Abstract

In recent years there has been an increasing interest in studying timedelayed coupled networks of oscillators since these occur in many real life applications. In many cases symmetry patterns can emerge in these networks, as a consequence a part of the system might repeat itself, and properties of this symmetric subsystem are representative of the whole dynamics. In this paper an analysis of the second order N-node time-delay fully connected network is made based on previous work by Correa and Piqueira [8] for a 2-node network. This study is carried out using symmetry groups. We show the existence of multiple eigenvalues forced by symmetry, as well as the existence of steady-state and Hopf bifurcations (in [8] only Hopf bifurcations were found). Three different models are used to analyze the network dynamics, namely, the full-phase, the phase, and the phase difference model. We determine a finite set of frequencies ω , that might correspond to Hopf bifurcations in each case for critical values of the delay. The S_n map proposed in [10] is used to actually find Hopf bifurcations along with numerical calculations using the Lambert W function. Numerical simulations are used in order to confirm the analytical results. Although we restrict attention to second order nodes, the results could be extended to higher order networks provided the time delay in the connections between nodes remains equal.

Keywords: Symmetry, Lie group, oscillator network, time-delay system, bifurcations, delay differential equations.

1 Introduction

Coupled oscillators present a great variety of interesting phenomena and provide models for many different areas in engineering, biology, chemistry, economy, etc. There is a considerable body of literature on coupled oscillators, see e.g. [5, 6, 8, 27–29], in particular on different network configurations without time-delay. In [2] a global bifurcation analysis for a network of linear coupled oscillators without delay was presented with applications in chemical processes, and in [33] a natural extension of this work was presented considering the lag among nodes as bifurcation parameter using neural networks with symmetry; an analysis of several configurations of oscillators coupled with smooth functions is presented in [20, 21]; similar results considering patterns emerging in networks of coupled oscillators with time-delay can be found in [34].

We are interested in obtaining the simplest model for an N-oscillator secondorder network considering time delay between oscillators; for this purpose we shall choose a Phase-Locked Loop (PLL) as node, see [4]; the main difference between a PLL and other kinds of oscillators used frequently in the literature is that a PLL presents an oscillator whose frequency can be controlled by an external signal, see [15]. In order to obtain a proper mathematical model for a single node we shall take as a starting point the classical approach as presented by Floyd [15] and Kudrewicz [23], and for the network we will use the model introduced by Piqueira-Monteiro [27], but here additionally we shall compare three different models, namely, the full-phase model, the phase-model and the phase-difference model. It is important to note that a fully connected network of PLLs imposes rigid constraints on the kind of synchronization that can emerge among nodes, due mainly to the fact that in every single oscillator, when it is in its lock state (A lock state refers to a synchronous state), input and output signals are in quadrature (90-degrees constant phase shift between local signal and the incoming signal) [15](p.25). Numerical results obtained with these models are used in order to validate our analytical conclusions, especially when discussing bifurcation points, which is the main aim of our research.

The structure of this paper is as follows: In section 2 the full-phase model for an N-node fully connected time-delay network is reviewed, the focus is the symmetry of the network and to find irreducible representations, bifurcations are analysed in each one of the isotypic components. In sections 3 and 4 a comparative analysis between the phase model and the phase difference model is performed using the results obtained for the full-phase model, and finally conclusions and insights for future research are presented in section 5.

2 Full-phase model

In [27] the model for a fully connected N-node network with time delay is presented, each node is a second-order PLL oscillator capable to generate a self sustained sinusoidal signal whose phase has to follow the phase of the weighted mean of the incoming signals, the corrections in the local phase to achieve this goal are possible due to a feedback loop inside the PLL, see [4, 15]; in this model the so called "double-frequency" term is neglected arguing that its influence is easy suppressed by the local dynamic in each node, see [1, 5, 8, 15, 23, 26, 27, 29]. In what follows we will use this model but include the double-frequency term, thus we have that equation (3.9) in [27] becomes

$$\hat{\phi}_{i}(t) + \mu \dot{\phi}_{i}(t) - \mu \omega_{M} = \frac{K\mu}{N-1} \sum_{\substack{j=1\\j\neq i}}^{N} \left[\sin(\phi_{j}(t-\tau) - \phi_{i}(t)) + \sin(\phi_{j}(t-\tau) + \phi_{i}(t)) \right], \qquad (2.1)$$

i=1,..., N. The "double-frequency" term is embedded in the term $\sin(\phi_j(t - \tau) + \phi_i(t))$. This equation models the dynamics for the *i*-th oscillator in the

N-node network; we call $\phi_i(t)$

$$\phi_i(t) := \theta_i(t) + \omega_M t, \quad i = 1, \dots, N,$$

the full-phase of the *i*-th oscillator where where $\theta(t)$ is the local instantaneous phase which is rectified to achieve the phase of the weighted mean of the incoming signals, ω_M represents the local frequency, K and μ are gains, and τ is the time delay between nodes.

Note that (2.1) has equilibria at $\phi_i = \phi^{\pm}$, where

$$2\phi^{+} = \arcsin\left(-\frac{\omega_{M}}{K}\right) + 2k\pi,$$

$$2\phi^{-} = \pi - \arcsin\left(-\frac{\omega_{M}}{K}\right) + 2k\pi,$$
(2.2)

if $\omega_M/K \leq 1$.

2.1 S_N -symmetry and irreducible representations in the full-phase model

We now show that (2.1) has \mathbf{S}_N -symmetry, where \mathbf{S}_N is the group of all permutations $\gamma \in \operatorname{Mat}(n)$ of N elements. A differential equation $\dot{X}(t) = F(X(t))$ posed on a phase space \mathcal{X} is equivariant with respect to the action of a Lie group Γ on \mathcal{X} if

$$\gamma F(X) = F(\gamma X)$$
 for all $X \in \mathcal{X}, \gamma \in \Gamma$,

see [16, 17]. In this case the phase space is $\mathcal{X} = \mathcal{C}([-\tau, 0), \mathbb{R}^{2N})$, the Banach space of continuous functions from $[-\tau, 0]$ into \mathbb{R}^{2N} equipped with the usual supremum norm

$$||x|| = \sup_{-\tau \le \theta \le 0} |x(\theta)|, \quad x \in \mathcal{C}([-\tau, 0], \mathbb{R}^{2N}),$$

see, e.g., [22]; we write $\phi = (\phi_1, \ldots, \phi_N)$, with $\phi_j \in \mathcal{C}([-\tau, 0), \mathbb{R})$, $j = 1, \ldots, N$, and let $x = (x^{(1)}, \ldots, x^{(N)}) \in \mathcal{X}$ where $x^{(i)} = (x_1^{(i)}, x_2^{(i)})$, and $x_1^{(i)} = \phi_i$ and $x_2^{(i)} = \dot{\phi}_i$, $i = 1, \ldots, N$. If $x : [-\tau, A] \to \mathbb{R}^n$ is a continuous function with A > 0and if $t \in [0, A]$, then $X(t) \in \mathcal{C}([-\tau, 0], \mathbb{R}^n)$ is defined by

$$X(t)(\theta) = x(t+\theta), \quad \theta \in [-\tau, 0], t \in [0, A].$$

Then (2.1) takes the form

$$\frac{\mathrm{d}}{\mathrm{d}t}X(t) = F(X(t),\eta)$$

where

$$(F(x))(\theta) = \begin{cases} \frac{\partial x}{\partial \theta}(\theta) &, \quad -\tau \le \theta \le 0\\ f(x(0), x(-\tau), \eta) &, \quad \theta = 0. \end{cases}$$

Here $\eta = (\mu, K, \omega_M, \tau) \in \mathbb{R}^4$ is a parameter and $f = (f^{(1)}, \ldots, f^{(N)})$ is such that (2.1) can also be rewritten as autonomous nonlinear delay differential equation (DDE)

$$\dot{x}(t) = f(x(t-\tau), x(t), \eta),$$
(2.3)

i.e., $f^{(i)} = (f_1^{(i)}, f_2^{(i)})$, where

$$\begin{aligned}
f_1^{(i)}(x, x_{\tau}) &= x_2^{(i)}, \\
f_2^{(i)}(x, x_{\tau}) &= -\mu x_2^{(i)} + \mu \omega_M \\
&+ \frac{K\mu}{N-1} \sum_{\substack{j=1\\j \neq i}}^N \left[\sin(x_{1,\tau}^{(j)} - x_1^{(i)}) + \sin(x_{1,\tau}^{(j)} + x_1^{(i)}) \right].
\end{aligned}$$
(2.4)

Here $\Gamma = \mathbf{S}_N$ acts on \mathcal{X} via

$$(\gamma\phi)_j(\theta) = (\gamma\phi_j)(\theta), \quad \theta \in [-\tau, 0].$$

Note that \mathbf{S}_N is generated by the transpositions $\pi_{ij} \in \operatorname{Mat}(N)$, which swap ϕ_i with ϕ_j . To show that (2.1) has \mathbf{S}_N -symmetry it is thus sufficient to prove that $f \circ \pi_{ij} = \pi_{ij} \circ f$ for all π_{ij} . We compute that

$$(f \circ \pi_{ij})_{2}^{(i)}(x, x_{\tau}) = -\mu x_{2}^{(j)} + \mu \omega_{M} + \frac{K\mu}{N-1} \sum_{\substack{l=1\\ \ell \neq j}}^{N} \left[\sin(x_{1,\tau}^{(\ell)} - x_{1}^{(j)}(t)) + \sin(x_{1,\tau}^{(\ell)} + x_{1}^{(j)}) \right] = f_{2}^{(j)}(x, x_{\tau}) = (\pi_{ij} \circ f)_{2}^{(i)}(x, x_{\tau});$$

Since $\pi_{ij} = \pi_{ji}$, this argument also gives $(f \circ \pi_{ji})^{(j)} = (\pi_{ji} \circ f)^{(j)}$, and, since for all $k \neq i, j$ we have $(\pi_{ij} \circ f)^{(k)} = f^{(k)} = (f \circ \pi_{ij})^{(k)}$ we see that f and π_{ij} commute for all i, j which proves \mathbf{S}_N -symmetry of (2.1).

A space V is called Γ -invariant if $gV \subseteq V$, for all $g \in \Gamma$. When a compact group acts on a space V, we can decompose the space into Γ -invariant subspaces of smaller dimension. The smallest blocks for such a decomposition are said to be irreducible. Up to Γ -isomorphism there are a finite number of distinct Γ irreducible subspaces of V, call these U_1, \ldots, U_t . Define W_k to be the sum of all Γ -irreducible subspaces W of V such that W is Γ -isomorphic to U_k . Then

$$V = W_1 \oplus \cdots \oplus W_t.$$

This generates a unique decomposition of V into the so-called *isotypic* components W_j of V [17]. A representation of a group Γ on a vector space V is said to be absolutely irreducible if the only linear mapping on V that commute with Γ are scalar multiples of the identity, that is $\{cI \mid c \in \mathbb{R}\}$ is the only mapping that commute with Γ [17].

The \mathbf{S}_N symmetry acting \mathbb{R}^N by permuting coordinates is called the permutation representation. This has the trivial subrepresentation consisting of vectors whose coordinates are all equal. The orthogonal complement consists of those vectors whose coordinates sum to zero, and when $N \geq 2$, the representation on this subspace is an N-1-dimensional absolutely irreducible representation of \mathbf{S}_N , called the standard representation. In other words, \mathbb{R}^N decomposes as

$$\mathbb{R}^N = \operatorname{Fix}(\mathbf{S}_N) \oplus U,$$

where for any subgroup H of the action of a Lie group Γ on \mathcal{X} the fixed-point subspace of H is given by

$$\operatorname{Fix}_{\mathcal{X}}(H) = \operatorname{Fix}(H) = \{ X \in \mathcal{X}) \mid hX = X, \ \forall h \in H \}$$

and $U = (\operatorname{Fix}(\mathbf{S}_N))^{\perp} \cong \mathbb{R}^{N-1}$ is \mathbf{S}_N -invariant and irreducible. Moreover \mathbb{R}^{2N} , the phase space for $(\phi, \dot{\phi})$, decomposes as $\mathbb{R}^{2N} = \operatorname{Fix}(\mathbf{S}_N) \oplus W$ where $\operatorname{Fix}(\mathbf{S}_N) = \mathbb{R}^2$, and $W = U \oplus U$ are the isotypic components of the \mathbf{S}_N -action on \mathbb{R}^{2N} .

