# Abstract

We build on the formulation developed in Sridhar & Singh  $(JFM, 664, 265, 2010)$ , and present a theory of the shear dynamo problem for small magnetic and fluid Reynolds numbers, but for arbitrary values of the shear parameter. Specializing to the case of a mean magnetic field that is slowly varying in time, explicit expressions for the transport coefficients,  $\alpha_{il}$  and  $\eta_{iml}$ , are derived. We prove that, when the velocity field is non helical, the transport coefficient  $\alpha_{il}$  vanishes. We then consider forced, stochastic dynamics for the incompressible velocity field at low Reynolds number. An exact, explicit solution for the velocity field is derived, and the velocity spectrum tensor is calculated in terms of the Galilean–invariant forcing statistics. We consider forcing statistics that is non helical, isotropic and delta–correlated–in–time, and specialize to the case when the mean– field is a function only of the spatial coordinate  $X_3$  and time  $\tau$ ; this reduction is necessary for comparison with the numerical experiments of Brandenburg, Rädler, Rheinhardt & Käpylä  $(A \iota J, A \iota J, A \iota J)$ 676, 740, 2008). Explicit expressions are derived for all four components of the magnetic diffusivity tensor,  $\eta_{ij}(\tau)$ . These are used to prove that the shear-current effect cannot be responsible for dynamo action at small Re and Rm, but for all values of the shear parameter.

#### I. INTRODUCTION

Astrophysical systems like planets, galaxies and clusters of galaxies possess magnetic fields which exhibit definite spatial ordering, in addition to a random component. The ordered (or "large–scale") components are thought to originate from turbulent dynamo action in the electrically conducting fluids in these objects. The standard model of such a process involves amplification of seed magnetic fields due to turbulent flows which lack mirror– symmetry (equivalently, which possess helicity) [\[1](#page-25-0)[–3](#page-25-1)]. The turbulent flows generally possess large–scale shear, which is expected to have significant effects on transport properties [\[4\]](#page-25-2); however, it is not clear whether the turbulent flows are always helical. Recent work has explored the possiblity that non–helical turbulence in conjunction with background shear may give rise to large–scale dynamo action [\[5](#page-25-3)[–10\]](#page-26-0). The evidence for this comes mainly from direct numerical simulations [\[5](#page-25-3)[–7\]](#page-26-1), but it by no means clear what physics drives such a dynamo. One possibility that has received some attention is the shear–current effect [\[10\]](#page-26-0), where an extra component of the mean electromotive force (EMF) is thought to result in the generation of the cross–shear component of the mean magnetic field from the component parallel to the shear flow. However, there is no agreement yet whether the sign of such a coupling is favorable to the operation of a dynamo; some analytic calculations [\[11](#page-26-2), [12](#page-26-3)] and numerical experiments [\[5](#page-25-3)] find that the sign of the shear–current term is unfavorable for dynamo action.

A quasilinear kinematic theory of dynamo action in a linear shear flow of an incompressible fluid which has random velocity fluctuations was presented in [\[13\]](#page-26-4), who used the "second order correlation approximation" (SOCA) in the limit of zero resistivity. Unlike earlier analytic work which treated shear as a small perturbation, this theory did not place any restriction on the strength of the shear. They arrived at an integro–differential equation for the evolution of the mean magnetic field and argued that the shear-current assisted dynamo is essentially absent. The theory was extended to take account of non zero resistivity in [\[14](#page-26-5)]; this is again nonperturbative in the shear strength, uses SOCA, and is rigorously valid in the limit of small magnetic Reynolds number (Rm) but with no restriction on the fluid Reynolds number  $(Re)$ . The kinematic approach to the *shear dynamo problem* taken in [\[13,](#page-26-4) [14](#page-26-5)] uses in an essential manner the shearing coordinate transformation and the Galilean invariance (which is a fundamental symmetry of the problem) of the velocity fluctuations.

The present work extends [\[14\]](#page-26-5) by giving definite form to the statistics of the velocity field; specifically, the velocity field is assumed to obey the forced Navier–Stokes equation, in the absence of Lorentz forces.

In section II we begin with a brief review of the salient results of [\[14](#page-26-5)]. The expression for the Galilean–invariant mean EMF is then worked out for the case of a mean magnetic field that is slowly varying in time. Thus the mean–field induction equation, which is an integro–differential equaton in the formulation of [\[14\]](#page-26-5) now simplifies to a partial differential equation. This reduction is an essential first step to the later comparision with the numerical experiments of [\[5\]](#page-25-3). Explicit expressions for the transport coefficients,  $\alpha_{il}$  and  $\eta_{iml}$ , are derived in terms of the two–point velocity correlators. We then recall some results from [\[14](#page-26-5)], which express the velocity correlators in terms of the velocity spectrum tensor. This tensorial quantity is real when the velocity field is non helical; we are able to prove that, in this case, the transport coefficient  $\alpha_{il}$  vanishes. Section III develops the dynamics of the velocity field at low Re, using the Navier–Stokes equation with stochastic external forcing. An explicit solution for the velocity field is presented and the velocity spectrum tensor is calculated in terms of the Galilean–invariant forcing statistics. For non helical forcing, the velocity field is also non helical and the transport coefficient  $\alpha_{il}$  vanishes, as noted above. We then specialize to the case when the forcing is not only non helical, but isotropic and delta–correlated–in– time as well. In section IV we specialize to the case when the mean–field is a function only of the spatial coordinate  $X_3$  and time  $\tau$ ; this reduction is necessary for comparision with the numerical experiments of [\[5](#page-25-3)]. Explicit expressions are derived for all four components of the magnetic diffusivity tensor,  $\eta_{ij}(\tau)$ , in terms of the velocity power spectrum; the late–time saturation values,  $\eta_{ij}^{\infty}$ , have direct bearing on the growth (or otherwise) of the mean magnetic field. Comparisons with earlier work—in particular [\[5\]](#page-25-3)—are made, and the implications for the shear–current effect are discussed. We then conclude in section V.

## II. MEAN–FIELD ELECTRODYNAMICS IN A LINEAR SHEAR FLOW

# A. Mean–field induction equation for small Rm

We begin with a brief review of the main results of [\[14\]](#page-26-5). Let  $(e_1, e_2, e_3)$  be the unit basis vectors of a Cartesian coordinate system in the laboratory frame. Using notation,  $\mathbf{X} = (X_1, X_2, X_3)$  for the position vector and  $\tau$  for time, we write the fluid velocity as  $(SX_1e_2 + v)$ , where S is the rate of shear parameter and  $v(X, \tau)$  is an incompressible and randomly fluctuating velocity field with zero mean. The mean magnetic field,  $B(X, \tau)$ , obeys the following (mean–field induction) equation:

<span id="page-3-1"></span>
$$
\left(\frac{\partial}{\partial \tau} + SX_1 \frac{\partial}{\partial X_2}\right) \boldsymbol{B} - SB_1 \boldsymbol{e}_2 = \boldsymbol{\nabla} \times \boldsymbol{\mathcal{E}} + \eta \boldsymbol{\nabla}^2 \boldsymbol{B}
$$
 (1)

where  $\eta$  is the microscopic resistivity, and  $\mathcal E$  is the mean electromotive force (EMF),  $\mathcal E$  =  $\langle v \times b \rangle$ , where v and b are the fluctuations in the velocity and magnetic fields.

To lowest order in Rm, the evolution of the magnetic field fluctuations, now denoted by  $\bm{b}^{(0)}$ , is governed by,

<span id="page-3-0"></span>
$$
\left(\frac{\partial}{\partial \tau} + SX_1 \frac{\partial}{\partial X_2}\right) \boldsymbol{b}^{(0)} - Sb_1^{(0)} \boldsymbol{e}_2 = (\boldsymbol{B} \cdot \boldsymbol{\nabla}) \boldsymbol{v} - (\boldsymbol{v} \cdot \boldsymbol{\nabla}) \boldsymbol{B} + \eta \boldsymbol{\nabla}^2 \boldsymbol{b}^{(0)} \qquad (2)
$$

This equation was solved by making a shearing–coordinate transformation to new spacetime coordinates and new field variables. The new spacetime variables,  $(x, t)$ , are given by,

$$
x_1 = X_1
$$
,  $x_2 = X_2 - S\tau X_1$ ,  $x_3 = X_3$ ,  $t = \tau$ , (3)

where  $x$  may be thought of as the Lagrangian coordinates of a fluid element in the background shear flow. The new field variables are component–wise equal to the old variables:

$$
H(x,t) = B(X,\tau), \qquad h(x,t) = b^{(0)}(X,\tau), \qquad u(x,t) = v(X,\tau) \qquad (4)
$$

In the new variables, equation [\(2\)](#page-3-0) becomes,

$$
\frac{\partial \mathbf{h}}{\partial t} - Sh_1 \mathbf{e}_2 = \left( \mathbf{H} \cdot \frac{\partial}{\partial x} - St H_1 \frac{\partial}{\partial x_2} \right) \mathbf{u} - \left( \mathbf{u} \cdot \frac{\partial}{\partial x} - St u_1 \frac{\partial}{\partial x_2} \right) \mathbf{H} + \eta \nabla^2 \mathbf{h} \tag{5}
$$

