Abstract

We extract the pole positions, hadronic and $\gamma\gamma$ widths of σ and $f_0(980)$, from $\pi\pi$ and $\gamma\gamma$ scattering data using an improved analytic K-matrix model. Our results favour a large gluon component for the σ and a $\bar{s}s$ or/and gluon component for the $f_0(980)$ but neither a large four-quark nor a molecule component. Gluonium σ_B production from $J/\psi, \phi$ radiative and D_s semi-leptonic decays are also discussed.

Keywords: $\gamma\gamma$ and $\pi\pi$ scatterings, radiative decays, light scalars, gluonia, four-quark states, QCD spectral sum rules.

1. Introduction

-The hadronic and $\gamma\gamma$ couplings of light scalar mesons could provide an important information about their nature.

-K-matrix model has been used to describe $\pi\pi$ and $\gamma\gamma$ processes [1].

-This model is improved by introducing a form factor *shape function* in a single channel [2], which is generalized [3–5] to the coupled channels case in order to extract the pole postions and the previous couplings of the σ and $f_0(980)$.

In this talk, we review these recent results.

2. Phenomenology of $\pi\pi$ scattering

1 channel $\oplus 1$ "bare" resonance

We introduce a real analytic form factor *shape function* [2]:

$$f_P(s) = \frac{s - s_{AP}}{s - \sigma_{DP}}, \quad P = \pi, K \quad (1)$$

¹Speaker

It allows for an Alder zero $s = s_{AP}$ and a pole at $\sigma_{DP} < 0$ to simulate left hand singularities. The unitary $I = 0$ S wave $\pi\pi$ scattering amplitude is then written as:

$$T_{PP} = \frac{g_P^2 f_P(s)}{s_R - s - g_P^2 \tilde{f}_P(s)} = \frac{g_P^2 f_P(s)}{\mathcal{D}_P(s)}, \quad (2)$$

where:

$$\text{Im}\mathcal{D} = \text{Im}(-g_\pi^2 \tilde{f}_P) = -(\theta\rho_P)g_P^2 f_P. \quad (3)$$

and hence:

$$\text{Im}(\tilde{f}_P) = (\theta\rho_P)f_P, \quad \rho_P = \sqrt{1 - 4m_P^2/s}. \quad (4)$$

The real part of \tilde{f}_P is obtained from a dispersion relation with subtraction at $s = 0$,

$$\tilde{f}_P(s) = \frac{2}{\pi}(h_0(s) - h_0(0)), \quad (5)$$

where $h_0(s)$ has been defined in Ref. [2].

0 bare resonance $\equiv \lambda\phi^4$ model

In this case, one can introduce another shape function $f_2(s)$:

$$T_{PP} = \frac{\Lambda f_2(s)}{1 - \Lambda \tilde{f}_2(s)}, \quad f_2(s) = \frac{s - s_{AP}}{(s - \sigma_{D1})(s - \sigma_{D2})}. \quad (6)$$

where $\sigma_{D1} = \sigma_{D_\pi}$, and $\tilde{f}_2(s) = \frac{2}{\pi}[h_2(s) - h_2(0)]$. The single channel results are shown in Fig. 1 and Table 1. The result of $\lambda\phi^4$ model shows that the existence of σ is not an artifact of a "bare" resonance entering into the parametrization of T_{PP} .

$2 \text{ channels} \oplus 2 \text{ "bare" resonances}$

The generalization to coupled channels is conceptually straightforward. We consider the $\pi\pi - K\bar{K}$ coupled channels and introduce 2 "bare" resonances labeled a and b , with bare masses squared s_{Ra} and s_{Rb} . To leading order in SU(3) breakings, we shall approximately work in the *minimal case* with only one shape function. The phase shifts and inelasticity η are defined by:

$$ne^{2i\delta_P} = 1 + 2i\rho_P T_{PP}. \quad (7)$$

We refer to [4] for the explicit expressions of T_{PP} . We

analyze 3 cases using different groups of $\pi\pi - K\bar{K}$ data, which are shown in Table 2. With these choices, we expect to span all possible regions of space of parameters. The fit results are shown in Fig. 2 and Table 3, from which we derive the pole positions and hadronic couplings of the σ and $f_0(980)$.

