## 1 Introduction

The Quantum Ising Model with a transverse magnetic field is well known [1] [2]. In one dimension it has the Hamiltonian

$$\mathcal{H}_{N} = -J \sum_{n=1}^{N} \sigma_{n}^{x} \sigma_{n+1}^{x} + B \sum_{n=1}^{N} \sigma_{n}^{z} + H \sum_{n=1}^{N} \sigma_{n}^{x}, \qquad (1)$$

where J > 0 is the coupling constant and  $\sigma^x = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ ,  $\sigma^y = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}$ and  $\sigma^z = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$  are the Pauli matrices. *B* and *H* are transverse and longitudinal magnetic fields, respectively. The partition function is

$$Z_N = \operatorname{tr} e^{-\beta \mathcal{H}_N} \tag{2}$$

where  $\beta$  is the inverse temperature. In the case where H = 0 this model has been exactly solved [1] [3]. The free energy is [2]

$$f(\beta, J, B) = -\lim_{N \to \infty} \frac{1}{\beta N} \log Z_N$$
$$= -\frac{1}{2\pi\beta} \int_0^{2\pi} \log 2 \cosh \beta \Delta(x) \, dx \tag{3}$$

where

$$\Delta(x) = \sqrt{J^2 + B^2 - 2BJ\cos x}.$$
(4)

In particular the ground state energy is given by

$$f_{\infty}(J,B) = \lim_{\beta \to \infty} f(\beta, J, B) = -\frac{1}{2\pi} \int_0^{2\pi} \Delta(x) \, dx.$$
 (5)

In this limit there is a critical point in B at B = J. The correlation function

$$\langle \sigma_j^x \sigma_k^x \rangle = \lim_{N \to \infty} \frac{\operatorname{tr} \, \sigma_j^x \sigma_k^x e^{-\beta \mathcal{H}_N}}{Z_N} \tag{6}$$

can be written as a Toeplitz determinant of size |j - k| just as the correlation function of the two dimensional classical Ising model [4], but only in the limit  $\beta \to \infty$ . In fact the correlation function  $\lim_{\beta\to\infty} \langle \sigma_j^x \sigma_k^x \rangle$  is the same as the diagonal correlation function  $\langle \sigma_{jj}\sigma_{kk} \rangle$  of the two dimensional classical Ising lattice for  $T < T_c$ , the ratio B/J in the one dimensional quantum model corresponding to  $(\sinh 2E_1/k_{\rm B}T \sinh 2E_2/k_{\rm B}T)^{-1}$  in the two dimensional classical model. (Here  $E_1$  and  $E_2$  are the coupling constants in the horizontal and vertical directions, respectively). In particular the limit of infinite separation is given by [3]

$$\lim_{|j-k|\to\infty} \lim_{\beta\to\infty} \langle \sigma_j^x \sigma_k^x \rangle = \begin{cases} \{1 - (B/J)^2\}^{1/4} & \text{if } B < J, \\ 0 & \text{if } B \ge J, \end{cases}$$
(7)

which is most easily proved using Szegö's theorem [5] [6].

## 2 The quantum spherical model

In analogy with (1) we define a partition function of a (*d*-dimensional) isotropic quantum spherical model on a lattice  $\Lambda$  as follows:

$$Z_{N} = \int_{[0,\infty)^{N}} \int_{[0,2\pi)^{N}} \int_{[0,\pi]^{N}} e^{\sum_{j,k\in\Lambda} \langle jk\rangle} \beta Jr_{j}\cos\theta_{j}r_{k}\cos\theta_{k}}$$

$$e^{\sum_{j\in\Lambda}\beta(Br_{j}\sin\theta_{j}\cos\varphi_{j}+Hr_{j}\cos\theta_{j})}$$

$$\prod_{l=1}^{N} r_{l}^{2}\sin\theta_{l} \ d^{N}\theta \ d^{N}\varphi \ \delta\left(\sum_{m=1}^{N} r_{m}^{2}-N\right) d^{N}r$$

$$= \int_{\mathbf{R}^{3N}} e^{\sum_{\langle jk\rangle}\beta Jz_{j}z_{k}+\sum_{j}\beta(Bx_{j}+Hz_{j})} \delta\left(\sum_{k=1}^{N} (x_{k}^{2}+y_{k}^{2}+z_{k}^{2})-N\right) d^{3N}\mathbf{x}(8)$$