We need the particular solution (i.e. the *forced solution*) which vanishes at  $t = 0$ . This is given in component form as,

<span id="page-4-0"></span>
$$
h_m(\boldsymbol{x},t) = \int_0^t dt' \int d^3x' G_\eta(\boldsymbol{x}-\boldsymbol{x}',t,t') \left[ u'_{ml} + S(t-t') \delta_{m2} u'_{1l} \right] \times
$$
  
 
$$
\times \left[ H'_l - St' \delta_{l2} H'_1 \right]
$$
  
- 
$$
\int_0^t dt' \int d^3x' G_\eta(\boldsymbol{x}-\boldsymbol{x}',t,t') \left[ H'_{ml} + S(t-t') \delta_{m2} H'_{1l} \right] \times
$$
  

$$
\times \left[ u'_l - St' \delta_{l2} u'_1 \right]
$$
 (6)

The primes in  $H'_l$  and  $u'_l$  mean that these functions are evaluated at  $(\mathbf{x}', t')$ . The quantities  $H'_{ml}$  and  $u'_{ml}$  are shorthand for  $(\partial H'_{m}/\partial x'_{l})$  and  $(\partial u'_{m}/\partial x'_{l})$ , respectively. Here  $G_{\eta}(\mathbf{r},t,t')$  is the resistive Green's function for the linear shear flow [\[14,](#page-26-5) [15\]](#page-26-6), which takes the form of a sheared heat kernel. The one property we will use is that  $G_{\eta}(r, t, t')$  is an even function of r. Otherwise, its spatial Fourier transform, defined by

<span id="page-4-1"></span>
$$
\widetilde{G}_{\eta}(\boldsymbol{k},t,t') = \int d^3r \, G_{\eta}(\boldsymbol{r},t,t') \, \exp\left[-i\,\boldsymbol{k}\cdot\boldsymbol{r}\right] \n= \exp\left[-\eta \left(k^2(t-t') - S\,k_1\,k_2(t^2-t'^2) + \frac{S^2}{3}\,k_2^2(t^3-t'^3)\right)\right]
$$
\n(7)

is more useful for our purposes.

The mean EMF is given by  $\mathcal{E} = \langle v \times b^{(0)} \rangle = \langle u \times h \rangle$ , where equation [\(6\)](#page-4-0) for h should be substituted. The averaging,  $\langle \rangle$ , acts only on the velocity variables but not the mean field; i.e.  $\langle uuH \rangle = \langle uu \rangle H$  etc. The uu velocity correlators can be rewritten in terms of the  $vv$  velocity correlators; this is a useful step because the latter are referred to the laboratory frame. The velocity correlators have a very important property called Galilean invariance, which is shared by *comoving observers*, who translate uniformly with the background shear flow. If a comoving observer is at position  $\boldsymbol{\xi} = (\xi_1, \xi_2, \xi_3)$  at the initial time, then at a later time  $t$ , her location is given by,

$$
\mathbf{X}_c(\xi, t) = (\xi_1, \xi_2 + St \xi_1, \xi_3) \tag{8}
$$

Velocity fluctuations are defined to be Galilean–invariant, if and only if the statistical properties of the fluctuations, as seen by any comoving observer, are identical to the statistical

properties seen in the laboratory frame; it follows that all comoving observers see the same statistics. There are two basic Galilean–invariant two–point velocity correlation functions,  $Q_{jml}$  and  $R_{jm}$ , which are defined as:

<span id="page-5-0"></span>
$$
Q_{jml}(\boldsymbol{r},t,t') = \left\langle v_j \left( \boldsymbol{X}_c \left( \frac{\boldsymbol{r}}{2},t \right),t \right) \frac{\partial v_m}{\partial X_l} \left( \boldsymbol{X}_c \left( -\frac{\boldsymbol{r}}{2},t' \right),t' \right) \right\rangle
$$
  

$$
R_{jm}(\boldsymbol{r},t,t') = \left\langle v_j \left( \boldsymbol{X}_c \left( \frac{\boldsymbol{r}}{2},t \right),t \right) v_m \left( \boldsymbol{X}_c \left( -\frac{\boldsymbol{r}}{2},t' \right),t' \right) \right\rangle
$$
(9)

Then the mean EMF is a *functional* of the mean magnetic field,  $H_l$ , and its first spatial derivative,  $H_{lm} = (\partial H_l / \partial x_m)$ :

<span id="page-5-2"></span>
$$
\mathcal{E}_i(\boldsymbol{x},t) = \epsilon_{ijm} \int_0^t dt' \int d^3r \ G_\eta(\boldsymbol{r},t,t') \ C_{jml}(\boldsymbol{r},t,t') H_l(\boldsymbol{x}-\boldsymbol{r},t') - \int_0^t dt' \int d^3r \ G_\eta(\boldsymbol{r},t,t') \ [\epsilon_{ijl} + S(t-t')\delta_{l1}\epsilon_{ij2}] \ D_{jm}(\boldsymbol{r},t,t') H_{lm}(\boldsymbol{x}-\boldsymbol{r},t') \ .
$$
\n(10)

where  $C_{jml}$  and  $D_{jm}$  are two–point velocity correlators, which are derived from the more basic two–point velocity correlators,  $Q_{jml}$  and  $R_{jm}$ , of equations [\(9\)](#page-5-0):

$$
C_{jml}(\mathbf{r},t,t') = Q_{jml}(\mathbf{r},t,t') + S(t-t')\delta_{m2} Q_{j1l}(\mathbf{r},t,t'),
$$
  

$$
D_{jm}(\mathbf{r},t,t') = R_{jm}(\mathbf{r},t,t') - St'\delta_{m2} R_{j1}(\mathbf{r},t,t').
$$
 (11)

Then the time evolution of the mean magnetic field is given in the new variables by,

<span id="page-5-1"></span>
$$
\frac{\partial \mathbf{H}}{\partial t} - SH_1 \mathbf{e}_2 = \nabla \times \mathbf{\mathcal{E}} + \eta \nabla^2 \mathbf{H},
$$
  

$$
(\nabla)_p \equiv \frac{\partial}{\partial X_p} = \frac{\partial}{\partial x_p} - St \delta_{p1} \frac{\partial}{\partial x_2},
$$
 (12)

Equations [\(12\)](#page-5-1) and [\(10\)](#page-5-2) form a closed system of integro–differential equations, determining the time evolution of the mean magnetic field,  $\boldsymbol{H}(\boldsymbol{x}, t)$ .

#### B. The mean EMF for a slowly varying magnetic field

The mean EMF given in equation [\(10\)](#page-5-2) is a functional of  $H_l$  and  $H_{lm}$ . When the mean–field is slowly varying compared to velocity correlation times, we expect to be able to approximate  $\mathcal E$  as a function of  $H_l$  and  $H_{lm}$ . In this case, the mean–field induction equation would reduce to a set of coupled partial differential equations, instead of the more formidable set of coupled integro–differential equations given by [\(12\)](#page-5-1) and [\(10\)](#page-5-2). Sheared coordinates are essential for the calculations, but physical interpretation is simplest in the laboratory frame; hence we derive an expression for the mean EMF in terms of  $B(X, \tau)$ .

The first step involves a Taylor expansion of the quantitites,  $H_l$  and  $H_{lm}$ , occuring in equation [\(10\)](#page-5-2) for the mean EMF. Neglecting spacetime derivatives higher than the first order ones, we have

<span id="page-6-0"></span>
$$
H_l(\boldsymbol{x} - \boldsymbol{r}, t') = H_l(\boldsymbol{x}, t) - r_p H_{lp}(\boldsymbol{x}, t) - (t - t') \frac{\partial H_l(\boldsymbol{x}, t)}{\partial t} + \dots
$$
  

$$
H_{lm}(\boldsymbol{x} - \boldsymbol{r}, t') = H_{lm}(\boldsymbol{x}, t) - (t - t') \frac{\partial H_{lm}(\boldsymbol{x}, t)}{\partial t} + \dots
$$
 (13)

