

# Nonlinear stability for steady vortex pairs

Geoffrey R. Burton, Helena J. Nussenzveig Lopes  
and Milton C. Lopes Filho

## Abstract

In this article, we prove nonlinear orbital stability for steadily translating vortex pairs, a family of nonlinear waves that are exact solutions of the incompressible, two-dimensional Euler equations. We use an adaptation of Kelvin's variational principle, maximizing kinetic energy penalised by a multiple of momentum among mirror-symmetric isovortical rearrangements. This formulation has the advantage that the functional to be maximized and the constraint set are both invariant under the flow of the time-dependent Euler equations, and this observation is used strongly in the analysis. Previous work on existence yields a wide class of examples to which our result applies.

## 1 Introduction.

From a mathematical viewpoint, steady vortex pairs are a class of nonlinear waves, travelling wave solutions of the incompressible, two dimensional Euler equations in the full plane. Two special examples are Lamb's circular vortex-pair, see [12, p. 245], and a pair of point vortices with equal magnitude and opposite signs.

The literature of vortex pairs goes back to the work of Pocklington in [24], with contemporary interest beginning from the work of Norbury, Deem & Zabusky and Pierrehumbert, see [8, 21, 23]. The existence (and abundance) of steady vortex pairs has been rigorously established in two different ways, as a nonlinear eigenvalue problem, see [28, 21] or by optimization in rearrangement classes, see [5, 4]. The literature on vortex pairs includes asymptotic studies, see [29], numerical studies, see [25] and experimental work, see [11]. Some analytical results (see [20]) and numerical evidence, [22], suggest orbital stability of steady vortex pairs under appropriate conditions. Still, this stability has been an interesting open problem, see [26].

Vortex pairs are one instance of a large collection of coherent structures found in two dimensional vortex dynamics, for example, single vortices, co-rotating pairs and vortex

streets. In the stability theory of such structures, there has long been a view, growing out of ideas of Kelvin [27], that steady fluid flows representing extrema of kinetic energy relative to an “isovortical surface” are stable; this viewpoint is exemplified by the formal arguments of Arnol’d [2] and informs the variational principles for steady vortex-rings in three dimensions proposed by Benjamin [3], which provides the impetus for our work.

The present paper is a piece of real analysis proving a theorem of this type, the first one that applies to steady vortex pairs. Vortex pairs can be viewed equivalently as the dynamics of vorticity which is odd with respect to a straight line or as general vortex dynamics on a half plane, see [16] for a full discussion. For convenience, we formulate our analysis in terms of steady vortices in a uniform flow in the half-plane, which corresponds in the full plane to stability under symmetric perturbations. Maximizers of a linear combination of the classically preserved quantities of kinetic energy and impulse over all vorticities that are equimeasurable rearrangements of a fixed non-negative function with bounded support are considered. The argument is not along the lines envisaged by Arnol’d, but is analogous to that used in [7] for bounded planar domains; the velocity field of a flow with nearby initial vorticity is used to convect the steady state and the differences in energy are estimated.

The vorticity is assumed to be in  $L^p \cap L^1$  for some  $p > 2$  and a distance between vorticity fields is defined in terms of the 2-norm and the impulse. Because of the invariance under translations parallel to the edge of the half-plane, maximizers will not be isolated, so our notion of stability is one of *orbital stability*, in which solutions starting close to the set of maximizers remain close. These results allow discontinuous vorticity, and the solutions studied are known not in closed form, but rather via existence theory. Some stability results in a more symmetric setting, also allowing discontinuous vorticity, have been given by Marchioro & Pulvirenti [18] and Wan & Pulvirenti [30]. Precise definitions and formulations of the theorems are given in Section 2.

Methodologically, a major difficulty is loss of compactness caused by the unbounded domain of the flow; this is overcome using a concentration-compactness argument.

## 2 Notation and Definitions.

We denote by  $\Pi$  the half-plane

$$\Pi = \{x = (x_1, x_2) \in \mathbb{R}^2 \mid x_2 > 0\}.$$

Let  $\mathcal{G}$  denote the inverse for  $-\Delta$  in  $\Pi$ , given by

$$\mathcal{G}\xi(x) = \int_{\Pi} G(x, y)\xi(y)dy, \quad (1)$$

whenever this integral converges; here  $G$  is the Green's function given by

$$G(x, y) = \frac{1}{4\pi} \log \left( \frac{(x_1 - y_1)^2 + (x_2 + y_2)^2}{(x_1 - y_1)^2 + (x_2 - y_2)^2} \right).$$

It is shown in [6] that finiteness of  $\|\xi\|_X := \|\xi\|_2 + I(|\xi|)$  is sufficient for convergence of the integral in (1), where  $I$  is defined below.

The kinetic energy due to vorticity  $\xi$  is then given by

$$E(\xi) = \frac{1}{2} \int_{\Pi} \xi(x)\mathcal{G}\xi(x)dx$$

and the impulse of linear momentum in the  $x_1$ -direction is given by

$$I(\xi) = \int_{\Pi} \xi(x_1, x_2)x_2dx.$$

It is shown in [6] that  $E$  is continuous with respect to  $\|\cdot\|_X$ . We also make use of  $\|\xi\|_Y := \|\xi\|_2 + |I(\xi)|$ , which is a non-equivalent, and incomplete, norm on  $X$ . The Lebesgue measure, of appropriate dimension, of a measurable set  $\Omega$  is denoted  $|\Omega|$ .

The evolution of vorticity  $\omega$  is governed by the weak form of the vorticity equation

$$\begin{cases} \partial_t \omega + \operatorname{div}(\omega u) = 0, \\ u = \lambda e_1 + \nabla^\perp \mathcal{G}\omega, \quad (x, t) \in \Pi \times \mathbb{R}, \end{cases} \quad (2)$$

where  $\lambda e_1$  represents the velocity of the fluid at infinity, which is a uniform flow parallel to the  $x_1$ -axis and  $\nabla^\perp = (-\partial_{x_2}, \partial_{x_1})$ ; the stream function is then  $-\lambda x_2 + \mathcal{G}\omega(x)$ .

If  $\xi$  is a non-negative Lebesgue integrable function on  $\Pi$ , then  $\mathcal{R}(\xi)$ , the set of *rearrangements* of  $\xi$  on  $\Pi$ , is defined by

$$\mathcal{R}(\xi) = \{0 \leq \zeta \in L^1(\Pi) \text{ s.t. } \forall \alpha > 0 \ |\{x : \zeta(x) > \alpha\}| = |\{x : \xi(x) > \alpha\}|\}.$$

We also define

$$\mathcal{R}_+(\xi) = \{ \zeta 1_\Omega \mid \zeta \in \mathcal{R}(\xi), \Omega \subset \Pi \text{ measurable} \}.$$

This is larger than the class  $\mathcal{RC}(\xi)$  of *curtailments of rearrangements* defined by Douglas [10] as

$$\mathcal{RC}(\xi) = \{ 0 \leq \eta \in L^1(\Pi) \mid \eta^\Delta = \xi^\Delta 1_{[0,A)} \text{ for some } 0 \leq A \leq \infty \},$$

where  $^\Delta$  denotes decreasing rearrangement onto  $[0, \infty)$ . We have, from the definitions,

$$\mathcal{R}(\xi) \subset \mathcal{RC}(\xi) \subset \mathcal{R}_+(\xi) \subset \overline{\mathcal{R}(\xi)^w}, \quad (3)$$

where  $\overline{\mathcal{R}(\xi)^w}$  denotes the closure of  $\mathcal{R}(\xi)$  in the weak topology of  $L^2(\Pi)$ , this last inclusion requiring additionally  $\xi \in L^2(\Pi)$ . Moreover  $\overline{\mathcal{R}(\xi)^w}$  is convex, see [10].

For example, in the case of a vortex patch, i.e.  $\xi = 1_\Omega$ , where  $\Omega$  is a bounded measurable subset of the half-plane, we have  $\mathcal{R}(\xi)$  is the set of all characteristic functions of sets with the same measure as  $\Omega$ ,  $\mathcal{RC}(\xi)$  is the set of characteristic functions of sets with measure less than or equal to the measure of  $\Omega$ , which is the same as  $\mathcal{R}_+(\xi)$ . The set  $\overline{\mathcal{R}(\xi)^w}$  is much larger, a convex set containing, in particular, functions bounded by 1 which are not piecewise constant.

The (*strong*) *support*  $\text{suppt} f$  of a real measurable function  $f$  on  $\Pi$  is defined to be the set of points of Lebesgue density 1 for the set  $\{x \in \Pi \mid f(x) \neq 0\}$  and is independent of the choice of representative for  $f$ .

Our stability results are expressed in terms of  *$L^p$ -regular solutions* of the vorticity equation, defined below.

