}(y, \gamma(y))$.

We may assume that on the shortest path from x to y there is no vertex fixing by α [β] other than x [y respectively]. Since $\alpha(x) = x$, $\alpha(y) = \gamma(y) \neq y$ and $\gamma(x) = \alpha(\beta(x)) \neq \alpha(x) = x$, the shortest path from y to $\gamma(x)$ first goes through x and then through $\gamma(y)$ (see Figure 2.1). Therefore by (♠), γ is a translation by $\text{dist}(y, \gamma(y)) = 2 \text{dist}(y, x)$. \square

Remark 2.2. If $T \subseteq \text{Aut}(A)$ and

$$T \cup TT$$

does not contain translations, then the group generated by T also does not contain translations. Hence T stabilize some vertex, an edge or an end of A .

Proof. It is enough to prove that $G = \langle T \rangle$ does not contain translations (the rest follows from [5, Proposition 3.4]). The set T splits into a disjoint union of rotations T_r and symmetries.

If $T_r = \emptyset$, then by the preceding lemma T (and thus also G) stabilize some edge (because, by adding some vertices to A we may regard every symmetry as a rotation, and then use Lemma 2.1).

In the general case we may assume that every element of T is a rotation. By the preceding lemma, the family of fixed trees of automorphisms from T

$$\{\text{Fix}(\alpha) : \alpha \in T\}$$

is linearly ordered by inclusion. Therefore for $\alpha_1, \dots, \alpha_n \in T$, $\text{Fix}(\alpha_1 \circ \dots \circ \alpha_n) = \text{Fix}(\alpha_1) \cap \dots \cap \text{Fix}(\alpha_n) \neq \emptyset$, so $\alpha_1 \circ \dots \circ \alpha_n$ is not a translation. Hence, $G = \langle T \rangle$ does not contain translations. \square

Some groups of automorphisms of trees we are going to deal with, will satisfy a *property (P)* of Tits ([5, 4.2]). Namely, let $G < \text{Aut}(A)$ and C be an arbitrary (finite or infinite) path in A . Consider a natural projection

$$\pi: S(A) \rightarrow S(C)$$

($\pi(x) \in S(C)$ is the closest vertex to x) and for every $s \in S(C)$ an induced projection of stabilizer

$$\rho_s: \text{Stab}^G(C) \longrightarrow \text{Aut}(\pi^{-1}[s]).$$

Definition 2.3. We say that $G < \text{Aut}(A)$ has the property (P) is for an arbitrary path C in A , the mapping

$$\rho = (\rho_s)_{s \in S(C)}: \text{Stab}^G(C) \longrightarrow \prod_{s \in S(C)} \text{Im}(\rho_s)$$

is an isomorphism.

For example, the full group of automorphism $\text{Aut}(A)$ has property (P).

Definition 2.4. Let A be a tree and $G < \text{Aut}(A)$.

- (1) A vertex having at least three edges adjacent to it is called a *ramification point*.
- (2) G^+ is a subgroup of $\text{Aut}(A)$ generated by stabilizers of edges

$$G^+ = \langle \text{Stab}^G(x, y) : \{x, y\} \in \text{Ar}(A) \rangle.$$

Remark 2.5. Every element of G^+ is either a rotation or a translation by an even distance.

Proof. Consider an equivalence relation E on $S(A)$:

$$E(x, y) \iff \text{distance from } x \text{ to } y \text{ is even.}$$

Every stabilizer of an edge preserves E , so G^+ preserves E . On the other hand, only rotations and translations by an even distance preserve E . \square

Assume that $G < \text{Aut}(A)$ has property (P) and does not preserve any proper subtree nor end of A . [5, Theorem 4.5] says then, that every subgroup of G normalizing by G^+ is trivial or contains G^+ . In particular G^+ is a simple group. Modifying one step in the proof of this theorem (using Remark 2.2), we can show a more precise result regarding conjugacy classes in G^+ .

By $h^H = \{x^{-1}hx : x \in H\}$ we mean the conjugacy class of element h of the group H .

Theorem 2.6. Let A be a tree and $G < \text{Aut}(A)$. Assume that G has property (P) and G leaves no nonempty proper subtree nor an end of A invariant. Then for every $g \in G^+$ and edge $\{x, y\} \in \text{Ar}(A)$

$$\text{Stab}^G(x, y) \subseteq \left(g^{G^+} \cdot \left(g^{G^+} \cup \{e\} \right) \cdot \left(g^{-1G^+} \cup \{e\} \right) \cdot g^{-1G^+} \right)^2.$$