We now use the mean–field induction equation [\(12\)](#page-5-1), to express  $(\partial H/\partial t)$  in terms of spatial derivatives. Let  $L$  be the spatial scale over which the mean-field varies. When the meanfield varies slowly, L is large and the contributions from both the resistive term and the mean EMF are small, as is shown below. Let  $\ell$  and  $v_{\rm rms}$  be the spatial scale and root–mean– squared amplitude of the velocity fluctuations. The resistive term makes a contribution of order  $(\ell/L)^2 \text{Rm}^{-1}$ , which we now assume is much less than unity. Using equation [\(10\)](#page-5-2), we can verify that  $\nabla \times \mathcal{E}$  contributes terms of five different orders;  $(\ell/L)$ ,  $(\ell/L)(S\ell/v_{\rm rms})$ ,  $(\ell/L)^2$ ,  $(\ell/L)^2(S\ell/v_{\rm rms})$  and  $(\ell/L)^2(S\ell/v_{\rm rms})^2$ . These are all small when  $(\ell/L)$  and  $(\ell/L)(S\ell/v_{\rm rms})$ are both much smaller than unity. That we must have  $(\ell/L) \ll 1$  is natural from the familiar case of zero shear. The presence of shear introduces an additional requirement that  $(\ell/L)(S\ell/v_{\rm rms}) \ll 1$ . We now define the small parameter,  $\mu \ll 1$ , to be equal to the largest of the three small quantities,  $(\ell/L)^2 \text{Rm}^{-1} \ll 1$ ,  $(\ell/L) \ll 1$  and  $(\ell/L)(S\ell/v_{\text{rms}}) \ll 1$ . Then,

$$
\frac{\partial H_l}{\partial t} = S \delta_{l2} H_1 + O(\mu) \tag{14}
$$

and equations [\(13\)](#page-6-0) give,

<span id="page-7-0"></span>
$$
H_l(\boldsymbol{x} - \boldsymbol{r}, t') = H_l(\boldsymbol{x}, t) - r_p H_{lp}(\boldsymbol{x}, t) - S(t - t') \delta_{l2} H_1 + O(\mu)
$$
  

$$
H_{lm}(\boldsymbol{x} - \boldsymbol{r}, t') = H_{lm}(\boldsymbol{x}, t) - S(t - t') \delta_{l2} H_{1m} + O(\mu)
$$
(15)

We substitute equation [\(15\)](#page-7-0) in [\(10\)](#page-5-2) to get,

$$
\mathcal{E}_i(\boldsymbol{x},t) = \epsilon_{ijm} H_l(\boldsymbol{x},t) \int_0^t dt' \int d^3r \, G_\eta(\boldsymbol{r},t,t') \, [C_{jml}(\boldsymbol{r},t,t') - S(t-t') \, \delta_{l1} \, C_{jml}(\boldsymbol{r},t,t')]
$$

$$
- \epsilon_{ijm} H_{lp}(\boldsymbol{x},t) \int_0^t dt' \int d^3r \, r_p \, G_\eta(\boldsymbol{r},t,t') \, C_{jml}(\boldsymbol{r},t,t')
$$

$$
- \epsilon_{ijl} H_{lm}(\boldsymbol{x},t) \int_0^t dt' \int d^3r \, G_\eta(\boldsymbol{r},t,t') \, D_{jm}(\boldsymbol{r},t,t') + O(\mu^2) \tag{16}
$$

The final step is to rewrite the above expression in terms of the original magnetic field variable, using,

$$
H_l(\boldsymbol{x},t) = B_l(\boldsymbol{X},\tau)
$$
  

$$
H_{lm}(\boldsymbol{x},t) \equiv \frac{\partial H_l(\boldsymbol{x},t)}{\partial x_m} = \left(\frac{\partial}{\partial X_m} + S\tau \delta_{m1} \frac{\partial}{\partial X_2}\right) B_l(\boldsymbol{X},\tau)
$$
(17)

Therefore, for a slowly varying magnetic field, the mean EMF is given by,

<span id="page-7-1"></span>
$$
\mathcal{E}_i = \alpha_{il}(\tau) B_l(\mathbf{X}, \tau) - \eta_{iml}(\tau) \frac{\partial B_l(\mathbf{X}, \tau)}{\partial X_m}
$$
(18)

where the *transport coefficients* are given by,

<span id="page-7-2"></span>
$$
\alpha_{il}(\tau) = \epsilon_{ijm} \int_0^{\tau} d\tau' \int d^3r \, G_{\eta}(\mathbf{r}, \tau, \tau') \left[ C_{jml}(\mathbf{r}, \tau, \tau') - S(\tau - \tau') \, \delta_{l1} \, C_{jm2}(\mathbf{r}, \tau, \tau') \right]
$$
\n
$$
\eta_{iml}(\tau) = \epsilon_{ijp} \int_0^{\tau} d\tau' \int d^3r \left[ r_m + S\tau \delta_{m2} r_1 \right] G_{\eta}(\mathbf{r}, \tau, \tau') \, C_{jpl}(\mathbf{r}, \tau, \tau') +
$$
\n
$$
+ \epsilon_{ijl} \int_0^{\tau} d\tau' \int d^3r \, G_{\eta}(\mathbf{r}, \tau, \tau') \left[ D_{jm}(\mathbf{r}, \tau, \tau') + S\tau \delta_{m2} D_{j1}(\mathbf{r}, \tau, \tau') \right] \tag{19}
$$
\non the mean field induction equation (1), together with equations (18), and (10), is a

Then the mean–field induction equation [\(1\)](#page-3-1), together with equations [\(18\)](#page-7-1) and [\(19\)](#page-7-2), is a closed partial differential equation (which is first order in temporal and second order in spatial derivatives).

### C. Velocity correlators expressed in terms of the velocity spectrum tensor

The Galilean invariance of the two–point velocity correlators can be stated most compactly in Fourier–space. Let  $\tilde{\boldsymbol{v}}(\boldsymbol{K}, \tau)$  be the spatial Fourier transform of  $\boldsymbol{v}(\boldsymbol{X}, \tau)$ , defined by

$$
\tilde{\boldsymbol{v}}(\boldsymbol{K},\tau) = \int d^3 X \, \boldsymbol{v}(\boldsymbol{X},\tau) \, \exp\left[-i \boldsymbol{K} \cdot \boldsymbol{X}\right]; \qquad [\boldsymbol{K} \cdot \tilde{\boldsymbol{v}}(\boldsymbol{K},\tau)] = 0 \qquad (20)
$$

New Fourier variables are defined by the Fourier–space shearing transformation,

<span id="page-8-1"></span>
$$
k_1 = K_1 + S\tau K_2, \qquad k_2 = K_2, \qquad k_3 = K_3, \qquad t = \tau \tag{21}
$$

It is proved in [\[14](#page-26-5)] that a Galilean–invariant Fourier–space two–point velocity correlator must be of the form

<span id="page-8-2"></span>
$$
\langle \tilde{v}_j(\boldsymbol{K},\tau) \tilde{v}_m^*(\boldsymbol{K}',\tau') \rangle = (2\pi)^6 \delta(\boldsymbol{k}-\boldsymbol{k}') \Pi_{jm}(\boldsymbol{k},t,t')
$$
(22)

where  $\Pi_{jm}$  is the *velocity spectrum tensor*, which must possess the following properties:

<span id="page-8-0"></span>
$$
\Pi_{ij}(\mathbf{k},t,t') = \Pi_{ij}^*(-\mathbf{k},t,t') = \Pi_{ji}(-\mathbf{k},t',t)
$$
\n
$$
K_i \Pi_{ij}(\mathbf{k},t,t') = (k_i - St \,\delta_{i1} k_2) \Pi_{ij}(\mathbf{k},t,t') = 0
$$
\n
$$
K'_j \Pi_{ij}(\mathbf{k},t,t') = (k_j - St' \,\delta_{j1} k_2) \Pi_{ij}(\mathbf{k},t,t') = 0
$$
\n(23)

Now, the various two–point velocity correlators can be written as:

<span id="page-8-3"></span>
$$
R_{jm}(\boldsymbol{r},t,t') = \int d^3k \Pi_{jm}(\boldsymbol{k},t,t') \exp[i\boldsymbol{k}\cdot\boldsymbol{r}]
$$
  
\n
$$
Q_{jml}(\boldsymbol{r},t,t') = -i \int d^3k [k_l - St'\delta_{l1}k_2] \Pi_{jm}(\boldsymbol{k},t,t') \exp[i\boldsymbol{k}\cdot\boldsymbol{r}]
$$
  
\n
$$
D_{jm}(\boldsymbol{r},t,t') = \int d^3k [\Pi_{jm}(\boldsymbol{k},t,t') - St'\delta_{m2} \Pi_{j1}(\boldsymbol{k},t,t')] \exp[i\boldsymbol{k}\cdot\boldsymbol{r}]
$$
  
\n
$$
C_{jml}(\boldsymbol{r},t,t') = -i \int d^3k [k_l - St'\delta_{l1}k_2] [\Pi_{jm}(\boldsymbol{k},t,t') + S(t-t')\delta_{m2} \Pi_{j1}(\boldsymbol{k},t,t')] \exp[i\boldsymbol{k}\cdot\boldsymbol{r}]
$$
\n(24)

Using the above expressions for  $D_{jm}$  and  $C_{jml}$  in equations [\(19\)](#page-7-2), the transport coefficients  $\alpha_{il}(\tau)$  and  $\eta_{iml}(\tau)$  can also be written in terms of the velocity spectrum tensor.

