Abstract

A (v, k, t) packing of size b is a system of b subsets (blocks) of a v -element underlying set such that each block has k elements and every t -set is contained in at most one block. $P(v, k, t)$ stands for the maximum possible b . A packing is called *abundant* if $b > v$. We give new estimates for $P(v, k, t)$ around the critical range, slightly improving the Johnson bound and asymptotically determine the minimum $v = v_0(k, t)$ when *abundant* packings exist.

For a graph G and a positive integer c , let $\chi_\ell(G, c)$ be the minimum value of k such that one can properly color the vertices of G from any assignment of lists $L(v)$ such that $|L(v)| = k$ for all $v \in V(G)$ and $|L(u) \cap L(v)| \leq c$ for all $uv \in E(G)$. Kratochvíl, Tuza and Voigt in 1998 asked to determine $\lim_{n \rightarrow \infty} \chi_\ell(K_n, c)/\sqrt{cn}$ (if exists). Using our bound on $v_0(k, t)$, we prove that the limit exists and equals 1. Given c , we find the exact value of $\chi_\ell(K_n, c)$ for infinitely many n .

1 Preliminaries on hypergraphs

A *hypergraph* $\mathcal{H} = (V, \mathcal{E})$ consists of a set of vertices $V = V(\mathcal{H})$ and a collection \mathcal{E} of subsets of V called edges or blocks, i.e., multiple copies of edges are allowed. Often we take $V(\mathcal{H}) = [v]$, where $[v] := \{1, 2, 3, \dots, v\}$. The *degree* of a vertex $x \in V$, denoted by $d_{\mathcal{H}}(x)$ or just by d_x , is the number of edges containing the vertex x .

Key words and phrases: Packing of sets, t -designs, choosability, complete graph, graph colorings

A set of distinct vertices $\{x_1, \dots, x_m\}$ is called a *system of distinct representatives* (SDR, for short) of the (multi)family $\mathcal{E} = \{E_1, \dots, E_m\}$ if $x_i \in E_i$ for each $i \in [m]$. By classic Hall's Theorem [6], \mathcal{E} has an SDR if and only if it satisfies Hall's condition

$$\left| \bigcup_{E \in \mathcal{E}'} E \right| \geq |\mathcal{E}'| \quad \text{for all } \mathcal{E}' \subseteq \mathcal{E}. \quad (1)$$

A hypergraph is *k-uniform* if all of its edges has k elements. It is a *t-packing* if $|E \cap E'| < t$ for any two distinct edges $E, E' \in \mathcal{E}$. The following theorem is usually attributed to Johnson [8], who used it to get upper bounds for error-correcting codes. It was rediscovered several times, e.g., Bassalygo [1], Corrádi [2]. Let $\mathcal{E} := \{E_1, \dots, E_m\}$ be a family of k -sets such that $|E_i \cap E_j| < t$ for all $1 \leq i < j \leq m$. Then

$$v := \left| \bigcup_{i=1}^m E_i \right| \geq \frac{mk^2}{(m-1)(t-1) + k}. \quad (2)$$

A (v, k, t) packing of size b is a system of b subsets (blocks) of a v -element underlying set such that each block has k -elements and every t -set is contained in at most one block. $P(v, k, t)$ stands for the maximum possible b . A packing is called *abundant* if $b > v$. For example, the finite affine plane $AG(2, q)$ of order q is a (perfect) $(q^2, q, 2)$ packing with $q^2 + q$ blocks, so it is abundant.

Let $v_0(k, t)$ stand for the minimum v that $P(v, k, t) > v$. For example, we have $v_0(q, 2) \leq q^2$ if an $AG(2, q)$ exists. Applying (2) to $v + 1$ blocks of an abundant packing one gets $v \geq (v + 1)k^2 / (v(t - 1) + k)$. Rearranging we get $v(v(t - 1) - k^2 + k) \geq k^2$ and thus

$$v_0(k, t) > (k^2 - k) / (t - 1). \quad (3)$$

2 Main result and an application

Our main aim here is to show that (3) gives the true order of magnitude of v_0 .

