On the Use of the Borel-Cantelli Lemma in Markov Chains

Alexei Stepanov,* Immanuel Kant Baltic Federal University, Russia

In the present paper, we propose technical generalizations of the Borel-Cantelli lemma. These generalizations can be further used to derive strong limit results for Markov chains. In our work, we obtain some strong limit results.

Keywords and Phrases: Markov chains; the Borel-Cantelli lemma; strong limit laws; the concomitants of order statistics; the F^{α} -scheme.

AMS 2000 Subject Classification: 60F99, 60F15.

1 Introduction

Suppose A_1, A_2, \cdots is a sequence of events on a common probability space and that A_i^c denotes the complement of event A_i . The Borel-Cantelli lemma, presented here as Lemma 1.1, is used for producing strong limit theorems.

- **Lemma 1.1.** 1. If, for any sequence A_1, A_2, \cdots of events, $\sum_{n=1}^{\infty} P(A_n) < \infty$, then $P(A_n \ i.o.) = 0$, where i.o. is an abbreviation for "infinitively often".
 - 2. If A_1, A_2, \cdots is a sequence of independent events and if $\sum_{n=1}^{\infty} P(A_n) = \infty$, then $P(A_n \ i.o.) = 1$.

The first part of the Borel-Cantelli lemma is generalized in Barndorff-Nielsen (1961) and Balakrishnan and Stepanov (2010). These results are presented below as Lemma 1.2 and Lemma 1.3, respectively.

Lemma 1.2. Let A_1, A_2, \ldots be a sequence of events such that $P(A_n) \rightarrow 0$. If $\sum_{n=1}^{\infty} P(A_n A_{n+1}^c) < \infty$, then $P(A_n \ i.o.) = 0$.

^{*}Immanuel Kant Baltic Federal University, A.Nevskogo 14, Kaliningrad, 236041 Russia; e-mail: *alexeis-tep45@mail.ru*

Lemma 1.3. Let A_1, A_2, \ldots be a sequence of events such that $P(A_n) \to 0$. If, for some $m \ge 0, \sum_{n=1}^{\infty} P(A_n^c \ldots A_{n+m-1}^c A_{n+m}) < \infty$, then $P(A_n i.o.) = 0$.

Many publications were devoted to the second part of the Borel-Cantelli lemma in attempts to weaken the independence condition. Erdös and Rényi (1959) discovered that this condition can be replaced by the weaker condition of pairwise independence of events A_1, A_2, \ldots They also found that the later condition, in its turn, can be replaced by the condition: $P(A_iA_j) \leq P(A_i)P(A_j)$ for every $i \neq j$. Further generalizations of the Borel-Cantelli lemma were obtained independently by Kochen and Stone (1964) and Spitzer (1964). Lamperti (1963) formulated the following proposition. If C is a positive constant, $\sum_{n=1}^{\infty} P(A_n) = \infty$ and $P(A_iA_j) \leq CP(A_i)P(A_j)$ for all large enough $i \neq j$, then $P(A_n \ i.o.) > 0$. Petrov (2002) showed that if $C \geq 1$, then $P(A_n \ i.o.) \geq 1/C$. Recently Frolov (2012) extended the results of Petrov (2002), (2004) and found more sophisticated lower bounds for $P(A_n \ i.o.)$. The second part of the Borel-Cantelli lemma was also discussed in the works of Chang and Erdös (1952), Kounias (1968), Móri and Székely (1983), Martikainen and Petrov (1990), and Petrov (1995). For a review on the Borel-Cantelli lemma, one may refer to the book of Chandra (2012).

An alternative way to get around the independence assumption in the second part of the Borel-Cantelli lemma is to use conditioning, as was proposed in Lévy (1937).

Lemma 1.4. Let A_1, A_2, \ldots be a sequence of events and I_{A_n} the indicator function of the event A_n . Then with probability one

$$\sum_{n=1}^{\infty} I_{A_n} = \infty \quad iff \quad \sum_{n=2}^{\infty} P(A_n \mid \sigma\{A_1, \dots, A_{n-1}\}) = \infty.$$

Lévy's lemma implies the classical form of the Borel-Cantelli lemma.

In our work, we are going to formulate a version of the Borel-Cantelli lemma which is applicable to Markov chains. Let us define the sequences of events with Markov property.

Definition 1.1. We say that A_n $(n \ge 1)$ is a Markov sequence of events if the sequence of random variables I_{A_n} $(n \ge 1)$ is a Markov chain.