**Definition 1.** *By an  $L^p$ -regular solution of the vorticity equation we mean  $\zeta \in L^\infty_{\text{loc}}([0, \infty), L^1(\Pi)) \cap L^\infty_{\text{loc}}([0, \infty), L^p(\Pi))$  satisfying, in the sense of distributions,*

$$\begin{cases} \partial_t \zeta + \text{div}(\zeta u) = 0, \\ u = \lambda e_1 + \nabla^\perp \mathcal{G} \zeta, \end{cases} \quad (x, t) \in \Pi \times \mathbb{R}, \quad (4)$$

*such that  $E(\zeta(t, \cdot))$  and  $I(\zeta(t, \cdot))$  are constant.*

Existence of a smooth solution of the initial-boundary-value problem for (4) can be obtained by considering the auxiliary problem

$$\begin{cases} \partial_t v + (v \cdot \nabla) v + \lambda \partial_{x_1} v = -\nabla p, \\ \text{div } v = 0 \\ |v| \rightarrow 0 \end{cases} \quad \text{as } |x| \rightarrow \infty, (x, t) \in \Pi \times \mathbb{R} \quad (5)$$

and taking  $\zeta = \text{curl } v$ . Indeed, taking the curl of (5) leads to (4) with  $u = v + \lambda e_1$ .

Now, existence of a smooth solution for (5), when the initial vorticity is compactly supported, is a trivial adaptation of the analogous result for the 2D incompressible Euler equations, see [17, Chapter 3], given that the  $L^2$ -norm of  $v$  is a conserved quantity under evolution by (5). Once smooth existence has been established, standard weak convergence methods yield existence of weak  $L^p$  solutions, see [15, Theorem 2.1], again assuming the initial vorticity has compact support. The only remaining issue, to obtain an  $L^p$ -regular solution for compactly supported initial vorticities, is whether  $E$  and  $I$  are conserved for these weak solutions; this will be the case, easily, if  $p > 2$  since, in this case,  $v$  is bounded *a priori* in  $L^r$ ,  $2 \leq r \leq \infty$ , in terms of  $L^p$  and  $L^1$ -norms of vorticity. We note, in particular, that  $L^\infty$ -regular solutions with compactly supported vorticity are unique, by an easy adaptation of the celebrated work of Yudovich, see [31]. Moreover, these  $L^\infty$ -regular solutions are constant along particle paths associated with the flow  $u$ . Our results do not, however, rely on uniqueness.

Our main result is as follows:

**Theorem 1. (Stability Theorem.)** *Let  $\zeta_0$  be a non-negative function whose support has finite positive area  $\pi a^2$  ( $a > 0$ ) in the half-plane  $\Pi$ . Suppose  $\zeta_0 \in L^p(\Pi)$ , for some  $2 < p \leq \infty$ , and suppose  $\lambda > 0$ . Let  $\Sigma_\lambda$  denote the set of maximizers of  $E - \lambda I$  relative to  $\overline{\mathcal{R}(\zeta_0)^w}$ , and suppose  $\emptyset \neq \Sigma_\lambda \subset \mathcal{R}(\zeta_0)$ . Then  $\Sigma_\lambda$  is orbitally stable, in the sense that, for every  $\varepsilon > 0$  and  $A > \pi a^2$ , there exists  $\delta > 0$  such that, if  $\omega(0) \geq 0$  satisfies  $\text{dist}_Y(\omega(0), \Sigma_\lambda) < \delta$  and  $|\text{suppt}(\omega(0))| < A$ , then, for all  $t \in \mathbb{R}$ , we have  $\text{dist}_2(\omega(t), \Sigma_\lambda) < \varepsilon$ , whenever  $\omega(t)$  denotes an  $L^p$ -regular solution of (2) with initial data  $\omega(0)$ .*

Theorem 1 is an analogue, for unbounded domains, of [7, Theorem 1], and is deduced, by a similar argument, from the following result:

**Theorem 2. (Maximization Theorem.)** *Let non-negative  $\zeta_0 \in L^p(\Pi)$ , for some  $2 < p \leq \infty$  and suppose  $|\text{suppt}(\zeta_0)| = \pi a^2$  for some  $0 < a < \infty$ . Let  $0 < \lambda < \infty$  and suppose that the set  $\Sigma_\lambda$  in which  $E - \lambda I$  attains its supremum  $S_\lambda$  relative to  $\overline{\mathcal{R}(\zeta_0)^w}$  satisfies  $\Sigma_\lambda \subset \mathcal{R}(\zeta_0)$ . Then, in the context of maximizing  $E - \lambda I$  relative to  $\overline{\mathcal{R}(\zeta_0)^w}$ , we have:*

(i) *every maximizing sequence comprising elements of  $\mathcal{R}_+(\zeta_0)$  contains a subsequence whose elements, after suitable translations in the  $x_1$ -direction, converge in  $\|\cdot\|_2$  to an element of  $\Sigma_\lambda$ ;*

- (ii) every maximizing sequence  $\{\zeta_n\}_{n=1}^\infty$  comprising elements of  $\mathcal{R}_+(\zeta_0)$  satisfies  $\text{dist}_2(\zeta_n, \Sigma_\lambda) \rightarrow 0$  as  $n \rightarrow \infty$ ;
- (iii)  $\Sigma_\lambda$  is non-empty;
- (iv) each element  $\zeta$  of  $\Sigma_\lambda$  is a translate of a function Steiner-symmetric about the  $x_2$  axis, compactly supported and satisfies  $\zeta = \varphi \circ (\mathcal{G}\zeta - \lambda x_2)$  a.e. in  $\Pi$  for some increasing function  $\varphi$ .

**Remarks.** The hypotheses of Theorem 1 exclude 0 as a maximizer, and therefore the supremum is positive.

We also show in Lemma 10 that given non-negative  $\zeta_0 \in L^p(\Pi)$ ,  $p > 2$ , having compact support, there exists  $\Lambda > 0$  such that if  $0 < \lambda < \Lambda$  then  $\emptyset \neq \Sigma_\lambda \subset \mathcal{R}(\zeta_0)$ , so that the hypotheses of Theorem 1 are satisfied. Lemma 10 incidentally provides a mild improvement on the existence result [5, Theorem 16(i)].

It also follows from Theorem 2(i) that  $\Sigma_\lambda$  comprises a compact set of functions in  $L^2(\Pi)$  together with their  $x_1$ -translations.

Theorem 2(iv) proves that the maximizers have compact support and therefore fit into the context of [5, Theorem 16(i)], which yields the conclusion, repeated above, that  $\psi := \mathcal{G}\zeta - \lambda x_2$  satisfies an equation

$$-\Delta\psi = \varphi \circ \psi \text{ in } \Pi$$

which is the classical equation governing stream functions of steady planar ideal fluid flows, so that elements of  $\Sigma_\lambda$  do indeed represent steady vortices of finite extent.

It has been noted above that Theorem 1 applies to a wide class of examples. It is unfortunate that this class does not include Lamb's semicircular vortex, because 0 is a maximizer, relative to the weak closure of the rearrangements, of the relevant variational problem; see [6]. Lamb's vortex is a particularly interesting example because it is a closed-form solution, and the maximizers, relative to the class of rearrangements, are known from [6] to be the translates parallel to the  $x_1$ -axis of a single function.

### 3 Concentration-compactness and Theorem 2.

Here we present a sequence of Lemmas leading to the proof of Theorem 2. The first is a slight reformulation of Lions [14, Lemma 1.1], and we omit the proof:

**Lemma 1. (Concentration-Compactness.)** *Let  $\{\xi_n\}_{n=1}^\infty$  be a sequence of non-negative elements of  $L^1(\mathbb{R}^N)$  and suppose*

$$\limsup_{n \rightarrow \infty} \int_{\mathbb{R}^N} \xi_n = \mu$$

where  $0 \leq \mu < \infty$ . Then, after passing to a subsequence, one of the following holds:

(i) (Compactness) *There exists a sequence  $\{y_n\}_{n=1}^\infty$  in  $\mathbb{R}^N$  such that  $\forall \varepsilon > 0 \exists R > 0$  such that*

$$\forall n \quad \int_{y_n + B_R} \xi_n \geq \mu - \varepsilon ;$$

(ii) (Vanishing)

$$\forall R > 0 \quad \lim_{n \rightarrow \infty} \sup_{y \in \mathbb{R}^N} \int_{y + B_R} \xi_n = 0 ;$$

(iii) (Dichotomy) *There exists  $\alpha$ ,  $0 < \alpha < \mu$ , such that for all  $\varepsilon > 0$  and all large  $n$ , there exist  $\xi_n^{(1)} = 1_{\Omega_n^{(1)}} \xi_n$  and  $\xi_n^{(2)} = 1_{\Omega_n^{(2)}} \xi_n$ , for some disjoint measurable  $\Omega_n^{(1)}, \Omega_n^{(2)} \subset \mathbb{R}^N$ , such that, for all  $n$ ,*

$$\begin{aligned} 0 &\leq \int_{\mathbb{R}^N} \xi - (\xi_n^{(1)} + \xi_n^{(2)}) < \varepsilon \\ -\varepsilon &< \int_{\mathbb{R}^N} \xi_n^{(1)} - \alpha < \varepsilon \\ -\varepsilon &< \int_{\mathbb{R}^N} \xi_n^{(2)} - (\mu - \alpha) < \varepsilon \\ \text{dist}(\Omega_n^{(1)}, \Omega_n^{(2)}) &\rightarrow \infty \text{ as } n \rightarrow \infty . \end{aligned}$$

**Remarks.** Notice that if  $\mu = 0$  then the whole sequence has the Vanishing Property.

We will apply this result to maximizing sequences of  $E - \lambda I$  in  $\mathcal{R}_+(\xi)$ , for suitable  $\xi$  and  $\lambda$ . In this connection, it should be noted that if  $\xi \in L^2(\Pi)$  is non-negative and has compact support then, for sequences in  $\mathcal{R}_+(\xi)$ , it follows from Hölder's inequality and equimeasurability that convergence in  $\|\cdot\|_1$  and  $\|\cdot\|_2$  are equivalent.