Proof. This is just the proof of [5, Theorem 4.5], so we will be brief. Removing the edge $\{x, y\}$ from A , gives us two subtrees A' and A'' of A . Using property (P) we have

$$\text{Stab}^G(x, y) = \text{Stab}^G(A') \cdot \text{Stab}^G(A'').$$

Hence, it is enough to show that

$$\clubsuit \quad \text{Stab}^G(A') \subseteq g^{G^+} \cdot \left(g^{G^+} \cup \{e\} \right) \cdot \left(g^{-1G^+} \cup \{e\} \right) \cdot g^{-1G^+}.$$

By [5, Lemma 4.4], g^{G^+} does not preserve any proper subtree nor end of A . Therefore by Remark 2.2, $g^{G^+} \cup g^{G^+} \cdot g^{G^+}$ contains a translation h along some double infinite path D . Using arguments from the proof of [5, Theorem 4.5], we find a natural number n such that

$$D' = h^n(g^{-1}[D])$$

is in A' . Thus $h' = h^{g^{h^{-n}}}$ is a translation from $g^{G^+} \cdot (g^{G^+} \cup \{e\})$ along a double infinite path D' from A' . Finally, by [5, Lemma 4.3]

$$\text{Stab}^G(D') = \{h' f h'^{-1} f^{-1} : f \in \text{Stab}^G(D')\},$$

so we have (\clubsuit)

$$\text{Stab}^G(A') < \text{Stab}^G(D') = h' \cdot h'^{-1} \text{Stab}^G(D') \subseteq g^{G^+} \cdot (g^{G^+} \cup \{e\}) \cdot (g^{-1G^+} \cup \{e\}) \cdot g^{-1G^+}.$$

□

We recall from [5, Section 5] a convenient way to describe trees. Let I be a set of “colors” and

$$f: S(A) \rightarrow I$$

a coloring function. Define a group of automorphisms preserving f as

$$\text{Aut}_f(A) = \{\alpha \in \text{Aut}(A) : f \circ \alpha = f\}.$$

We say that f is *normal* if f is onto and for every $i \in I$, $\text{Aut}_f(A)$ is transitive on $f^{-1}[i]$. Clearly, for every coloring function f there is a normal coloring function f' such that $\text{Aut}_f(A) = \text{Aut}_{f'}(A)$, hence we always assume that f is normal.

It is easy to see that $\text{Aut}_f(A)$ has the property (P) (see Definition 2.3).

Let $(A, f: S(A) \rightarrow I)$ be an arbitrary colored tree (f is normal). Define a function

$$a: I \times I \rightarrow \text{Card}$$

as follows: take an arbitrary $x \in f^{-1}[i]$ and set

$$a(i, j) = |\{y \in f^{-1}[j] : \{x, y\} \in \text{Ar}(A)\}|.$$

Since f is normal, the value $a(i, j)$ does not depend on the choice of x from $f^{-1}[i]$. Functions a arising this way can be characterized by two conditions [5, Proposition 5.3]:

- (1) if $a(i, j) = 0$, then $a(j, i) = 0$
- (2) a directed graph $G(a) = (I, E)$, where $E = \{\{i, j\} \subseteq I : a(i, j) \neq 0\}$, is connected.

If some function $a: I \times I \rightarrow \text{Card}$ has (1) and (2), then there is a colored tree $(A, f: S(A) \rightarrow I)$ with a normal function f such that for every $x \in f^{-1}[i]$, $a(i, j) = |\{y \in f^{-1}[j] : \{x, y\} \in \text{Ar}(A)\}|$. We say then, that a is a *code* of colored tree $(A, f: S(A) \rightarrow I)$. We note also [5, 5.7] that if $1 \notin a[I \times I]$, then $\text{Aut}_f(A)$ leaves no nonempty proper subtree nor an end of the tree invariant (hence by [5, Theorem 4.5] or our Theorem 2.6, $\text{Aut}_f^+(A)$ is a simple group).

An element $i \in I$ is a *ramification color*, if $i = f(x)$, for some ramification point $x \in S(A)$. The set of all ramification colors we denote by I^{ram} .

3. BOUNDED SIMPLICITY OF $\text{Aut}_f^+(A)$

We begin with the criterion for bounded simplicity of G^+ .

Proposition 3.1. *Let A be a tree. Assume that $G < \text{Aut}(A)$ has property (P) and leaves no nonempty proper subtree nor an end of A invariant (so G^+ is simple).*

Then G^+ is boundedly simple if and only if there is a natural number K such that

- (1) *every translation from G^+ is a product of K rotations from G^+ ,*
- (2) *every rotation from G^+ is a product of K elements from $\bigcup_{\{x,y\} \in \text{Ar}(A)} \text{Stab}^G(x,y)$.*

Proof. \Rightarrow is clear. \Leftarrow Let $g \in G^+$ be nontrivial. By Theorem 2.6 (\clubsuit), for an arbitrary edge $\{x,y\} \in \text{Ar}(A)$

$$\text{Stab}^G(x,y) \subseteq \left(g^G \cup g^{-1G} \right)^{\leq 8}.$$

Remark 2.5 with the assumption lead to $G^+ = \left(g^G \cup g^{-1G} \right)^{\leq 8K^2}$. \square

Next remark states that the condition (2) from Proposition 3.1 is always satisfied in $\text{Aut}_f^+(A)$ (with $K = 2$).