Here J > 0,  $B \ge 0$  and H > 0.  $\delta$  signifies the Dirac distribution. The notation  $\langle jk \rangle$  means that j and k are nearest neighbors on  $\Lambda$ . Unlike the

Quantum Ising Model with H = 0, in this model the critical point is B = 2Jd(in the limit  $H \to 0$ ). In fact, it will be shown that in this limit the ground state free energy  $f_{H,\infty} := -\lim_{\beta \to \infty} \lim_{N \to \infty} (N\beta)^{-1} \log Z_N$  is given by

$$f_{0,\infty} = \lim_{H \to 0} f_{H,\infty} = -\begin{cases} Jd + B^2/4Jd & \text{if } B \le 2Jd, \\ B & \text{if } B > 2Jd. \end{cases}$$
(9)

We shall now give a proof of (9).

#### **2.1** The case B > 2Jd

We use the method of steepest descent to prove this result, following the calculation by Baxter [7]. We let H = 0 in (8). Clearly the integrand in (8) may be multiplied by a factor  $\exp a(\sum_{k=1}^{N} (x_k^2 + y_k^2 + z_k^2) - N)$  without changing the partition function  $Z_N$ . Using the identity

$$\delta(x) = \frac{1}{2\pi} \int_{-\infty}^{\infty} e^{isx} ds, \qquad (10)$$

together with (8) and letting a > 0, we get

$$Z_N = \frac{\pi^{N-1}}{2} \int_{\mathbf{R}^N} \int_{-\infty}^{\infty} \left(\frac{1}{a+is}\right)^N \exp\frac{N(\beta B)^2}{4(a+is)}$$
$$\exp\left[\sum_{\langle jk \rangle} \beta J z_j z_k + \sum_j (a+is)(1-z_j^2)\right] ds \ d^N z \tag{11}$$

after integrating over  $\mathbf{x}$  and  $\mathbf{y}$ . Let  $\mathbf{V}$  be the symmetric matrix such that

$$\mathbf{z}^T \mathbf{V} \mathbf{z} = (a+is) \sum_{j=1}^N z_j^2 - \beta J \sum_{\langle jk \rangle}^N z_j z_k.$$
(12)

In this way (11) can be written as

$$Z_N = \frac{\pi^{N-1}}{2} \int_{\mathbf{R}^N} \int_{-\infty}^{\infty} \left(\frac{1}{a+is}\right)^N \exp\frac{N(\beta B)^2}{4(a+is)} \exp\left[-\mathbf{z}^T \mathbf{V} \mathbf{z} + N(a+is)\right] ds \ d^N z.$$
(13)

We now choose the constant a so large that all the eigenvalues of **V** have positive real part. This allows us to change the order of integration, and we may now write (13) as

$$Z_N = \frac{\pi^{3N/2-1}}{2} \int_{-\infty}^{\infty} \left(\frac{1}{a+is}\right)^N (\det \mathbf{V})^{-1/2} \\ \exp\left[\frac{N(\beta B)^2}{4(a+is)} + N(a+is)\right] ds.$$
(14)

We need to calculate the eigenvalues of  $\mathbf{V}$ . Since  $\mathbf{V}$  is cyclic, this is easily done. We let the lattice be *d*-dimensional hypercubic, so that

$$N = L^d \tag{15}$$

for some positive integer L. It now follows from (12) that the eigenvalues are

$$\lambda(\omega_1, ..., \omega_d) = a + is - \beta J \sum_{j=1}^d \cos \omega_j$$
(16)

where each  $\omega_j$  takes the values  $\{2\pi k/L\}_{k=0}^{L-1}$ , and  $a > \beta Jd$ . The determinant of **V** is the product of its eigenvalues, so

$$\log \det \mathbf{V} = \sum_{\omega_j \ : \ 1 \le j \le d} \log \lambda(\omega_1, ..., \omega_d).$$
(17)