The *correlation helicity* may be defined as.

$$
H_{\text{cor}}(t,t') = \epsilon_{jlm} \langle v_j(\mathbf{0},t) v_{ml}(\mathbf{0},t') \rangle = \mathbf{i} \int \mathrm{d}^3 k \, [k_l - St' \delta_{l1} k_2] \, \epsilon_{ljm} \Pi_{jm}(\mathbf{k},t,t') \qquad (25)
$$

From the first of equations [\(23\)](#page-8-0), it is clear that the real part of  $\Pi_{jm}(\mathbf{k}, t, t')$  is an even function of  $k$ , whereas the imaginary part is an odd function of  $k$ . Hence only the imaginary part of  $\Pi_{jm}(\mathbf{k}, t, t')$  contributes to the correlation helicity. We shall see that the forced velocity fields we deal with later in this article possess a real velocity spectrum, and their correlation helicity vanishes. In this case,

$$
Q_{jml}(\boldsymbol{r},t,t') = \int d^3k \left[ k_l - St' \delta_{l1} k_2 \right] \Pi_{jm}(\boldsymbol{k},t,t') \sin[\boldsymbol{k}\cdot\boldsymbol{r}]
$$
  

$$
C_{jml}(\boldsymbol{r},t,t') = \int d^3k \left[ k_l - St' \delta_{l1} k_2 \right] \left[ \Pi_{jm}(\boldsymbol{k},t,t') + S(t-t') \delta_{m2} \Pi_{j1}(\boldsymbol{k},t,t') \right] \sin[\boldsymbol{k}\cdot\boldsymbol{r}]
$$
 (26)

are both odd functions of r. Since the resistive Green's function,  $G_{\eta}(r, t, t')$ , is an even function of r, equation [\(19\)](#page-7-2) implies that the transport coefficient  $\alpha_{il}(\tau)$  vanishes.

#### III. FORCED STOCHASTIC VELOCITY DYNAMICS

#### A. Forced velocity dynamics for small Re

We consider the simplest of dynamics for the velocity field by ignoring Lorentz forces, and assuming that the fluid is stirred randomly by some external means. If the velocity fluctuations have root–mean–squared (rms) amplitude  $v_{\rm rms}$  on some typical spatial scale  $\ell$ , the fluid Reynolds number may be defined as  $\text{Re} = (v_{\text{rms}}\ell/\nu)$ , where  $\nu$  is the kinematic viscosity; note that Re has been defined with respect to the fluctuation velocity field, not the background shear velocity field. In the limit of small Reynolds number (Re  $\ll 1$ ), the nonlinear term in the Navier–Stokes equation may be ignored. Then the dynamics of the velocity field,  $v(X, \tau)$ , is governed by the randomly forced, linearized Navier–Stokes equation,

<span id="page-10-0"></span>
$$
\left(\frac{\partial}{\partial \tau} + SX_1 \frac{\partial}{\partial X_2}\right) \boldsymbol{v} + Sv_1 \boldsymbol{e}_2 = -\boldsymbol{\nabla} p + \nu \nabla^2 \boldsymbol{v} + \boldsymbol{f} \tag{27}
$$

 $f(X, \tau)$  is the random stirring force per unit mass which is assumed to be divergence–free with zero mean:  $\nabla \cdot \mathbf{f} = 0$  and  $\langle \mathbf{f} \rangle = 0$ . The pressure variable, p, is determined by requiring that equation [\(27\)](#page-10-0) preserves the condition,  $\nabla \cdot \mathbf{v} = 0$ . Then p satisfies the Poisson equation,

<span id="page-10-1"></span>
$$
\nabla^2 p = -2S \frac{\partial v_1}{\partial X_2} \tag{28}
$$

It should be noted that the linearity of the equations [\(27\)](#page-10-0) and [\(28\)](#page-10-1) implies that the velocity fluctuations have zero mean,  $\langle v \rangle = 0$ . It is clear from equation [\(28\)](#page-10-1) that p is a non local function of the velocity field, so it is best to work in Fourier–space. Taking the spatial Fourier transform of equation [\(27\)](#page-10-0), we can see that the Fourier transform of the velocity field,  $\tilde{v}(\boldsymbol{K}, \tau)$ , obeys,

<span id="page-10-2"></span>
$$
\left(\frac{\partial}{\partial \tau} - SK_2 \frac{\partial}{\partial K_1} + \nu K^2\right) \tilde{v}_i - 2S\left(\frac{K_2 K_i}{K^2} - \frac{\delta_{i2}}{2}\right) \tilde{v}_1 = \tilde{f}_i \tag{29}
$$

where  $\tilde{f}_i(\mathbf{K}, \tau)$  is the spatial Fourier transform of  $f_i$ . It can be verified that the equation [\(29\)](#page-10-2) preserves the incompressibility condition  $K_m\tilde{v}_m = 0$ .

We can get rid of the inhomogeneous term,  $(K_2\partial/\partial K_1)$ , in equation [\(29\)](#page-10-2) by transforming from the old variables  $(K, \tau)$  to new variables  $(k, t)$ , through the Fourier–space shearing transformation of equation [\(21\)](#page-8-1). First, we need to define new velocity and forcing variables,  $a_i(\mathbf{k}, t)$  and  $q_i(\mathbf{k}, t)$ , respectively, by

<span id="page-10-3"></span>
$$
\tilde{v}_i(\mathbf{K}, \tau) = \tilde{G}_{\nu}(\mathbf{k}, t, 0) a_i(\mathbf{k}, t)
$$
\n(30)

<span id="page-10-4"></span>
$$
\tilde{f}_i(\boldsymbol{K},\tau) = \tilde{G}_{\nu}(\boldsymbol{k},t,0) g_i(\boldsymbol{k},t) \tag{31}
$$

where  $\widetilde{G}_{\nu}(\mathbf{k}, t, 0)$  is the Fourier–space viscous Green's function, defined by

$$
\widetilde{G}_{\nu}(\boldsymbol{k},t,t') = \exp\left[-\nu \int_{t'}^{t} ds K^2(\boldsymbol{k},s)\right]
$$
\n(32)

Noting the fact that  $\mathbf{K}(\mathbf{k},s) = (k_1 - Ssk_2, k_2, k_3)$  and  $K^2(\mathbf{k},s) = |\mathbf{K}(\mathbf{k},s)|^2$ , the viscous Green's function can be calculated in explicit form as

$$
\widetilde{G}_{\nu}(\mathbf{k},t,t') = \exp\left[-\nu\left(k^2(t-t') - Sk_1k_2(t^2-t'^2) + \frac{S^2}{3}k_2^2(t^3-t'^3)\right)\right] \tag{33}
$$

The Green's function possesses the following properties:

$$
\widetilde{G}_{\nu}(\mathbf{k},t,t') = \widetilde{G}_{\nu}(-\mathbf{k},t,t')
$$
\n
$$
\widetilde{G}_{\nu}(k_1,k_2,k_3,t,t') = \widetilde{G}_{\nu}(k_1,k_2,-k_3,t,t')
$$
\n
$$
\widetilde{G}_{\nu}(\mathbf{k},t,t') = \widetilde{G}_{\nu}(\mathbf{k},t,s) \times \widetilde{G}_{\nu}(\mathbf{k},s,t'), \qquad \text{for any s}
$$
\n(34)

Using the inverse transformation,

<span id="page-11-0"></span>
$$
K_1 = k_1 - Stk_2, \qquad K_2 = k_2, \qquad K_3 = k_3, \qquad \tau = t \tag{35}
$$

and the fact that partial derivatives transform as,

$$
\frac{\partial}{\partial K_j} = \frac{\partial}{\partial k_j} + St \delta_{j2} \frac{\partial}{\partial k_1}; \qquad \frac{\partial}{\partial \tau} = \frac{\partial}{\partial t} + Sk_2 \frac{\partial}{\partial k_1}
$$
(36)

equation [\(29\)](#page-10-2) leads to the following equation for the new velocity variables,  $a_i(\mathbf{k}, t)$ :

<span id="page-11-1"></span>
$$
\frac{\partial a_i}{\partial t} - 2S\left(\frac{K_2 K_i}{K^2} - \frac{\delta_{i2}}{2}\right) a_1 = g_i \tag{37}
$$

where  $\mathbf{K}(\mathbf{k},t) = (k_1 - Stk_2, k_2, k_3)$  and  $K^2(\mathbf{k},t) = |\mathbf{K}(\mathbf{k},t)|^2$  as given by equation [\(35\)](#page-11-0). It can be verified that equation [\(37\)](#page-11-1) preserves the dot product,  $K_i a_i = 0$ . We also note that the dependence of the velocities,  $\tilde{v}_i(K, \tau)$  on the viscosity  $\nu$  arises solely through the Fourier–space Green's function. It is helpful to display in explicit form all three components of equation [\(37\)](#page-11-1):

<span id="page-11-2"></span>
$$
\frac{\partial a_1}{\partial t} - 2S\left(\frac{K_1 K_2}{K^2}\right) a_1 = g_1 \tag{38}
$$

$$
\frac{\partial a_2}{\partial t} - 2S\left(\frac{K_2^2}{K^2} - \frac{1}{2}\right) a_1 = g_2 \tag{39}
$$

$$
\frac{\partial a_3}{\partial t} - 2S\left(\frac{K_2 K_3}{K^2}\right) a_1 = g_3 \tag{40}
$$