Remark 3.2. Assume that $(A, f: S(A) \rightarrow I)$ is a colored tree and the group $\text{Aut}_f^+(A)$ is nontrivial. Then every nontrivial rotation from $\text{Aut}_f^+(A)$ fixes some ramification point and is a composition of two elements from $\bigcup_{\{x,y\} \in \text{Ar}(A)} \text{Stab}^{\text{Aut}_f(A)}(x,y)$.

Proof. By [5, 6.1], if $\alpha \in \text{Aut}_f^+(A)$ stabilizes a ramification point, then α is a product of two elements from $\bigcup_{\{x,y\} \in \text{Ar}(A)} \text{Stab}^{\text{Aut}_f(A)}(x,y)$.

We prove, that every rotation $\alpha \in \text{Aut}_f^+(A)$ fixes some ramification point. Let x be a non-ramification point and $\alpha(x) = x$. We may assume that x has two adjacent vertices y and z of the same color. It is enough to show, that $\alpha(y) = y$ and $\alpha(z) = z$. If $f(x) = f(y)$, then A is just a double infinite path, so let $i = f(x) \neq f(y)$. Consider on $S(A)$ the following equivalence relation: $E(r,s)$ if and only if on the shortest path from r to s there is even number of vertices of color i . Clearly $\neg E(y,z)$. It suffices to show that for every $\beta \in \text{Aut}_f^+(A)$ and $r \in S(A)$

$$E(r, \beta(r)).$$

Let $\beta \in \text{Stab}^{\text{Aut}_f(A)}(x',y')$ (where $\{x',y'\} \in \text{Ar}(A)$) and consider the shortest path C from r to $\beta(r)$. β fixes some ramification point t from C . Since x is not a ramification point, $f(t) \neq i$. Therefore $E(r, \beta(r))$. \square

One of the main ingredient in proofs of results of this paper is a classification of translations up to conjugation (in $\text{Aut}_f(A)$). We associate (in the next definition) with each translation, a finite sequence of colors from I .

Definition 3.3. Let $(A, f: S(A) \rightarrow I)$ be an arbitrary colored tree. *The type* of a translation $\alpha \in \text{Aut}_f(A)$ along a double-infinite path C (in A) is a set of all cyclic shifts of a particular finite sequence from I :

$$t = [i_1, \dots, i_n] = \{(i_1, \dots, i_n), (i_2, \dots, i_n, i_1), \dots, (i_n, i_1, \dots, i_{n-1})\}$$

such that if for some $x \in C$, $x = x_1, \dots, x_n, x_{n+1} = \alpha(x)$ is a subpath of C , then

$$f(x_1) = i_1, \dots, f(x_n) = i_n$$

(note that $f(x_{n+1}) = i_1$). We also say that t is the type of α and n is the length of t .

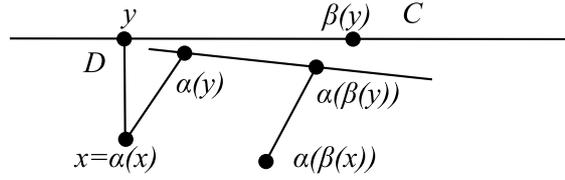

FIGURE 3.1. Composition of translation and rotation

A conjugacy class of a translation α from $\text{Aut}_f(A)$ is uniquely determined by a type, i.e. consists on translation of the same type.

We calculate types of some translations.

Using Lemma 2.1 (\spadesuit) we do this for the compositions of two rotations. Take $\alpha, \beta \in \text{Aut}(A)$ such that $\alpha(x) = x$, $\beta(y) = y$ and on the shortest path D from y to x there is no vertex except x [y] fixing by α [β respectively]. If the type of D is

$$(\square) \quad (i_1, \dots, i_n), \quad f(y) = i_1, \quad f(x) = i_n, \quad n \geq 2,$$

then the type of $\alpha \circ \beta$ is

$$(\heartsuit) \quad [i_1, i_2, \dots, i_{n-1}, i_n, i_{n-1}, \dots, i_2].$$

On the other hand, every translation of the type (\heartsuit) is a composition of two rotations. As a consequence we see, that the type of $\alpha \circ \beta$ depends only on the type of the shortest path between $\text{Fix}(\beta)$ and $\text{Fix}(\alpha)$.

