Abstract

An interface between the UrQMD-1.3cr model (version 1.3 for cosmic air showers) and the Geant4 transport toolkit has been developed. Compared to the current Geant4 (hybrid) hadronic models, this provides the ability to simulate at the microscopic level hadron, nucleus, and anti-nucleus interactions with matter from 0 to 10^{12} eV/A with a single transport code. This document provides installation requirements and instructions, as well as class and member function descriptions of the software.

1 Introduction

Geant4 [1] use many transport codes to generate non-elastic reactions in macroscopic targets. The motivation was to provide a satisfactory level of description of final state hadron production for accurate and comprehensive simulations of particle detectors used in modern particle and nuclear physics experiments.

In Geant4 [1] there are mainly 4 codes which are frequently applied for simulating N-body collisions within the hadronic cascade models, namely, Binary [2], Bertini [3], FTF[4] and QGS[5]. The Geant4 Binary and Bertini cascade models implement large resonance collision term but multiparticle production through string formation and fragmentation is not considered, which sets the upper limit of model applicability in nucleon induced reactions to about 5 GeV/c incident momentum. In contrast to **Binary** and **Bertini** cascade models, **FTF** and **QGS**, takes multiparticle production into account, to handle interaction for particles above about 15-20 GeV/c.

For a reliable description of secondaries produced in high and low energy domains, Geant4 invoke **Binary (Bertini)** in the **FTF(QGS)** models. The corresponding hybrid model is called **FTFB(QGSB)**.

To improve the simulation, it is worthwhile to supplement Geant4 toolkit with a single transport code which takes into account both resonance and multiparticle production. The UrQMD (Ultra relativistic Quantum Molecular Dynamics) model [6], which is first released in 1998, is designed to simulate (ultra) relativistic heavy ion collisions in a wide energy range from Bevalac and SIS up to AGS, SPS and RHIC. Thanks to the UrQMD collaborators, the UrQMD is provided as open source Fortran code on its website.

Geant4-UrQMD interface offers interactions of Protons, neutrons, pions and kaons (and their antiparticles) as well as light and heavy ions interactions with matter. It gives type, mass, energy, and momentum of all secondary

particles that are created in matter. Similar to CORSIKA-UrQMD [7] interface, the upper energy limit is recommended to be about several 100 GeV. For the simulation, the appropriate **UrQMD** cross sections (for determining the mean free path between interacting particles) are used. However, the probability for an interaction with matter at a given point is computed by the Geant4 cross sections classes.

This document provides installation requirements and instructions of the Geant4-UrQMD interface. More details about validation with Geant4 cascade models can be found in Ref.[8]. This interface is sponsored by [King Abdulaziz City for Science and Technology /National Center for Mathematics and Physics- Saudi Arabia](#) under the contract number **31-465**.

2 Brief description of UrQMD model

The UrQMD model version 1.3cr (for cosmic air shower) is a Monte Carlo event generator for simulating hadron-hadron, hadron-nucleus, nucleus-nucleus interactions from 0 to 10^6 MeV. The main goal is to gain understanding about Physical phenomena within a single transport mode. As such, it is relevant both to high-energy hadron/ion accelerators and cosmic radiation environments.

The UrQMD model is based analogous principles as the quantum molecular dynamic (QMD) model and the relativistic QMD (RQMD): the mean field potential applied to hadrons is treated similar to QMD, while the treatment of the collision term is similar to RQMD.

Compared with Geant4 simulation codes (e.g., Binary, Bertini, FTF, QGSM...), UrQMD has the following improvements to its physics (see Ref.[6] for full description):

- The collision term of the UrQMD treats 55 different baryon species (including nucleon, Δ , Λ , Σ , Ξ and Ω and their resonances with masses up to $2.25 \text{ GeV}/c^2$) and 32 different meson species (including strange meson resonances with masses up to $1.9 \text{ GeV}/c^2$) as well as their antiparticles and explicit isospin projected states. For excitations with higher masses than $2 \text{ GeV}/c^2$ the string model is used (The excited hadronic states can either be produced in inelastic hh collision, resonance decays or string decays).
- All of these hadronic states can propagate and re-interact in phase-space.
- A mean field potential can be applied for the scattered nucleons.