Note that if A is a linear operator on a vector space V with a Lie group Γ acting on \mathcal{X} and A is Γ -invariant, i.e. gA = Ag for all $g \in \Gamma$ then A has a block decomposition, more precisely, $A(W_j) \subseteq W_j$ for all isotypic components W_j of V. Moreover if W_j is the isotypic component of an absolutely irreducible representation U_j of dimension n then $A|_{W_j}$ consists of n identical blocks.

The equilibria x^{\pm} with $(x_1^{(i)}, x_2^{(i)}) = (\phi^{\pm}, 0), i = 1, ..., N$, from (2.2) are \mathbf{S}_N -invariant and hence their linearization $A(\eta) = \mathrm{D}F(x^*, \eta)$ with F as in (2.1) is \mathbf{S}_N -equivariant. Note that

$$(A(\eta)x)(\theta) = \begin{cases} \frac{dx}{d\theta} &, \quad -\tau \le \theta < 0\\ U(\eta)x(0) + V(\eta)x(-\tau) &, \quad \theta = 0, \end{cases}$$

where $U(\eta) = \frac{\partial}{\partial x(t)} f(x^*, x^*, \eta), V(\eta) = \frac{\partial}{\partial x(t-\tau)} f(x^*, x^*, \eta), f$ is as in (2.1) and defined in (2.4) and $x^* = x^{\pm}$.

The characteristic equation for $A(\eta)$ is obtained by looking for nontrivial solution of the form $e^{\lambda t}c$ where c is a constant vector. Then $A(\eta)$ has an eigenvalue λ with eigenfunction $e^{\lambda t}c$ if and only if

$$\det(\triangle(\lambda,\tau,\eta)) := \det(\lambda \mathrm{Id} - L(\eta,\tau)) = 0, \qquad (2.5)$$

where

$$\Delta(\lambda, \tau, \eta) := \lambda \mathrm{Id} - L(\eta, \tau) \tag{2.6}$$

is the *characteristic matrix* and

$$L(\eta, \tau) := U(\eta) + V(\eta)e^{-\lambda\tau} \in \operatorname{Mat}(n)$$
(2.7)

with n = 2N here, see [18, 33]. We define the transcendental characteristic function associated to $A(\eta)$ as

$$P(\lambda, \tau, \eta) := \det(\triangle(\lambda, \tau, \eta)) = 0.$$

Since F in (2.1) is \mathbf{S}_N -equivariant, the matrix $\Delta(\lambda, \tau)$ is also \mathbf{S}_N -equivariant [30]. Thus L from (2.7), can be decomposed as

$$L \cong \left(\begin{array}{cc} L_1 \\ & L_{N-1} \end{array}\right),$$

 $L_1 \in Mat(2,2)$ and

$$L_{N-1} = \begin{pmatrix} L_2 & & & \\ & L_2 & & \\ & & \ddots & \\ & & & \ddots & \\ & & & & L_2 \end{pmatrix},$$

Computing L from (2.4) we get:

$$Lx = \begin{pmatrix} x_2^{(1)} \\ K\mu(-1+\cos(2x_1^*))x_1^{(1)} - \mu x_2^{(1)} + \frac{K\mu}{N-1}(1+\cos(2x_1^*))e^{-\lambda\tau} \sum_{\substack{j=1\\j\neq 1}}^N x_1^{(j)} \\ \vdots \\ x_2^{(N)} \\ K\mu(-1+\cos(2x_1^*))x_1^{(N)} - \mu x_2^{(N)} + \frac{K\mu}{N-1}(1+\cos(2x_1^*))e^{-\lambda\tau} \sum_{\substack{j=1\\j\neq N}}^N x_1^{(j)} \end{pmatrix}$$

Hence, the characteristic matrix $\triangle(\lambda, \tau) = \lambda I_{2N} - L \in \text{Mat}(2N)$ from (2.6) has the form

$$\triangle(\lambda,\tau) = \begin{pmatrix} m_{\lambda} & m_{b} & \cdots & m_{r} \\ m_{r} & m_{\lambda} & \cdots & m_{r} \\ \vdots & \vdots & \ddots & \vdots \\ m_{r} & m_{r} & \cdots & m_{\lambda} \end{pmatrix}$$

where the blocks m_{λ} and $m_r \in Mat(2)$ are

$$m_{\lambda} = \begin{pmatrix} \lambda & -1 \\ q & \lambda + \mu \end{pmatrix}, \quad m_r = \begin{pmatrix} 0 & 0 \\ r & 0 \end{pmatrix},$$

with

$$q = -K\mu(-1 + \cos(2x_1^*)), \quad r = -\frac{K\mu}{N-1}(1 + \cos(2x_1^*))e^{-\lambda\tau}.$$
 (2.8)

Let \mathbb{Z}_N be the cyclic group of order m which are generated by the transformation ζ that sends ϕ_j to $\phi_{(j+1) \mod N}$, $j = 0, \ldots, N-1$. Then each (complex) irreducible representation of \mathbb{Z}_N , such that ζ acts as $e^{2\pi i j/N}$, appears exactly once in the permutation representation of \mathbf{S}_N on \mathbb{R}^N , hence the *j*-th isotypic component W_j of \mathbb{Z}_N on \mathbb{R}^{2N} is two-dimensional and spanned by

$$W_j = \operatorname{span} \frac{1}{\sqrt{N}} \begin{pmatrix} \lambda_{0j} & 0 & \lambda_{1j} & 0 & \dots & \lambda_{(N-1)j} & 0 \\ 0 & \lambda_{0j} & 0 & \lambda_{1j} & \dots & 0 & \lambda_{(N-1)j} \end{pmatrix}^T, \quad (2.9)$$

where $\lambda_{kj} = \lambda_{(k \cdot j) \mod N} = e^{i\pi((k \cdot j) \mod N)/N}$ and $W_0 = Fix(\mathbf{S}_N)$; then the restriction of the characteristic matrix $\Delta(\lambda, \tau)$ to W_j is

$$\Delta(\lambda,\tau)|_{W_j} = \overline{W_j}^T \Delta(\lambda,\tau) W_j$$

$$= \frac{1}{N} (\overline{\lambda}_{0j} I_2, \dots, \overline{\lambda}_{(N-1)j} I_2) \begin{pmatrix} m_\lambda & m_r & \cdots & m_r \\ m_r & m_\lambda & \cdots & m_r \\ \vdots & \vdots & \ddots & \vdots \\ m_r & m_r & \cdots & m_\lambda \end{pmatrix} \begin{pmatrix} \lambda_{0j} I_2 \\ \vdots \\ \lambda_{(N-1)j} I_2 \end{pmatrix}$$

$$= \frac{1}{N} (\overline{\lambda}_{0j} m_{\lambda} + m_r \sum_{\substack{k=0\\k\neq 0}}^{N-1} \overline{\lambda}_{kj}, \dots, \overline{\lambda}_{(N-1)j} m_{\lambda} + m_r \sum_{\substack{k=0\\k\neq N-1}}^{N-1} \overline{\lambda}_{kj}) \begin{pmatrix} \lambda_{0j} I_2 \\ \vdots \\ \lambda_{(N-1)j} I_2 \end{pmatrix}$$
$$= \frac{1}{N} \left(\sum_{\ell=0}^{N-1} \left(m_{\lambda} \lambda_{\ell j} + m_r \sum_{\substack{k=0\\k\neq \ell}}^{N-1} \lambda_{kj} \right) \overline{\lambda}_{\ell j} I_2 \right)$$
$$= \frac{1}{N} \left(\sum_{\ell=0}^{N-1} m_{\lambda} \lambda_{\ell j} \overline{\lambda}_{\ell j} + m_r \sum_{\ell=0}^{N-1} \sum_{\substack{k=0\\k\neq \ell}}^{N-1} \lambda_{kj} \overline{\lambda}_{\ell j} \right)$$

$$= m_{\lambda} + \frac{1}{N} m_r \sum_{\ell=0}^{N-1} \sum_{\substack{k=0\\k\neq\ell}}^{N-1} \lambda_{kj} \overline{\lambda}_{\ell j}.$$

Moreover,

if
$$j = 0$$
,
$$\sum_{\ell=0}^{N-1} \sum_{\substack{k=0\\k\neq\ell}}^{N-1} \lambda_{kj} \overline{\lambda}_{\ell j} = N(N-1)$$

if $i \neq 0$,
$$\sum_{k=0}^{N-1} \sum_{\substack{k=0\\k\neq\ell}}^{N-1} \lambda_{kj} \overline{\lambda}_{\ell j} = \sum_{k=0}^{N-1} \lambda_{kj} \overline{\lambda}_{\ell j} = 0$$

if
$$j \neq 0$$
, $\sum_{\ell=0}^{N-1} \sum_{\substack{k=0\\k\neq\ell}}^{N-1} \lambda_{kj} \overline{\lambda}_{\ell j} = -\sum_{\ell=0}^{N-1} \lambda_{\ell j} \overline{\lambda}_{\ell j} = -N.$

Therefore

$$\triangle(\lambda,\tau)|_{W_j} = \begin{cases} m_\lambda + (N-1)m_r, & j = 0, \\ \\ m_\lambda - m_r, & j = 1, \dots, N-1. \end{cases}$$

The characteristic matrix decomposition is

$$\Delta(\lambda,\tau) = \operatorname{diag}\left(\Delta(\lambda,\tau)|_{\operatorname{Fix}(\mathbf{S}_N)}, \Delta(\lambda,\tau)|_{W_1}, \dots, \Delta(\lambda,\tau)|_{W_{(N-1)}}\right),$$

where $\triangle(\lambda, \tau)|_{\text{Fix}(\mathbf{S}_N)} = \triangle(\lambda, \tau)|_{W_0}$. The characteristic function $P(\lambda, \tau)$ defined in equation (2.1) becomes

$$P(\lambda,\tau) = \det(\triangle(\lambda,\tau)|_{\mathrm{Fix}(\mathbf{S}_N)}) \prod_{j=1}^{N-1} \det(\triangle(\lambda,\tau)|_{X_j}) = 0,$$

 or

$$P(\lambda,\tau) = \det(m_{\lambda} + (N-1)m_{r})(\det(m_{\lambda} - m_{r}))^{N-1} = 0,$$
(2.10)
and using (2.1) we obtain
$$P_{\mathrm{Fix}(\mathbf{S}_{N})}(\lambda,\tau) = \det(\triangle(\lambda,\tau)|_{\mathrm{Fix}(\mathbf{S}_{N})})$$

$$\begin{aligned}
\mathcal{P}_{\mathrm{Fix}(\mathbf{S}_N)}(\lambda,\tau) &= \det(\triangle(\lambda,\tau)|_{\mathrm{Fix}(\mathbf{S}_N)}) \\
&= \lambda^2 + \mu\lambda - q + (N-1)r = 0 \\
P_j(\lambda,\tau) &= \det(\triangle(\lambda,\tau)|_{W_j}) \\
&= \lambda^2 + \mu\lambda - q - r = 0,
\end{aligned}$$
(2.11)

for $j = 1, \ldots, N - 1$, where q and r are as in (2.8).