We find the type of a composition of a translation and a rotation. Let α be a rotation ($\alpha(x) = x$) and β be a translation of the type

$$(\triangle) \quad [i_1, j_2, \dots, j_m], \quad m \geq 2,$$

along a double-infinite path C . There are two cases.

- (\boxtimes) x lies outside C . Take a vertex $y \in C$ — the closest vertex to x in C (a projection of x on C). Let D be the shortest path from y to x . We may assume that x is the only vertex in D fixed by α . Let the type of D be (\square) with $f(y) = i_1, f(x) = i_n$. Then by (\spadesuit) in Lemma 2.1, (applied to $y, x, \alpha(\beta(y)), \alpha(\beta(x))$), see Figure 3.1) $\alpha \circ \beta$ and $\beta \circ \alpha$ are translations of the type

$$(\diamond) \quad (\heartsuit)(\triangle) = [i_1, i_2, \dots, i_{n-1}, i_n, i_{n-1}, \dots, i_2, i_1, j_2, \dots, j_m].$$

Also every translation of the type (\diamond) is a composition of a rotation, and translation of the type (\triangle) . Hence, the type of $\alpha \circ \beta$ only depends on the type of β and the type of the shortest from C to $\text{Fix}(\alpha)$.

- (\boxplus) x lies on C . Let D be the shortest path from x to $\beta(x)$ and assume that $f(x) = i_1$. Let y be a vertex from D next to x (so $f(y) = j_2$). If $\beta(\alpha(y))$ lies outside D , then by (\spadesuit) applied to $x, y, \beta(x) = \beta(\alpha(x))$ and $\beta(\alpha(y))$, $\beta \circ \alpha$ is a translation of the same type as β , i.e. $[i_1, j_2, \dots, j_m]$. Assume that $\beta(\alpha(y))$ is on D (so $j_2 = j_m$). Take $y' \neq x$ — a vertex from D , next to y (so $f(y') = j_3$). Again, if $\beta(\alpha(y'))$ is outside D , then by (\spadesuit) applied to $y, y', \beta(\alpha(y))$ and $\beta(\alpha(y'))$, $\beta \circ \alpha$ is a translation of the type

$$[j_2, \dots, j_{m-1}].$$

Continuing this way we see, that either $\beta \circ \alpha$ is a translation of the type being the subtype of (\triangle) or $\beta \circ \alpha$ is a rotation. In the last case m is even and

$$j_2 = j_m, j_3 = j_{m-1}, \dots, j_{\frac{m}{2}-1} = j_{\frac{m}{2}+2}.$$

Thus, $\beta \circ \alpha$ stabilizers vertex of type $j_{\frac{m}{2}+1}$ and β has type (\heartsuit) , so is a composition of two rotations. Since $\alpha \circ \beta = (\beta \circ \alpha)^{\alpha^{-1}}$, the same applies to $\alpha \circ \beta$.

A (n, m) -regular (bi-regular) tree $A_{n,m}$, is a 2-colored tree with the following code:

$$a(0, 0) = a(1, 1) = 0, \quad a(0, 1) = n, \quad a(1, 0) = m,$$

where $I = \{0, 1\}$ and n, m are some cardinal numbers ≥ 3 . Intuitively, in a bi-regular tree every vertex is black or white, every white vertex is connected with n black vertices and every black vertex is connected with m white vertices (if $n = 2$ and $m \geq 3$, then after removing vertices of color 0 we get the m -regular tree).

Corollary 3.4. $\text{Aut}^+(A_{n,m})$ is 32-boundedly simple.

Proof. Clearly, $\text{Aut}^+(A_{n,m})$ has property (P) and $1 \notin a[I \times I]$ (so $\text{Aut}^+(A_{n,m})$ leaves no nonempty proper subtree nor an end of $A_{n,m}$ invariant). $\text{Aut}^+(A_{n,m})$ consists on translations by even distances and rotations. Using our description of types of translations, it easy to see that this group satisfies the condition from Proposition 3.1 with $K = 2$. \square

Definition 3.5. An almost (n, m) -regular tree (almost bi-regular tree) is the (n, m) -regular tree expanding (in a symmetric way) by non ramification points. Namely, it is the tree with the set of colors $I = \{0, \dots, k\}$ and the following code: $a(0, 1) = n$, $a(k, k-1) = m$ and $a(i, i+1) = a(i+1, i) = 1$ for $i \in I \setminus \{0, k\}$. For all other pairs (p, q) from I^2 , a has value 0.

It is obvious, that if A is the almost (n, m) -regular tree, then $\text{Aut}_f^+(A) \cong \text{Aut}^+(A_{n,m})$, so $\text{Aut}_f^+(A)$ is 32-boundedly simple too.