- An analytic expression for the differential cross section of in-medium NN elastic scattering derived from the collision term of the relativistic Boltzmann-Uehling-Uhlenbeck (RBUU) equation is used to determine the scattering angles between the outgoing particles in hh collisions.
- An introduction of the formation time and leading pre-hadron effects. For the leading pre-hadrons, a reduced cross section is adopted according to the constituent quark model.

UrQMD-1.3cr is freely available from the website <http://urqmd.org/>.

3 Installation requirements

The Geant4 interface to UrQMD-1.3cr (for cosmic air showers) uses the following software tools and packages:

1. UrQMD-1.3cr (available at <http://urqmd.org/> website)
2. The following Geant4 versions:
 - *ver.9.3.p01* or *ver.9.5*

The interface and original UrQMD-1.3cr source code have been compiled and tested using:

- *gcc 4.1.2 with g77 (FORTRAN77), gfortran (FORTRAN95) and GNUmake)*

Operating systems used for this test is : *Red Hat Linux 4.1.2-64*

4 Interface design

The use of UrQMD-1.3cr physics in Geant4 has resulted in the introduction of a new event model ([G4UrQMD1_3Model](#)).

4.1 Logical description of [G4UrQMD1_3Model](#)

The general steps in the logical sequence of the design are:

1. [Instantiation of G4UrQMD1_3Model](#)

Upon instantiation of the UrQMD-1.3cr interface, the class constructor initialises variables associated with the class and the UrQMD-1.3cr FORTRAN model. The latter involves initialisation of a series of common-block variables from the C++ code, mimicking the initialisation process performed by the FORTRAN code when used in standalone mode.

2. [Generation of the interaction events](#)

In order to generate interaction events, the [ApplyYourself](#) member function of Geant4 is executed. The details of the projectile and target are determined (e.g., mass number, charge, projectile energy...).

If no data exist for the specific projectile-target combination, a “waning” is declared, and the program is stopped.

4.2 Class structure for model

The interface comprises **G4UrQMD1_3Model** class, which is derived from **G4HadronicInteraction**, and is defined within the Geant4 user physics list if access to **UrQMD1_3** physics is required. It controls initialisation of **UrQMD-1.3cr** through common block variables.

A small FORTRAN subroutine is included with the G4UrQMD distribution. This is required to ensure that block data initialisation in G4UrQMD-1.3c is performed (through FORTRAN EXTERNAL statements). Specifically the new FORTRAN subroutine is:

- **g4urqmdblockdata.f**

5 Instructions for software installation in geant4-9.3

5.1 Installing UrQMD-1.3cr and building the libG4hadronic_urqmd13 library

Copy the file **g4urqmd-1.3cr.2012.tar** (available at <https://twiki.cern.ch/twiki/bin/view/Sandbox/Geant4UrQMDinterface>)