Theorem 1. *Let $t \geq 2$ and suppose that $k \rightarrow \infty$. Then $v_0(k, t) = (1 + o(1)) \frac{k^2}{t - 1}$.*

Leaving out an arbitrary element from each block of a (v, k, t) packing one obtains a $(v, k - 1, t)$ packing of the same size (for $k > t \geq 2$). In this way one can see that the sequence $\{v_0(k, t) : k = t, t + 1, t + 2, \dots\}$ is strictly increasing. So Theorem 1 follows from (3) and an explicit construction of an infinite series of abundant packings for a dense sequence of k 's giving us an asymptotically matching upper bound. From now on, it will be more convenient to use c for $t - 1$. The following construction is presented in Section 4.

Construction 2. *Let $c \geq 1$ and suppose that q is a prime power, $c < q - 1$ and c divides $q - 1$. Then*

$$P\left(\frac{q^2 - 1}{c} + 1, q, c + 1\right) \geq \frac{q^2 - 1}{c} + \left\lfloor \frac{q + 1}{c} \right\rfloor.$$

We obtain for these values that

$$v_0(q, c + 1) \leq \frac{q^2 - 1}{c} + 1. \quad (4)$$

It is known (see [7]) that for every sufficiently large real k there exists a prime $q \in [k, k + k^{0.6}]$ such that c divides $q - 1$. Then the monotonicity of v_0 and (4) yield

$$v_0(k, c + 1) \leq v_0(q, c + 1) \leq \frac{q^2 - 1}{c} + 1 < \frac{k^2}{c} + O(k^{1.6}).$$

This together with (3), completes the proof of Theorem 1.

Theorem 1 allows to answer a question on list colorings of graphs. Recall that a *list* L for a graph G is an assignment to every $v \in V(G)$, a set $L(v)$ of colors that may be used for coloring v . Graph G is *L -colorable*, if there exists a proper coloring f of the vertices of G from L , i.e., if $f(v) \in L(v)$ for all $v \in V(G)$ and $f(u) \neq f(v)$ for all $uv \in E$. The *list chromatic number* of G , $\chi_\ell(G)$, is the least k such that G is L -colorable, whenever $|L(v)| = k$ for all $v \in V(G)$.

A list L for a graph G is a (k, c) -*list* if $|L(v)| = k$ for all $v \in V(G)$ and $|L(u) \cap L(v)| \leq c$ for all $uv \in E(G)$. Kratochvíl, Tuza and Voigt [9] introduced $\chi_\ell(G, c)$, the least k such that G is L -colorable from each (k, c) -list L . They showed that $\sqrt{cn/2} \leq \chi_\ell(K_n, c) \leq \sqrt{2ecn}$, where K_n is the complete graph on n vertices. They asked whether the limit $\lim_{n \rightarrow \infty} \chi_\ell(K_n, c)/\sqrt{cn}$ exists. In Section 5 we use Theorem 1 to prove that the limit exists and is 1. We also find the exact value of $\chi_\ell(K_n, c)$ for infinitely many values of n .

3 Explicit gaps

There are many results concerning packings when equality holds in (2). These packings have $1 + (k^2 - k)/(t - 1)$ blocks and are called *symmetric* $(t - 1)$ -*designs*, see [6]. By improving (3) we establish large explicit gaps between $v_0(k, t)$ and $v_0(k + 1, t)$ for many cases. These gaps will be used in our second topic concerning (k, c) -list colorings of graphs (see Section 5).

Claim 3. *Let $q > c \geq 1$. Then $v_0(q + 1, c + 1) \geq \frac{1}{c} \left(q^2 + q + \frac{2(q - c + 1)}{c + 1} \right) + 1$.*

Note that using (2), i.e., the inequality $v \geq (v + 1)(q + 1)^2/(vc + q + 1)$, leads to the bound $v_0 > (q^2 + q)/c + O(1)$. So we have a slight improvement on the Johnson bound in this critical range.

One can summarize (4) and Claim 3 in one formula:

$$v_0(q, c + 1) \leq \frac{q^2 - 1}{c} + 1 < \frac{1}{c} \left(q^2 + q + \frac{2(q - c + 1)}{c + 1} \right) + 1 \leq v_0(q + 1, c + 1) \quad (5)$$

whenever q is a prime power, $1 \leq c < q - 1$, and c divides $q - 1$.