Then equation [\(38\)](#page-11-2) can be solved to get an explicit expression for  $a_1(\mathbf{k}, t)$ . When this is substituted in equations [\(39\)](#page-11-2) and [\(40\)](#page-11-2), they can be integrated directly to obtain expressions for  $a_2(\mathbf{k}, t)$  and  $a_3(\mathbf{k}, t)$ . The forced (or particular) solution, with initial condition  $a_i(\mathbf{k}, 0)$  =  $0$  is

<span id="page-12-0"></span>
$$
a_i(\mathbf{k},t) = \int_0^t ds\, g_i(\mathbf{k},s) + \int_0^t ds\, \left[ \Lambda_i(\mathbf{K}(\mathbf{k},t)) - \Lambda_i(\mathbf{K}(\mathbf{k},s)) \right] \frac{K^2(\mathbf{k},s)}{K_\perp^2} g_1(\mathbf{k},s) \quad (41)
$$

where  $K_{\perp}^2 \equiv K_2^2 + K_3^2 = k_2^2 + k_3^2 \equiv k_{\perp}^2$ , and the function,  $\Lambda_i$ , is defined as

$$
\Lambda_i(\boldsymbol{K}) = \delta_{i1} - \frac{K_1 K_i}{K^2} + \frac{K_3}{K_\perp} \left[ \frac{K_3}{K_2} \delta_{i2} - \delta_{i3} \right] \arctan\left(\frac{K_1}{K_\perp}\right) \tag{42}
$$

#### B. Velocity spectrum tensor expressed in terms of the forcing

Our goal is to express the velocity spectrum tensor in terms of the statistical properties of the forcing. If the forcing is Galilean–invariant, then we must have,

<span id="page-12-1"></span>
$$
\left\langle \tilde{f}_j(\boldsymbol{K},\tau) \tilde{f}_m^*(\boldsymbol{K}',\tau') \right\rangle = (2\pi)^6 \delta(\boldsymbol{k}-\boldsymbol{k}') \Phi_{jm}(\boldsymbol{k},t,t')
$$
(43)

where  $\Phi_{jm}$  is the *forcing spectrum tensor*. We are now ready to use the dynamical solution of the last subsection. Using equations [\(30\)](#page-10-3) and [\(41\)](#page-12-0), Fourier–space, unequal–time, two–point velocity correlator is given by,

<span id="page-13-0"></span>
$$
\langle \tilde{v}_j(\mathbf{K},\tau) \tilde{v}_m^*(\mathbf{K}',\tau') \rangle = \tilde{G}_{\nu}(\mathbf{k},t,0) \tilde{G}_{\nu}(\mathbf{k}',t',0) \langle \tilde{a}_j(\mathbf{k},t) \tilde{a}_m^*(\mathbf{k}',t') \rangle
$$
  
\n
$$
= \tilde{G}_{\nu}(\mathbf{k},t,0) \tilde{G}_{\nu}(\mathbf{k}',t',0) \int_0^t ds \int_0^{t'} ds' \times
$$
  
\n
$$
\times \left\{ \langle g_j(\mathbf{k},s) g_m^*(\mathbf{k}',s') \rangle +
$$
  
\n
$$
+ [\Lambda_j(\mathbf{K}(\mathbf{k},t)) - \Lambda_j(\mathbf{K}(\mathbf{k},s))] \frac{K^2(\mathbf{k},s)}{K_{\perp}^2} \langle g_1(\mathbf{k},s) g_m^*(\mathbf{k}',s') \rangle +
$$
  
\n
$$
+ [\Lambda_m(\mathbf{K}(\mathbf{k}',t')) - \Lambda_m(\mathbf{K}(\mathbf{k}',s')] \frac{K^2(\mathbf{k}',s')}{K_{\perp}^{\prime 2}} \langle g_j(\mathbf{k},s) g_1^*(\mathbf{k}',s') \rangle +
$$
  
\n
$$
+ [\Lambda_j(\mathbf{K}(\mathbf{k},t)) - \Lambda_j(\mathbf{K}(\mathbf{k},s))] [\Lambda_m(\mathbf{K}(\mathbf{k}',t')) - \Lambda_m(\mathbf{K}(\mathbf{k}',s'))] \times
$$
  
\n
$$
\times \frac{K^2(\mathbf{k},s) K^2(\mathbf{k}',s')}{K_{\perp}^2 K_{\perp}^{\prime 2}} \langle g_1(\mathbf{k},s) g_1^*(\mathbf{k}',s') \rangle \right\}
$$
(44)

Using equations [\(31\)](#page-10-4) and [\(43\)](#page-12-1), we write

<span id="page-13-1"></span>
$$
\langle g_j(\mathbf{k},s) g_m^*(\mathbf{k}',s') \rangle = \frac{1}{\widetilde{G}_{\nu}(\mathbf{k},s,0)} \frac{1}{\widetilde{G}_{\nu}(\mathbf{k}',s',0)} \left\langle \widetilde{f}_j(\mathbf{K}(\mathbf{k},s),s) \widetilde{f}_m^*(\mathbf{K}(\mathbf{k}',s'),s') \right\rangle
$$
  
= 
$$
\frac{1}{\widetilde{G}_{\nu}(\mathbf{k},s,0)} \widetilde{G}_{\nu}(\mathbf{k}',s',0) \left(2\pi\right)^6 \delta(\mathbf{k}-\mathbf{k}') \Phi_{jm}(\mathbf{k},s,s')
$$
(45)

Using  $\widetilde{G}_{\nu}(\mathbf{k}, t, 0)(\widetilde{G}_{\nu}(\mathbf{k}, s, 0))^{-1} = \widetilde{G}_{\nu}(\mathbf{k}, t, s)$ , equations [\(44\)](#page-13-0), [\(45\)](#page-13-1) and [\(22\)](#page-8-2) give,

<span id="page-14-0"></span>
$$
\Pi_{jm}(\mathbf{k},t,t') = \int_0^t ds \int_0^{t'} ds' \widetilde{G}_{\nu}(\mathbf{k},t,s) \widetilde{G}_{\nu}(\mathbf{k},t',s') \times
$$
\n
$$
\times \left\{ \Phi_{jm}(\mathbf{k},s,s') + \left[ \Lambda_j(\mathbf{K}(\mathbf{k},t)) - \Lambda_j(\mathbf{K}(\mathbf{k},s)) \right] \frac{K^2(\mathbf{k},s)}{K_{\perp}^2} \Phi_{1m}(\mathbf{k},s,s') + \left[ \Lambda_m(\mathbf{K}(\mathbf{k},t')) - \Lambda_m(\mathbf{K}(\mathbf{k},s')) \right] \frac{K^2(\mathbf{k},s')}{K_{\perp}^2} \Phi_{j1}(\mathbf{k},s,s') + \left[ \Lambda_j(\mathbf{K}(\mathbf{k},t)) - \Lambda_j(\mathbf{K}(\mathbf{k},s)) \right] \left[ \Lambda_m(\mathbf{K}(\mathbf{k},t')) - \Lambda_m(\mathbf{K}(\mathbf{k},s')) \right] \times \left[ \Lambda_m(\mathbf{K}(\mathbf{k},t')) - \Lambda_m(\mathbf{K}(\mathbf{k},s')) \right] \times \frac{K^2(\mathbf{k},s)K^2(\mathbf{k},s')}{K_{\perp}^4} \Phi_{11}(\mathbf{k},s,s') \right\}
$$
\n(46)

When  $\Phi_{jm}(\mathbf{k}, t, t')$  is real, the forcing may be called non helical. Then equaton [\(46\)](#page-14-0) proves that the velocity spectrum tensor,  $\Pi_{jm}(\mathbf{k}, t, t')$  is also a real quantity. In other words, non helical forcing of an incompressible fluid at low Re, in the absence of Lorentz forces, gives rise to a non helical velocity field. In this case, as we noted earlier, the velocity correlators  $Q_{jml}(\bm{r},t,t')$  and  $C_{jml}(\bm{r},t,t')$  are odd functions of  $\bm{r}$  and,  $G_{\eta}(\bm{r},t,t')$  being an even function of r, equation [\(19\)](#page-7-2) implies that the transport coefficient,  $\alpha_{il}(\tau)$  vanishes. In other words, the  $\alpha$ –effect is absent for non helical forcing at low Re and Rm, for arbitrary values of the shear parameter. This may not seem like a particularly surprising conclusion, but it is by no means an obvious one, because at high Re it may happen that  $\Pi_{jm}(\mathbf{k}, t, t')$  is complex even when  $\Phi_{jm}(\mathbf{k}, t, t')$  is real.

We now specialize to the case when the forcing is not only non helical, but *isotropic* and  $delta-correlated-in-time$  as well; in this case,

<span id="page-14-1"></span>
$$
\Phi_{jm}(\mathbf{k}, s, s') = \delta(s - s') P_{jm}(\mathbf{K}(\mathbf{k}, s)) F\left(\frac{K(\mathbf{k}, s)}{K_F}\right) \tag{47}
$$

where  $K(\mathbf{k},s) = |\mathbf{K}(\mathbf{k},s)|$ ,  $K_F = \ell^{-1}$  is the wavenumber at which the fluid is stirred,  $P_{jm}(\boldsymbol{K}) = (\delta_{jm} - K_j K_m/K^2)$  is a projection operator, and  $F(K/K_F) \geq 0$  is the forcing power spectrum.