The following alternative form of the Green's function will be useful:

$$G(x, y) = \frac{1}{4\pi} \log \left( 1 + \frac{4x_2 y_2}{(x_1 - y_1)^2 + (x_2 - y_2)^2} \right). \quad (6)$$

The following estimates are derived in Burton [5, Lemmas 1 & 5]:

**Lemma 2.** *Given  $A > 0$ , we can choose positive numbers  $b, c, d, e$ , and  $0 < \beta < 1$ , depending only on  $A$ , such that if  $\xi \in L^2(\Pi)$  satisfies  $|\text{suppt}(\xi)| \leq A$  then we have*

- (i)  $|\mathcal{G}\xi(x_1, x_2)| \leq \|\xi\|_2 (b + c \log x_2)$ ,  $x_2 > e$ ;
- (ii)  $|\mathcal{G}\xi(x_1, x_2)| \leq d|x_2|^\beta \|\xi\|_2$ ,  $0 < x_2 < e$ .

**Lemma 3.** (i) Given  $A > 0$  and  $2 < p < \infty$  we can choose a positive number  $N$  such that  $|\nabla \mathcal{G}\xi(x_1, x_2)| \leq N\|\xi\|_p$  for all  $\xi \in L^p(\Pi)$  vanishing outside a set of area  $A$ .

(ii) Given  $A > 0$ ,  $Z > 0$  and  $2 < p < \infty$ , we can choose a positive number  $f$  such that if  $\xi \in L^p(\Pi)$  is Steiner-symmetric about the  $x_2$ -axis,  $\xi$  satisfies  $|\text{suppt}(\xi)| \leq A$  and  $\xi(x_1, x_2) = 0$  for  $x_2 > Z$  then we have

$$|\mathcal{G}\xi(x_1, x_2)| \leq f\|\xi\|_p x_2 \min\{1, |x_1|^{-1/2p}\}.$$

The following Lemma shows that  $E(\zeta) < \infty$  provided that  $\|\zeta\|_1$ ,  $\|\zeta\|_2$  and  $I(|\zeta|)$  are all finite. If  $I(\zeta) = \infty$  we adopt the convention  $E(\zeta) - \lambda I(\zeta) = -\infty$  for  $\lambda > 0$ .

**Lemma 4.** There is a constant  $C > 0$  such that

$$\|\mathcal{G}\zeta\|_\infty \leq C(\|\zeta\|_1 + \|\zeta\|_2 + I(|\zeta|))$$

for all measurable functions  $\zeta$ , provided that the right-hand side is finite.

*Proof.* It is enough to consider the case  $\zeta \geq 0$ . We note the inequality

$$\begin{aligned} \log(a + b + c) &\leq \log(3 \max\{a, b, c\}) \\ &\leq \log 3 + (\log a)_+ + (\log b)_+ + (\log c)_+ \end{aligned}$$

for positive  $a, b, c$ , and write  $\rho := |x - y|$  in the formula (6) for  $G$  to obtain

$$\int_{y_2 \geq x_2/2} \log\left(1 + \frac{4x_2y_2}{\rho^2}\right) \zeta(y) dy \leq \int_{\Pi} \log\left(1 + \frac{8y_2^2}{\rho^2}\right) \zeta(y) dy.$$

Now

$$\int_{\Pi} (\log(8y_2^2))_+ \zeta(y) dy \leq \int_{\Pi} (\log 8 + 2y_2) \zeta(y) dy = (\log 8)\|\zeta\|_1 + 2I(\zeta),$$

and

$$\begin{aligned} \int_{\Pi} (\log \rho^{-2})_+ \zeta(y) dy &= \int_{\rho \leq 1} (-2 \log \rho) \zeta(y) dy \\ &\leq \left( \int_{\rho \leq 1} 4(\log \rho)^2 dy \right)^{1/2} \|\zeta\|_2, \end{aligned}$$

hence

$$\int_{y_2 \geq x_2/2} \log\left(1 + \frac{4x_2y_2}{\rho^2}\right) \zeta(y) dy \leq \text{const.}(\|\zeta\|_1 + I(\zeta) + \|\zeta\|_2).$$

Also

$$\begin{aligned} \int_{y_2 \leq x_2/2} \log \left( 1 + \frac{4x_2 y_2}{\rho^2} \right) \zeta(y) dy &\leq \int_{\Pi} \log \left( 1 + \frac{2x_2^2}{x_2^2/4} \right) \zeta(y) dy \\ &= (\log 9) \|\zeta\|_1, \end{aligned}$$

and the desired inequality follows.  $\square$

**Lemma 5.** *Given positive numbers  $M_1, M_2, M_3$ , the functional  $E$  is Lipschitz continuous in  $\|\cdot\|_2$  relative to*

$$V := \{\zeta \in L^2(\Pi) \mid |\text{suppt}(\zeta)| \leq M_1, I(|\zeta|) \leq M_2, \|\zeta\|_2 \leq M_3\}.$$

*Proof.* For  $\xi, \eta \in V$  we have

$$\begin{aligned} |E(\xi) - E(\eta)| &= \frac{1}{2} \int_{\Pi} (\xi + \eta) \mathcal{G}(\xi - \eta) \\ &\leq \|\xi - \eta\|_1 \|\mathcal{G}(\xi + \eta)\|_{\infty} \\ &\leq (2M_1)^{1/2} \|\xi - \eta\|_2 C(\|\xi + \eta\|_1 + \|\xi + \eta\|_2 + I(|\xi + \eta|)) \\ &\leq (2M_1)^{1/2} \|\xi - \eta\|_2 C(2M_1^{1/2} M_3 + 2M_3 + 2M_2), \end{aligned}$$

where  $C$  is the constant provided by Lemma 4.  $\square$

**Lemma 6.** *Let  $\zeta_0 \in L^2$  be non-negative, suppose  $|\text{suppt}(\zeta_0)| = \pi a^2$  for some  $0 < a < \infty$ , and let  $\lambda > 0$ . Then*

(i) *there exists  $Z > 0$  (depending on  $a, \lambda$  and  $\|\zeta_0\|_2$  only) such that, for all  $\zeta \in \mathcal{R}_+(\zeta_0)$ ,*

$$\mathcal{G}\zeta(x_1, x_2) - \lambda x_2 < 0 \quad \forall x_2 > Z;$$

(ii) *if  $\zeta \in \mathcal{R}_+(\zeta_0)$  and  $h = \zeta \mathbf{1}_U$  where  $U$  is a set on which  $\mathcal{G}\zeta - \lambda x_2$  is nowhere positive, then*

$$(E - \lambda I)(\zeta - h) \geq (E - \lambda I)(\zeta)$$

*with strict inequality unless  $h = 0$ , and in particular we can take  $U = \mathbb{R} \times (Z, \infty)$ ;*

(iii) *any maximizer of  $E - \lambda I$  relative to  $\overline{\mathcal{R}(\zeta_0)^w}$  is supported in  $\mathbb{R} \times [0, Z]$ ;*

(iv) *if  $\zeta \in \overline{\mathcal{R}(\zeta_0)^w}$  with  $\|\zeta\|_X < \infty$ , and  $h = \zeta \mathbf{1}_{\mathbb{R} \times (Z, \infty)}$ , then there is a rearrangement  $h'$  of  $h$  supported in  $\mathbb{R} \times [0, Z] \setminus \text{suppt}(\zeta)$  such that*

$$(E - \lambda I)(\zeta - h + h') \geq (E - \lambda I)(\zeta);$$

*moreover  $\zeta - h + h'$  is a rearrangement of  $\zeta$ .*

*Proof.* (i) follows easily from the estimate of Lemma 2.

For (ii), observe that

$$\begin{aligned} (E - \lambda I)(\zeta - h) &= (E - \lambda I)(\zeta) - \int_{\Pi} (\mathcal{G}\zeta - \lambda x_2)h + E(h) \\ &= (E - \lambda I)(\zeta) - \int_U (\mathcal{G}\zeta - \lambda x_2)h + E(h) \\ &\geq (E - \lambda I)(\zeta) + E(h), \end{aligned}$$

since on  $U$  we have  $(\mathcal{G}\zeta - \lambda x_2) \leq 0$  and  $h \geq 0$ . The result follows since  $E(h) > 0$  unless  $h = 0$ .