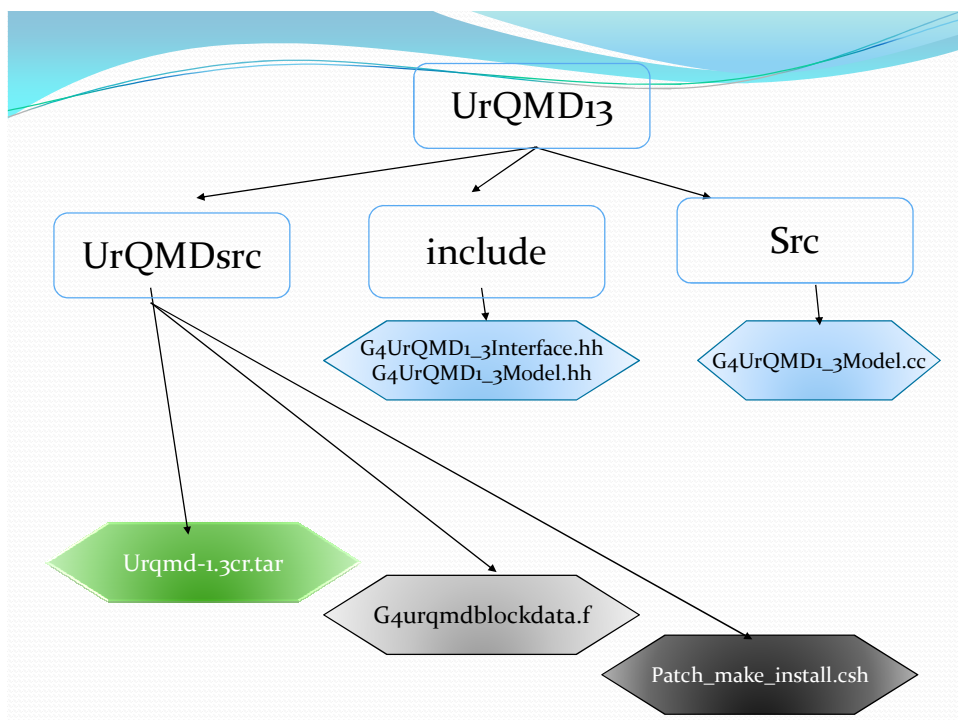

to the directory:

```
cd $G4INSTALL/source/processes/hadronic/models
```

Unzip or untar the files, *e.g.*:

```
tar -xvzf g4urqmd-1.3cr.2012.tar
```

This creates the directory **UrQMD13**, which looks like:

Note that the header and C++ files (**G4UrQMD1_3Interface.hh** & **G4UrQMD1_3Model.hh**) and **G4UrQMD1_3Model.cc** are in **UrQMD13/include** and **UrQMD13/src** respectively.

Change directory:

```
cd UrQMD13/UrQMD13src
```

If the file **urqmd-1.3cr.tar** doesn't already exist in the directory, copy it from the web-site: <http://urqmd.org/> .

Execute the script **patch_make_and_install.csh** from a **csh/tcsh** environment. This initiates 2 steps:

1- All the relevant FORTRAN files are compiled in **UrQMD13src**, using

FC= g77

LD=g77

FFLAGS=-g -Wall -Wsurprising -fbound -check

LDFLAGS= -g

2- The object files are copied to the directory:

\$G4TMP/\$G4SYSTEM/G4hadronic_UrQMD13

Change directory and execute **make** on the C++ source:

cd ..

make

This will build the library:

\$G4LIB/\$G4SYSTEM/libG4hadronic_UrQMD13.a

but note that the **Gnumake** file of your application must explicitly identify this library and the **UrQMD1_3** headers. So in **GNUmake** file for you application, please add the following line:

CPPFLAGS += -I\$(G4BASE)/processes/hadronic/models/UrQMD13/include

Note that if you perform:

make clean

from **UrQMD13** directory, this **deletes** the FORTRAN-compiled object files which were from **UrQMD13/UrQMD13src** to **\$G4TMP/\$G4SYSTEM/ libG4hadronic_urqmd13**. Therefore, you should either re-copy the files, or re-run the script

patch_make_and_install.csh before performing a make in directory **UrQMD13**.

5.2 The main () program

Geant4 does not provide the **main()**. In the **main()**, one has to construct **G4ProcessManager**, in order to process a run for the interface.