From the equilibria in (2.2) we have

$$\cos(2x_1^*) = \pm \frac{1}{K}\sqrt{K^2 - \omega_M^2}, \text{ if } x_1^* = \phi^{\pm}$$

with $K \ge \omega_M$ in order to keep $\phi_{1,2} \in \mathbb{R}$. By scaling $\tilde{K} = K/\omega_M$, $\tilde{\mu}_1 = \mu/\omega_M$, $\tilde{\lambda} = \lambda/\omega_M$, and $\tilde{\tau} = \omega_M \tau$, and removing the tilde in the variables we obtain the normalized equilibria:

$$\cos(2x_1^*) = \pm \sqrt{1 - \frac{1}{K^2}}, \text{ if } x_1^* = \phi^{\pm}$$
 (2.12)

with

$$K \ge 1. \tag{2.13}$$

2.2 Symmetry-preserving bifurcation

In the next two sections bifurcations in the two isotypic components $Fix(\mathbf{S}_N)$ and V of \mathbf{S}_N found previously will be analyzed, conditions for the existence of eigenvalues $\lambda = \pm i\omega$ with $\omega \in \mathbb{R}^+$ shall be given in terms of the parameters $K, \mu, \tau \in \mathbb{R}^+$, and $N \in \mathbb{N} > 1$; and the critical time-delays τ switching stability shall be computed. When $\tau = 0$ the transcendental characteristic functions in (2.11) become ordinary characteristic polynomials with two roots each. Since we are interested in analyzing the influence of the time delay between the nodes in the network it is important to know whether the system is stable or not at $\tau = 0$. If it is, we would like to determine, if there exists some $\tau \in \mathbb{R}^+$ such that a finite number of roots cross the imaginary axis from the left to the right switching stability with $d\lambda/d\tau|_{\lambda=i\omega} \neq 0$, for this analysis we use the S_n map which we will discuss in section 2.2.2. If some roots are unstable at the equilibrium at $\tau = 0$ we will look for some $\tau \in \mathbb{R}^+$ such that all unstable roots (always a finite number) cross from the right to the left at τ switching stability from unstable to stable; this task will be addressed using the Lambert W function see [3, 7, 25, 31] and the Nyquist criteria see [14, 32]. We will start analyzing bifurcations in $Fix(\mathbf{S}_N)$. Note that \mathbf{S}_N -symmetry implies that (2.1) maps $\operatorname{Fix}_{\mathcal{X}}(\mathbf{S}_N)$, this means that we can restrict (2.1) to the subspace $\operatorname{Fix}(\mathbf{S}_N)$ [17].

Note that bifurcations in $Fix(\mathbf{S}_N)$, which will study first, preserve the \mathbf{S}_N -symmetry, so bifurcating periodic orbits are synchronized, i.e., satisfy, $\phi_i = \phi_j$ for all i, j. In section 2.3 we will study bifurcation in the other blocks which are symmetry-breaking, i.e., bifurcating periodic orbits are not fully-synchronized, for more details see Section 2.4.

2.2.1 Roots in the characteristic function $P_{\text{Fix}(\mathbf{S}_N)}(\lambda, \tau)$ at $\tau = 0$ and as $\tau \to \infty$

In the fixed-point space in equation (2.11) when $\tau = 0$ we have two roots

$$\lambda_{1,2} = -\frac{1}{2}\mu \pm \frac{1}{2} \left(\mu^2 + 8K\mu\cos(2x_1^*)\right)^{1/2};$$

here we have two cases corresponding to the two equilibria $x_1^* = \phi^{\pm}$ from (2.12)

$$\lambda_{1,2} = -\frac{1}{2}\mu \pm \frac{1}{2} \left(\mu^2 \pm 8\mu\sqrt{K^2 - 1}\right)^{1/2}, \qquad (2.14)$$

and remembering $K \ge 1$, see (2.13), we obtain that

- If K > 1, there is an unstable root for $x_1^* = \phi^+$, and both roots are stable when $x_1^* = \phi^-$.
- If K = 1, there is a constant root at $\lambda = 0$ and another one at $\lambda = -\mu$, for both $x_1^* = \phi^{\pm}$.

In the limit when $\tau \to \infty$ in equation (2.11) for both equilibria ϕ^{\pm} , assuming that $\operatorname{Re}(\lambda) > 0$, we obtain

$$\lambda_{1,2} = -\frac{1}{2}\mu \pm \frac{1}{2}\left(\mu^2 - 4K\mu\left(1 \mp \sqrt{1 - \frac{1}{K^2}}\right)\right)^{1/2},$$
 (2.15)

but these roots are not in the right-side of the complex plane neither for ϕ^+ nor ϕ^- , which is a contradiction, therefore at $\tau \to \infty$ all both equilibria are spectrally stable in Fix(\mathbf{S}_N).

2.2.2 The S_n map

In [10] a criterium is presented to find critical imaginary roots for a transcendental function of the form

$$P(\lambda,\tau) = R(\lambda,\tau) + S(\lambda,\tau)e^{-\lambda\tau} = 0, \qquad (2.16)$$

where

$$R(\lambda,\tau) = \sum_{k=0}^{n} r_k(\tau)\lambda^k, \quad S(\lambda,\tau) = \sum_{k=0}^{m} s_k(\tau)\lambda^k.$$
(2.17)

In (2.17), $n, m \in \mathbb{N}_0$, n > m, and $r_k(\cdot)$, $s_k(\cdot) : \mathbb{R}_0^+ \to \mathbb{R}$ are continuous and differentiable functions of τ . We shall describe the method briefly and then apply it to the full phase model, and other models subsequently.

We are looking for solutions $\lambda = \pm i\omega$ to $P(\lambda, \tau)$ in (2.16), with $\omega \in \mathbb{R}^+$, since the roots appear in complex conjugate pairs (or pure reals), we only need to look for non-negative imaginary roots. Substituting $\lambda = i\omega$ into (2.16) we have

$$\sin(\omega\tau) = \frac{R_I S_R - S_I R_R}{|S|^2}, \quad |S| \neq 0, \quad (2.18)$$
$$\cos(\omega\tau) = -\frac{S_I R_I + S_R R_R}{|S|^2}$$

where S_R , S_I , R_R , and R_I stand for the real part and the imaginary part of $S(i\omega, \tau)$ and $R(i\omega, \tau)$ respectively, and |S| represents the usual norm of $S(i\omega, \tau)$.

On the other hand, we can eliminate the exponential term in (2.16) and define the polynomial in ω

$$F(\omega,\tau) := |R(i\omega,\tau)|^2 - |S(i\omega,\tau)|^2 = 0.$$
(2.19)

Definition 2.1. The function $\operatorname{Arctan}(\cdot)$. Let $x, y \in \mathbb{R}, r \in \mathbb{R}^+$, and $\theta \in [0, 2\pi)$ satisfying $x = r \cos \theta$ and $y = r \sin \theta$. We define the function $\operatorname{Arctan}(\cdot) : \mathbb{R} \setminus \{0\} \times \mathbb{R} \setminus \{0\} \to [0, 2\pi)$, such that $\operatorname{Arctan}(x, y) = \theta$. This function is the extension of the trigonometrical function $\operatorname{arctan}(y/x) : \mathbb{R} \to (-\pi/2, \pi/2)$.

Now, given a $\tau \in \mathbb{R}^+$ we can compute $\omega = \omega(\tau)$ using the polynomial F in (2.19). Since $\sin(\omega\tau)$ and $\cos(\omega\tau)$ in (2.18) are both functions of $\omega(\tau)$ and τ , we can calculate the argument $\theta(\tau) = \omega\tau + 2n\pi$, for $n \in \mathbb{Z}$; then we define the map $\tau_n : \mathbb{R}^+ \to \mathbb{R}$

$$\tau_n(\tau) := \frac{\theta(\tau) + 2n\pi}{\omega(\tau)},\tag{2.20}$$

the argument $\theta(\tau)$ is then computed using (2.18)

$$\theta(\tau) = \operatorname{Arctan}\left(-\frac{R_I S_R - S_I R_R}{S_I R_I + S_R R_R}\right).$$

Finally, if τ_n in (2.20) matches with the given τ , then $\tau = \tau^*$ is a bifurcation time delay, and $\omega(\tau^*)$ is the sought imaginary root to equation (2.16); this can be formally expressed by the map

$$S_n := \tau - \tau_n(\tau), \tag{2.21}$$

whose zeros are the critical bifurcation time delays for equation (2.16).

Now, we need to know in which direction the roots found above cross the imaginary axis, if they go from stable to unstable or from unstable to stable in the complex plane. We need to calculate

$$\delta(\omega(\tau^*)) := \operatorname{Re}\left(\frac{d\lambda}{d\tau}\Big|_{\lambda=i\omega(\tau^*)}\right) = \operatorname{Re}\left(-\frac{dP}{d\tau}\left(\frac{dP}{d\lambda}\right)_{\lambda=i\omega(\tau^*)}^{-1}\right); \quad (2.22)$$

from the definition of $P(\lambda, \tau)$ in (2.16) we have

$$\left. \frac{d\lambda}{d\tau} \right|_{\lambda=i\omega(\tau^*)} = \frac{e^{-i\omega\tau}(i\omega S(i\omega,\tau) - S'_{\tau}(i\omega,\tau)) - R'_{\tau}(i\omega,\tau)}{R'_{\lambda}(i\omega,\tau) + e^{-i\omega\tau}(S'_{\lambda}(i\omega,\tau) - \tau S(i\omega,\tau))},\tag{2.23}$$

where R'_{λ} means derivative of $R(\lambda, \tau)$ with respect to λ , R'_{τ} derivative of $R(\lambda, \tau)$ with respect to τ and the same for $S(\lambda, \tau)$. Then we have

$$\delta(\omega(\tau^*)) = \frac{AC + BD}{C^2 + D^2},\tag{2.24}$$

where

$$A = \operatorname{Re}(e^{-i\omega\tau}(i\omega S(i\omega,\tau) - S'_{\tau}(i\omega,\tau)) - R'_{\tau}(i\omega,\tau))$$

$$B = \operatorname{Im}(e^{-i\omega\tau}(i\omega S(i\omega,\tau) - S'_{\tau}(i\omega,\tau)) - R'_{\tau}(i\omega,\tau))$$

$$C = \operatorname{Re}(R'_{\lambda}(i\omega,\tau) + e^{-i\omega\tau}(S'_{\lambda}(i\omega,\tau) - \tau S(i\omega,\tau)))$$

$$D = \operatorname{Im}(R'_{\lambda}(i\omega,\tau) + e^{-i\omega\tau}(S'_{\lambda}(i\omega,\tau) - \tau S(i\omega,\tau))).$$
(2.25)

If $\delta(\omega(\tau^*)) > 0$ the root crosses from the left to the right (stable to unstable), and if $\delta(\omega(\tau^*)) < 0$ the root crosses in the opposite direction. It is important to note that condition $\delta(\omega(\tau^*)) \neq 0$, called transversality condition, is necessary for Hopf bifurcation occur [19].

2.2.3 Conditions for the existence of symmetry preserving bifurcations

Since our aim is to analyze bifurcations in $\operatorname{Fix}(\mathbf{S}_N)$, it is convenient evaluate the necessary conditions for the existence of roots $\lambda = \pm i\omega$, $\omega \in \mathbb{R}^+$ given by the polynomial $F(\omega)$ from (2.19). From (2.16), (2.17) with n = 2 and m = 0and (2.11) we have

$$R(\lambda) = \lambda^{2} + \mu\lambda + K\mu(1 - \cos(2x_{1}^{*}))$$

$$S(\lambda) = -K\mu(1 + \cos(2x_{1}^{*})),$$
(2.26)

then $F(\omega)$ becomes

$$F(\omega) = \omega^4 + \left(\mu^2 - 2K\mu\left(1 - \cos(2x_1^*)\right)\right)\omega^2 - 4K^2\mu^2\cos(2x_1^*) = 0, \quad (2.27)$$

and

$$\omega_{\pm}^{2} = -\frac{1}{2} \left(\mu^{2} - 2K\mu \left(1 - \cos(2x_{1}^{*}) \right) \right) \\ \pm \frac{1}{2} \left[\left(\mu^{2} - 2K\mu \left(1 - \cos(2x_{1}^{*}) \right) \right)^{2} + 16K^{2}\mu^{2}\cos(2x_{1}^{*}) \right]^{1/2}.$$
(2.28)

For the sake of notation we write

$$\omega_{\pm}^2 = -\frac{1}{2}b \pm \frac{1}{2}\sqrt{b^2 - 4c},\tag{2.29}$$

where

$$b = \mu^2 - 2K\mu \left(1 - \cos(2x_1^*)\right) c = -4K^2\mu^2\cos(2x_1^*),$$
(2.30)

with $\cos(2x_1^*) = \pm \sqrt{1 - (1/K^2)}$.

Lemma 2.1. A necessary condition for the existence of $\omega_{\pm} \in \mathbb{R}$ is

$$b^2 - 4c \ge 0. \tag{2.31}$$

Moreover,

- 1. If $b \ge 0$
 - (a) If $c \leq 0$ then $\omega_+ \in \mathbb{R}_0^+$ and $\omega_- \in \mathbb{C} \setminus \mathbb{R}$.
 - (b) If c > 0 then $\omega_{\pm} \in \mathbb{C} \setminus \mathbb{R}$.
- 2. If b < 0
 - (a) If $c \leq 0$ then $\omega_+ \in \mathbb{R}^+$, $\omega_- \in \mathbb{C} \setminus \mathbb{R}$.
 - (b) If c > 0 then $\omega_{\pm} \in \mathbb{R}^+$.