Figure 2: The coupled channels fit results.

Final results

– For the σ , we take the average value of the single and coupled channels results:

$$\begin{aligned} M_\sigma - i\Gamma_\sigma/2 &= 452(12) - i 260(15) \text{ MeV}, \\ |g_{\sigma\pi^+\pi^-}| &= 2.65(10) \text{ GeV}, \\ r_{\sigma K} &\equiv \frac{|g_{\sigma K^+K^-}|}{|g_{\sigma\pi^+\pi^-}|} = 0.37(6). \end{aligned} \quad (8)$$

The mass and width shown in Table 5 are in good agreement with other ones in the literature.

The sizeable coupling of the σ to $\bar{K}K$ disfavors the usual

Average	452(12) - i 260(15)

$\pi\pi$ molecule and 4-quark assignment of the σ , where this coupling is expected to be negligible. Moreover, a broad $\pi\pi$ width (compared with ρ meson) can not be explained within a $q\bar{q}$ scenario.

- For the $f_0(980)$, we have:

$$\begin{aligned} M_f &= 981(34) - i 18(11) \text{ MeV}, \\ |g_{f\pi^+\pi^-}| &= 1.17(26) \text{ GeV}, \\ r_{f\pi K} &\equiv \frac{|g_{fK^+K^-}|}{|g_{f\pi^+\pi^-}|} = 2.59(1.34). \end{aligned} \quad (9)$$

A large value of $r_{f\pi K}$ together with a narrow width disfavor a pure ($u\bar{u} + d\bar{d}$) assignment of the $f_0(980)$, while its non-negligible width into $\pi\pi$ indicates that it cannot be a pure $s\bar{s}$ or $K\bar{K}$ molecule.

- A possible gluonium component mixed with a $q\bar{q}$ state of the σ and $f_0(980)$ seems to be necessary for evading the previous difficulties.

3. $\gamma\gamma \rightarrow \pi\pi$ process

The $I = 0$ S-wave amplitude consists of two parts, the Born and unitarized amplitudes shown in Fig. 3, and the direct $\gamma\gamma$ couplings shown in Fig. 4. The unitarized amplitude can be calculated using chiral lagrangian. The only ambiguity comes from the direct term. We introduce the direct couplings of σ and $f_0(980)$ to $\gamma\gamma$ [1]:

$$T_\pi^S = \sqrt{2}\alpha s[(f_{\sigma\gamma} + sf'_{\sigma\gamma})\tilde{T}_{\sigma\pi} + (f_{f_0\gamma} + sf'_{f_0\gamma})\tilde{T}_{f_0\pi}]. \quad (10)$$

for the S-wave and:

$$T_\pi^D = \frac{\alpha}{\sqrt{2}}[s^2 f_{f_2\gamma}^{l=0} + s f_{f_2\gamma}^{l=2}]\tilde{T}_{f_2\pi}. \quad (11)$$

for the D-wave with helicity 0 and 2 respectively. We refer to [5] for the expressions of the reduced amplitudes,

Figure 3: Born and Unitarized amplitudes T_P^u : $P \equiv \pi, K; V \equiv \rho, \omega; A \equiv b_1, h_1, a_1$.

Figure 4: Direct couplings of the resonances to $\gamma\gamma$

$\tilde{T}_{\sigma\pi}, \tilde{T}_{f_0\pi}$ and $\tilde{T}_{f_2\pi}$.

We also include crossing channel contributions from vector(1^{--}) and axial-vector($1^{+-}, 1^{++}$) exchanges using normal vector description.