(iii) now follows from (ii), since if  $\zeta \in \overline{\mathcal{R}(\zeta_0)^w}$  then  $\zeta - h \in \overline{\mathcal{R}(\zeta_0)^w}$  also, using results of Douglas [10].

(iv) is trivial if  $h = 0$ . Suppose therefore that  $h \neq 0$ . Let

$$\varepsilon = (E - \lambda I)(\zeta - h) - (E - \lambda I)(\zeta)$$

which is positive by (ii). In view of the decay of  $\mathcal{G}(\zeta - h)$  at the  $x_2$ -axis quantified in Lemma 2(ii) it is enough to form  $h'$  by rearranging  $h$  on the part of a narrow strip along the  $x_2$ -axis outside  $\text{suppt}(\zeta)$ ; this is justified since any two sets of equal finite positive Lebesgue measure are measure-theoretically equivalent.  $\square$

**Lemma 7.** *Let  $\zeta_0 \in L^2(\Pi)$  be a non-negative function with support of finite area, and let  $\lambda > 0$ . Then  $E - \lambda I$  has the same supremum on all of the sets  $\overline{\mathcal{R}(\zeta_0)^w}$ ,  $\mathcal{R}_+(\zeta_0)$ ,  $\mathcal{RC}(\zeta_0)$ , and  $\mathcal{R}(\zeta_0)$ .*

*Proof.* In view of the inclusions (3) it will be enough to prove equality of the suprema on the first and last sets in the list. Let  $\xi \in \overline{\mathcal{R}(\zeta_0)^w}$ . Then  $\xi' := \xi 1_{\mathbb{R} \times (0, Z)} \in \overline{\mathcal{R}(\zeta_0)^w}$  and, by Lemma 6(ii),

$$(E - \lambda I)(\xi') \geq (E - \lambda I)(\xi).$$

By the monotone convergence theorem, given  $\varepsilon > 0$  we can choose  $R > 0$  such that  $\xi'' := \xi' 1_{(-R, R) \times \mathbb{R}} = \xi 1_{(-R, R) \times (0, Z)}$ , which also belongs to  $\overline{\mathcal{R}(\zeta_0)^w}$ , satisfies

$$(E - \lambda I)(\xi'') > (E - \lambda I)(\xi) - \varepsilon.$$

Now, by compactness of  $\mathcal{G}$  as an operator on  $L^2((-R, R) \times (0, Z))$ , within every weak neighbourhood of  $\xi''$  we can find  $\xi''' \in \mathcal{R}_+(\zeta_0)$  supported in  $(-R, R) \times (0, Z)$  with

$$-\varepsilon < (E - \lambda I)(\xi''') - (E - \lambda I)(\xi'') < \varepsilon.$$

Finally, if  $\xi''' \notin \mathcal{R}(\zeta_0)$ , given  $\delta > 0$  sufficiently small, we may choose any rearrangement  $\eta_\delta$  of  $\zeta_0^\Delta - \xi^\Delta$  on a subset of  $(1/\delta, \pi a^2/\delta) \times (0, \delta)$  to find that  $\xi_\delta := \xi''' + \eta_\delta$  is a rearrangement of  $\zeta_0$  supported in a bounded subset of  $\mathbb{R} \times (0, Z)$ , and that as  $\delta \rightarrow 0$  we have  $\xi_\delta \rightarrow \xi'''$  weakly in  $L^2$  and  $(E - \lambda I)(\xi_\delta) \rightarrow (E - \lambda I)(\xi''')$ .  $\square$

**Lemma 8. (Vanishing excluded.)** *Suppose that  $\zeta_0$ ,  $a$ ,  $\lambda$  and  $\Sigma_\lambda$  satisfy the hypotheses of the Maximization Theorem 2. Then no maximizing sequence for  $E - \lambda I$  relative to  $\mathcal{R}_+(\zeta_0)$  has the Vanishing Property of Lemma 1.*

*Proof.* Suppose  $\{\zeta_n\}_{n=1}^\infty$  is a maximizing sequence for  $E - \lambda I$  relative to  $\mathcal{R}_+(\zeta_0)$  that has the Vanishing Property, reformulated by the equivalence of  $\|\cdot\|_1$  and  $\|\cdot\|_2$  on  $\mathcal{R}_+(\zeta_0)$  as

$$\forall R > 0 \quad \lim_{n \rightarrow \infty} \sup_{y \in \mathbb{R}^N} \int_{y+B_R} \zeta_n^2 = 0.$$

By Lemma 6(ii), we can modify the  $\zeta_n$  so they are supported in  $\mathbb{R} \times [0, Z]$ , while remaining a maximizing sequence with the Vanishing Property. Consider any  $R > 0$ . Then for  $x \in \Pi$ , relative to  $B := x + B_R$ , we have

$$\left. \begin{aligned} \|\zeta_n\|_{L^2(B)} &\rightarrow 0 \\ \|\zeta_n\|_{L^1(B)} &\leq \text{const.} \|\zeta_n\|_{L^2(B)} \rightarrow 0 \text{ (by Hölder's inequality)} \\ I(\zeta_n 1_B) &\leq Z \|\zeta_n\|_{L^1(B)} \rightarrow 0 \end{aligned} \right\}$$

uniformly over  $x \in \Pi$ , so  $\mathcal{G}(\zeta_n 1_B)(x) \rightarrow 0$  as  $n \rightarrow \infty$  uniformly over  $x \in \Pi$ , by Lemma 4.

By writing the Green's function in the form (6) we estimate

$$\mathcal{G}(\zeta_n(1 - 1_B))(x) \leq \frac{Z^2}{\pi R^2} \|\zeta_n\|_1 \leq \frac{Z^2}{\pi R^2} \|\zeta_0\|_1.$$

Hence, as  $n \rightarrow \infty$ ,

$$E(\zeta_n) \leq \|\zeta_n\|_1 \left( \frac{Z^2}{\pi R^2} \|\zeta_0\|_1 + o(1) \right) \leq \|\zeta_0\|_1 \left( \frac{Z^2}{\pi R^2} \|\zeta_0\|_1 + o(1) \right).$$

This holds for every  $R > 0$ , hence  $E(\zeta_n) \rightarrow 0$  as  $n \rightarrow \infty$ . Hence

$$\limsup_{n \rightarrow \infty} (E - \lambda I)(\zeta_n) \leq 0.$$

But the hypotheses of the Lemma, together with Lemma 7 ensure that the supremum of  $E - \lambda I$  relative to  $\mathcal{R}_+(\zeta_0)$  is positive. Thus Vanishing does not occur.  $\square$

**Lemma 9. (Dichotomy excluded.)** *Suppose that  $\zeta_0$ ,  $a$ ,  $\lambda$ ,  $\Sigma_\lambda$  and  $S_\lambda$  satisfy the hypotheses of the Maximization Theorem 2. Then no maximizing sequence for  $E - \lambda I$  relative to  $\mathcal{R}_+(\zeta_0)$  has the Dichotomy Property of Lemma 1.*

*Proof.* Suppose  $\{\zeta_n\}_{n=1}^\infty$  is a maximizing sequence for  $E - \lambda I$  relative to  $\mathcal{R}_+(\zeta_0)$  that has the Dichotomy Property. In view of the remarks on convergence following Lemma 1 we can assume that, for some  $0 < \alpha < \mu$ , and some restrictions  $\{\zeta_n^{(i)}\}_{i=1}^3$  of  $\zeta_0$  to sets  $\{\Omega_n^{(i)}\}_{n=1}^3$  partitioning  $\Pi$ , we have

$$\left. \begin{aligned} \|\zeta_n^{(3)}\|_2 &\rightarrow 0, \\ \|\zeta_n^{(1)}\|_2^2 &\rightarrow \alpha, \\ \|\zeta_n^{(2)}\|_2^2 &\rightarrow \beta := \mu - \alpha, \\ \text{dist}(\text{suppt}(\zeta_n^{(1)}), \text{suppt}(\zeta_n^{(2)})) &\rightarrow \infty, \\ (E - \lambda I)(\zeta_n^{(1)} + \zeta_n^{(2)} + \zeta_n^{(3)}) &\rightarrow S_\lambda, \end{aligned} \right\} \quad (7)$$

as  $n \rightarrow \infty$ .