Except for groups $\text{Aut}^+(A_{n,m})$ there are no other examples of colored trees A with boundedly simple groups $\text{Aut}_f^+(A)$ and with the property that $\text{Aut}_f^+(A)$ leaves no nonempty proper subtree of A invariant (Theorem 3.9). Next theorem is the main technical step in the proof of this. We prove that, if $\text{Aut}_f^+(A)$ is boundedly simple, then some particular configuration in the code of A is forbidden.

Theorem 3.6. Assume that $(A, f: S(A) \rightarrow I)$ is a colored tree and $\text{Aut}_f^+(A)$ is non-trivial and boundedly simple. Take two rotations α, β from $\text{Aut}_f^+(A)$. Suppose that for three different ramification points $x, y, z \in S(A)$,

- $\alpha(x) = x, \beta(y) = y$ and $\beta \circ \alpha$ is a translation along a double infinite path C ,
- t is the projection of z onto C (see Figure 3.2) and s is a vertex next to z lying on the shortest path from z to t ,
- on the shortest paths: from x to y and from s to t , there are no vertices of color $f(z)$.

If γ is an arbitrary rotation from $\text{Aut}_f^+(A)$ fixing z , then γ fixes also s

$$\gamma(s) = s.$$

Proof. There is a normal function

$$f^+: S(A) \rightarrow I^+ = \{\text{orbits of } \text{Aut}_f^+(A) \text{ on } S(A)\},$$

such that if $f^+(x) = f^+(y)$, then $f(x) = f(y)$ and

$$\text{Aut}_f^+(A) = \text{Aut}_{f^+}(A).$$

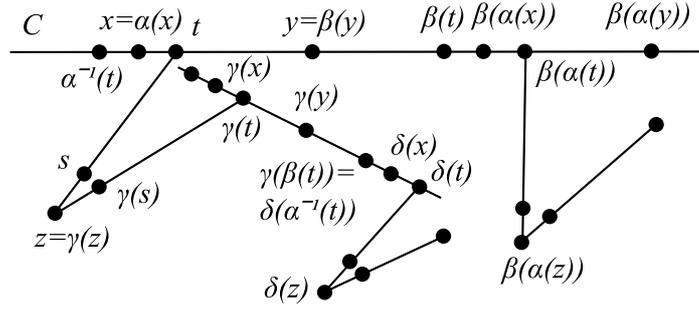

FIGURE 3.2. Composition of three rotations

For f^+ just take the quotient map. Then inclusion \subseteq is obvious. On the other hand, if $\alpha \in \text{Aut}_{f^+}(A)$ and $r \in S(A)$ is a ramification point, then $\alpha(r) \in \text{Aut}_{f^+}(A) \cdot r$. Thus $\alpha \in \text{Stab}^{\text{Aut}_f(A)}(r) \cdot \text{Aut}_{f^+}(A) = \text{Aut}_{f^+}(A)$.

Therefore we may assume further that $f = f^+$ and $I = I^+$.

Suppose, contrary to our claim, that $\gamma(s) \neq s$. For each natural K we construct a composition of some rotations which cannot be written as a composition of K rotations. Then, Proposition 3.1 implies that $\text{Aut}_{f^+}(A)$ is not boundedly simple.

According to the analysis of types of translations, we may assume that our situation is described by Figure 3.2. We may also assume that t belong to the path in C from x to y (if t belongs to the path from $(\beta \circ \alpha)^n(x)$ to $(\beta \circ \alpha)^n(y)$, for some integer n , then just take $z := (\beta \circ \alpha)^{-n}(z)$ and conjugate $\gamma := \gamma^{(\beta \circ \alpha)^n}$).

Denote by 0, 1 and 2 types of some paths in Figure 3.2. Namely, let

- 0 be the type of the shortest path from t to $\gamma(t)$ (through z) without the last term of color $f(t)$,
- 1 — from $\alpha^{-1}(t)$ to t (through x) without the last term of color $f(t)$,
- 2 — from t to $\beta(t)$ (through y) without the last term of color $f(t)$.

For example, $\delta = \gamma \circ \beta \circ \alpha$ has type $[1, 0, 2]$.

Define by induction the following types

$$t_2 = (1, 2, 1, 0, (1, 2)^2, 1, 0), \quad t_{n+1} = (1, 2, 1, 0, (1, 2)^{2n-1}, t_n, (1, 2)^{2n-1}, 1, 0),$$

for $n \geq 2$. Let α_{K+1} be a translation of type $[t_{K+1}]$. Then α_{K+1} is in $\text{Aut}_{f^+}(A)$ (because x, y, z and t are ramification points) and it is the composition of some number of rotations (because $[1, 2, 1, 0, (1, 2)^{2n-1}, (1, 2)^{2n-1}, 1, 0]$ is a type of composition of two rotations from $\text{Aut}_{f^+}(A)$, then inductively, by adding some rotations we obtain $[t_{n+1}]$).