Ensure that the **GNUmake** file for you application (in “**main**” directory) includes the following lines:

```
CPPFLAGS += -I$(G4BASE)/processes/hadronic/models/UrQMD13/include
```

```
EXTRALIBS += -L$(G4INSTALL)/lib/$(G4SYSTEM) -IG4hadronic_UrQMD13
```

*If you want to compile the Geant4-UrQMD interface from your “main” directory, please add these lines in **GNUmake** file:*

```
EXTRA_LINK_DEPENDENCIES:= $(G4INSTALL)/lib/$(G4SYSTEM)/  
libG4hadronic_UrQMD13.so
```

```
$(G4INSTALL)/lib/$(G4SYSTEM)/ libG4hadronic_UrQMD13.so:  
cd $(G4BASE)/processes/hadronic/models/UrQMD13; $(MAKE)
```

6 Class descriptions (summary)

Class [G4UrQMD1_3Model](#)

Public member functions

<code>G4UrQMD1_3Model(const G4String& name = "UrQMD1_3");</code>
<code>virtual ~G4UrQMD1_3Model ();</code>
<code>virtual G4HadFinalState *ApplyYourself (const G4HadProjectile&, 4Nucleus&);</code>

Private member functions

<code>G4int operator==(G4UrQMD1_3Model& right){return (this == &right);}</code>
<code>G4int operator!=(G4UrQMD1_3Model& right){return (this != &right);}</code>
<code>void WelcomeMessage () const;</code>
<code>void InitialiseDataTables ();</code>
<code>G4bool offshell</code>

7 Class descriptions (full descriptions)

The following sub-sections describe in detail each of the new or modified classes introduced into Geant4 to treat the interface with UrQMD-1.3cr. The descriptions include the overall purpose of the class, the constructor, destructor, and private/public member functions of the classes, including identification of the arguments and quantities returned. It should be noted that, the *units of all inputted and returned quantities are default units used in Geant4*, e.g. **lengths** (such as nuclear radii) are stated in **millimetres**, **areas** (e.g. interaction cross-sections) in **square-millimetres**, and **energies** are stated in **MeV**.

7.1 Class G4UrQMD1_3Model

The **G4UrQMD1_3Model** class is the main class driving the UrQMD-1.3cr FORTRAN code and primarily acts as an event generator to Geant4 to determine the final state of an interaction. It is derived from **G4HadronicInteraction** class.

Public constructors, operators and member functions

```
G4UrQMD1_3Model (constG4String&name=UrQMD1_3");
```

public constructor which calls **InitialiseDataTables** (). This initialises all of the variables as required by UrQMD-1.3cr and held in FORTRAN common blocks based on the DEFAULT values, *i.e.* largely based on the UrQMD-1.3cr defaults, see CTPParam(X) and CTOption(X) from Tables 5 and 6 of the UrQMD user guide (<http://urqmd.org/>).

```
~G4UrQMD1_3Model ();
```

Class destructor.

```
virtual G4HadFinalState *ApplyYourself (const G4HadProjectile  
&theTrack, G4Nucleus &theTarget);
```

Member function to determine the **Final State** of the interaction process. The **Final state** is for the results of (and secondaries from) the projectile, described by **theTrack**, and **the target** nucleus, described by theTarget. This member function drives the UrQMD-1.3cr FORTRAN to enter information about an interaction event, and interprets the results into a product vector as a **G4HadFinalState** object.

Private constructors, operators and member functions

```
const G4UrQMD1_3Model& operator=(G4UrQMD1_3Model  
&right);
```

Operator which is required by Geant4 physics lists.

```
void WelcomeMessage ();
```

Prints to standard output (stdout) the information about the **G4UrQMD1_3Model** when the class is instantiated.

```
void InitialiseDataTables ();
```

Initialises the UrQMD-1.3cr variables during the execution of either of the constructors. This is an initialisation process, primarily setting common block variables directly or through block data calls.

Gbool offshell;

Option to be fixed by the user:

true if nucleons are put “**off-mass-shell**” (default UrQMD option) and **false** if nucleons are “**on-mass-shell**” (recommended by the authors).

Note that this option strongly affects low energy cascade particles.

7.2 G4UrQMD1_3Interface: C++ --FORTRAN interface for common blocks and subroutines

Although not representing a class in itself, **G4UrQMD1_3Interface.hh** contains a series of structure definitions in order to permit access to FORTRAN common block variables. For each common block used by the Geant4 interface, there is an associated C/C++ struct. For example, common block **urqmdparams** becomes the variable **urqmdparams_** of struct type **ccurqmd13urqmdparams**, and variables **real*8 u_elab** and **integer u_at** in that common block are designated as **urqmdparams_.u_elab** and **urqmdparams_.u_at** respectively in the C/C++ interface.