We may multiply the functions  $\{\zeta_n^{(i)}\}_{i=1}^3$  by  $1_{\mathbb{R} \times (0, Z)}$ , where  $Z$  is the number provided by Lemma 6(i), yet still assume the last two lines of (7) to hold, in view of Lemma 6(ii). We also have

$$\begin{aligned} (E - \lambda I)(\zeta_n^{(1)} + \zeta_n^{(2)}) &= (E - \lambda I)(\zeta_n) - \lambda I(\zeta_n^{(3)}) \\ &\quad - \int_{\Pi} \zeta_n^{(3)} \mathcal{G}(\zeta_n^{(1)} + \zeta_n^{(2)} + \frac{1}{2}\zeta_n^{(3)}) \\ &\rightarrow S_\lambda \quad \text{as } n \rightarrow \infty \end{aligned}$$

by Lemma 4, so we may replace  $\zeta_n^{(3)}$  by 0 and suppose  $\zeta_n = \zeta_n^{(1)} + \zeta_n^{(2)}$  for all  $n$ .

Formula (6) for the Green's function leads to the estimate

$$\begin{aligned} \int_{\Pi} \zeta_n^{(1)} \mathcal{G} \zeta_n^{(2)} &\leq \pi^{-1} \|\zeta_n^{(1)}\|_1 \|\zeta_n^{(2)}\|_1 Z^2 \text{dist}(\text{suppt}(\zeta_n^{(1)}), \text{suppt}(\zeta_n^{(2)}))^{-2} \\ &\rightarrow 0 \quad \text{as } n \rightarrow \infty. \end{aligned}$$

Consequently

$$\begin{aligned} (E - \lambda I)(\zeta_n^{(1)}) + (E - \lambda I)(\zeta_n^{(2)}) &= (E - \lambda I)(\zeta_n) - \int_{\Pi} \zeta_n^{(1)} \mathcal{G} \zeta_n^{(2)} \\ &\rightarrow S_\lambda \quad \text{as } n \rightarrow \infty. \end{aligned} \quad (8)$$

Let  $\zeta_n^{(1)*}$ ,  $\zeta_n^{(2)*}$  denote the Steiner symmetrizations of  $\zeta_n^{(1)}$ ,  $\zeta_n^{(2)}$  about the  $x_2$ -axis. Then we have

$$(E - \lambda I)(\zeta_n^{(i)*}) \geq (E - \lambda I)(\zeta_n^{(i)}), \quad i = 1, 2, \quad (9)$$

by Riesz's rearrangement inequality in conjunction with formula (6) for  $G$ , and the symmetrization-invariance of  $I$ .

From the estimate of Lemma 3(ii) (in case  $p = \infty$  replacing  $p$  by any  $2 < p < \infty$ ), there is a positive number  $k$  such that  $\mathcal{G}\zeta(x) - \lambda x_2 > 0$  only if  $x \in (-k, k) \times (0, Z)$ , uniformly over Steiner symmetric  $\zeta \in \mathcal{R}_+(\zeta_0)$ . Let

$$\zeta_n^{(i)**} = \zeta_n^{(i)*} 1_{\{x | \mathcal{G}\zeta_n^{(i)*}(x) - \lambda x_2 > 0\}}, \quad i = 1, 2.$$

Then from (9) and Lemma 6(ii) we have

$$(E - \lambda I)(\zeta_n^{(i)**}) \geq (E - \lambda I)(\zeta_n^{(i)*}) \geq (E - \lambda I)(\zeta_n^{(i)}), \quad i = 1, 2. \quad (10)$$

Moreover we have

$$\text{supp}(\zeta_n^{(i)**}) \subset \{x \mid -k < x_1 < k\}, \quad i = 1, 2.$$

Now define

$$\begin{aligned} \zeta_n^{(1)***}(x) &= \zeta_n^{(1)**}(x_1 - k, x_2), \\ \zeta_n^{(2)***}(x) &= \zeta_n^{(2)**}(x_1 + k, x_2), \end{aligned}$$

which are supported in  $(0, 2k) \times (0, Z)$  and  $(-2k, 0) \times (0, Z)$  respectively. Then, from (10),

$$(E - \lambda I)(\zeta_n^{(i)***}) = (E - \lambda I)(\zeta_n^{(i)**}) \geq (E - \lambda I)(\zeta_n^{(i)}), \quad i = 1, 2.$$

From the definitions and (3) we have  $\zeta_n^{(1)***} + \zeta_n^{(2)***} \in \mathcal{R}_+(\zeta_0) \subset \overline{\mathcal{R}(\zeta_0)^w}$  and after passing to a subsequence we can assume that  $\zeta_n^{(1)***} \rightarrow \overline{\zeta^{(1)}}$  and  $\zeta_n^{(2)***} \rightarrow \overline{\zeta^{(2)}}$ , say, weakly in  $L^2$ , and so  $\overline{\zeta} := \overline{\zeta^{(1)}} + \overline{\zeta^{(2)}} \in \overline{\mathcal{R}(\zeta_0)^w}$ . Now, using compactness of  $\mathcal{G}$  as an operator on  $L^2((-2k, 2k) \times (0, Z))$ , from (8) we have

$$\begin{aligned} (E - \lambda I)(\overline{\zeta^{(1)}}) &+ (E - \lambda I)(\overline{\zeta^{(2)}}) \\ &= \lim_{n \rightarrow \infty} ((E - \lambda I)(\zeta_n^{(1)***}) + (E - \lambda I)(\zeta_n^{(2)***})) \\ &\geq S_\lambda \end{aligned}$$

and therefore

$$\begin{aligned} (E - \lambda I)(\overline{\zeta}) &= (E - \lambda I)(\overline{\zeta^{(1)}}) + (E - \lambda I)(\overline{\zeta^{(2)}}) + \int_{\Pi} \overline{\zeta^{(1)}} \mathcal{G} \overline{\zeta^{(2)}} \\ &\geq (E - \lambda I)(\overline{\zeta^{(1)}}) + (E - \lambda I)(\overline{\zeta^{(2)}}) \\ &\geq S_\lambda. \end{aligned} \quad (11)$$

Therefore  $\bar{\zeta} \in \Sigma_\lambda$  so, by hypothesis,  $\bar{\zeta} \in \mathcal{R}(\zeta_0)$ . It follows that

$$\|\bar{\zeta}^{(1)}\|_2^2 + \|\bar{\zeta}^{(2)}\|_2^2 = \|\bar{\zeta}\|^2 = \mu.$$

Since  $\|\bar{\zeta}^{(1)}\|_2^2 \leq \alpha$  and  $\|\bar{\zeta}^{(2)}\|_2^2 \leq \beta$ , we deduce  $\|\bar{\zeta}^{(1)}\|_2^2 = \alpha$  and  $\|\bar{\zeta}^{(2)}\|_2^2 = \beta$ , so both  $\bar{\zeta}^{(1)}$  and  $\bar{\zeta}^{(2)}$  are non-zero. Hence

$$\int_{\Pi} \bar{\zeta}^{(1)} \mathcal{G} \bar{\zeta}^{(2)} > 0.$$

Therefore strict inequality holds in (11) contradicting the definition of  $S_\lambda$ .  $\square$

**Proof of Theorem 2.** There is no loss of generality in supposing  $2 < p < \infty$ .

To prove (i), we first consider a maximizing sequence  $\{\zeta_n\}_{n=1}^\infty$  for  $E - \lambda I$  comprising elements of  $\mathcal{R}_+(\zeta_0)$  and having the Compactness Property. There is thus a sequence  $\{y_n\}_{n=1}^\infty$  in  $\Pi$  such that

$$\forall \varepsilon > 0 \exists R > 0 \text{ s.t. } \forall n \|\zeta_n \mathbf{1}_{\Pi \setminus (y_n + B_R)}\|_2^2 < \varepsilon. \quad (12)$$

We assume the  $y_n$  to lie on the  $x_2$  axis, which results in no loss of generality in view of the invariance of  $E - \lambda I$  under translations in the  $x_1$ -direction.

Let  $\zeta_n^0 = \zeta_n \mathbf{1}_{\mathbb{R} \times (0, Z)}$  and  $\zeta_n^R = \zeta_n \mathbf{1}_{(-R, R) \times (0, Z)}$ , where  $Z$  is the number given in Lemma 6(i) and  $R > 0$  is arbitrary. Then  $\{\zeta_n^0\}_{n=1}^\infty$  is also a maximizing sequence by Lemma 6(ii), and (12) has the consequence that

$$\forall \varepsilon > 0 \exists R > 0 \text{ s.t. } \forall n \|\zeta_n^0 - \zeta_n^R\|_2^2 < \varepsilon. \quad (13)$$

After passing to a subsequence, we can suppose that  $\{\zeta_n^0\}_{n=1}^\infty$  converges weakly in  $L^2(\Pi)$  to a limit  $\zeta^0$ , hence  $\zeta_n^R \rightarrow \zeta^R := \zeta^0 \mathbf{1}_{(-R, R) \times (0, Z)}$  weakly as  $n \rightarrow \infty$ . With this notation (13) takes the form

$$\|\zeta_n^0 - \zeta_n^R\|_2 \rightarrow 0 \text{ as } R \rightarrow \infty, \text{ uniformly over } n. \quad (14)$$

Now  $E(\zeta_n^R) \rightarrow E(\zeta^R)$  as  $n \rightarrow \infty$ , for each  $R$ . We have

$$E(\zeta_n^0) = E(\zeta_n^R + (\zeta_n^0 - \zeta_n^R)) = E(\zeta_n^R) + E(\zeta_n^0 - \zeta_n^R) + \int_{\Pi} \zeta_n^R \mathcal{G}(\zeta_n^0 - \zeta_n^R),$$

whence

$$|E(\zeta_n^0) - E(\zeta_n^R)| \leq \text{const.} \|\zeta_n^0 - \zeta_n^R\|_2 \quad (15)$$

by Lemma 5, and the constant is independent of  $R$  and  $n$ . Now from (14) and (15) we have

$$|E(\zeta_n^0) - E(\zeta_n^R)| \rightarrow 0 \text{ as } R \rightarrow \infty, \text{ uniformly over } n. \quad (16)$$

But  $E(\zeta_n^R) \rightarrow E(\zeta^R)$  as  $n \rightarrow \infty$  for each fixed  $R$  by weak continuity, and  $E(\zeta^R) \rightarrow E(\zeta^0)$  as  $R \rightarrow \infty$  by the Monotone Convergence Theorem, and in conjunction with (16) this yields  $E(\zeta_n^0) \rightarrow E(\zeta^0)$ .