For $I = 0$ D-wave, we assume that it is dominated by the direct production of $f_2(1270)$ with helicity 2 [11], and fix the direct coupling of $f_2(1270)$ to $\gamma\gamma$ from the total width given by PDG, $|f_{f_2\gamma}| = 0.136 \text{ GeV}^{-1}$. Indeed, we show in [5] that, at the f_2 mass, there is a cancellation between the unitarized and Born contributions. The free parameters $f_{\sigma\gamma}, f'_{\sigma\gamma}, f_{f_0\gamma}$ and $f'_{f_0\gamma}$ can be determined by fitting the $\gamma\gamma \rightarrow \pi^0\pi^0$ total and differential cross section data [12] [13]. The fit result is shown in Fig. 5. The $\gamma\gamma$ decay width from different contributions are given in Tab. 6.

4. Gluonium from $J/\psi, \phi \rightarrow \gamma\sigma_B$ and $D_s \rightarrow l\nu\sigma_B$

The previous possible gluonium assignment of the σ can be tested from $J/\psi, \phi \rightarrow \gamma\sigma_B$ and $D_s \rightarrow l\nu\sigma_B$ processes (σ_B is a n unmixed hypothetical gluonium state) as discussed respectively in [20–23] and [24]. We expect to have the branching ratios $\times 10^3$:

$$\begin{aligned} B(J/\psi \rightarrow \sigma_B\gamma) \times B(\sigma_B \rightarrow \text{all}) &\simeq (0.4 \sim 1.0), \\ B(\phi \rightarrow \sigma_B\gamma) &\simeq 0.12, \end{aligned} \quad (12)$$

Figure 5: Fit up to 1.09GeV, $\chi^2_{d.o.f} = \frac{39.5}{41} = 0.96$. $\Sigma = \pi + K$. Dotted blue (S-wave contribution); dashed green (D-wave contribution); continuous red (S+D contribution); dash-dotted orange (all partial wave contribution).

Table 6: $\gamma\gamma$ decay width(in unit of keV). $r_0 \equiv \Gamma_{f_2 \rightarrow \gamma\gamma}^{l=0} / \Gamma_{f_2 \rightarrow \gamma\gamma}^{tot}$

	Set 2	Set 3	[2]	[14]	[15]	[16]	[16]	[17]	[18]	PDG[19]
\sqrt{s}	1.09	1.09	0.8	1.44	0.8	1.44	1.44	1.4		
r_0	0	0				0.13	0.26	0.15

Γ_{σ}^{tot}	3.11	3.10	3.90		1.7	3.1	2.4	2.1	1.2	
$\Gamma_{f_0}^{dir}$	0.29	0.27		0.015						
$\Gamma_{f_0}^{resc}$	0.90	0.81								
$\Gamma_{f_0}^{tot}$	0.17	0.15			0.42	0.10	0.13		0.29 ± 0.08	

and:

$$\frac{\Gamma[D_s \rightarrow \sigma_B(gg)l\nu]}{\Gamma[D_s \rightarrow S_2(\bar{q}q)l\nu]} \approx \frac{1}{|f_+(0)|^2} \left(\frac{f_{\sigma_B}}{M_c} \right)^2 \simeq O(1), \quad (13)$$

for $M_c \approx 1.5$ GeV, $f_{\sigma_B} \approx 1$ GeV [20, 22, 23], where $|f_+(0)| \approx 0.5$ [25] is the form factor associated to the $\bar{q}q$ semileptonic production. The rates of these productions are in fair agreement with existing data supporting again or not excluding a large gluonium component of the σ .

5. Conclusions

-We use an improved coupled channel K-matrix model, taking into account Adler zero and left hand singularities. We extract the pole positions and widths, as well as the hadronic and $\gamma\gamma$ couplings of σ and $f_0(980)$ by fitting experimental data.

-The values of their direct widths favour a large gluon

content for the σ meson but are not decisive for explaining the substructure of the $f_0(980)$ meson, which can mainly be either a $\bar{s}s$ or a gluonium.

-The large values of the rescattering widths, due to meson loops, can be also obtained if they are gluonia states but not necessarily if they are four-quark or molecule states.