Lemma 4. *Let $c \geq 1$ and suppose that \mathcal{E} is a q -uniform hypergraph on vertex set Y such that $|\mathcal{E}| = q + 2$ and $|E \cap E'| \leq c - 1$ for any two edges. Then $|Y| \geq \frac{1}{c} \left(q^2 + q + \frac{2(q - c + 1)}{c + 1} \right)$.*

Proof. Let d_y be the degree of the vertex y . We have

$$\sum_{y \in Y} \binom{d_y}{2} = \sum_{E, E' \in \mathcal{E}} |E \cap E'| \leq (c - 1) \binom{q + 2}{2}, \quad (6)$$

$$\sum_{y \in Y} d_y = \sum_{E \in \mathcal{E}} |E| = (q + 2)q. \quad (7)$$

Multiply (6) by -2 , (7) by $2c$, add them up and rearrange. We get

$$c(c+1)|Y| + \sum_y -(d_y - c)(d_y - c - 1) \geq -(c-1)(q+2)(q+1) + 2c(q+2)q.$$

Rearranging we get the desired lower bound for $|Y|$. \square

Proof of Claim 3. Let \mathcal{P} be an abundant $(v, q+1, c+1)$ packing on the vertex set V . Since

$$\sum_{x \in V} d_x = \sum_{P \in \mathcal{P}} |P| = |\mathcal{P}|(q+1) > v(q+1),$$

there exists an $x \in V$ with $d_x > q+1$. So one can find $q+2$ edges of \mathcal{P} of the form $\{x\} \cup E_i$ where the family $\{E_1, \dots, E_{q+2}\}$ is a $(v-1, q, c)$ packing on the vertex set $Y = V \setminus \{x\}$. One can now apply Lemma 4 to complete the proof. \square

4 Construction of a packing

In this section we present Construction 2, a $\left(\frac{q^2-1}{c} + 1, q, c+1\right)$ packing \mathcal{P} of size $\frac{q^2-1}{c} + \left\lfloor \frac{q+1}{c} \right\rfloor$ whenever $c \geq 1$, q is a prime power, $c < q-1$, and c divides $q-1$.

Let \mathbf{F} be the q -element finite field and let g be an element of order c in the multiplicative group $\mathbf{F} \setminus \{0\}$. Set $H = \{1, g, g^2, \dots, g^{c-1}\}$, it is a c -element subgroup of $\mathbf{F} \setminus \{0\}$. For $(a, b), (a', b') \in (\mathbf{F} \times \mathbf{F})$ we say that $(a, b) \sim (a', b')$ if there exists an $h \in H$ such that $(a', b') = (ha, hb)$. This is an equivalence relation with $\{(0, 0)\}$ being a 1-element class. Each other equivalence class is a collection of c elements in $(\mathbf{F} \times \mathbf{F}) \setminus \{(0, 0)\}$. So there are $1 + (q^2 - 1)/c$ equivalence classes. The equivalence class containing (a, b) is denoted by $\langle a, b \rangle$. These equivalence classes form the vertex set V of the packing \mathcal{P} .

For $(a, b) \neq (0, 0)$, define the set $L\langle a, b \rangle = \{\langle x, y \rangle : ax + by \in H\}$. Since H is a group, $ax + by \in H$ implies $(h'a)x + (h'b)y \in H$, for all $h' \in H$. Hence $L\langle a, b \rangle$ is a well-defined subset of V . The next statement is a consequence of basic linear algebra.

Claim 5 (Furedi [5]). *Let (V, \mathcal{L}) be the hypergraph with vertex set $V = \{\langle a, b \rangle : a, b \in \mathbf{F}\}$ and edge set $\mathcal{L} = \{L\langle a, b \rangle : a, b \in \mathbf{F}, (a, b) \neq (0, 0)\}$. Then*

(i) \mathcal{L} is a q -uniform hypergraph, $|L\langle a, b \rangle| = q$,

(ii) V has $1 + (q^2 - 1)/c$ vertices,

(iii) \mathcal{L} has $(q^2 - 1)/c$ edges.