Provided $\omega_+ \in \mathbb{R}$ or $\omega_- \in \mathbb{R}$, we can find the critical time-delay $\tau \in \mathbb{R}^+$ such that $i\omega$ is a root of $P_{\text{Fix}(\mathbf{S}_N)}$ using the S_n map in section 2.2.2, thus, from (2.18) and (2.20) we have

$$\sin(\omega_{\pm}\tau) = -\frac{\omega_{\pm}}{K(1+\cos(2x_{1}^{*}))}$$

$$\cos(\omega_{\pm}\tau) = \frac{-\omega_{\pm}^{2} + K\mu(1-\cos(2x_{1}^{*}))}{K\mu(1+\cos(2x_{1}^{*}))},$$
(2.32)

and

$$\tau_{\pm}(\omega_{\pm}; K, \mu, n) = \frac{1}{\omega_{\pm}} \left[\operatorname{Arctan} \left(\frac{\sin(\omega_{\pm}\tau)}{\cos(\omega_{\pm}\tau)} \right) + 2n\pi \right], \quad n \in \mathbb{Z}.$$
(2.33)

Here we want to stress that τ_{\pm} does not depend on τ . In what follows we will write $\tau_{\pm}(n) = \tau(\omega_{\pm}, n)$ to emphasize the dependence on ω_{\pm} or n respectively according to need.

The direction in which the roots cross the imaginary axis, if there are any, can be obtained by looking at the sign of $\delta(\omega)$ defined in (2.24), where the constants from (2.25) are

$$A = \mu \omega_{\pm}^{2}$$
(2.34)

$$B = \omega_{\pm}^{3} - K \mu \omega_{\pm} (1 - \cos(2x_{1}^{*}))$$

$$C = \mu - \tau_{\pm} \omega_{\pm}^{2} + \tau_{\pm} K \mu (1 - \cos(2x_{1}^{*}))$$

$$D = \omega_{\pm} (2 + \mu \tau).$$

It is clear from (2.24) that the sign of δ depends on the numerator AC + BD, then using (2.34) we compute

$$AC + BD = \omega_{\pm}^2 \left(2\omega_{\pm}^2 + b\right) \tag{2.35}$$

but from equation (2.29) we know that $b = -2\omega_{\pm}^2 \pm \sqrt{b^2 - 4c}$, then substituting into (2.35) we have

$$AC + BD = \pm \omega_{\pm}^2 \sqrt{b^2 - 4c},$$

thus the sign of $\delta(\omega_{\pm})$ is

$$\operatorname{sign}(\delta(\omega_{\pm})) = \begin{cases} +1 & \text{for } \omega_{+} \\ -1 & \text{for } \omega_{-} \end{cases}$$
(2.36)

2.2.4 Symmetry-preserving bifurcation curves

In this section we shall analyze the bifurcation curves in $Fix(\mathbf{S}_N)$, from which fully synchronized periodic orbits emanate, in three cases:

• When K = 1 the following is valid for both equilibria ϕ^{\pm} . In this case the roots of the characteristic function $P_{\text{Fix}(\mathbf{S}_N)}$ in (2.11) when $\tau = 0$ are,

$$\lambda_1 = 0, \quad \lambda_2 = -\mu.$$

The equation $F(\omega) = 0$ in (2.27), which represents a necessary condition for the existence of roots at $\lambda = \pm i\omega$, becomes

$$F(\omega) = \omega^4 + (\mu^2 - 2\mu) \,\omega^2 = 0,$$

and here we have two roots

$$\omega_{\pm}^2 = -\frac{1}{2}(\mu^2 - 2\mu) \pm \frac{1}{2}\sqrt{(\mu^2 - 2\mu)^2},$$
(2.37)

clearly, these conjugate roots exist provided the condition

$$0 < \mu < 2,$$
 (2.38)

holds true; then we have

$$\begin{aligned} \omega_{-} &= & 0 \\ \omega_{+} &= & \pm \sqrt{2\mu - \mu^{2}}, \quad \omega \in \mathbb{R}^{+} \end{aligned}$$

If the condition (2.38) does not hold, the roots in $P_{\text{Fix}(\mathbf{S}_N)}$ will remain in the left hand side of the complex plane with a constant root at zero, for all $\tau \in \mathbb{R}^+$. When $\mu = 2$ there are two constant zero roots of $P_{\text{Fix}(\mathbf{S}_N)}$. From (2.18) and (2.26) with $R_R = -\omega_+^2 + \mu$, $R_I = \mu\omega_+$, $S_R = -\mu$ and $S_I = 0$ we obtain $\sin(\omega_+ \tau) = -\omega_+$

$$\sin(\omega_+ \tau) = \omega_+$$

$$\cos(\omega_+ \tau) = \frac{\mu - \omega_+^2}{\mu}.$$
(2.39)

Combining (2.37) and (2.39) we compute τ as a function of ω_+ and the other free parameters,

$$\tau_{+}(\omega_{+};\mu,n) = \frac{1}{\omega_{+}} \left[\operatorname{Arctan} \left(\frac{-\omega_{+}\mu}{-\omega_{+}^{2}+\mu} \right) + 2n\pi \right], \quad n \in \mathbb{Z}.$$
 (2.40)

We already know from (2.36) that the roots $\lambda = i \pm \omega_+$ cross from the left to the right. In figure 1 the curves for $\tau(\omega_+; \mu, n)$ from (2.40) are shown for different values of n, only positive values of τ are considered which correspond to $n \in \mathbb{N}$. The curve $\tau_+(n) = \tau(\omega_+; \mu, n)$ for n = 1 determines the first root crossing from the left to the right. For each curve $\tau_+(n)$ with n > 1 a new root crosses from the left-hand side to the right-hand side of the imaginary axis.

Figure 1: Symmetry preserving bifurcation curves for the equilibrium $x_1^* = \phi^{\pm}$, with K = 1 and $0 < \mu < 2$.

Remark. Although the equilibria are spectrally stable in Fix(\mathbf{S}_N) (no roots of $P_{\text{Fix}(\mathbf{S}_N)}$ with positive real part) with K = 1 at $\tau = 0$ for both equilibria $x_1^* = \phi^{\pm}$, see (2.14), and the first bifurcation root appears on the curve $\tau_+(\mu; 1)$, nothing can be said about the stability of the equilibria in Fix(\mathbf{S}_N) below this curve because there exists a constant zero root $\lambda = \pm \omega_- = 0$.

• Next we analyze the unstable equilibrium $x_1^* = \phi^+$ when K > 1. We are interested in any values of parameters μ and τ such that the roots in $P_{\text{Fix}(\mathbf{S}_N)}(\lambda, \tau)$ become stable, i.e., if in any $\mu, \tau \in \mathbb{R}^+$ for which we have max($\text{Re}\lambda$) < 0, for all roots λ of $P_{\text{Fix}(\mathbf{S}_N)}$. We shall use the Lambert W function, see [3, 7, 25, 31], to find the rightmost root when μ and τ vary. The initial λ_0 guess needed in both Newton's and Halley's schemes used to calculate the rightmost root is found using the rightmost root in an auxiliary polynomial as proposed in [31, 32], and for the following iterations the root found in the previous iteration is used as initial guess. Results of the numerical simulation with $\mu = \{0.1, 0.2, 0.4, 0.6, 0.8\}$ and K = 2 are shown in figure 2. As expected at $\tau = 0$ the rightmost root is positive and increases monotonically with μ , see (2.14). On the other hand, when τ grows the rightmost root tends to a non positive value as shown in (2.15) and predicted in Section 2.2.1. Using the Matlab routines

Figure 2: Real part of the rightmost root for the characteristic function $P_{\text{Fix}(\mathbf{S}_N)}(\lambda, \tau)$ with K = 2 and $x_1^* = \phi^+$, for $\mu = \{0.1, 0.2, 0.4, 0.6, 0.8\}$.

DDE-Biftool [11, 12] we observe that the other characteristic roots converge when $\tau \to \infty$, see figure 3. Although, roots can become stable when $\tau \to \infty$, we are interested only in finite values of time-delay, consequently there is numerical evidence that some roots in $P_{\text{Fix}(\mathbf{S}_N)}$ remain unstable when $x_1^* = \phi^+$ for any finite value of $\mu, \tau \in \mathbb{R}^+$.

• For the equilibrium $x_1^* = \phi^-$ with K > 1 the characteristic function $P_{\text{Fix}(\mathbf{S}_N)}$ in equation (2.11) becomes

$$P_{\mathrm{Fix}(\mathbf{S}_N)} = \lambda^2 + \mu\lambda + K\mu\left(1 + \sqrt{1 - \frac{1}{K^2}}\right) - K\mu\left(1 - \sqrt{1 - \frac{1}{K^2}}\right)e^{-\lambda\tau}.$$

From (2.14) we know both roots are stable when $\tau = 0$, and from (2.15) we also know there are no roots in the right-side of the complex plane when $\tau \to \infty$.

Figure 3: Real part of the rightmost roots for the characteristic function $P_{\text{Fix}(\mathbf{S}_N)}(\lambda, \tau)$ with K = 2 and $x_1^* = \phi^+$, for $\mu = 0.9$ using DDE-Biftool.

From $F(\omega) = 0$ in (2.27) with $x_1^* = \phi^-$, we obtain

$$\omega_{\pm}^{2} = -\frac{1}{2} \left(\mu^{2} - 2K\mu \left(1 + \sqrt{1 - \frac{1}{K^{2}}} \right) \right)$$
$$\pm \frac{1}{2} \left[\left(\mu^{2} - 2K\mu \left(1 + \sqrt{1 - \frac{1}{K^{2}}} \right) \right)^{2} - 16K^{2}\mu^{2}\sqrt{1 - \frac{1}{K^{2}}} \right]^{1/2}$$

Then by Lemma 2.1 with c>0, $\omega\in\mathbb{R}^+$ if and only if the discriminant is positive and b<0, i.e., the first term is positive which implies,

$$\mu < 2\left(K + \sqrt{K^2 - 1}\right). \tag{2.41}$$

The discriminant is positive if and only if

$$\left| \mu - 2\left(K + \sqrt{K^2 - 1} \right) \right| > 4\sqrt{K\sqrt{K^2 - 1}},$$

and so, by (2.41)

$$\mu < 2\left(K + \sqrt{K^2 - 1}\right) - 4\sqrt{K\sqrt{K^2 - 1}} =: \mu_{\max}, \qquad (2.42)$$

is a necessary condition for the existence of bifurcations in $Fix(\mathbf{S}_N)$ when $x_1^* = \phi^-$ with K > 1. When K = 1 this condition becomes condition (2.38).

Remark. We know the roots in $P_{\text{Fix}(\mathbf{S}_N)}$ are stable when $x_1^* = \phi^-$ for $K \geq 1$ at $\tau = 0$, see (2.14); using the time-delay as parameter bifurcations can occur for time-delays τ satisfying (2.33) provided condition (2.42) holds. If condition (2.42) does not hold then the roots of $P_{\text{Fix}(\mathbf{S}_N)}$ will remain stable for all τ . In that sense μ_{max} sets the lower limit to μ for the stability of the equilibrium in Fix(\mathbf{S}_N) for all time delays τ in this case.

As an example we choose K = 1.05. Condition (2.42) becomes $0 < \mu <$ $\mu_{\text{max}} = 0.4211$. With these parameters and using (2.28), (2.32), (2.33), and (2.24), with $x_1^* = \phi^-$, figure 4 shows the curves corresponding to τ_{\pm} (τ_{+} in solid line and τ_{-} in dashed line) for different values of n (a lobe $\tau_{+}(n)$ and $\tau_{-}(n)$ for each n) considering only positive values of τ ; we already know from (2.36) that $\delta_{+}(\omega_{+}) > 0$ and $\delta_{-}(\omega_{-}) < 0$, thus the shadowed area indicates the region where the equilibrium is stable in Fix(\mathbf{S}_N). These results are tested using DDE-Biftool [11, 12]; with $\mu = 0.3$ and K = 1.05 we found the time delays τ_1 to τ_5 corresponding to critical time delays leading to Hopf bifurcations ($\tau_1 = 6.34, \tau_2 = 11, \tau_3 = 15.41$, $\tau_4 = 23.51$, and $\tau_5 = 24.48$) which match with those found using the S_n map, see figure 4; In figure 5 the real part of the rightmost root is shown as a black curve, the critical time delays τ_1 to τ_5 are also shown, each peak is related to the corresponding lobe in figure 4; the numerics confirms that at τ_1 , τ_3 and τ_5 the root crosses from the left to the right of the imaginary axis switching stability from stable to unstable, and at τ_2 , τ_4 the roots come back to the left-hand side of the complex plane, switching stability from unstable to stable again; these time delays are the same as shown in figure 4, clearly for $\tau > \tau_5$ the equilibrium becomes unstable in $Fix(\mathbf{S}_N)$. Thus, for the given parameters the equilibrium is spectrally stable in Fix(\mathbf{S}_N) within the interval $(0, \tau_1) \cup (\tau_2, \tau_3) \cup (\tau_4, \tau_5)$, when $\mu < \mu_{\max}$.