We have

$$|I(\zeta_n^0) - I(\zeta_n^R)| \leq R \|\zeta_n^0 - \zeta_n^R\|_1. \quad (17)$$

Let  $\varepsilon > 0$ . Now

$$|I(\zeta_n^0) - I(\zeta^0)| \leq |I(\zeta_n^0) - I(\zeta_n^R)| + |I(\zeta_n^R) - I(\zeta^R)| + |I(\zeta^R) - I(\zeta^0)|;$$

we may choose  $R > 0$  to make the first term less than  $\varepsilon/3$  for all  $n$  by (14) and (17), and the last term less than  $\varepsilon/3$  for all  $n$  by the Monotone Convergence Theorem, then the middle term is less than  $\varepsilon/3$  for all sufficiently large  $n$  by weak convergence. Hence  $I(\zeta_n^0) \rightarrow I(\zeta^0)$  as  $n \rightarrow \infty$ .

Thus  $(E - \lambda I)(\zeta_n^0) \rightarrow (E - \lambda I)(\zeta^0)$  as  $n \rightarrow \infty$ , so  $(E - \lambda I)(\zeta^0) = S_\lambda$ . Therefore  $\zeta^0 \in \mathcal{R}(\zeta_0)$  by hypothesis, so  $\zeta_n^0 \rightarrow \zeta^0$  strongly in  $L^2(\Pi)$  by uniform convexity.

Since  $\zeta_n^0$  and  $\zeta_n - \zeta_n^0$  are supported on disjoint sets,

$$\|\zeta_n - \zeta_n^0\|_2^2 = \|\zeta_n\|_2^2 - \|\zeta_n^0\|_2^2 \leq \|\zeta_0\|_2^2 - \|\zeta_n^0\|_2^2 \rightarrow 0,$$

so  $\zeta_n \rightarrow \zeta^0$  as  $n \rightarrow \infty$ . We have thus proved that a compact maximizing sequence has a subsequence which, after suitable translations in the  $x_1$ -direction, converges strongly in  $L^2(\Pi)$  to an element of  $\Sigma_\lambda$ . Now Lemmas 1, 8 and 9 show that every maximizing sequence contains a subsequence having the Compactness Property, and (i) follows.

To prove (ii), let  $\{\zeta_n\}_{n=1}^\infty$  be a maximizing sequence for  $E - \lambda I$  relative to  $\overline{\mathcal{R}(\zeta_0)^w}$  comprising elements of  $\mathcal{R}_+(\zeta_0)$ . Suppose that  $\text{dist}_2(\zeta_n, \Sigma_\lambda) \not\rightarrow 0$  as  $n \rightarrow \infty$ . Then, after discarding a subsequence, we can suppose

$$\text{dist}_2(\zeta_n, \Sigma_\lambda) > \delta \quad \forall n, \quad (18)$$

where  $\delta$  is some positive number.

But, by (i),  $\{\zeta_n\}_{n=1}^\infty$  can be replaced by a subsequence that, after suitable translations in the  $x_1$ -direction, converges in  $\|\cdot\|_2$  to an element of  $\Sigma_\lambda$ . This contradicts the supposition (18), showing that  $\text{dist}_2(\zeta_n, \Sigma_\lambda) \rightarrow 0$  as  $n \rightarrow \infty$ , proving (ii).

To prove (iii) observe that Lemma 7 shows the existence of maximizing sequences in  $\mathcal{R}_+(\zeta_0)$ , which can, by (i), be assumed to contain subsequences converging to elements of  $\Sigma_\lambda$ , which is therefore non-empty.

Finally, to prove (iv) observe that, for fixed  $x_2$  and  $y_2$ , formula (6) shows that  $G(x, y)$  is a positive strictly decreasing function of  $|x_1 - y_1|$  alone, so we can apply the one-dimensional case of Lieb's analysis [13, Lemma 3] of equality in Riesz's rearrangement inequality, on pairs of lines parallel to the  $x_1$ -axis, to deduce that every  $\zeta \in \Sigma_\lambda$  is, after a translation, Steiner-symmetric about the  $x_2$ -axis. From Lemma 6(ii) we know that every  $\zeta \in \Sigma_\lambda$  is supported in the set where  $\mathcal{G}\zeta(x) - \lambda x_2 > 0$ , which is bounded by Lemma 2(i) and Lemma 3(ii). The functional relationship  $\zeta = \varphi \circ (\mathcal{G}\zeta - \lambda x_2)$ , where  $\zeta \in \Sigma_\lambda$  is any element and  $\varphi$  is some (*a priori* unknown) increasing function, is given by [5, Theorem 16(i)] (where it forms the first variation condition at a maximum).  $\square$

## 4 Existence, Transport and Theorem 1.

**Lemma 10.** *Let  $0 \leq \zeta_0 \in L^p(\Pi)$ , for some  $2 < p \leq \infty$  and suppose  $|\text{suppt}(\zeta_0)| = \pi a^2$  for some  $0 < a < \infty$ . For  $0 < \lambda < \infty$  let  $S_\lambda$  be the supremum of  $E - \lambda I$  relative to  $\overline{\mathcal{R}(\zeta_0)^w}$  and let  $\Sigma_\lambda$  be the set of maximizers of  $E - \lambda I$  relative to  $\overline{\mathcal{R}(\zeta_0)^w}$ . Then, there exists  $\Lambda > 0$  such that, if  $0 < \lambda < \Lambda$ , then  $\emptyset \neq \Sigma_\lambda \subset \mathcal{R}(\zeta_0)$ .*

*Proof.* There is no loss of generality in supposing  $2 < p < \infty$ . Since  $E$  is unbounded above on  $\mathcal{R}(\zeta_0)$ , which may be seen by translating  $\zeta_0$  away to infinity in the  $x_2$ -direction, we have  $S_\lambda \rightarrow \infty$  as  $\lambda \rightarrow 0$ . Therefore we can choose  $\Lambda > 0$  such that, if  $0 < \lambda < \Lambda$  then  $S_\lambda > M$ , where  $M$  is a positive number to be chosen later.

Consider  $\lambda$  with  $0 < \lambda < \Lambda$ , and consider  $\bar{\zeta} \in \Sigma_\lambda$ . Arguing as in Douglas [10, Theorem 4.1], the strict convexity of  $E - \lambda I$  ensures that  $\bar{\zeta}$  is an extreme point of  $\overline{\mathcal{R}(\zeta_0)^w}$  so  $\bar{\zeta} \in \mathcal{RC}(\zeta_0) \subset \mathcal{R}_+(\zeta_0)$  by [10, Theorem 2.1]. Let  $m := \sup_{x \in \Pi} (\frac{1}{2}\mathcal{G}\bar{\zeta}(x) - \lambda x_2)$ . Then

$$M < S_\lambda = \int_{\Pi} \bar{\zeta}(x) \left( \frac{1}{2}\mathcal{G}\bar{\zeta}(x) - \lambda x_2 \right) dx \leq m \|\bar{\zeta}\|_1 \leq m \|\zeta_0\|_1,$$

so  $m > M/\|\zeta_0\|_1$ . From Lemma 3(i) we have

$$|\nabla \mathcal{G}\bar{\zeta}(x)| \leq N \|\bar{\zeta}\|_p \quad \forall x \in \Pi$$

where  $N$  is a positive constant independent of  $\lambda$  and  $M$ , hence if  $x \in \Pi$  is such that  $\frac{1}{2}\mathcal{G}\bar{\zeta}(x) - \lambda x_2 > m/2$ , and  $y \in \Pi$  is such that  $|y - x| < 2a$  and  $y_2 < x_2$ , then

$$\begin{aligned} \frac{1}{2}\mathcal{G}\bar{\zeta}(y) - \lambda y_2 &> \frac{1}{2}(\mathcal{G}\bar{\zeta}(x) - 2aN\|\zeta_0\|_1) - \lambda x_2 \\ &> \frac{m}{2} - 2aN\|\zeta_0\|_1 > \frac{M}{2\|\zeta_0\|_1} - 2aN\|\zeta_0\|_1 > 0, \end{aligned}$$

provided we choose  $M = 5aN\|\zeta_0\|_1^2$ ; note this shows  $x_2 > a$  because  $\frac{1}{2}\mathcal{G}\bar{\zeta}(y) - \lambda y_2$  vanishes when  $y_2 = 0$ . Hence

$$|\{y \in \Pi \mid \mathcal{G}\bar{\zeta}(y) - \lambda y_2 > 0\}| > |\{y \in \Pi \mid \frac{1}{2}\mathcal{G}\bar{\zeta}(y) - \lambda y_2 > 0\}| > 2\pi a^2.$$