(iv) Suppose that $(a, b) \approx (a', b')$. Then $|L\langle a, b \rangle \cap L\langle a', b' \rangle| = c$ whenever $\det \begin{pmatrix} a & b \\ a' & b' \end{pmatrix} \neq 0$ and $|L\langle a, b \rangle \cap L\langle a', b' \rangle| = 0$ whenever this determinant is 0.

Define the sets $V_m := \{\langle x, y \rangle : y = mx, (x, y) \neq (0, 0)\}$ for $m \in \mathbf{F}$ and let $V_\infty := \{\langle x, y \rangle : x = 0, (x, y) \neq (0, 0)\}$. Then $|V_\alpha| = (q-1)/c$ and these sets form a partition of $V \setminus \{(0, 0)\}$. Moreover, $|V_\alpha \cap L\langle a, b \rangle| \leq 1$ for each $\langle a, b \rangle \in V$.

Select $\lfloor (q+1)/c \rfloor$ disjoint c -sets C_1, C_2, \dots from $\mathbf{F} \cup \{\infty\}$ and define $L(i) := \cup\{V_\alpha : \alpha \in C_i\} \cup \{(0, 0)\}$. Then these are q -element sets pairwise meeting in $\langle 0, 0 \rangle$. Moreover, $|L(i) \cap L\langle a, b \rangle| \leq c$. Finally, $\mathcal{P} := \mathcal{L} \cup \{L(1), L(2), \dots\}$ is a packing we were looking for.

5 List colorings

In this section we answer the question of Kratochvíl, Tuza and Voigt [9] on colorings of complete graphs from (k, c) -lists.

Theorem 6. *Let $c \geq 1$, then*

(i) $\lim_{n \rightarrow \infty} \chi_\ell(K_n, c) / \sqrt{cn} = 1$.

(ii) *If q is a prime power, $c < q - 1$ and c divides $q - 1$, then $\chi_\ell(K_n, c) = q + 1$ for all*

$$n \in \left[\frac{q^2 - 1}{c} + 2, \frac{1}{c} \left(q^2 + q + \frac{2(q - c + 1)}{c + 1} \right) + 1 \right].$$

Proof. The complete graph K_n is L -colorable if and only if the set of lists $\{L(v) : v \in [n]\}$ satisfy Hall's condition (1). (This observation is due to Vizing [10].) A (k, c) -list corresponds to a $(c + 1)$ -packing of k -sets. So $\chi_\ell(K_n, c) > k$ if and only if there is an abundant $(v, k, c + 1)$ packing with $v \leq n$. Hence

$$\chi_\ell(K_n, c) = q + 1 \iff v_0(q, c + 1) < n \leq v_0(q + 1, c + 1). \quad (8)$$

To make (8) more clear, let us explain. If $v_0(q, c + 1) < n$, then there exists a $(v, q, c + 1)$ packing \mathcal{P} of size $v + 1 \leq n$. Assign the members of \mathcal{P} to the first $v + 1$ vertices of K_n and assign completely disjoint q -sets to the rest of the vertices. This assignment does not satisfy Hall's condition, so we obtain $\chi_\ell(K_n, c) > q$. On the other hand, if $n \leq v_0(q + 1, c + 1)$ then any $(q + 1, c)$ -list assignment L of K_n is a $(c + 1)$ -packing of $(q + 1)$ -sets of size at most $v_0(q + 1, c + 1)$. So neither $\{L(v) : v \in [n]\}$ is abundant, nor any part of it is abundant. Therefore, it satisfies Hall's condition and thus implying K_n is L -colorable.

Finally, Theorem 6 is now a corollary of Theorem 1, (5), and (8). \square

For a fixed $c \geq 1$, one might be interested in knowing what is the maximum value of $\chi_\ell(G, c)$ over all n -vertex graphs G . Note that if H is an induced subgraph of G , then $\chi_\ell(H, c) \leq \chi_\ell(G, c)$, but this may not hold true for non-induced subgraphs. We have the following conjecture.

Conjecture 7. *If $c, n \geq 1$ and G is an n -vertex graph, then $\chi_\ell(G, c) \leq \chi_\ell(K_n, c)$.*

Work [9] generated lots of further research, especially concerning planar graphs, e.g., [11]. For further recent results concerning separated list colorings see [3, 4].