Figure 4: Symmetry-preserving bifurcation curves for the equilibrium $x_1^* = \phi^-$, with K = 1.05. Within the shadowed regions there are no roots with positive real part.

Figure 5: Real part of the rightmost root of $P_{\text{Fix}(\mathbf{S}_N)}$ for $x_1^* = \phi^-$, $\mu = 0.3$, and K = 1.05, using DDE-Biftool.

2.3 Symmetry-breaking bifurcations

2.3.1 Roots in the characteristic function $P_j(\lambda, \tau)$ at $\tau = 0$ and as $\tau \to \infty$

Remembering that $K \geq 1$, $N \in \mathbb{N} > 1$ and $\mu \in \mathbb{R}^+$, we have that the characteristic function $P_j(\lambda, \tau)$ in (2.11) when $\tau = 0$ becomes

$$P_j(\lambda, 0) = \lambda^2 + \mu\lambda + K\mu(1 - \cos(2x_1^*)) + \frac{K\mu}{N-1}(1 + \cos(2x_1^*)) = 0, \quad (2.43)$$

which has the two roots

$$\lambda_{1,2} = -\frac{\mu}{2} \pm \frac{1}{2} \left(\mu^2 - 4 \left[K\mu (1 - \cos(2x_1^*)) + \frac{K\mu}{N-1} (1 + \cos(2x_1^*)) \right] \right)^{1/2}.$$

since $|\cos(2x_1^*)| < 1$, see (2.12), the discriminant is always smaller than μ^2 , consequently $\operatorname{Re}(\lambda_{\pm}) < 0$.

When $\tau \to \infty$, assuming $\operatorname{Re}(\lambda) > 0$ in (2.11), we obtain,

$$\lim_{\tau \to \infty} \lambda_{\pm} = -\frac{\mu}{2} \pm \frac{1}{2} \left(\mu^2 - 4K\mu \left(1 - \cos(2x_1^*) \right) \right)^{1/2}, \qquad (2.44)$$

here again the discriminant is always smaller than μ^2 , thus $\operatorname{Re}(\lambda_{\pm}) < 0$, which contradicts the assumption $\operatorname{Re}(\lambda) > 0$, therefore the roots of $P_j(\lambda, \tau)$ are not in the right-hand side of the complex plane when $\tau \to \infty$; These results are valid for both equilibria $x_1^* = \phi^{\pm}$.

2.3.2 Conditions for the existence of symmetry-breaking bifurcations

For the characteristic function $P_j(\lambda, \tau)$ from (2.11), following (2.16) we have

$$\begin{aligned} R(\lambda) &= \lambda^2 + \mu\lambda + K\mu(1 - \cos(2x_1^*)) \\ S(\lambda) &= \frac{K\mu}{N-1}(1 + \cos(2x_1^*)), \end{aligned}$$

and substituting $\lambda = i\omega$ we obtain

$$R(i\omega) = (-\omega^{2} + K\mu(1 - \cos(2x_{1}^{*}))) + i\mu\omega$$

$$S(i\omega) = \frac{K\mu}{N-1}(1 + \cos(2x_{1}^{*})).$$
(2.45)

Then the polynomial $F(\omega)$ from (2.19) becomes

$$F(\omega) = \omega^{4} + (\mu^{2} - 2K\mu (1 - \cos(2x_{1}^{*}))) \omega^{2} + (K\mu)^{2} (1 - \cos(2x_{1}^{*}))^{2} - \left(\frac{K\mu}{N-1}\right)^{2} (1 + \cos(2x_{1}^{*}))^{2} = 0,$$
(2.46)

from which we get

$$\omega_{\pm}^{2} = -\frac{1}{2} \left(\mu^{2} - 2K\mu \left(1 - \cos(2x_{1}^{*}) \right) \right) \\
\pm \frac{1}{2} \left[\left(\mu^{2} - 2K\mu \left(1 - \cos(2x_{1}^{*}) \right) \right)^{2} \\
-4 \left\{ \left(K\mu \right)^{2} \left(1 - \cos(2x_{1}^{*}) \right)^{2} - \left(\frac{K\mu}{N-1} \right)^{2} \left(1 + \cos(2x_{1}^{*}) \right)^{2} \right\} \right]^{1/2}.$$
(2.47)

For sake of simplicity we write

$$\omega_{\pm} = \sqrt{-\frac{b}{2} \pm \frac{1}{2}\sqrt{b^2 - 4c}},\tag{2.48}$$

where

$$b = \mu^2 - 2K\mu(1 - \cos(2x_1^*))$$

$$c = (K\mu)^2(1 - \cos(2x_1^*))^2 - \left(\frac{K\mu}{N-1}\right)^2(1 + \cos(2x_1^*))^2.$$
(2.49)

The first necessary condition for the existence of bifurcations in P_j is (2.31) then substituting b and c in this condition we obtain

$$\mu^2 - 4\mu K (1 - \cos(2x_1^*)) + \left(\frac{2K}{N-1}\right)^2 (1 + \cos(2x_1^*))^2 \ge 0.$$

By calculating the real roots of this equation it is possible to find the boundaries in which this inequality holds true; these real roots are the two curves depending on K with N,

$$\mu_{\pm}(K;N) = 2K(1 - \cos(2x_1^*)) \pm \left[\left(K(1 - \cos(2x_1^*)) \right)^2 - \left(\frac{K}{N-1} \right)^2 (1 + \cos(2x_1^*))^2 \right]_{(2.50)}^{1/2}.$$

Note that the discriminant is always smaller than the square of the first term, therefore $\mu_{\pm} \in \mathbb{R}^+$. The set M of all values μ satisfying condition (2.31) is

$$M = \{ \mu \in \mathbb{R}^+ / \mu \in \{ \langle 0, \mu_{1-}] \cup [\mu_{1+}, +\infty \rangle \} \}.$$
 (2.51)

Additional necessary conditions for the existence of Hopf bifurcations are given in Lemma 2.1 The condition $b \ge 0$ is equivalent to

$$\mu \ge 2K(1 - \cos(2x_1^*)),\tag{2.52}$$

and the condition c > 0 means

$$(N-1)^2 \left(1 - \cos(2x_1^*)\right)^2 - \left(1 + \cos(2x_1^*)\right)^2 > 0,$$

since all factors are greater than zero, this is equivalent to

$$\frac{N-2}{N} > \cos(2x_1^*). \tag{2.53}$$

Now we will start the analysis of the conditions for the existence of bifurcations in X_j considering three cases:

• When K = 1. In this case $\cos(x_1^*) = 0$, see (2.12), therefore the following analysis will be valid for both equilibria $x_1^* = \phi_1^{\pm}$. For this case the curves μ_{\pm} from (2.50) become

$$\mu_{\pm}(N) = 2 \pm \frac{1}{N-1} \sqrt{N(N-2)}, \qquad (2.54)$$

clearly, for $N \in \mathbb{N} > 1$ we have

$$0 < \mu_{-}(N) \le 2 \le \mu_{+}(N). \tag{2.55}$$

From (2.53) we see that $c \ge 0$ is always true for this case. From Lemma 2.1, case 2b), we know that b from (2.49) has to satisfy b < 0 for real solutions ω of (2.46) to exist which becomes

$$\mu < 2, \tag{2.56}$$

thus from (2.55) and (2.56), we see from (2.51) that these bifurcations in W_j can appear if and only if

$$\mu \in (0, \mu_{-}]. \tag{2.57}$$

• For the equilibrium $x_1^* = \phi^+$, with K > 1 we have $\cos(2x_1^*) = \frac{1}{K}\sqrt{K^2 - 1}$. We know this equilibrium is unstable in Fix(\mathbf{S}_N), see sections 2.2.3 and 2.2.1. The curves for μ_{\pm} in (2.50) for this case become

$$\mu_{\pm}(K;N) = 2\left(K - \sqrt{K^2 - 1}\right) \pm 2\left[\left(K - \sqrt{K^2 - 1}\right)^2 - \frac{1}{(N - 1)^2}\left(K + \sqrt{K^2 - 1}\right)^2\right]^{1/2}$$
(2.58)

In this point is better to express conditions in (2.52) and (2.53) in terms of the curves b = 0 and c = 0. The curve b = 0 is equivalent to

$$\mu = \mu_b(K) := 2\left(K - \sqrt{K^2 - 1}\right), \qquad (2.59)$$

and the curve c = 0 is equivalent to

$$K = \mathcal{K}_N := \frac{N}{2} \sqrt{\frac{1}{N-1}}.$$
(2.60)

In figure 6, the curves from (2.58), (2.59) and (2.60) are shown for various values of N. The curves $\mu_+(K, N)$ are shown in dotted lines and the curves $\mu_-(K, N)$ in dashed lines; the curve $\mu_b(K)$ is the solid black line. Here the conditions b > 0 and b < 0 correspond to the regions above and below the curve μ_{1b} respectively; the conditions c < 0 and c > 0 are identified with the right and left of each vertical line \mathcal{K}_N . Let us take as an example N = 2, from (2.60) we see that $\mathcal{K}_2 = 1$, but we know that K has to be greater than one, thus bifurcation can occur at the right-hand side of the vertical line $K = \mathcal{K}_2$, where c < 0. From the additional conditions for the existence of bifurcations given in Lemma 2.1, we see that with c < 0 bifurcations occur only for ω_+ ; the two curves μ_{\pm} in (2.58) are, for this case, in $\mathbb{C} \setminus \mathbb{R}$, therefore bifurcations can occur for all $\mu > 0$.

Figure 6: Curves showing the conditions for existence of symmetry-breaking bifurcations with $x_1^* = \phi^+$ and K > 1.

• For the equilibrium $x_1^* = \phi^-$ with K > 1 the curves μ_{\pm} from (2.50) become

$$\mu_{\pm} = 2\left(K + \sqrt{K^2 - 1}\right) \pm 2\left[\left(K + \sqrt{K^2 - 1}\right)^2 - \frac{1}{(N - 1)^2}\left(K - \sqrt{K^2 - 1}\right)^2\right]^{1/2}$$
(2.61)

and the condition c > 0 from (2.53) becomes

$$\frac{\mathcal{N}-1}{\mathcal{N}} > -\frac{1}{K}\sqrt{K^2 - 1}$$

which is always true since K > 1 and $N \in \mathbb{N} > 1$. From the conditions for existence of bifurcations in X_j given in Lemma 2.1 we see that for c > 0 we need b < 0 in order for bifurcations to occur, i.e.,

$$\mu < 2(K + \sqrt{K^2 - 1}), \tag{2.62}$$

therefore from (2.61) and (2.62) we see that bifurcations can occur in W_j at the equilibrium $x_1^* = \phi^-$ with K > 1 if

$$\mu \in (0, \mu_{-}),$$

with μ_{-} from (2.61). This also means that bifurcations can occur for both ω_{\pm} .