It follows that if  $\bar{\zeta}$  is a proper curtailment of a rearrangement of  $\zeta_0$ , then we have the freedom to choose  $\zeta_1$  supported in  $\{y \in \Pi \mid \mathcal{G}\bar{\zeta}(y) - \lambda y_2 > 0\} \setminus \text{suppt}(\bar{\zeta})$  such that  $\bar{\zeta} + \zeta_1 \in \mathcal{R}(\zeta_0)$ , and then

$$(E - \lambda I)(\bar{\zeta} + \zeta_1) = (E - \lambda I)(\bar{\zeta}) + E(\zeta_1) + \int_{\Pi} (\mathcal{G}\bar{\zeta} - \lambda x_2)\zeta_1 > (E - \lambda I)(\bar{\zeta}),$$

contradiction. So every maximizer belongs to  $\mathcal{R}(\zeta_0)$ .  $\square$

Recall the definition of an  $L^p$ -regular solution given in Definition 1.

**Lemma 11.** *Let  $2 < p < \infty$  and let  $\zeta$  be an  $L^p$ -regular solution of the vorticity equation. Let  $\psi(t, x) = \mathcal{G}\zeta(t, x) - \lambda x_2$  and set  $u(t, x) = \nabla^\perp \psi(t, x) - \lambda e_1$ . Suppose  $\omega_0 \in L^p(\Pi)$ . Then the initial value problem for the linear transport equation*

$$\begin{cases} \partial_t \omega + \text{div}(\omega u) = 0 \\ \omega(0) = \omega_0 \end{cases} \quad (19)$$

has a unique weak solution  $\omega \in L_{\text{loc}}^\infty([0, \infty), L^p(\Pi))$ . Moreover,  $\omega \in C([0, \infty), L^p(\Pi))$  and  $\omega$  satisfies the renormalisation property in the form  $\omega(t) \in \mathcal{R}(\omega_0)$  for almost all  $t > 0$ .

*Proof.* We begin by extending  $\psi$  to the whole of  $\mathbb{R}^2$  as a function odd in  $x_2$ , which is accomplished by allowing arbitrary  $x \in \mathbb{R}^2$  in the formula (1); then extending  $\zeta$  to  $\mathbb{R}^2$  as a function odd in  $x_2$  gives  $-\Delta\psi = \zeta$  throughout  $\mathbb{R}^2$  and we take  $u = \nabla^\perp \psi + \lambda e_1$  throughout  $\mathbb{R}^2$ . Similarly we extend  $\omega_0$  to  $\mathbb{R}^2$  as a function odd in  $x_2$ . Write  $\psi_0(x) = \psi(x) + \lambda x_2$ .

Now  $\|\psi_0(t, \cdot)\|_\infty$  is bounded by Lemma 4 and it then follows from elliptic regularity theory, specifically Agmon [1, Thm. 6.1], that  $\|\psi_0(t, \cdot)\|_{2,p,B}$  is bounded over all unit

balls  $B$  uniformly over every bounded interval of  $t$ . Hence  $\|u(t, \cdot)\|_\infty$  is bounded on every bounded interval of  $t$ .

The DiPerna-Lions theory of transport equations [9, Thm. II.2, Cor. II.1 and Cor. II.2] assures us of the existence of a unique solution  $\omega \in L^\infty_{\text{loc}}([0, \infty), L^p(\mathbb{R}^2))$  to (19), that  $\omega \in C([0, \infty), L^p(\mathbb{R}^2))$  and that  $\omega$  has the renormalisation property

$$\partial_t(\beta \circ \omega) + \text{div}((\beta \circ \omega)u) = 0$$

for every  $\beta \in C^1(\mathbb{R})$  that satisfies  $|\beta'(s)| \leq \text{const.}(1 + |s|^{p/2})$ . Moreover  $\omega$  is odd in  $x_2$  from the uniqueness.

Now consider a test function of the form  $\chi(t)\varphi_R(x)$  where  $\chi \in \mathcal{D}(\mathbb{R})$  and  $\varphi_R \in \mathcal{D}(\mathbb{R}^2)$  satisfies  $0 \leq \varphi_R \leq 1$  everywhere,  $\varphi_R(x) = 1$  if  $|x| < R$ ,  $\varphi_R(x) = 0$  if  $|x| > 2R$  and  $|\nabla\varphi_R| < 2/R$  everywhere. Then, for any  $\beta$  as above,

$$\int_{\mathbb{R}^2} \int_{\mathbb{R}} \chi'(t)\varphi_R(x)\beta(\omega(t, x))dt dx + \int_{\mathbb{R}^2} \int_{\mathbb{R}} \chi(t)\nabla\varphi_R(x) \cdot u(t, x)\beta(\omega(t, x))dt dx = 0. \quad (20)$$

We now suppose further that  $|\beta(s)| \leq \text{const.}|s|^p$  for all  $s$ , choose  $\sigma > 2$  such that  $1/2 + 1/p + 1/\sigma = 1$  and deduce

$$\begin{aligned} \left| \int_{\mathbb{R}^2} \beta(\omega(t, x))\nabla\varphi_R(x) \cdot u(t, x)dx \right| &\leq \|\beta(\omega(t, \cdot))\|_p \|u(t, \cdot)\|_2 \|\nabla\varphi_R\|_\sigma \\ &\leq \text{const.}\|\omega(t, \cdot)\|_p \|u(t, \cdot)\|_2 R^{2/\sigma-1} \\ &\rightarrow 0 \text{ as } R \rightarrow \infty \text{ uniformly over } t \in \text{suppt}\chi. \end{aligned}$$

From (20) we now have

$$\int_{\mathbb{R}^2} \beta(\omega(t, x))dx = \text{const.}$$

for each  $\beta$ ; taking  $\beta$  to be a mollification of  $1_{[\alpha, \infty)}$  for  $\alpha > 0$  we deduce that the positive part of  $\omega(t)$  is a rearrangement of the positive part of  $\omega_0$  and similarly for the negative parts.  $\square$

**Remark** Note that it follows from Lemma 11, in particular, that  $\|\zeta(t, \cdot)\|_p$  and  $\|\zeta(t, \cdot)\|_1$  are conserved if  $\zeta$  is an  $L^p$ -regular solution.

We also observe that a version of Lemma 11, in the case  $\lambda = 0$ , was established in [19, Proposition 1].

**Proof of Theorem 1.** There is no loss of generality in supposing  $2 < p < \infty$ . Choose  $Z > 0$  such that  $\mathcal{G}\omega(x) - \lambda x_2 < 0$  for  $x_2 > Z$  provided

$$\left. \begin{aligned} \omega &\geq 0 \\ |\text{suppt}(\omega)| &< A \\ \|\omega\|_2 &\leq \|\zeta_0\|_2 + 1 \\ I(\omega) &\leq \sup I(\Sigma_\lambda) + 1 \end{aligned} \right\} \quad (21)$$

by Lemma 4. Write

$$\tilde{\omega} = \omega \mathbf{1}_{\mathbb{R} \times (0, Z)}.$$

Recall the notation  $S_\lambda$  introduced in Theorem 2, as the supremum of  $E - \lambda I$  relative to  $\overline{\mathcal{R}(\zeta_0)^w}$ .

Then we have

$$(E - \lambda I)(\tilde{\omega}) \geq (E - \lambda I)(\omega)$$

and

$$(E - \lambda I)(\omega) \rightarrow S_\lambda \quad \text{as} \quad \text{dist}_Y(\omega, \Sigma_\lambda) \rightarrow 0,$$

for  $\omega$  satisfying (21), by Lemma 5.