Obviously, Markov sequences of events are associated with Markov chains.

The rest of our paper is organized as follows. In Section 2, we present technical generalizations of the Borel-Cantelli lemma. These generalizations are stated in terms of Markov sequences of events and can be further applied to the asymptotic theory of Markov chains. In Section 3, the results of Section 2 are used to derive strong limit results for Markov chains.

2 The Borel-Cantelli Lemma for Markov Sequences of Events

In this section, we consider Markov sequences of events and discuss conditions for the validity of $P(A_n \ i.o.) = 0/1$. It is easy to show that the condition $P(A_n) \not\rightarrow 0$ implies that $P(A_n \ i.o.) > 0$. In the following generalization of the Borel-Cantelli lemma we assume that $P(A_n) \rightarrow 0$.

Lemma 2.1. Let A_1, A_2, \ldots be a Markov sequence of events such that $P(A_n) \to 0$, and N be a number such that $P(A_n) \neq 1$ for $n \geq N$. Let us consider the series

$$\sum_{n=N}^{\infty} P(A_{n+1} \mid A_n^c).$$
 (2.1)

If the series in (2.1) is convergent, then $P(A_n \ i.o.) = 0$. If the series in (2.1) is divergent, then $P(A_n \ i.o.) = 1$.

Proof Let us choose $n \geq N$. It follows from the Markov property that

$$1 - P(A_n \cup A_{n+1} \cup \ldots \cup A_{n+k}) = P(A_n^c A_{n+1}^c \dots A_{n+k}^c) = P(A_n^c) P(A_{n+1}^c \mid A_n^c) \dots P(A_{n+k}^c \mid A_{n+k-1}^c).$$

Then

$$1 - P(\bigcup_{i=n}^{\infty} A_i) = e^{\log P(A_n^c) + \sum_{i=n}^{\infty} \log P(A_{i+1}^c | A_i^c)}.$$
(2.2)

Since $\log(1-x) \sim -x$ as $x \to 0$, the convergence/divergence of the series $\sum_{i=n}^{\infty} P(A_{i+1} \mid A_i^c)$ implies the convergence/divergence of the series $\sum_{i=n}^{\infty} \log P(A_{i+1}^c \mid A_i^c)$ (and vice verse). Observe that $P(A_n \ i.o.) = \lim_{n \to \infty} P(\bigcup_{i=n}^{\infty} A_i)$. The result of Lemma 2.1 readily follows from (2.2). \Box

Remark 2.1. It should be noted that the first statement in Lemma 2.1 can be derived from Lemma 1.3 and the second statement in Lemma 2.1 can be obtained from Lemma 1.4.

Since $P(A_{n+1} \mid A_n^c) = \frac{P(A_n^c A_{n+1})}{P(A_n^c)}$ and in Lemma 2.1 $P(A_n^c) \to 1$, one can rewrite Lemma 2.1 in the following way.

Lemma 2.2. Let A_1, A_2, \ldots be a Markov sequence of events such that $P(A_n) \rightarrow 0$. Let us consider the series

$$\sum_{n=1}^{\infty} P(A_n^c A_{n+1}).$$
 (2.3)

If the series in (2.4) is convergent, then $P(A_n \ i.o.) = 0$. If the series in (2.4) is divergent, then $P(A_n \ i.o.) = 1$.

Obviously, if the Markov property holds for some sequence A_n , then

$$P(A_n^c A_{n+1}^c \dots A_{n+k}^c) = P(A_n^c \mid A_{n+1}^c) \dots P(A_{n+k-1}^c \mid A_{n+k}^c) P(A_{n+k}^c)$$

With little modifications in the above proofs, one can show the following result.

Lemma 2.3. Let A_1, A_2, \ldots be a Markov sequence of events such that $P(A_n) \rightarrow 0$. Let us consider the series

$$\sum_{n=1}^{\infty} P(A_n A_{n+1}^c).$$
 (2.4)

If the series in (2.4) is convergent, then $P(A_n \ i.o.) = 0$. If the series in (2.4) is divergent, then $P(A_n \ i.o.) = 1$.

We present some further simple generalizations of the Borel-Cantelli lemma which are applicable to the theory of Markov chains. It is known that a sequence X_1, X_2, \ldots forms a Markov chain of order k (with memory k) if for all n > k

$$P(X_n = x_n \mid X_{n-1} = x_{n-1}, \dots, X_1 = x_1) = P(X_n = x_n \mid X_{n-1} = x_{n-1}, \dots, X_{n-k} = x_{n-k}).$$

Definition 2.1. We say that A_n $(n \ge 1)$ is a Markov sequence of events of order k if the sequence of random variables I_{A_n} $(n \ge 1)$ is a Markov chain of order k.