The analysis of the roots of the polynomial $F(\omega)$ from (2.46) in the above paragraphs gives us necessary conditions for the existence of roots of $P_j(i\omega, \tau)$, i.e. $\omega \in \mathbb{R}^+$. However it is necessary to also impose the conditions on $\sin(\omega\tau)$ and $\cos(\omega\tau)$ given in section 2.2.2, to determine at which time-delays the linearization at the equilbrium has imaginary eigenvalues. From (2.18) and (2.45) we have

$$\sin(\omega_{\pm}\tau) = \frac{\omega_{\pm}(N-1)}{K(1+\cos(2x_{1}^{*}))}$$

$$\cos(\omega_{\pm}\tau) = \frac{\left(\omega_{\pm}^{2} - K\mu\left(1-\cos(2x_{1}^{*})\right)\right)(N-1)}{K\mu\left(1+\cos(2x_{1}^{*})\right)}.$$
(2.63)

Note that the denominator in those terms does not vanish for with $K, \mu \in \mathbb{R}^+$, $K \ge 1, N \in \mathbb{N} > 1$, since $\cos(2x_1^*)$ from (2.12) satisfies $|\cos(2x_1^*)| < 1$. The frequency ω_{\pm} is computed using (2.47). At this point we can calculate the time-delays $\tau \ge 0$ associated to ω_{\pm} using (2.20), which for this case becomes,

$$\tau_{\pm}(\mu, K; n) = \frac{1}{\omega_{\pm}} \left(\operatorname{Arctan} \left(\frac{\omega_{\pm} \mu}{\omega_{\pm}^2 - K\mu \left(1 - \cos(2x_1^*) \right)} \right) + 2n\pi \right), \quad n \in \mathbb{N}.$$
(2.64)

The last necessary condition for the existence of bifurcation points is the transversality condition, given in equation (2.22) and (2.24), where

$$A = \omega_{\pm}^{2} \mu$$

$$B = \omega_{\pm} \left(\omega_{\pm}^{2} - K \mu \left(1 - \cos(2x_{1}^{*}) \right) \right)$$

$$C = \mu - \tau \left(\omega_{\pm}^{2} - K \mu \left(1 - \cos(2x_{1}^{*}) \right) \right)$$

$$D = \omega_{\pm} (2 + \tau \mu)$$
(2.65)

The sign of $\delta(\mu, K; N)$ determines if the roots cross the imaginary axis from the left to the right or vice versa, this sign depends on the numerator AC + DB, and using (2.47), (2.63) and (2.65), we obtain

$$AC + DB = 2\omega^4 + \omega^2 \left(\mu^2 - 2K\mu(1 - \cos(2x_1^*))\right), \qquad (2.66)$$

from (2.47) and (2.48) we see that $b = \mu^2 - 2K\mu(1 - \cos(2x_1^*))$, then

$$AC + DB = \pm \omega_{\pm} \sqrt{b^2 - 4c}, \qquad (2.67)$$

here we use ω_{\pm} instead of ω to bring out that there are two possible values for ω ; we can express δ as a function of $\omega_{\pm}(\mu, k; N)$, thus the sign of δ is

$$\operatorname{sign}(\delta(\omega_{\pm}, \mu, K; N)) = \begin{cases} +1 & \text{for } \omega_{+} \\ -1 & \text{for } \omega_{-} \end{cases} .$$
 (2.68)

This last equation implies that when bifurcation occurs, whenever $\omega_{-} \in \mathbb{R}^{+}$ exists, the root $\lambda = i\omega_{-}$ crosses the imaginary axis from the right to the left, whereas whenever $\omega_{+} \in \mathbb{R}^{+}$ exists the root $\lambda = i\omega_{+}$ crosses the imaginary axis from the left to the right.

2.3.3 Symmetry-breaking bifurcation curves

In the previous section we have analyzed the conditions for the existence of symmetry-breaking bifurcations in terms of the parameters $\mu, K \in \mathbb{R}^+$ with $K \geq 1$ and $N \in \mathbb{N} > 1$ for both equilibria $x_1^* = \phi^{\pm}$. In this section we will obtain the bifurcation curves for W_j using the S_n map, see section 2.2.2, and we shall compare these curves with those obtained for Fix(\mathbf{S}_N) in section 2.2.

We will consider three cases:

• When K = 1 the results we obtain are valid for both equilibria $x_1^* = \phi^{\pm}$. We already know that bifurcations for K = 1 can occur only for $\mu < 2$, see (2.56); thus the frequency ω in (2.47) becomes

$$\omega_{\pm}^{2} = -\frac{1}{2}\mu(\mu - 2) \pm \frac{1}{2}\mu \left[(\mu - 2)^{2} - 4\left(1 - \frac{1}{(N-1)^{2}}\right) \right]^{1/2}, \quad (2.69)$$

here we distinguish two cases:

- When N = 2 we have $\omega_+ = \sqrt{\mu(2-\mu)}$ and $\omega_- = 0$, and from (2.67) we know that bifurcations associated to ω_+ cross the imaginary axis from the left to the right Then plotting the curves for $\tau_+(\mu; n)$ using (2.67), and comparing them with those curves obtained for $Fix(\mathbf{S}_N)$, see figure 1, we obtain the curves shown in the figure 7, the curves for τ_+ corresponding to the W_j are plotted in solid lines and the curves for τ_+ corresponding to the Fix(\mathbf{S}_N) are in dashed lines, with the time-delay as bifurcation parameter; note that each curve indicates a new root crossing the imaginary axis from the left to the right. Therefore within the shadowed region there are no roots in the righthand side of the complex plane, however due to the zero eigenvalues in $Fix(\mathbf{S}_N)$ and in W_j nothing can be said about the stability of the equilibrium in this region. In figure 8 the real part of the rightmost root for the case N = 2, K = 1 and $\mu = \{0.05, 0.5, 1\}$ was computed as a function of the time-delay using the Lambert W function, with both Newton's and Halley's schemes; it can be seen that this root crosses the imaginary axis at a low value of τ (approx. $\tau = 1$), and never comes back, but it approaches zero as $\tau \to \infty$.

Figure 7: Symmetry preserving bifurcation curves in dashed lines and symmetry breaking bifurcation curves in solid line for both equilibria $x_1^* = \phi^{\pm}$ with N = 2 and K = 1; bifurcations occur with roots crossing imaginary axis from the left to the right. There are no roots in the right-hand side of the complex plane within the shadowed region. However there is a constant zero root.

Figure 8: Real part of the rightmost root for the function P_j , for N = 2, K = 1 and $\mu = \{0.05, 0.5, 1\}$.

- When N > 2 we know from (2.54) and (2.57) that bifurcations can occur for $\mu \leq \mu_{1-}(N) < 2$, and from (2.69) we see that both $\omega_{\pm} \in \mathbb{R}^+$. We also know by looking at the sign of δ in (2.68) the direction in which these roots cross the imaginary axis. In figure 9 the curves τ_{\pm} as a function of μ from (2.64) for W_j with N = 3 and for Fix(\mathbf{S}_N) from (2.40) are shown. For Fix(\mathbf{S}_N) these curves are shown in solid line, as we already saw in section 2.2.4 these roots cross the imaginary axis from the left to the right. The curves for W_j are shown in dotted line for τ_+ and in dashed line for τ_- . The value of $\mu_-(N)$ for N = 3 is also shown, see (2.54), bounding the curves τ_{\pm} . Within the shadowed region there are no roots with negative real parts; however there is a zero root of $P_{\text{Fix}(\mathbf{S}_N)}$.

Figure 9: Symmetry preserving bifurcation curves in solid line and symmetry breaking bifurcation curves in dotted line for μ_+ and in dashed line for μ_- , these curves are valid for both equilibria $x_1^* = \phi^{\pm}$, for N = 3 and K = 1. Within the shadowed region there are no roots with positive real part.

- If K > 1 the equilibrium $x_1^* = \phi^+$ is, as we saw in section 2.2.1, unstable in Fix(\mathbf{S}_N), but we can find bifurcations of this unstable equilibrium in W_i . From Lemma 2.1 and (2.49) we see that
 - If $c \leq 0$ then $\omega_+ \in \mathbb{R}_0^+$.
 - If c > 0 and b < 0 then $\omega_{\pm} \in \mathbb{R}^+$.

The condition b < 0 implies

$$\mu < 2(K - \sqrt{K^2 - 1}) < 2,$$

and the condition c > 0 is equivalent to

 $K < \mathcal{K}_N,$

where \mathcal{K}_N is defined in (2.60). For a given N we see that for small values of μ and K bifurcations associated to ω_{\pm} (roots crossing the imaginary axis in both directions) are possible, however for $K \geq K_N$ only bifurcations related to ω_{\pm} appear, i.e., roots crossing the imaginary axis from the left to the right. • The equilibrium $x_1^* = \phi^-$ with K > 1 is stable in $\operatorname{Fix}(\mathbf{S}_N)$ at $\tau = 0$, see section (2.2.1). In figure 10 the curves $\tau_{\pm}(\mu)$ for both $\operatorname{Fix}(\mathbf{S}_N)$ and W_j are shown.

Figure 10: Symmetry preserving bifurcation curves at the right side in dashed/solid black lines and symmetry breaking bifurcation curves at the left side in dotted/solid red lines for the equilibrium $x_1^* = \phi^-$ with N = 3 and K = 1.05. Within the shadowed regions the system remains stable.

2.4 Equivariant Hopf bifurcation for N = 2, 3

Assume (2.3) has a periodic solution x(t) with period T. There are two types of symmetry that leave the solution invariant. The first one is the group of *spatial symmetries*

$$K = \{ \gamma \in \Gamma, \gamma x(t) = x(t), \text{ for all } t \},\$$

which is the isotropy group of each point on the solution. The second is the group of *spatio-temporal symmetries*

$$H = \{\gamma \in \Gamma, \gamma x(t) = x(t + t_0(\gamma)T), \text{ for all } t\}$$

where $t_0(\gamma) \in \mathbb{R}/\mathbb{Z} \cong \mathbf{S}^1$.

The full-phase model (2.1) for two nodes has $\mathbf{S}_2 = \mathbb{Z}_2$ as symmetry group. In this case purely imaginary roots of $P_{\text{Fix}(\mathbf{S}_2)}$ lead to symmetry-preserving Hopf bifurcation of fully-synchronized periodic orbits with spatial symmetry group $K = \mathbf{S}_2$. Purely imaginary roots of P_1 lead to symmetry-breaking Hopf bifurcation of periodic orbits with \mathbb{Z}_2 spatiotemporal symmetry and trivial spatial symmetry, i.e., the first and second oscillator are half a period out of phase. This follows from the Equivariant Hopf Theorem, for details see [17].

The full-phase model (2.1) for three nodes has $\mathbf{S}_3 = \mathbf{D}_3$ as symmetry group where \mathbf{D}_m the *dihedral group* of order 2m (rotation and reflections in the plane. In this case purely imaginary roots of $P_{\text{Fix}(\mathbf{S}_3)}$ lead to symmetry-preserving Hopf bifurcation of fully-synchronized periodic orbits with spatial symmetry group $K = \mathbf{S}_3$ as before. Purely imaginary roots of P_1 lead tosymmetry-breaking Hopf bifurcation of two families of periodic orbits (modulo symmetry), one with $H = \mathbb{Z}_3$ as spatiotemporal symmetry group, corresponding to coordinate shifts $i \to i + 1 \mod 3$ and trivial spatial symmetry group, and one with with $K = \mathbb{Z}_2(\pi_{1,2})$ -spatial symmetry and $H/K = \mathbb{Z}_2(\pi_{1,3})$ as spatio-temporal symmetry group, for details see [17]. For the first family of periodic orbits the oscillators are 1/3 of a period out of phase. In the second family of periodic orbits, the first and second oscillator are in phase and oscillate with twice the period of the third one. For systems with \mathbf{S}_N -symmetry where N > 3 the spatial and spatio-temporal symmetry groups of bifurcating periodic orbits in the case of equivariant Hopf bifurcation have been classified in [9].

3 Phase model

In this section a bifurcation analysis for the model of a fully connected Nnode network of second-order PLLs oscillators using the instantaneous phase is addressed. As in the classical approach to the PLL network we neglect the double-frequency term and use the instantaneous phase $\theta(t)$ instead of the fullphase $\phi(t)$. The model for the *i*-th node can be obtained following [24, 27]

$$\ddot{\theta}_i(t) + \mu \dot{\theta}_i(t) - \frac{K\mu}{N-1} \sum_{j=1, j \neq i}^N \sin(\theta_j(t-\tau) - \theta_i(t) - \omega_M \tau) = 0, \ i = 1, \dots, N.$$
(3.1)

This model presents $\mathbf{S}_N \times \mathbb{S}^1$ symmetry; the demonstration for the \mathbf{S}_N symmetry is similar to the full-phase model and will be omitted here. The translational $C \in \mathbb{S}^1 = \mathbb{R}/(2\pi\mathbb{Z})$ acts on $\theta \in \mathbb{T}^N$, $\mathbb{T}^N = I\mathbb{R}/2\pi\mathbb{Z})^N$ as $\theta_j \to (\theta_j + C) \mod 2\pi$, $j = 1, \ldots, N$, and it is not difficult to see that if $\theta(t) = [\theta_1(t), \ldots, \theta_N t)]^T$ is a solution to (3.1) then any translated solution $\tilde{\theta}(t)$ with $\tilde{\theta}_j(t) = \theta_j(t) + C$ is also a solution which proves that (3.1) has translation symmetry. This system presents relative equilibria.