Suppose, to seek a contradiction, that  $\{\omega^n(\cdot)\}_{n=1}^\infty$  are non-negative  $L^p$ -regular solutions of the vorticity equation (2) for which

$$\text{dist}_Y(\omega^n(0), \Sigma_\lambda) \rightarrow 0$$

as  $n \rightarrow \infty$ , but

$$\sup_{t>0} \text{dist}_2(\omega^n(t), \Sigma_\lambda) > \theta \quad \forall n, \quad (22)$$

where  $\theta > 0$ . For each  $n$  choose  $t_n > 0$  such that

$$\text{dist}_2(\omega^n(t_n), \Sigma_\lambda) > \theta, \quad (23)$$

and choose  $\zeta_0^n \in \Sigma_\lambda$  such that

$$\|\zeta_0^n - \omega^n(0)\|_2 \rightarrow 0 \quad \text{as} \quad n \rightarrow \infty.$$

In view of Theorem 2(i), after translating in the  $x_1$ -direction, and passing to a subsequence, we may additionally suppose that  $\{\zeta_0^n\}_{n=1}^\infty$  converges in  $L^2(\Pi)$  to a limit in  $\Sigma_\lambda$ . Re-assigning the label  $\zeta_0$  we shall suppose

$$\zeta_0^n \rightarrow \zeta_0 \in \Sigma_\lambda \quad \text{as} \quad n \rightarrow \infty \quad \text{in} \quad \|\cdot\|_2.$$

Now

$$\inf_{t>0} (E - \lambda I)(\tilde{\omega}^n(t)) \geq S_\lambda - o(1) \text{ as } n \rightarrow \infty. \quad (24)$$

Let  $\zeta(\cdot) = \zeta^n(\cdot)$  be the solution of the transport equation

$$\begin{cases} \partial_t \zeta + \operatorname{div}(\zeta u) = 0, \\ u = \lambda e_1 + \nabla^\perp \mathcal{G}\omega^n \end{cases}$$

with initial data  $\zeta_0^n$ . Then, continuing to use  $\tilde{\cdot}$  for restriction to  $\mathbb{R} \times (0, Z)$ , we have

$$\begin{aligned} |I(\tilde{\zeta}^n(t)) - I(\tilde{\omega}^n(t))| &\leq Z \|\tilde{\zeta}^n(t) - \tilde{\omega}^n(t)\|_1 \\ &\leq Z \|\zeta_0^n - \omega^n(0)\|_1 \\ &\leq Z(\pi a^2 + A)^{1/2} \|\zeta_0^n - \omega^n(0)\|_2 \end{aligned}$$

and

$$\|\tilde{\zeta}^n(t) - \tilde{\omega}^n(t)\|_2 \leq \|\zeta^n(t) - \omega^n(t)\|_2 = \|\zeta_0^n - \omega^n(0)\|_2,$$

hence

$$\begin{aligned} |E(\tilde{\zeta}^n(t)) - E(\tilde{\omega}^n(t))| &\leq \operatorname{const.} \|\tilde{\zeta}^n(t) - \tilde{\omega}^n(t)\|_2 \\ &\leq \operatorname{const.} \|\zeta_0^n - \omega^n(0)\|_2. \end{aligned} \quad (25)$$

by Lemma 5. It now follows from (24) and (25) that  $\{\tilde{\zeta}^n(t_n)\}_{n=1}^\infty$  is a maximizing sequence for  $E - \lambda I$  relative to  $\overline{\mathcal{R}(\zeta_0)^w}$ . It follows from Theorem 2 that

$$\operatorname{dist}_2(\tilde{\zeta}^n(t_n), \Sigma_\lambda) \rightarrow 0$$

as  $n \rightarrow \infty$ .

From this it follows that

$$\|\tilde{\zeta}^n(t_n) - \zeta^n(t_n)\|_2 \rightarrow 0,$$

since the functions  $\tilde{\zeta}^n(t_n) - \zeta^n(t_n)$  and  $\tilde{\zeta}^n(t_n)$  have disjoint supports and are therefore orthogonal in  $L^2$ , so

$$\|\tilde{\zeta}^n(t_n) - \zeta^n(t_n)\|_2^2 = \|\zeta^n(t_n)\|_2^2 - \|\tilde{\zeta}^n(t_n)\|_2^2 = \|\zeta_0\|_2^2 - \|\tilde{\zeta}^n(t_n)\|_2^2 \rightarrow 0.$$

Hence

$$\operatorname{dist}_2(\zeta^n(t_n), \Sigma_\lambda) \rightarrow 0.$$

Since

$$\|\zeta^n(t_n) - \omega^n(t_n)\|_2 = \|\zeta_0^n - \omega^n(0)\|_2 \rightarrow 0$$

we deduce

$$\text{dist}_2(\omega^n(t_n), \Sigma_\lambda) \rightarrow 0,$$

and this contradicts the choices of  $\theta$  and  $t_n$  made in (22) and (23).  $\square$

## 5 Further Remarks.

If we only consider perturbations formed by adding non-negative vorticity to a maximizer then we can prove the following variant of Theorem 1 concerning stability in  $\|\cdot\|_Y$ :

**Theorem 3.** *Let  $\zeta_0$  be a non-negative function whose support has finite positive area  $\pi a^2$  ( $a > 0$ ) in the half-plane  $\Pi$ , suppose  $\zeta_0 \in L^p(\Pi)$  for some  $2 < p \leq \infty$ , and suppose  $\lambda > 0$ . Let  $\Sigma_\lambda$  denote the set of maximizers of  $E - \lambda I$  relative to  $\overline{\mathcal{R}(\zeta_0)^w}$ , and suppose  $\emptyset \neq \Sigma_\lambda \subset \mathcal{R}(\zeta_0)$ . Then  $\Sigma_\lambda$  is orbitally stable, in the sense that, for every  $\varepsilon > 0$  and  $A > \pi a^2$ , there exists  $\delta > 0$  such that, if  $\omega(0)$  satisfies  $\omega(0) \geq \zeta_0$  for some element of  $\Sigma_\lambda$ , again denoted  $\zeta_0$ , and if  $\text{dist}_Y(\omega(0), \Sigma_\lambda) < \delta$  and  $|\text{suppt}(\omega(0))| < A$ , then for all  $t \in \mathbb{R}$ , then we have  $\text{dist}_Y(\omega(t), \Sigma_\lambda) < \varepsilon$ , whenever  $\omega(t)$  denotes an  $L^p$ -regular solution of (2) with initial data  $\omega(0)$ .*

*Proof.* We indicate the modifications that should be made to the proof of Theorem 1. We have  $I(\zeta^n(t_n)) - I(\omega^n(t_n)) \leq 0$ . Therefore

$$\begin{aligned} S_\lambda - (E - \lambda I)(\omega^n(t_n)) &\geq (E - \lambda I)(\zeta^n(t_n)) - (E - \lambda I)(\omega^n(t_n)) \\ &\geq E(\zeta^n(t_n)) - E(\omega^n(t_n)). \end{aligned}$$

Now  $E(\zeta^n(t_n)) - E(\omega^n(t_n)) \rightarrow 0$  by Lemma 5, whereas, by conservation of the impulse and energy of  $\omega^n(t)$ , we have

$$(E - \lambda I)(\omega^n(t_n)) = (E - \lambda I)(\omega^n(0)) \rightarrow S_\lambda,$$

using Lemma 5.

What is now required is to choose a maximizer  $\sigma_n$  close to  $\omega^n(t_n)$  in  $\|\cdot\|_2$ , and then after taking a subsequence, and suitably translating the  $\sigma_n$  in the  $x_1$ -direction to  $\sigma'_n$ , obtain convergence in  $\|\cdot\|_2$ , say to  $\sigma_0$ . Then  $E(\omega^n(t_n)) \rightarrow E(\sigma_0)$  and

$$(E - \lambda I)(\omega^n(t_n)) \rightarrow S_\lambda = (E - \lambda I)(\sigma_0)$$

so  $I(\omega^n(t_n)) \rightarrow I(\sigma_0)$ . For large  $n$ , we then have a contradiction to the choice of  $\theta$  and  $t_n$  in (3) and (22), which in this case would have been

$$\sup_{t>0} \text{dist}_Y(\omega^n(t), \Sigma_\lambda) > \theta, \quad \text{dist}_Y(\omega^n(t_n), \Sigma_\lambda) > \theta.$$

Hence  $\sup_t \text{dist}_Y(\omega(t), \Sigma_\lambda) \rightarrow 0$  as  $\text{dist}_Y(\omega(0), \Sigma_\lambda) \rightarrow 0$ , as desired.  $\square$

We conclude this article with some final remarks. Although we describe our result as a nonlinear stability theorem, it falls short of what one would desire because we only show that, for a class of steady vortex pairs  $\zeta_0$ , the perturbed trajectories stay close to the set  $\Sigma_\lambda(\zeta_0)$ , but not necessarily to the orbit of the unperturbed steady wave  $\{\zeta_0(\cdot - (\lambda t, 0)), t \in \mathbb{R}\}$ . In consequence, the most natural problem raised by this work is to further investigate the structure of  $\Sigma_\lambda$ . Another issue that bears further scrutiny is that the notions of closeness employed for the perturbation of initial vorticity and the change in the evolving vorticity are slightly different. An extension of this work in any way which would include Lamb's circular vortex-pair (the one case where we have a precise characterization of  $\Sigma_\lambda$ ) would also be very interesting.