The other function of **G4UrQMD1_3Interface.hh** is to define cross-references between the **UrQMD1.3cr** FORTRAN **subroutines** and C/C++ **subroutines**.

8 Changes to usage of geant4-9.5

In version 9.3.p01 (and older ones) the anti-nucleus characteristics and cross sections are not supplied with the geant4 source. Therefore, one has to install the most recent version of geant4 (9.5) in order to allow anti-nucleus interactions using UrQMD code. For installation, one has to use the so called **CMAKE** build system to compile and install the toolkit. **CMAKE** has been chosen to replace the old **Configure/Make** system. For more information on **CMAKE** itself, please visit <http://www.cmake.org/>.

8.1 Building and installing CMAKE

Unpack the **cmake-2.8.7.tar.gz** to a location of your choice. For illustration only, assume it is unpacked in a directory **/home/path**, so that the CMAKE source sits in the directory

```
$ /home/path/make
```

```
$tar -xvzf cmake-2.8.7.tar.gz
```

To configure the build:

```
$/bootstrap
```

(The following step is not written in the CMAKE manual)

```
$/configure - - prefix=/home/path/cmake
```

```
$make
```

```
$make install
```

*Here the Configure variable **prefix** is used to set the **install** directory, the directory under which **CMAKE** libraries, binaries and headers are installed.*

Finally you will get the directory “cmake” which contains:

+cmake

+Bin/

 |+ccmake

 |+**cmake**

 |+cpack

 |+ctest

+cmake-2.8.7/

+doc/

 |+cmake-2.8/

+man/

 |+man1/

+share/

 |+alocal/

 |+cmake-2.8/

To make sure that everything is O.K., please write

```
$ cmake -version
```

You will get

```
$cmake version 2.8.7
```

To run **cmake** in any path terminal, you have to add few lines in your **.bash_profile** as follows.

First open your **.bash_profile**:

```
$nano .bash_profile
```

Write

```
PATH=/home/path/cmake/bin:$PATH
```

```
LD_LIBRARY_PATH=/home/path/cmake/lib:$LD_LIBRARY_PATH
```

Save your **.bash_profile**.

Finally, execute:

```
$source .bash_profile
```

8.2 Building and installing geant4.9.5

First make sure that there is no previous version of `geant4` in your system.

To do this, please type:

```
$ printenv | grep G4
```

Maybe you find something in your **.bash_profile**. If you do, go to main terminal and write

```
$nano .bash_profile
```

Erase or mark anything starts with **G4**.

To ensure that everything is O.K., write:

```
$source .bash_profile
```

```
$printenv | grep G4
```

If you find no “**G4**” proceed as follows:

Unpack the **geant4.9.5.tar.gz** to the location **/home/path/geant4**, so that the `geant4` “unpacked files” sits in the subdirectory

```
/home/path/geant4/geant4.9.5
```

The next step is to create a directory to configure and run the build and store the build products. This directory should be alongside your source directory (geant4-9.5):

```
$mkdir geant4.9.4-build
```

```
$ls
```

```
+-geant4/          +-geant4.9.5/          +-geant4.9.5-build/
```

To configure and build, change into the build directory:

```
$cd geant4.9.5-build
```

Since geant4 source is in `/home/path/geant4/geant4.9.5`, it is recommended to install it in `/home/path/geant4/geant4.9.5-install` by typing:

```
$cmake -DCMAKE_INSTALL_PREFIX=/home/path/geant4/geant4.9.5-install ../geant4.9.5
```