Clearly

$$Z_N = \frac{\beta J}{2\pi i} \left(\frac{\pi}{\beta J}\right)^{3N/2} \int_{c-i\infty}^{c+i\infty} e^{N\phi(w)} dw, \qquad (18)$$

where

$$\phi(w) = \beta J w - \frac{1}{2} g(w) + (\beta B)^2 / 4\beta J w,$$
(19)

 $c = (a - \beta J d) / \beta J$  and

$$g(z) = 2\log w + \frac{1}{N}\sum_{\omega_j}\log\left(w - \sum_j\cos\omega_j\right).$$
(20)

Since  $\phi$  approaches  $+\infty$  as w approaches 0 or  $+\infty$  along the real line,  $\phi$  has a minumum at some  $w_0$ ,  $0 < w_0 < \infty$ . Thus  $\Re \phi$  has a maximum at  $w_0$  along the line  $(w_0 - i\infty, w_0 + i\infty)$ . Since B > 2Jd, we may choose  $c = w_0$ . We now use the method of steepest descent (see for instance Murray [8]), by letting N approach infinity. In this way, the free energy is

$$f = -\beta^{-1} \lim_{N \to \infty} N^{-1} \log Z_N = -\frac{3}{2\beta} \ln (\pi/\beta J) - \beta^{-1} \phi(w_0).$$
(21)

Now

$$\lim_{\beta \to \infty} w_0 = B/2J,\tag{22}$$

and thus the ground state energy is

$$\lim_{\beta \to \infty} f = -\lim_{\beta \to \infty} \beta^{-1} \phi(w_0)$$
$$= -B.$$
(23)

#### **2.2** The case $B \leq 2Jd$

In this case we let H > 0, so instead of (13) we have

$$Z_N = \frac{\pi^{N/2-1}}{2} \int_{\mathbf{R}^N} \int_{-\infty}^{\infty} \left(\frac{1}{a+is}\right)^N \exp\frac{N(\beta B)^2}{4(a+is)}$$
$$\exp\left[-\mathbf{z}^T \mathbf{V} \mathbf{z} + \mathbf{h}^T \mathbf{z} + N(a+is)\right] \, ds \, d^N z, \tag{24}$$

where  $\mathbf{h} = \beta H(1, ..., 1)$ . We change variables to  $\mathbf{t} = \mathbf{z} - \frac{1}{2}\mathbf{V}^{-1}\mathbf{h}$ , and rotate the axes in  $(t_1, ..., t_N)$  to make **V** diagonal. Thus we get

$$Z_N = \frac{\pi^{N/2-1}}{2} \int_{-\infty}^{\infty} \left(\frac{1}{a+is}\right)^N (\det \mathbf{V})^{-1/2} \exp \frac{N(\beta B)^2}{4(a+is)} \exp\left[\mathbf{h}^T \mathbf{V}^{-1} \mathbf{h}/4 + N(a+is)\right] ds.$$
(25)

Thus

$$Z_N = \frac{\pi^{N/2}}{2\pi i} \int_{c-i\infty}^{c+i\infty} e^{N\phi(w)} dw, \qquad (26)$$

where  $a + is - \beta Jd = \beta Jw$  and

$$\phi(w) = \beta J(w+d) + \frac{(\beta H)^2}{4\beta Jw} + \frac{(\beta B)^2}{4\beta J(w+d)}$$
  
-  $\log \beta J(w+d) - \frac{1}{2} \sum_{\omega_j} \log (\beta J(w+d) - \beta J \sum_j \cos \omega_j).$  (27)

We proceed in the same way as before, taking the limit  $N \to \infty$  and then  $\beta \to \infty$ . In this case  $w_0 \to 0$  as  $H \to 0$ . The free energy is thus

$$f = -Jd - \frac{B^2}{4Jd}.$$
(28)

This ends the proof.

## 3 Discussion

Comparison of (5) and (9) shows that the susceptibilities of the two models at B = 0 are equal when d = 1; that is  $-\partial^2 f_{\infty}/\partial B^2|_{B=0} = 1/2J$  and  $-\partial^2 f_{0,\infty}/\partial B^2|_{B=0} = 1/2Jd$ . While the Quantum Ising Model has only been exactly solved in the one dimensional case, the quantum spherical modelcan be solved in any finite dimension.