Substitute equation  $(47)$  in  $(46)$ , and reduce the double–time integrals to a single–time integral using,

$$
\int_0^t ds \int_0^{t'} ds' \delta(s - s') w(\boldsymbol{k}, s, s') = \int_0^{t} ds w(\boldsymbol{k}, s, s)
$$
\n(48)

where  $t_{\leq} = \text{Min}(t, t')$ . Then the velocity spectrum tensor,

<span id="page-15-0"></span>
$$
\Pi_{jm}(\mathbf{k},t,t') = \int_0^{t<}\mathrm{d}s \widetilde{G}_{\nu}(\mathbf{k},t,s) \widetilde{G}_{\nu}(\mathbf{k},t',s) F\left(\frac{K(\mathbf{k},s)}{K_F}\right) \times \times \left\{ P_{jm}(\mathbf{K}(\mathbf{k},s)) + \\ + \left[ \Lambda_j(\mathbf{K}(\mathbf{k},t)) - \Lambda_j(\mathbf{K}(\mathbf{k},s)) \right] \frac{K^2(\mathbf{k},s)}{K_{\perp}^2} P_{1m}(\mathbf{K}(\mathbf{k},s)) + \\ + \left[ \Lambda_m(\mathbf{K}(\mathbf{k},t')) - \Lambda_m(\mathbf{K}(\mathbf{k},s)) \right] \frac{K^2(\mathbf{k},s)}{K_{\perp}^2} P_{j1}(\mathbf{K}(\mathbf{k},s)) + \\ + \left[ \Lambda_j(\mathbf{K}(\mathbf{k},t)) - \Lambda_j(\mathbf{K}(\mathbf{k},s)) \right] \left[ \Lambda_m(\mathbf{K}(\mathbf{k},t')) - \Lambda_m(\mathbf{K}(\mathbf{k},s)) \right] \times \\ \times \frac{K^4(\mathbf{k},s)}{K_{\perp}^4} P_{11}(\mathbf{K}(\mathbf{k},s)) \right\} \tag{49}
$$

is completely determined when the forcing power spectrum,  $F(K/K_F)$ , has been specified.

Let an observer located at the origin of the laboratory frame correlate fluid velocities at time  $\tau = t$  and at time  $\tau' = t'$ . The two-point function that measures this quantity is given by,

$$
\langle v_j(\mathbf{0},\tau)v_m(\mathbf{0},\tau')\rangle = R_{jm}(\mathbf{0},t,t') = \int d^3k \, \Pi_{jm}(\mathbf{k},t,t') \tag{50}
$$

It can be proved that, in the long time limit when  $t \to \infty$  and  $t' \to \infty$ ,  $R_{jm}(\mathbf{0}, t, t')$ is a function only of the time difference,  $(t - t')$ . The equal-time correlator, defined by  $R_{jm}(\mathbf{0}, t, t)$ , is symmetric:  $R_{jm}(\mathbf{0}, t, t) = R_{mj}(\mathbf{0}, t, t)$ . A related quantity is the root-meansquared velocity,  $v_{\text{rms}}(t)$ , defined by

$$
v_{\text{rms}}^2(t) = R_{11}(\mathbf{0}, t, t) + R_{22}(\mathbf{0}, t, t) + R_{33}(\mathbf{0}, t, t) \tag{51}
$$

In the long–time limit, both  $R_{jm}(\mathbf{0}, t, t)$  and  $v_{\text{rms}}(t)$  saturate due to the balance reached between forcing and viscous dissipation; let  $v_{\text{rms}}^{\infty} = \lim_{t \to \infty} v_{\text{rms}}(t)$ .

We now define various dimensionless quantities: The fluid Reynolds number,  $\text{Re}$  =  $v_{\text{rms}}^{\infty}/(\nu K_F)$ ; the magnetic Reynolds number, Rm =  $v_{\text{rms}}^{\infty}/(\eta K_F)$ ; the Prandtl number,  $Pr = \nu/\eta$ ; the dimensionless *Shear parameter*,  $S_h = S/(v_{\text{rms}}^{\infty} K_F)$ .

For numerical computations, it is necessary to choose a form for the forcing power spectrum. A quite common choice, used especially in numerical simulations, is forcing which is confined to a spherical shell of magnitude  $K_F$ . Therefore, whenever we need to choose a form for the forcing power spectrum, we take it to be,

<span id="page-16-0"></span>
$$
F\left(\frac{K}{K_F}\right) = F_0 \delta\left(\frac{K}{K_F} - 1\right) \tag{52}
$$

### IV. PREDICTIONS AND COMPARISON WITH NUMERICAL EXPERIMENTS

We have already established that the transport coefficient  $\alpha_{il} = 0$  when the stirring is non helical. The other transport coefficient  $\eta_{iml}$  can be calculated by the following steps:

- (i) Computing the velocity spectrum tensor,  $\Pi_{im}$ , using equations [\(49\)](#page-15-0) and [\(52\)](#page-16-0).
- (ii) Using this in equation [\(24\)](#page-8-3) to compute the velocity correlators  $C_{jml}$  and  $D_{jm}$ .
- (iii) Substituting these correlators in the second of equations [\(19\)](#page-7-2).

We also seek to compare our analytical results with measurements of numerical simulations, which use the test–field method [\[5](#page-25-3)]. In this method, the mean–magnetic field is averaged over the coordinates  $X_1$  and  $X_2$ . So we consider the case when the mean magnetic field,  $\mathbf{B} = \mathbf{B}(X_3, \tau)$ . The condition  $\nabla \cdot \mathbf{B} = 0$  implies that  $B_3$  is uniform in space, and it can be set to zero; hence we have  $\mathbf{B} = (B_1, B_2, 0)$ . Thus, equation [\(18\)](#page-7-1) for the mean EMF gives  $\mathcal{E} = (\mathcal{E}_1, \mathcal{E}_2, 0)$ , with

<span id="page-16-1"></span>
$$
\mathcal{E}_i = -\eta_{ij}(\tau) J_j; \qquad \qquad \mathbf{J} = \nabla \times \mathbf{B} = \left(-\frac{\partial B_2}{\partial X_3}, \frac{\partial B_1}{\partial X_3}, 0\right) \tag{53}
$$

where 2-indexed magnetic diffusivity tensor  $\eta_{ij}$  has four components,  $(\eta_{11}, \eta_{12}, \eta_{21}, \eta_{22})$ , which are defined in terms of the 3-indexed object  $\eta_{iml}$  by

<span id="page-16-2"></span> $\eta_{ij}(\tau) = \epsilon_{lj3} \eta_{i3l}(\tau)$ ; which implies that  $\eta_{i1}(\tau) = -\eta_{i32}(\tau)$ ,  $\eta_{i2}(\tau) = \eta_{i31}(\tau)$  (54)

Equation [\(53\)](#page-16-1) for  $\mathcal E$  can now be substituted in equation [\(1\)](#page-3-1). Then the mean–field induction becomes,

<span id="page-17-0"></span>
$$
\frac{\partial B_1}{\partial \tau} = -\eta_{21} \frac{\partial^2 B_2}{\partial X_3^2} + (\eta + \eta_{22}) \frac{\partial^2 B_1}{\partial X_3^2}
$$
  

$$
\frac{\partial B_2}{\partial \tau} = SB_1 - \eta_{12} \frac{\partial^2 B_1}{\partial X_3^2} + (\eta + \eta_{11}) \frac{\partial^2 B_2}{\partial X_3^2}
$$
(55)

The diagonal components,  $\eta_{11}(\tau)$  and  $\eta_{22}(\tau)$ , augment the microscopic resistivity,  $\eta$ , whereas the off-diagonal components,  $\eta_{12}(\tau)$  and  $\eta_{21}(\tau)$ , lead to cross-coupling of  $B_1$  and  $B_2$ .