When complete, do

```
$make
```

```
$make install
```

Finally, you will get “**geant4.9.5-install**” directory which contains

```
+-geant4.9.5-install
```

```
+-bin/
```

```
  |+-geant4.csh
```

```
  |+-geant4.sh
```

```
  |+-geant4-config
```

```
+-include/
```

```
  |+-Geant4/
```

```
  |+-globals.hh
```

```
  |+-G4ParticleDefinition.hh
```

- |+-G4AntiDeuteron.hh
- |+-...
- |+-CLHEP/
- |+-tools/
- +lib/**
- |+-libG4global.so
- |+-...
- +share/**
- +Geant4-9.5.0/**
- +geant4make/**
- |+-**config/**
- |+- **geant4make.sh**
- |+-geant4make.csh
- |+...

Finally, make sure that `geant4` binaries and libraries are available on your path. This is done by writing (in your **.bash_profile**):

```
PATH=$PATH:$HOME/geant4_workdir/bin/Linux-g++/
```

```
Source /home/path/geant4/geant4.9.5-install/share/Geant4-9.5.0/geant4make/geant4make.sh
```

8.3 Building and installing Geant4-UrQMD interface for version 9.5

With version 9.5, you may have problems linking C++ geant4 code against FORTRAN-UrQMD code. In order to resolve these problems it is recommended to use **gfortran** instead of **g77**.

Thus go to the **GNUmake** file in the directory:

```
$cd /home/path/geant4/geant4.9.5/source/processes/hadronic/models/UrQMD13
```

and make sure that these lines

```
FC= g77
```

```
LD=g77
```

```
FFLAGS=-g -Wall -Wsurprising -fbound -check
```

```
LDFLAGS= -g
```

are replaced with:

```
FC=gfortran
```

```
LD=gfortran
```

```
FFLAGS=-Fpic
```

```
LDFLAGS="-L/usr/lib64 -lgfortran"
```

Also, it would be better to abandon the **patch_make_and_install.csh** environment and write few lines in **GNUmake** file:

```
.PHONY: all
```

```
all: urqmd lib
```

```
ifdef G4INCLUDE
```

```
CPPFLAGS += -I $(G4INCLUDE)
```

```
endif
```

```
UrQMDDIRNAME= UrQMDsrc
```

```
urqmd:
```

```
(cd ${URQMDDIRNAME} && \
```

```
tar -xzf urqmd-1.3cr.tar.gz && \
```

```
cp GNUmakefile urqmd-1.3cr && cp *.f urqmd-1.3cr && \
```

```
cd urqmd-1.3cr && ${MAKE} FFLAGS=-Fpic FC=gfortran LD=gfortran
```

```
LDFLAGS="-L/usr/lib64 -lgfortran");
```

```
(mv ${URQMDDIRNAME}/urqmd-1.3cr/obj_Linux/*.o ${G4TMPDIR});
```

This will:

1- Move the object files to the directory

```
$/home/path/geant4_workdir/tmp/Linux-g++/G4hadronic_UrQMD13
```

2- Create UrQMD library in the directory:

```
$/home/path/geant4/geant4-9.5.0/Linux-g++ libGhadronic_UrQMD13.so
```

If the linking is O.K. goto **UrQMD13** directory and type:

```
$ make includes
```

This will move the include files (**G4UrQMD1_3Interface.hh & G4UrQMD1_3Model.hh**) to **Geant4** directory:

```
/home/path/geant4/geant.9.5-install/include/Geant4
```

Finally in the **GNUmake** file of your “**main()**” application, make sure that this line:

```
EXTRALIBS += -L/{G4lib}/${G4SYSTEM} -lG4hadronic_UrQMD13
```

is inserted.

9 The output file

```

Acknowledgments

Kh. Abdel-Waged and N. Felemban would like to thank geant4 group, especially Dr Andrea Dotti for his efforts in making the software compatible with geant4-9.5. This work is supported by the King Abdul-Aziz City for Science and Technology, the National Centre of Mathematics and Physics, Saudi Arabia, contract number 31-465. Kh Abdel-Waged and N. Felemban are thankful to the members of Geant4 hadronic group for stimulating discussions and help.