Lemma 2.1 and Lemma 2.2 can be easily extended to such sequences.

n

Lemma 2.4. Let A_1, A_2, \ldots be a Markov sequence of events of order k such that $P(A_n) \to 0$, and N be a number such that $P(A_n) \neq 1$ for $n \geq N$. Let us consider the series

$$\sum_{m=\max\{k,N\}}^{\infty} P(A_{n+1} \mid A_n^c \dots A_{n-k+1}^c).$$
(2.5)

If the series in (2.5) is convergent, then $P(A_n \ i.o.) = 0$. If the series in (2.5) is divergent, then $P(A_n \ i.o.) = 1$.

Lemma 2.5. Let A_1, A_2, \ldots be a Markov sequence of events of order k such that $P(A_n) \rightarrow 0$. Let us consider the series

$$\sum_{n=1}^{\infty} P(A_n^c \dots A_{n+k-1}^c A_{n+k}).$$
(2.6)

If the series in (2.6) is convergent, then $P(A_n \ i.o.) = 0$. If the series in (2.6) is divergent, then $P(A_n \ i.o.) = 1$.

3 Applications

In this section, we discuss two applications to the results of Section 2. In Subsection 3.1, we derive a strong limit theorem for the concomitants of maxima. In Subsection 3.2, we obtain strong limit results for the F^{α} -scheme.

3.1 Strong Limit Results for the Concomitants of Maxima

Assume in this subsection that $(X, Y), (X_1, Y_1), (X_2, Y_2), \ldots, (X_n, Y_n)$ are independent and identically distributed random vectors with continuous bivariate distribution function F(x, y)and corresponding marginal distributions functions H(x) and G(y). In the case of existence the bivariate density of (X, Y) will be denoted as f(x, y). Let $X_{1,n} \leq X_{2,n} \leq \ldots \leq X_{n,n}$ be the order statistics obtained from the sample X_1, X_2, \ldots, X_n and $Y_{[1,n]}, Y_{[2,n]}, \ldots, Y_{[n,n]}$ the corresponding concomitants of these order statistics, which relate to the sample Y_1, Y_2, \ldots, Y_n . We will also use the designations $Z_{[1]} = (X_{1,1}, Y_{[1,1]}), \ldots, Z_{[n]} = (X_{n,n}, Y_{[n,n]})$. The concept of concomitants of order statistics is introduced in David (1973) and Bhattacharya (1974).

The limit behavior of $P(Y_{[n-k,n]} \leq y)$ when $k \geq 0$ is fixed and $n \to \infty$ is studied in many research works, see for example, David and Galambos (1974), (1987), Egorov and Nevzorov (1984), David (1994), Goel and Hall (1994), and David and Nagaraja (2003); see also the references therein.

Strong limit results for the concomitants of order statistics are rarely discussed. One can mention the publication of Goel and Hall (1994), where some strong limit theorems for differences between order statistics and concomitants are obtained, and the work of Sen (1981), in which the strong invariance principle for concomitants is discussed. In this subsection, to show the power of Lemma 2.2, we establish a new strong limit theorem for $Y_{[n,n]}$. This result can be further extended to the concomitants of top order statistics.

Let $l_H = \inf\{x \in \mathbb{R} : H(x) > 0\}$ and $r_H = \sup\{x \in \mathbb{R} : H(x) < 1\}$ be the left and right extremities of H, respectively.

In the absolutely continuous case, when the bivariate density f(x, y) exists, one can write the joint density of $Z_{[1]}, \ldots, Z_{[n]}$ as

$$f_{Z_{[1]},\dots,Z_{[n]}}(x_1,y_1,\dots,x_n,y_n) = f(x_1,y_n)\dots f(x_n,y_n) \quad (x_1 \le \dots \le x_n, \ y_i \in \mathbb{R}).$$

It follows that

$$f_{Z_{[n+1]}|Z_{[n]}\dots Z_{[1]}}(x_{n+1}, y_{n+1} \mid x_n, y_n, \dots, x_1, y_1) = f(x_{n+1}, y_{n+1}) \quad (x_{n+1} \ge x_n, \ y_n, y_{n+1} \in \mathbb{R}).$$

The last equality implies that the sequence $Z_{[1]}, Z_{[2]}, \ldots$ forms a Markov chain. The Markov property also holds in the continuous case.