The proof will be completed by showing that α_{K+1} cannot be written as a composition of less than $K+1$ rotations. In order to do this, we introduce a notion describing distances of colors in types.

For $i \in I$ and a type t of length n

$$t = [i_1, \dots, i_n]$$

define an i -sequence of t in the following way:

- if there is not occurrence of i in t , then i -sequence for t is empty,
- let i_k be the first occurrence of i in (i_1, \dots, i_n) . Then an i -sequence for t , is a sequence (modulo cyclic shifts) of distances between consecutive occurrences of i in sequence

$$(i_k, i_{k+1}, \dots, i_{n-1}, i_n, i_1, \dots, i_k).$$

For example, 0-sequence for $[1, 2, 1, 0, 1, 2, 1, 2, 1, 0]$ is $[6, 4]$.

Note that if t has N occurrences of i , then its i -sequence is of length N .

To prove the lower bound for the number of rotations needed to generate α_{K+1} , we will use the next lemma.

Lemma 3.7. *Let t be a type of composition of K rotations ($K \geq 2$). If t has N occurrences of i , then in its i -sequence there is at least*

$$N - 2K + 2$$

terms with multiple occurrences.

For example, 0-sequence for $[0, 1, 2, 1, 0, 1, 0, 1, 2, 1]$ is $[4, 2, 4]$ and the only term with multiple occurrences here is 4.

Proof. We prove it by induction on K . For $K = 2$ it is easy to see, that in the type of the form (\heartsuit) , some $N - 2$ distances between i 's have multiple occurrences.

Let t be the type of composition of $K + 1$ rotations. We may assume that t is of the form (\diamond) , where (\triangle) is the type of the composition of K rotations. Assume that in (\triangle) there is M occurrences of i and in

$$s = (i_1, i_2, \dots, i_{n-1}, i_n, i_{n-1}, \dots, i_2, i_1)$$

we have N occurrences of i .

If $i_1 = 0$, then t has $N + M - 1$ occurrences of i and at least

$$(M - 2K + 2) + (N - 2) = N + M - 2K > (N + M - 1) - 2(K + 1) + 2$$

multiple occurrences in its i -sequence.

Assume that $i_1 \neq 0$. Now we have $N + M$ occurrences of i in t . When $N = 0$ (there is no i in s), the number of multiple occurrences may decrease at most by 2. Hence we still have $M - 2K + 2 - 2 = M - 2(K + 1) + 2$ multiple occurrences. If $N > 0$, then by an induction hypothesis, we have $N - 2 + M - 2K + 2 = N + M - 2(K + 1) + 2$ multiple occurrences. \square

Now, we show that α_{K+1} is not a composition of K or less than K rotations. We calculate $f(z)$ -sequence of $[t_{K+1}]$. There are $2K$ occurrences of 0 in t_{K+1} and one occurrence of $f(z)$ in 0. Since by the assumption 1 and 2 do not contain vertices of color $f(z)$, $[t_{K+1}]$ has $2K$ occurrences of $f(z)$. Considering 0 as a additional color, one can easily show that 0-sequence of $[t_{K+1}]$ is

$$(4K + 2, 4K - 2, \dots, 14, 10, 6, 8, 12, \dots, 4K - 4, 4K, 4).$$

There are no multiple occurrences here. Hence (because in 0 there is only one occurrence of $f(z)$) also in $f(z)$ -sequence of $[t_{K+1}]$ there will no multiple occurrences. Therefore, by the previous lemma, if α_{K+1} is a composition of R rotations, then $0 \geq 2K - 2R + 2$, so $R \geq K + 1$. This finishes the proof of the theorem. \square

We can derive from Theorem 3.6 that for many trees A , groups $\text{Aut}_f^+(A)$ are not boundedly simple. That is, after adding to an almost arbitrary tree A one new color k , such that for some old color j , $a(k, j) \geq 2$, we obtain a tree A' with non-boundedly simple group $\text{Aut}_f^+(A')$.

Corollary 3.8. *Assume that $(A, f: S(A) \rightarrow I)$ is a colored tree and $\text{Aut}_f^+(A)$ does not stabilize any vertex. Extend the code a of A by adding one new color $I' = I \cup \{k\}$ ($k \notin I$) to get a code $a' \supset a$ such that for every $i \in I$, $a'(i, k) = 0$ if and only if $a'(k, i) = 0$, and for some $j \in I$*

$$a'(k, j) \geq 2.$$

If $(A', f': S(A') \rightarrow I')$ is a tree corresponding to a' , then $\text{Aut}_{f'}^+(A')$ is not boundedly simple.