### A. The magnetic diffusivity tensor

We now use our dynamical theory to calculate  $\eta_{ij}(\tau)$ . From equations [\(54\)](#page-16-2) and [\(19\)](#page-7-2), we have

$$
\eta_{ij}(\tau) = \epsilon_{lj3} \eta_{i3l}(\tau)
$$
\n
$$
= \epsilon_{lj3} \epsilon_{ipm} \int_0^{\tau} d\tau' \int d^3r \, r_3 \, G_{\eta}(\mathbf{r}, \tau, \tau') \, C_{pml}(\mathbf{r}, \tau, \tau') +
$$
\n
$$
+ \delta_{ij} \int_0^{\tau} d\tau' \int d^3r \, G_{\eta}(\mathbf{r}, \tau, \tau') \, D_{33}(\mathbf{r}, \tau, \tau')
$$
\n(56)

Thus the "D" terms contribute only to the diagonal components,  $\eta_{11}$  and  $\eta_{22}$ . This is the expected behaviour of turbulent diffusion, which we now see is true for arbitrary shear. Using equation [\(24\)](#page-8-3), the velocity correlators  $C_{pml}$  and  $D_{33}$  can now be written in terms of  $\Pi_{jm}$ . After some lengthy calculations, the  $\eta_{ij}(\tau)$  can be expressed in terms of the velocity spectrum tensor by,

<span id="page-17-1"></span>
$$
\eta_{ij}(\tau) = 2\eta \int_0^{\tau} d\tau' \int d^3k \ \widetilde{G}_{\eta}(\mathbf{k}, \tau, \tau') (\tau - \tau') k_3 \left[ \delta_{j2}(k_1 - S\tau' k_2) - \delta_{j1} k_2 \right] \times
$$
  
 
$$
\times \left[ \delta_{i1} \left\{ \Pi_{23} - \Pi_{32} - S(\tau - \tau') \Pi_{31} \right\} + \delta_{i2} \left\{ \Pi_{31} - \Pi_{13} \right\} \right] +
$$
  
+ 
$$
\delta_{ij} \int_0^{\tau} d\tau' \int d^3k \ \widetilde{G}_{\eta}(\mathbf{k}, \tau, \tau') \Pi_{33} \tag{57}
$$

FIG. 1: Plots of the saturated quantities  $\eta_t$ ,  $\eta_{12}^{\infty}$  and  $\eta_{21}^{\infty}$  for Re = Rm = 0.1 and Re = Rm = 0.5, corresponding to Pr = 1, versus the dimensionless parameter  $(-S_h Re)$ . The bold lines are for  $Re = Rm = 0.1$ , and the dashed lines are for  $Re = Rm = 0.5$ .

where  $\Pi_{lm} = \Pi_{lm}(\mathbf{k}, \tau, \tau')$ , and the indices  $(i, j)$  run over values 1 and 2. Here  $\tilde{G}_{\eta}(\mathbf{k}, \tau, \tau')$ is the Fourier–space resistive Green's function defined in equation [\(7\)](#page-4-1). The final step in computing  $\eta_{ij}(\tau)$  is to use equations [\(49\)](#page-15-0) and [\(52\)](#page-16-0) for the velocity spectrum tensor,  $\Pi_{lm}$ .

The  $\eta_{ij}(\tau)$  saturate at some constant values at late times; let us denote these constant values by  $\eta_{ij}^{\infty} = \eta_{ij}(\tau \to \infty)$ . If the mean magnetic field changes over times that are longer than the saturation time, we may use  $\eta_{ij}^{\infty}$  instead of the time-varying quantitites  $\eta_{ij}(\tau)$ in equation [\(55\)](#page-17-0). Looking for solutions  $\mathbf{B} \propto \exp[\lambda \tau + iK_3X_3]$ , we obtain the dispersion relation,

<span id="page-18-0"></span>
$$
\frac{\lambda_{\pm}}{\eta_{T} K_{3}^{2}} = -1 \pm \frac{1}{\eta_{T}} \sqrt{\eta_{21}^{\infty} \left( \frac{S}{K_{3}^{2}} + \eta_{12}^{\infty} \right) + \epsilon^{2}}
$$
(58)

given in [\[5](#page-25-3)], where the new constants are defined as,

FIG. 2: Plots of the saturated quantities  $\eta_t$ ,  $\eta_{12}^{\infty}$  and  $\eta_{21}^{\infty}$  for Re = 0.1 and Rm = 0.5, corresponding to Pr = 5, versus the dimensionless parameter  $(-S_h Re)$ .

$$
\eta_t = \frac{1}{2} (\eta_{11}^{\infty} + \eta_{22}^{\infty}), \qquad \eta_T = \eta + \eta_t, \qquad \epsilon = \frac{1}{2} (\eta_{11}^{\infty} - \eta_{22}^{\infty})
$$
(59)

Exponentially growing solutions for the mean magnetic field are obtained when the radicand in equation [\(58\)](#page-18-0) is both positive and exceeds  $\eta_T^2$ .

From equations [\(57\)](#page-17-1), [\(7\)](#page-4-1), [\(49\)](#page-15-0) and [\(52\)](#page-16-0), it can be verified that the saturated values of the magnetic diffusivities,  $\eta_{ij}^{\infty}$ , have the following general functional form:

<span id="page-19-0"></span>
$$
\eta_{ij}^{\infty} = \eta_T \text{Re}^2 \frac{f_{ij}(\text{S}_h \text{Re}, \text{Pr})}{1 + \chi(\text{S}_h, \text{Re}, \text{Pr})},
$$
\n(60)

where the  $f_{ij}$  are dimensionless functions of two variables, and  $\chi$  is a dimensionless function of three variables. Figures (1–3) display plots of  $\eta_t$ ,  $\eta_{12}^{\infty}$  and  $\eta_{21}^{\infty}$ , versus the dimensionless parameter  $(-S_h Re)$ . The scalings of the ordinates have been chosen for compatibility with the functional form displayed in equation [\(60\)](#page-19-0) above. These plots should be compared with

FIG. 3: Plots of the saturated quantities  $\eta_t$ ,  $\eta_{12}^{\infty}$  and  $\eta_{21}^{\infty}$  for Re = 0.5 and Rm = 0.1, corresponding to Pr = 0.2, versus the dimensionless parameter  $(-S_h Re)$ .

Figure (3) of [\[5\]](#page-25-3). However, it should be noted that we operate in quite different parameter regimes; we are able to explore larger values of  $|S_h|$ , whereas [\[5\]](#page-25-3) have done simulations for larger Re and Rm. The plots in Figure (1a–c) are for  $Pr = 1$ , but for two sets of values of the Reynolds numbers;  $Re = Rm = 0.1$ , and  $Re = Rm = 0.5$ . Figure (2a–c) are for  $Re = 0.1$ and Rm = 0.5, corresponding to Pr = 5. Figure (3a–c) are for Re = 0.5 and Rm = 0.1, corresponding to Pr = 0.2. As may be seen from equation [\(60\)](#page-19-0), the ratio,  $(\eta_{12}^{\infty}/\eta_{21}^{\infty})$ , is a function only of the two dimensionless parameters,  $(S_h Re)$  and Pr. In Figure (4) we plot this ratio versus  $(-S_h Re)$  for all the cases considered in Figures (1–3). Some noteworthy properties are as follows:

(i) We see that  $\eta_t$  is always positive. For a fixed value of  $(-S_h Re)$ , the quantity  $\eta_t/(\eta_T Re^2)$ increases with Pr and, for a fixed value of Pr, it increases as  $(-S_h Re)$  increases from zero (which is consistent with [\[5](#page-25-3)]), attains a maximum value near  $(-S_h Re) \approx 2$ , and then decreases while always remaining positive.

FIG. 4: Plots of the ratio  $(\eta_{12}^{\infty}/\eta_{21}^{\infty})$  versus the dimensionless parameter  $(-S_h Re)$  for all the cases considered in Figures (1–3). The bold line is for the two cases corresponding to  $Pr = 1$ , the dashed–dotted line is for  $Pr = 5$ , and the dotted line is for  $Pr = 0.2$ .

- (ii) As expected, the behaviour of  $\eta_{12}^{\infty}$  is more complicated. It is zero for  $(-S_h Re) = 0$ , and becomes negative for not too large values of  $(-S_h Re)$ . After reaching a minimum value, it then becomes an increasing function of  $(-S_h Re)$  and attains positive values for large ( $-S<sub>h</sub>Re$ ). Thus the sign of  $\eta_{12}^{\infty}$  is sensitive to the values of the control parameters. This may help reconcile, to some extent, the fact that different signs for  $\eta_{12}^{\infty}$  are reported in [\[12\]](#page-26-3) and [\[5\]](#page-25-3).
- (iii) As may be seen,  $\eta_{21}^{\infty}$  is always positive. This agrees with the result obtained in [\[5](#page-25-3)], [\[11\]](#page-26-2) and [\[12\]](#page-26-3).
- (iv) At first sight  $\eta_{12}^{\infty}$  and  $\eta_{21}^{\infty}$  appear to have quite different behaviour. However, closer inspection reveals certain systematics: as Pr increases, the overall range of values increases, while their shapes shift leftward to smaller values of  $(-S_h Re)$ . From equa-

tion [\(60\)](#page-19-0), it is clear that the ratio  $(\eta_1^{\infty}/\eta_2^{\infty})$  is a function only of the two variables,  $(S_h Re)$  and Pr. As Figure (4) shows, this ratio is nearly a linear function of  $(S_h Re)$ , whose slope increases with Pr.

(v) The magnitude of the quantity,  $\chi(S_h, Re, Pr)$ , that appears in equation [\(60\)](#page-19-0), is much smaller than unity. So  $\eta_t/(\eta_T \text{Re}^2)$ ,  $\eta_{12}^{\infty}/(\eta_T \text{Re}^2)$  and  $\eta_{21}^{\infty}/(\eta_T \text{Re}^2)$  can be thought of (approximately) as functions of  $(-S_h Re)$  and Pr. This is the reason why, in Figure (1), the bold and dashed lines lie very nearly on top of each other.