The following limit

$$\lim_{x \to r_H} \frac{G(y) - F(x, y)}{1 - H(x)} = \beta(y) \in [0, 1]$$
(3.1)

is considered in Bairamov and Stepanov (2010), (2011). They showed that if $\beta(y) = 0$ for any $y < r_G = \sup\{y \in \mathbb{R} : G(y) < 1\}$, then

$$Y_{[n-k,n]} \xrightarrow{p} r_G \quad (n \to \infty).$$

With some additional conditions on F one can formulate a strong limit law for $Y_{[n,n]}$.

Theorem 3.1. The convergence

$$Y_{[n,n]} \stackrel{a.s.}{\to} r_G \quad (n \to \infty)$$

holds true iff

$$\int_{\mathbb{R}} \frac{G(y) - F(x, y)}{(1 - H(x))^2} \left[dH(x) - F(dx, y) \right] < \infty$$
(3.2)

for any $y < r_G$.

Proof By symmetry and independence, we have

$$P(A_n) = P(Y_{[n,n]} \le y) =$$
$$n \int_{\mathbb{R}} \int_{l_G}^y P(X_2 \le x, \dots, X_n \le x) F(dx, dv).$$

It follows that

$$P(Y_{[n,n]} \le y) = n \int_{\mathbb{R}} H^{n-1}(x) F(dx, y).$$
(3.3)

By the argument that is used for obtaining (3.3), one can get

$$P(A_n^c A_{n+1}) = P(Y_{[n,n]} > y, Y_{[n+1,n+1]} \le y) =$$
$$n \int_{\mathbb{R}} H^{n-1}(x) (G(y) - F(x,y)) [dH(x) - F(dx,y)].$$

Then

$$\sum_{n=1}^{\infty} P(A_n^c A_{n+1}) = \int_{\mathbb{R}} \frac{G(y) - F(x, y)}{(1 - H(x))^2} [dH(x) - F(dx, y)].$$

Theorem 3.1 readily follows from Lemma 2.2. \Box

Remark 3.1. Observe that under condition (3.2) we have $\beta(y) = 0$.

3.2 Strong Limit Results for the F^{α} -Scheme

Let in the following, X_1, X_2, \ldots, X_n be independent continuous random variables with distribution functions $F^{\alpha_1}, F^{\alpha_2}, \ldots, F^{\alpha_n}$, where $\alpha_i > 0$ $(i \ge 2)$ and $\alpha_1 = 1$. These settings are known as the F^{α} -scheme, in which the independent variables X_1, X_2, \ldots, X_n have the same support. When $\alpha_i = 1$, the F^{α} -scheme reduces to the case when the variables X_i are independent and identically distributed. The F^{α} -scheme was first considered by Yang (1975) as a model of a non-stationary sequence of independent random variables. Later it was discussed by Nevzorov (1985, 1986), Pfeifer (1989, 1991), Bairamov and Stepanov (2013), and others.

Strong Limit Results for Maxima Let in the following, $M_n = \max\{X_1, \ldots, X_n\}$, $A_n = 1 + \alpha_2 + \ldots + \alpha_n$ and x_n be a nondecreasing sequence of real numbers. It is easily found that $P(M_n \leq x_n) = F^{A_n}(x_n)$. It follows from the Borel-Cantelli lemma that if

$$\sum_{n=1}^{\infty} F^{A_n}(x_n) < \infty, \tag{3.4}$$

then $P(M_n \leq x_n \ i.o.) = 0$. One can show that the sequence $M_n \ (n \geq 1)$ forms a Markov chain. Lemma 2.3 allows us to formulate the following result.

Proposition 3.1. The equality

$$P(M_n \le x_n \ i.o.) = \begin{cases} 0\\ 1 \end{cases}$$

holds true iff

$$\sum_{n=1}^{\infty} F^{A_n}(x_n) [1 - F^{\alpha_{n+1}}(x_{n+1})] \begin{cases} < \infty \\ = \infty. \end{cases}$$
(3.5)

Observe that if $F^{\alpha_n}(x_n) \to 1$, then the series in (3.5) converges under weaker conditions than the serious in (3.4). One can propose examples when the Borel-Cantelli lemma fails to produce strong limit results and Lemma 2.3 produces strong limit results in forms of "iff" statements. One of such examples is given below.