Proof. A' contains a subtree A corresponding to a . Let z be a vertex in A' of color k and let s be a vertex in A of color j adjacent to z . Since $\text{Aut}_f^+(A)$ does not stabilize any vertex, there is a translation in $\text{Aut}_f^+(A)$ along a double infinite path C in A . Let t be the projection of s onto C in the tree A . Applying Theorem 3.6 to z , s , t and C , we conclude that $\text{Aut}_{f'}^+(A')$ is not boundedly simple (because there is $\gamma \in \text{Aut}_{f'}^+(A')$, such that $\gamma(z) = z$ and $\gamma(s) \neq s$). \square

Now we characterize (in a large class) all colored trees $(A, f: S(A) \rightarrow I)$ with boundedly simple group $\text{Aut}_f^+(A)$.

Theorem 3.9. *Assume that $(A, f: S(A) \rightarrow I)$ is a colored tree and $\text{Aut}_f^+(A)$ leaves no nonempty proper subtree of A invariant. If $\text{Aut}_f^+(A)$ is boundedly simple (and non-trivial), then for some $n, m \geq 3$, A is almost (n, m) -regular tree, so $\text{Aut}_f^+(A)$ is 32-boundedly simple.*

Proof. As in the proof of Theorem 3.6, there is a normal function $f^+: S(A) \rightarrow I^+$ such that $\text{Aut}_f^+(A) = \text{Aut}_{f^+}(A)$. Let a^+ be the code for $(A, f^+: S(A) \rightarrow I^+)$.

Since $\text{Aut}_f^+(A)$ does not stabilize any vertex of A , there are rotations $\alpha, \beta \in \text{Aut}_f^+(A)$ such that $\alpha \circ \beta$ is a translation. Take such α and β with the shortest type of $\alpha \circ \beta$. Assume that $\alpha(x) = x$, $\beta(y) = y$ and our situation is like in Lemma 2.1. Let

$$P = (x = x_0, x_1, \dots, x_{k-1}, x_k = y)$$

be the shortest path in A from x to y . Consider colors of vertices of path P

$$f[S(P)] = (j_0, j_1, \dots, j_{k-1}, j_k).$$

Since $\alpha \circ \beta$ is a translation,

$$n = a^+(j_0, j_1), \quad m = a^+(j_k, j_{k-1}) \geq 2.$$

The minimality of P implies that

$$a^+(j_1, j_2) = \dots = a^+(j_{k-1}, j_k) = 1 \quad \text{and} \quad a^+(j_{k-1}, j_{k-2}) = \dots = a^+(j_1, j_0) = 1,$$

e.g. if $a^+(j_1, j_0) > 1$, then $j_1 = j_k$, and if $a^+(j_1, j_2) > 1$, then instead of x_0 we may consider x_1 .

We claim that for $s, t \in \{1, \dots, k-1\}$

$$(0) \quad j_s \neq j_t,$$

$$(1) \quad \text{if } |s - t| \neq 1, \text{ then } a^+(j_s, j_t) = 0,$$

$$(2) \quad \text{if } s \neq 1 \text{ and } t \neq k-1, \text{ then } a^+(j_0, j_s) = a^+(j_k, j_t) = a^+(j_0, j_k) = 0.$$

(0) and (1) follows from the minimality of P (otherwise we can shorten the path P). For (2) suppose, contrary to our claim, that $a^+(j_0, j_s) > 0$ (now $s \in \{2, \dots, k\}$). Then (by the minimality of P),

$$a^+(j_0, j_s) = 1.$$

Therefore, there is in $G(a^+)$ the path $(j_0, j_s, j_{s-1}, \dots, j_1, j_0)$. We may assume that $j_0 \notin \{j_1, \dots, j_s\}$. There is also a corresponding path

$$Q = (x_0, x'_s, x'_{s-1}, \dots, x'_1, x'_0)$$

in A , i.e. $f(x'_i) = j_i$. Since j_0, j_1, \dots, j_s are pairwise distinct, Q is the shortest path between x_0 and x'_0 . Vertices x_0 and x'_0 have the same color, so there is $\alpha \in \text{Aut}_f^+(A)$, with $\alpha(x_0) = x'_0$. α cannot be a rotation ($s \geq 2$ and j_0, j_1, \dots, j_s are pairwise distinct), so α is a translation and let t be its type. The length of t is ≥ 4 (because $s \geq 2$). On the other hand, the type of every translation from $\text{Aut}_f^+(A)$ is either of length 2 or of length ≥ 4 and then contains a multiple occurrence of some color (this follows from our analysis of types of translations). This proves (2).