### B. Implications for dynamo action and the shear–current effect

The mean magnetic field has a growing mode if the roots of equation [\(58\)](#page-18-0) have a positive real part. It is clear that the real part of  $\lambda$  is always negative. So, for the growth of the mean magnetic field, the real part of  $\lambda_+$  must be positive. Requiring this, we see from equation [\(58\)](#page-18-0) that the condition for dynamo action is,

<span id="page-22-0"></span>
$$
\frac{\eta_{21}^{\infty}S}{\eta_T^2 K_3^2} + \frac{\eta_{12}^{\infty} \eta_{21}^{\infty}}{\eta_T^2} + \frac{\epsilon^2}{\eta_T^2} > 1.
$$
\n(61)

In Figure (5) we plot the last two terms,  $(\eta_{12}^{\infty}\eta_{21}^{\infty}/\eta_T^2)$  and  $(\epsilon^2/\eta_T^2)$ , as functions of  $(-S_h Re)$ , for all the four cases,  $Re = Rm = 0.1$ ;  $Re = Rm = 0.5$ ;  $Re = 0.1$ ,  $Rm = 0.5$  and  $Re = 0.5$ , Rm = 0.1. As may be seen, the magnitudes of both terms are much smaller than unity, so they are almost irrelevant for dynamo action. Hence, there is growth of the mean magnetic field only when the first term,  $(\eta_{21}^{\infty}S/\eta_T^2K_3^2)$ , exceeds unity. This is possible for small enough  $K_3^2$ , so long as  $(\eta_{21}^{\infty}S)$  is positive. However, we see from Figures (1-3) that  $\eta_{21}^{\infty}$  is always positive, implying that the product  $(\eta_{21}^{\infty}S)$  is always negative. Therefore the inequality of [\(61\)](#page-22-0) cannot be satisfied, and the mean–magnetic field always decays, a conclusion which is in agreement with those of [\[5\]](#page-25-3), [\[11](#page-26-2)] and [\[12\]](#page-26-3). We can understand the above results more physically. Let us assume that  $|K_3|$  is small enough, and keep only the most important terms in equation [\(55\)](#page-17-0). Then we have,

$$
\frac{\partial B_1}{\partial \tau} = -\eta_{21}^{\infty} \frac{\partial^2 B_2}{\partial X_3^2} + \dots, \qquad \frac{\partial B_2}{\partial \tau} = SB_1 + \dots,
$$
 (62)

where we have used the saturated values of the magnetic diffusivity. If we now look for modes of the form  $\mathbf{B} \propto \exp \left[ \lambda \tau + i K_3 X_3 \right]$ , we obtain the dispersion relation,  $\lambda_{\pm} = \pm K_3 \sqrt{\eta_{21}^{\infty} S}$ . So

FIG. 5: Plots of  $(\epsilon^2/\eta_T^2)$  and  $(\eta_{12}^{\infty}\eta_{21}^{\infty}/\eta_T^2)$  versus the dimensionless parameter  $(-S_h Re)$  for all the four cases considered in Figures (1–3). The bold lines are for  $Re = Rm = 0.1$ ; the dashed lines are for  $Re = Rm = 0.5$ ; the dashed–dotted lines are for  $Re = 0.1, Rm = 0.5$  and the dotted lines are for  $Re = 0.5$ ,  $Rm = 0.1$ .

it is immediately obvious that  $\lambda_+$  is real and positive — i.e. the mean magnetic field grows — only when the product  $(\eta_{21}^{\infty}S)$  is positive. However, this product happens to be negative, and the mean magnetic field is a decaying wave.

The above results have direct bearing on the *shear-current effect* [\[10\]](#page-26-0). This effect refers to an extra contribution to the mean EMF which is perpendicular to both the mean vorticity (of the background shear flow) and the mean current. From equation [\(53\)](#page-16-1), we see that, in our case, the relevant term is the contribution,  $-\eta_{21}^{\infty}J_1$ , to  $\mathcal{E}_2$ . As Figures (1–3) show, the diffusivity,  $\eta_{21}^{\infty}$  is non zero only in the presence of shear, so the word *shear* refers to this. The word *current* refers to  $J_1$ , the cross–field component of the electric current associated with the mean–magnetic field [\[16\]](#page-26-7). The shear–current effect would lead to the growth of the

mean magnetic field (for small enough  $K_3$ ), if only the product  $(\eta_{21}^{\infty}S)$  is positive. However, as we have demonstrated, this product is negative, so the shear–current effect cannot be responsible for dynamo action, at least for small Re and Rm, but for all values of the shear parameter.

#### V. CONCLUSIONS

Building on the formulation of  $[14]$ , we have developed a theory of the *shear dynamo* problem for small magnetic and fluid Reynolds numbers, but for arbitrary values of the shear parameter. Our primary goal is to derive precise analytic results which can serve as benchmarks for comparisons with numerical simulations. A related goal is to resolve the controversy surrounding the nature of the shear–current effect, without treating the shear as a small parameter. We began with the expression for the Galilean–invariant mean EMF derived in [\[14](#page-26-5)], and specialized to the case of a mean magnetic field that is slowly varying in time. This resulted in the simplification of the mean–field induction equation, from an integro–differential equation to a partial differential equation. This reduction is the first step to the later comparison with the numerical experiments of [\[5](#page-25-3)]. Explicit expressions for the transport coefficients,  $\alpha_{il}$  and  $\eta_{iml}$ , were derived in terms of the two–point velocity correlators which, using results from [\[14\]](#page-26-5), were then expressed in terms of the velocity spectrum tensor. Then we proved that, when the velocity field is non helical, the transport coefficient  $\alpha_{il}$ vanishes; just like everything else in this paper, this result is non perturbative in the shear parameter. We then considered forced, stochastic dynamics for the incompressible velocity field at low Reynolds number. An exact, explicit solution for the velocity field was derived, and the velocity spectrum tensor was calculated in terms of the Galilean–invariant forcing statistics. For non helical forcing, the velocity field is also non helical and the transport coefficient  $\alpha_{il}$  vanishes, as noted above. We then specialized to the case when the forcing is not only non helical, but isotropic and delta–correlated–in–time as well. We considered the case when the mean–field was a function only of the spatial coordinate  $X_3$  and time  $\tau$ ; the purpose of this simplification was to facilitate comparison with the numerical experiments of [\[5\]](#page-25-3). Explicit expressions were derived for all four components,  $\eta_{11}(\tau)$ ,  $\eta_{22}(\tau)$   $\eta_{12}(\tau)$  and  $\eta_{21}(\tau)$ , of the magnetic diffusivity tensor, in terms of the velocity spectrum tensor. Important properties of this fundamental object are as follows:

- 1. All the components of  $\eta_{ij}$  are zero at  $\tau = 0$ , and saturate at finite values at late times, which we denote by  $\eta_{ij}^{\infty}$ .
- 2. The off-diagonal components,  $\eta_{12}$  and  $\eta_{21}$ , vanish when the microscopic resistivity vanishes.
- 3. The sign of  $\eta_{12}^{\infty}$  is sensitive to the values of the control parameters. This may help reconcile, to some extent, the fact that different signs for  $\eta_{12}^{\infty}$  are reported in [\[12](#page-26-3)] and [\[5\]](#page-25-3).

We derived the condition — the inequality  $(61)$  — required for the growth of the mean magnetic field: the sum of three terms must exceed unity. It was demonstrated that two of the terms are very small in magnitude, and hence dynamo action was controlled by the behaviour of one term. i.e. the mean magnetic field would grow if  $(\eta_{21}^{\infty}S/\eta_T^2K_3^2)$  exceeds unity. This is possible for small enough  $K_3^2$ , so long as  $(\eta_{21}^{\infty}S)$  is positive. However, we see from Figures (1–3) that  $\eta_{21}^{\infty}$  is always positive, implying that the product  $(\eta_{21}^{\infty}S)$  is always negative. Thus the mean–magnetic field always decays, a conclusion which is in agreement with those of [\[5\]](#page-25-3), [\[11](#page-26-2)] and [\[12](#page-26-3)]. We then related the above conclusions to the shear–current effect, and demonstrated that the shear–current effect cannot be responsible for dynamo action, at least for small Re and Rm, but for all values of the shear parameter. In [\[5\]](#page-25-3), it is suggested that the dynamo action observed in their numerical experiments might be due to a fluctuating  $\alpha$ –effect; addressing this issue is being the scope of our present calculations.

- <span id="page-26-7"></span>[16] Shear also makes an additional contribution through the  $SB_1$  contribution to  $(\partial B_2/\partial \tau)$ , which accounts for the product  $(\eta_{21}^{\infty}S)$  playing an important role. However, this is just the well– known physical effect of the shearing of cross-shear component of the mean magnetic field to generate a shear–wise component; it does not have any bearing on the word shear in the phrase shear–current effect.