Definition 3.1 (Relative Equilibrium). A relative equilibrium of a Γ -equivariant dynamical system $\dot{X} = F(X)$ is a group orbit that is invariant under the dynamics. A trajectory X(t) lies on a relative equilibrium if and only if it is an equilibrium in a comoving frame which generates a one-parameter family γ_t , $t \in \mathbb{R}$ of symmetries, see, e.g., [13].

(3.1) has \mathbf{S}_N -invariant relative equilibria

$$\theta_k(t) = \Omega(\tau)t + \theta^0, \quad k = 1, \dots, N,$$
(3.2)

where the rotation frequency $\Omega(\tau)$ satisfies

$$\Omega(\tau) = -K\sin((\Omega(\tau) + \omega_M)\tau), \qquad (3.3)$$

and θ^0 is an arbitrary constant; although Ω depends on ω_M , K and τ , we write $\Omega(\tau)$ because we are interested in the time delay as bifurcation parameter.

The S^1 -symmetry introduced by the simplification of the double-frequency term generates a zero eigenvalue in the characteristic function for the linearized system around any equilibrium or relative equilibrium. The \mathbf{S}_N -symmetry allows us to find a block decomposition of the linearization at a relative equilibrium as we did in section 2.1.

Remark. Relative equilibria which are not \mathbf{S}_N -invariant might exist if $\theta_i(t) = \Omega(\tau)t + \theta_i^0$ for all *i*, but $\theta_i^0 \neq \theta_j^0$, but this case is not studied here.

In a rotating frame with frequency $\Omega(\tau)$ such that

$$\vartheta_k(t) = \theta_k(t) - \Omega(\tau)t - \theta^0, \quad k = 1, \dots, N,$$
(3.4)

setting $\theta^0 = 0$ for simplicity, we can rewrite equation (3.1) with $x_1^{(j)} = \theta_j$, and $x_2^{(j)} = \dot{\theta}_j$, as

$$\dot{x}_{1}^{(i)} = x_{2}^{(i)}$$
$$\dot{x}_{2}^{(i)} = -\mu x_{2}^{(i)} - \mu \Omega(\tau) + \frac{K\mu}{N-1} \sum_{\substack{j=i\\j\neq 1}}^{N} \sin\left(x_{1\tau}^{(j)} - x_{1}^{(i)} - \Omega(\tau)\tau - \omega_{M}\tau\right), \quad (3.5)$$
$$i = 1, \dots, N.$$

Then (3.5) takes the form (2.4).

In this section we study bifurcation from \mathbf{S}_N -invariant relative equilibria. Hopf bifurcation from the equilibrium x = 0 in the comoving frame leads to relative Hopf bifurcation of relative periodic orbits (RPOs).

Definition 3.2 (Relative periodic orbit). A relative periodic orbit (RPO) of a Γ -equivariant dynamical system $\dot{X} = F(X)$ with phase space \mathcal{X} is periodic orbit in the space of group orbits \mathcal{X}/Γ . If Γ is compact then a trajectory X(t)lies on an RPO if and only if it is a periodic orbit in a comoving frame, see, e.g., [13].

In our case $\Gamma = \mathbb{S}^1 \times \mathbf{S}_N$ is compact and any RPO $\theta(t)$ satisfies $\theta_j(t) = \theta_j(t-\tau) + C$ for all $j = 1, \ldots, N$. Here $\tau \in \mathbb{R}^+$ is called the relative period of the RPO and $C \in \mathbb{R}$.

Linearising equation (3.5) around its equilibrium point x = 0 we can define the matrix L as in (2.7)

$$Lx = \begin{pmatrix} x_2^{(1)} \\ -K\mu\cos(\widehat{\Omega}\tau)x_1^{(1)} - \mu x_2^{(1)} + \frac{K\mu}{N-1}\cos(\widehat{\Omega}\tau)e^{-\lambda\tau}\sum_{\substack{i=1\\i\neq 1}}^N x_1^{(i)} \\ \vdots \\ x_2^{(N)} \\ -K\mu\cos(\widehat{\Omega}\tau)x_1^{(N)} - \mu x_2^{(N)} + \frac{K\mu}{N-1}\cos(\widehat{\Omega}\tau)e^{-\lambda\tau}\sum_{\substack{i=1\\i\neq N}}^N x_1^{(i)} \end{pmatrix}$$

where

$$\widehat{\Omega} = \Omega(\tau) + \omega_M, \qquad (3.6)$$

or

$$\widehat{\Omega} = -K\sin(\widehat{\Omega}\tau) + \omega_M. \tag{3.7}$$

From (3.3) we see that

$$-K \le \Omega(\tau) \le K. \tag{3.8}$$

Now, using the results obtained in section 2.1, in particular in (2.1), (2.10) with

$$a = K\mu\cos(\widehat{\Omega}\tau)$$
$$b = -\frac{K\mu}{N-1}\cos(\widehat{\Omega}\tau)e^{-\lambda\tau},$$

we obtain the characteristic functions

$$P_{\mathrm{Fix}(\mathbf{S}_{N})}(\lambda,\tau) = \det(\triangle(\lambda,\tau)|_{\mathrm{Fix}(\mathbf{S}_{N})})$$

$$= \lambda^{2} + \mu\lambda + K\mu\cos(\widehat{\Omega}\tau) - K\mu\cos(\widehat{\Omega}\tau)e^{-\lambda\tau}$$

$$P_{j}(\lambda,\tau) = \det(\triangle(\lambda,\tau)|_{X_{j}})$$

$$= \lambda^{2} + \mu\lambda + K\mu\cos(\widehat{\Omega}\tau) + \frac{K\mu}{N-1}\cos(\widehat{\Omega}\tau)e^{-\lambda\tau}.$$
(3.9)

Clearly, $P_{\text{Fix}(\mathbf{S}_N)}$ has a constant zero eigenvalue for all parameter values τ, K, μ due to the translational symmetry. As before, roots in function P_j have multiplicity N-1.

Remark. (The parameter k_v in the phase model and the rotating frame) In [8] a modification of the model (3.1) was presented by introducing the parameter k_v in order to avoid a zero eigenvalue in the characteristic equation $P_{\text{Fix}(\mathbf{S}_N)}(\lambda, \tau) = 0$ in (3.9); the phase-model using this new parameter becomes

$$\ddot{\theta}_{i}(t) + (\mu + k_{v})\dot{\theta}_{i}(t) + \mu k_{v}\theta_{i}(t) - \frac{K\mu}{N-1} \sum_{\substack{j=1\\j\neq i}}^{N} \sin(\theta_{j}(t-\tau) - \theta_{i}(t) - \omega_{M}\tau) = 0, i = 1, \dots, N.$$

The \mathbb{R} -symmetry disappears when $k_v \neq 0$.

3.1 Symmetry-preserving bifurcations

In the rotating frame $\vartheta(t) = \theta(t) - \Omega(\tau)$ the frequency $\Omega(\tau)$ is determined by the nonlinear equation (3.3); for a given τ there exists a whole family of solutions $\omega(\tau)$ satisfying this equation, clearly as τ increases more solutions appear. From (3.9) when $\tau = 0$ we have

$$P_{\mathrm{Fix}(\mathbf{S}_N)}(\lambda, 0) = \lambda^2 + \mu\lambda = 0,$$

whose roots are

$$\lambda_1 = 0, \quad \lambda_2 = -\mu.$$

In order to find critical delays leading to bifurcations in $\text{Fix}(\mathbf{S}_N)$ we will follow section 2.2.2, and using (2.16) we have that $P_{\text{Fix}(\mathbf{S}_N)}(\lambda, \tau) = R(\lambda, \tau) + S(\tau)e^{-\lambda\tau} = 0$ where

$$R(\lambda,\tau) = \lambda^2 + \mu\lambda + K\mu\cos(\widehat{\Omega}\tau)$$

$$S(\tau) = -K\mu\cos(\widehat{\Omega}\tau),$$
(3.10)

and from (2.18) we obtain

$$\sin(\omega\tau) = -\frac{\omega}{K\cos(\widehat{\Omega}\tau)}$$

$$\cos(\omega\tau) = \frac{-\omega^2 + K\mu\cos(\widehat{\Omega}\tau)}{K\mu\cos(\widehat{\Omega}\tau)},$$
(3.11)

for $K\mu\cos(\widehat{\Omega}\tau) \neq 0$. The polynomial $F(\omega,\tau)$ from (2.19) becomes

$$F(\omega,\tau) = \omega^2(\omega^2 - 2K\mu\cos(\widehat{\Omega}\tau) + \mu^2) = 0$$
(3.12)

and so

$$\omega^2 = 2K\mu\cos(\widehat{\Omega}\tau) - \mu^2, \quad \text{or} \quad \omega = 0.$$
(3.13)

From (3.7) we obtain

$$\cos(\widehat{\Omega}\tau) = \pm \frac{1}{K}\sqrt{K^2 - (\omega_M - \widehat{\Omega})^2},$$

thus

$$\omega = \pm \left(2\mu \sqrt{K^2 - (\omega_M - \hat{\Omega})^2} - \mu^2 \right)^{1/2}, \quad \text{or} \quad \omega = 0.$$
 (3.14)

Solutions $\omega \in \mathbb{R}^+$ exist provided

$$2\sqrt{K^2 - (\omega_M - \widehat{\Omega})^2} \ge \mu.$$
(3.15)

Given $\tau \in \mathbb{R}^+$, we can compute $\widehat{\Omega}$ using (3.6) and (3.3). For $\omega \in \mathbb{R}^+$ satisfying (3.14) we compute the S_n map, see section 2.2.2, whose zeros are the critical bifurcation time delays for Fix(\mathbf{S}_N). Using (2.24) we obtain $\delta(\omega(\tau^*))$ from (2.22) to find the direction in which roots, if any, cross the imaginary axis, where, from (3.10),

$$A = -K\mu\omega\cos(\widehat{\Omega}\tau)\sin(\omega\tau)$$
(3.16)
$$B = -K\mu\omega\cos(\widehat{\Omega}\tau)\cos(\omega\tau)$$

$$C = \mu + \tau K\mu\cos(\widehat{\Omega}\tau)\cos(\omega\tau)$$

$$D = 2\omega - \tau K\mu\cos(\widehat{\Omega}\tau)\sin(\omega\tau),$$

and from (3.7)

$$\widehat{\Omega}_{\tau}^{\prime} = \frac{d\widehat{\Omega}}{d\tau} = -\frac{\widehat{\Omega}K\cos(\widehat{\Omega}\tau)}{1 + \tau K\cos(\widehat{\Omega}\tau)}.$$
(3.17)

3.1.1 Bifurcation of fully symmetric relative equilibria

We know that the function $P_{\text{Fix}(\mathbf{S}_N)}$ has a constant root zero for all parameters; however the polynomial $F(\omega, \tau)$ from (3.12) has additional zero roots at some values of τ , namely at

$$\widehat{\Omega}\tau = \pm \arccos\left(\frac{\mu}{2K}\right) + 2k\pi, \quad k \in \mathbb{Z}.$$
 (3.18)

Combining this with (3.7) we obtain

$$\widehat{\Omega} = \mp \frac{1}{2} \left(4K^2 - \mu^2 \right)^{1/2} + \omega_M, \qquad (3.19)$$

and substituting $\widehat{\Omega}$ into (3.18) we get

$$\tau^* = \frac{\pm \arccos\left(\frac{\mu}{2K}\right) + 2k\pi}{\omega_M \mp \frac{1}{2} \left(4K^2 - \mu^2\right)^{1/2}}, \quad k \in \mathbb{Z}.$$
 (3.20)