Example 3.1. Let F be the unit uniform distribution. Let us choose

$$x_n = 1 - \frac{\log \log n}{n}, \quad \alpha_n = \gamma(1 + 1/n) \quad and \quad A_n \approx \gamma(n + \log n).$$

where $\gamma > 0$. Observe that $F^{A_n}(x_n) \to 0$ and $\sum_{n=1}^{\infty} F^{A_n}(x_n) = \infty$ for any $\gamma > 0$. It follows that the Borel-Cantelli lemma can not help us in this case.

The series $\sum_{n=1}^{\infty} F^{A_n}(x_n) [1 - F^{\alpha_{n+1}}(x_{n+1})]$ behaves like the series $\sum_{n=1}^{\infty} \frac{\log \log n}{n(\log n)^{\gamma}}$ when $\gamma > 0$. Lemma 2.3 then states that

$$P(M_n \le 1 - \frac{\log \log n}{n} \quad i.o.) = \begin{cases} 0\\ 1 \end{cases}$$

iff

$$\gamma \in \left\{ \begin{array}{c} (1,\infty)\\ (0,1]. \end{array} \right.$$

Could the newcomer be a maximum? Observe that if $X \sim F$, $Y \sim F^{\alpha}$ and $\alpha > 1$ ($0 < \alpha < 1$), then $Y \geq_{st} X$ ($Y \leq_{st} X$), where st means the stochastic comparison of X and Y. That way, choosing α_n as an increasing sequence for the F^{α} -scheme, we shift probability masses F^{α_n} towards the right end of the common support. This gives new members of the sequence $X_1, \ldots, X_n, X_{n+1}$ (we address to X_{n+1} as to a new member) better chances to become maxima. We will show that for properly chosen α_n and all large enough n each consecutive sample observation can be a maximum. On the contrary, choosing the sequence α_n as decreasing we can "prohibit" newcomers to be maxima.

Suppose that $\alpha_n \to \infty$, which means that $A_n \to \infty$. As was pointed out, under the proper rate of increase of α_n , each new sample observation can be a maximum. The corresponding conditions are proposed below in Proposition 3.2 and Remark 3.2.

Proposition 3.2. Let $\alpha_n \to \infty$ and $A_n/A_{n+1} \to 0$. Then

$$P(M_n - X_n > 0 \ i.o.) = \begin{cases} 0\\1 \end{cases}$$

iff

$$\sum_{n=1}^{\infty} A_n / A_{n+1} \begin{cases} < \infty \\ = \infty. \end{cases}$$
(3.6)

Proof Let us denote $B_n = \{M_n - X_n > 0\}$ and $B_n^c = \{M_n = X_n\}$. Then

$$P(B_n) = \int_{\mathbb{R}} F^{\alpha_n}(x) dF^{A_{n-1}}(x) = A_{n-1}/A_n$$
(3.7)

and

$$P(B_n B_{n+1}^c) = \int_{\mathbb{R}} F^{\alpha_n}(x) (1 - F^{\alpha_{n+1}}(x)) dF^{A_{n-1}}(x) = \frac{\alpha_{n+1}}{A_{n+1}} \cdot \frac{A_{n-1}}{A_n} \sim \frac{A_{n-1}}{A_n}.$$
(3.8)

The result follows from Lemma 2.3, (3.7) and (3.8).

Remark 3.2. If the series in (3.6) is convergent, then $M_n - X_n \to 0$ a.s., i.e. for all large enough n with probability one each new sample member is a maximum. This, in particular, happens when $\alpha_n = n^{2n}$.

As was mentioned above, a properly chosen α_n can "prohibit" newcomers to be maxima. This issue is discussed in the rest of our work.

Proposition 3.3. Let

$$\alpha_n / A_n \to 0. \tag{3.9}$$

Then

$$P(M_n = X_n \ i.o.) = \begin{cases} 0\\ 1 \end{cases}$$

iff

$$\sum_{n=1}^{\infty} \alpha_n / A_n \begin{cases} < \infty \\ = \infty. \end{cases}$$
(3.10)

Proof The proof is similar to the proof of Proposition 3.2. One should take $C_n = B_n^c, C_n^c = B_n$ and apply Lemma 2.3 to the sequence of events C_n . \Box

Remark 3.3. If the series in (3.10) is convergent, then $M_n > X_n$ a.s., i.e. for all large enough n with probability one no new sample member can be a maximum. This, in particular, happens when $\alpha_n = n^{-2}$.