We claim that

$$I^+ = \{j_0, j_1, \dots, j_{k-1}, j_k\}.$$

This follows from Theorem 3.6 and our assumption that $\text{Aut}_f^+(A)$ leaves no nonempty proper subtree of A invariant. That is, take $*$ in $I^+ \setminus \{j_0, j_1, \dots, j_{k-1}, j_k\}$, such that $*$ is adjacent in $G(a^+)$ to some j_s , $s \in \{0, \dots, k\}$. Then by Theorem 3.6, $a^+(*, j_s) = 1$. Therefore (e.g. by [5, Lemma 4.1]) the subtree A' of A , corresponding to the code $a^+_{\{j_0, \dots, j_k\}^2}$ is $\text{Aut}_f^+(A)$ -invariant, so $A' = A$.

Recall that $I^{+\text{ram}}$ is the set of ramification colors from I^+ . Clearly $I^{+\text{ram}} \neq \emptyset$. It cannot happen that $|I^{+\text{ram}}| = 1$. Otherwise, if e.g. $I^{+\text{ram}} = \{j_0\}$, then consider on the set of vertices of color j_0 , the following equivalence relation: $E(r, s)$ if and only if on the shortest path from r to s there is odd number of vertices of color j_0 . One can easily show that for every rotation $\alpha \in \text{Aut}_f^+(A)$ and $r \in S(A)$ with $f^+(r) = j_0$, $E(\alpha(r), r)$. Hence E is $\text{Aut}_f^+(A)$ -invariant. There is at least two vertices of color j_0 , thus for some such r and some $\beta \in \text{Aut}_f(A)$, $\neg E(r, \beta(r))$, which is impossible.

Therefore j_0 and j_k are ramification colors, so $n, m \geq 3$ and A is almost (n, m) -regular tree. \square

4. BOUNDEDLY SIMPLE ACTION ON TREES

In this section we extend our results to boundedly simple groups acting on trees.

For a group G acting on a tree A we may consider the following coloring function

$$f^G: S(A) \rightarrow \{\text{orbits of } G \text{ on } S(A)\}.$$

f^G is normal and $G < \text{Aut}_{f^G}(A)$. If G leaves no nonempty proper subtree nor an end of A invariant and G^+ is boundedly simple, then $\text{Aut}_{f^G}^+(A)$ is boundedly simple too.

Remark 4.1. Let $(A, f: S(A) \rightarrow I)$ be a colored tree and G be a simple subgroup of $\text{Aut}_f(A)$ which leaves no nonempty proper subtree nor an end of A invariant. If there is $e \neq g' \in G$ stabilizing some edge and a rotation $g \in G^+$ such that for some natural N

$$G = (g^G \cup g^{-1G})^{\leq N},$$

then $\text{Aut}_{f^G}^+(A)$ is $16(N+1)$ -boundedly simple.

Proof. G is simple and G^+ is a nontrivial ($e \neq g \in G^+$) and normal subgroup of G , so $G = G^+ < \text{Aut}_{f^G}^+(A)$. Take a ramification point $x \in S(A)$ and $\alpha \in \text{Aut}_{f^G}^+(A)$. There is $h \in G$ with

$$\alpha(x) = h(x).$$

Hence, for some rotation $\beta \in \text{Aut}_{fG}^+(A)$ fixing x ,

$$\alpha = \beta \circ h.$$

Thus α is a composition of $(N + 1)$ rotations from $\text{Aut}_{fG}^+(A)$ (h is a composition of N rotations). Since $G < \text{Aut}_{fG}(A)$, $\text{Aut}_{fG}(A)$ leaves no nonempty proper subtree nor an end of A invariant. Thus, by Proposition 3.1 and Remark 3.2, $\text{Aut}_{fG}^+(A)$ is $16(N + 1)$ -boundedly simple. \square

From the preceding remark we conclude a special form of bounded simplicity of $\text{Aut}_f^+(A)$. Namely, assume that $\text{Aut}_f^+(A)$ be non-trivial and leaves no nonempty proper subtree nor an end of A invariant, then $\text{Aut}_f^+(A)$ is boundedly simple if and only if for some natural N , there is a rotation $\alpha \in \text{Aut}_f^+(A)$ such that

$$\text{Aut}_f^+(A) = \left(\alpha^{\text{Aut}_f^+(A)} \cup \alpha^{-1\text{Aut}_f^+(A)} \right)^{\leq N}.$$

We can now apply previous remark and Theorem 3.9, to get

Corollary 4.2. *Suppose that a (nontrivial) simple group G acts faithfully on a colored tree $(A, f: S(A) \rightarrow I)$, there is $g' \in G$ stabilizing some edge and a rotation $g \in G^+$ such that for some natural N , $G = (g^G \cup g^{-1G})^{\leq N}$. Then*

- (1) *if G leaves no nonempty proper subtree nor an end of A invariant, then A is an almost bi-regular tree and G is a subgroup of $\text{Aut}^+(A_{n,m})$, for some $n, m \geq 3$,*
- (2) *if A is not almost bi-regular, then G leaves invariant some nonempty proper subtree of A .*