At these values $\tau = \tau^*$ we have additional roots $\omega = 0$. We can calculate $\delta(\omega(\tau^*))$ using (2.24) for the characteristic function $P_{\text{Fix}(\mathbf{S}_N)}(\lambda, \tau)$ with the constant zero root removed

$$\widetilde{P}_{\mathrm{Fix}(\mathbf{S}_N)}(\lambda,\tau) := \frac{1}{\lambda} P_{\mathrm{Fix}(\mathbf{S}_N)}(\lambda,\tau) = 0,$$

= $\widetilde{R}(\lambda,\tau) + \widetilde{S}(\lambda,\tau)e^{-\lambda\tau} = 0.$

where

$$\begin{split} \widetilde{R}(\lambda,\tau) &= \lambda + \mu + \frac{1}{\lambda} K \mu \cos(\widehat{\Omega}\tau) \\ \widetilde{S}(\lambda,\tau) &= -\frac{1}{\lambda} K \mu \cos(\widehat{\Omega}\tau). \end{split}$$

Thus, calculating $\delta(\omega(\tau^*))$ from (2.25) we have

$$\begin{split} A &= \omega^2 - K\mu \cos(\widehat{\Omega}\tau) - \mu \frac{\sin(\widehat{\Omega}\tau)}{\cos(\widehat{\Omega}\tau)} \left(\frac{\widehat{\Omega}}{1 + \tau K \cos(\widehat{\Omega}\tau)}\right) \\ B &= -\omega \left(\mu + \frac{\widehat{\Omega}\mu \sin(\widehat{\Omega}\tau)}{(1 + \tau K \cos(\widehat{\Omega}\tau))\cos(\widehat{\Omega}\tau)}\right) \\ C &= 2 + \mu\tau \\ D &= -\frac{1}{\omega} \left(\mu\omega + K\tau\mu\cos(\widehat{\Omega}\tau) - \tau\omega^2\right), \end{split}$$

then we obtain

$$\delta(\omega(\tau^*))\Big|_{\omega=0} = \frac{AC + BD}{C^2 + D^2}\Big|_{\omega=0} = \frac{\omega^2 \sum_{j=0}^2 a_j(\tau, K, \mu, \widehat{\Omega})\omega^j}{\sum_{r=0}^4 b_r(\tau, K, \mu, \widehat{\Omega})\omega^r}\Big|_{\omega=0} = 0,$$

with $b_0 \neq 0$.

3.1.2 Symmetry preserving bifurcation from equilibria

From (3.3) we see that $\Omega(\tau) = 0$ is a rotating co-frame solution and hence relative equilibrium becomes an equilbrium when $\omega_M \tau = n\pi$, with $n \in \mathbb{N}_0$. Now, here we have two possible cases:

• When $\omega_M \tau = 2n\pi$. We have $\widehat{\Omega} = \omega_M$ and $\cos(\widehat{\Omega}\tau) = 1$, thus from (3.11) we obtain ω

$$\sin(\omega\tau) = -\frac{\omega}{K}$$

$$\cos(\omega\tau) = \frac{K\mu - \omega^2}{K\mu},$$
(3.21)

and from condition (3.13) we obtain

$$\omega = \pm \sqrt{2K\mu - \mu^2}, \qquad (3.22)$$

provided $2K \ge \mu$. Substituting this into (3.21) we obtain a second condition

$$\pm \sqrt{2K\mu - \mu^2} = \frac{\omega_M}{2n\pi} \left(\operatorname{Arctan} \left(\frac{\pm \sqrt{2K\mu - \mu^2}}{\mu - K} \right) + 2m\pi \right), \quad (3.23)$$

with $n \in \mathbb{N}$, $m \in \mathbb{Z}$. Here we have two curves $K_{\pm}(\mu; \omega_M, n, r)$ for which a critical delay at $\omega_M \tau = 2n\pi$ exists with imaginary eigenvalue $\lambda = \pm i\omega(K, \mu)$ with ω from (3.22), and $\widehat{\Omega} = \omega_M$. Using (2.24) and (3.16) we can find the direction in which these roots cross the imaginary axis. Combining (3.21) and (3.22) with (3.16), and the fact that $\sin(\widehat{\Omega}\tau) = 0$, we obtain

$$A = -K\mu\omega\sin(\omega\tau)$$

$$B = -K\mu\omega\cos(\omega\tau)$$

$$C = \mu + \tau K\mu\cos(\omega\tau)$$

$$D = 2\omega - \tau K\mu\sin(\omega\tau).$$

(3.24)

Substituting ω from (3.22) we can compute $\operatorname{sign}(\delta(\omega(\tau^*))) = \operatorname{sign}(AC + BD)$, thus we have

$$AC + BD = \mu^2 (\mu - 2K)^2.$$
 (3.25)

Clearly, $\delta(\omega(\tau^*)) = 0$ only for $\mu = 2K$, which correspond to $\omega = 0$, see (3.22), for values $\mu \neq 2K$ we have sign $(\delta(\omega(\tau^*))) = 1$, i.e., the roots cross the imaginary axis from the left to the right. In figure 11 the curves $K_{\pm}(\mu; \omega_M, n, r)$ are shown for $r = \{-2, \ldots, 2\}$, $\omega_M = 1$ and n = 1.

Figure 11: Curves $K_{\pm}(\mu; \omega_M, n, r)$ from (3.23) with $\omega_M = 1$, n = 1 for different values of r.

• When $\omega_M \tau = (2n+1)\pi$. We have from condition (3.13) $\omega = \pm i\sqrt{2K\mu + \mu^2}$, but these solutions are disregarded, since we are looking for $\omega \in \mathbb{R}$.

3.1.3 Symmetry preserving bifurcation from relative equilibria

For this case, when $\Omega(\tau) \neq 0$, we carried out numerical computations to find time-delay τ leading to bifurcations in Fix(\mathbf{S}_N); the procedure is as follows:

- For a given $\tau \in \mathbb{R}^+$ and parameters $K, \omega_M, \mu \in \mathbb{R}^+$ we calculate all the *m* real solutions $\widehat{\Omega}^{(j)} = \widehat{\Omega}^{(j)}(\tau; K, \omega_M, \mu), j = 1, \dots, m$ of (3.7), noting (3.8) and that the number of solutions is finite and increases with τ .
- For each solution $\widehat{\Omega}^{(j)}$ we compute ω_{\pm} from (3.14), provided condition (3.15) holds.
- For each $\omega = \omega_{\pm} \left(\widehat{\Omega}^{(j)}; K, \omega_M, \mu \right), \omega \in \mathbb{R}^+$ we compute the S_n map using (3.11), see section 2.2.2; since these roots ω_{\pm} are conjugate pairs only one of them is necessary, lets say ω_+ ; the S_n map gives us the time-delay $\tau_n(\tau)$ from (2.20), which depends on the values calculated previously. If $\tau_n(\tau)$ matches with the given τ , then we have find a bifurcation time-delay, cf. (2.21).
- Finally in order to determine the direction in which these roots cross the imaginary axis we have to compute the sign of $\delta(\omega(\tau^*))$ using (2.24).

In figure 12 the eleven possible curves $\widehat{\Omega}^{(j)}$ within the interval $\tau \in [0, 5\pi]$ are shown with parameters $\mu = 1, K = 1$ and $\omega_M = 1$. In figure 13 all bifurcation

Figure 12: Curves $\widehat{\Omega}$ with $\mu = 1$, K = 1, and $\omega_M = 1$.

points within the interval $\tau \in [0, 5\pi]$ are shown, including $\tau_1^* \approx 7.8164$, and $\tau_2^* \approx 15.6328$ calculated using (3.20), for which bifurcation pf relative equilbria occurs in $\text{Fix}(\mathbf{S}_N)$. The sign for $\delta(\omega(\tau^*))$ is positive in all cases.

Figure 13: S_n maps for the curves $\widehat{\Omega}^{(j)}$ related to the characteristic function $P_{\text{Fix}(\mathbf{S}_N)}(\lambda, \tau)$ in (3.9); in all cases $\delta(\omega(\tau^*))$ is positive, i.e., the roots cross imaginary axis from the left to the right. At $S_n = 0$ along the curves $\widehat{\Omega}^{(j)}$ relative Hopf bifurcation occurs, and at τ_1^* and τ_2^* relative equilibria bifurcate.

3.2 Symmetry breaking bifurcation

When $\tau = 0$ the characteristic function P_j from (3.9) becomes

$$P_j(\lambda, 0) = \lambda^2 + \mu\lambda + K\mu\left(\frac{N}{N-1}\right), \qquad (3.26)$$

whose roots are

$$\lambda_{1,2} = -\frac{\mu}{2} \pm \frac{1}{2} \left(\mu^2 - 4K\mu \frac{N}{N-1} \right)^{1/2},$$

and since $\mu, K \in \mathbb{R}^+$ and $N \geq 2$, nonzero roots of P_j when $\tau = 0$ are always stable. In order to calculate the S_n map, see section 2.2.2, in particular (2.16), we note that by (3.9),

$$R(\lambda,\tau) = \lambda^{2} + \mu\lambda + K\mu\cos(\widehat{\Omega}\tau)$$

$$S(\tau) = \frac{K\mu}{N-1}\cos(\widehat{\Omega}\tau),$$
(3.27)

so by (2.18) we obtain

$$\sin(\omega\tau) = \frac{\omega(N-1)}{K\cos(\widehat{\Omega}\tau)}$$

$$\cos(\omega\tau) = \frac{\left(\omega^2 - K\mu\cos(\widehat{\Omega}\tau)\right)(N-1)}{K\mu\cos(\widehat{\Omega}\tau)},$$
(3.28)

and the polynomial F from (2.19) is

$$F(\omega,\tau) = \omega^4 + (\mu^2 - 2K\mu\cos(\widehat{\Omega}\tau))\omega^2 + \frac{N(N-2)}{(N-1)^2}K^2\mu^2\cos^2(\widehat{\Omega}\tau), \quad (3.29)$$

here again, $\widehat{\Omega} = \Omega(\tau) + \omega_M$ and $\Omega(\tau)$ satisfies (3.3). Hence,

$$\omega_{\pm}^{2} = -\frac{1}{2} \left(\mu^{2} - 2K\mu \cos(\widehat{\Omega}\tau) \right) \\
\pm \frac{1}{2} \left[\left(\mu^{2} - 2K\mu \cos(\widehat{\Omega}\tau) \right)^{2} - 4 \frac{N(N-2)}{(N-1)^{2}} K^{2} \mu^{2} \cos^{2}(\widehat{\Omega}\tau) \right]^{1/2}.$$
(3.30)

In (3.30) the discriminant is always smaller than the square of the first term, therefore in order to $\omega \in \mathbb{R}$ this first term has to be non-negative, i.e.,

$$\mu \le 2K\cos(\widehat{\Omega}\tau). \tag{3.31}$$

Hence, $\cos(\widehat{\Omega}\tau) \ge 0$. For $\omega \in \mathbb{R}$ the discriminant also has to be greater or equal to zero, i.e.,

$$2K\cos(\widehat{\Omega}\tau) - \mu \ge \frac{\sqrt{N(N-2)}}{(N-1)} 2K\cos(\widehat{\Omega}\tau).$$
(3.32)

(3.32) that $\omega \in \mathbb{R}$ if

$$\mu \le 2K\cos(\widehat{\Omega}\tau) \left(1 - \frac{\sqrt{N(N-2)}}{N-1}\right).$$
(3.33)

Using (2.24) we obtain $\delta(\omega(\tau^*))$ from (2.22) to find the direction in which roots, if any, cross the imaginary axis, where, from (2.25) and (3.27), where

$$A = K\mu\sin(\widehat{\Omega}\tau)(\widehat{\Omega} + \tau\widehat{\Omega}_{\tau}')\left(1 + \frac{1}{N-1}\cos(\omega\tau)\right) + \frac{K\mu\omega}{N-1}\sin(\omega\tau)\cos(\widehat{\Omega}\tau)$$
(3.34)

$$B = \frac{K\mu}{N-1} \left(\omega \cos(\widehat{\Omega}\tau) \cos(\omega\tau) - \sin(\widehat{\Omega}\tau) \sin(\omega\tau) \left(\widehat{\Omega} + \tau \widehat{\Omega}'_{\tau} \right) \right)$$
$$C = \mu - \frac{\tau K\mu}{N-1} \cos(\widehat{\Omega}\tau) \cos(\omega\tau)$$

$$D = 2\omega + \frac{\tau K \mu}{N-1} \cos(\widehat{\Omega}\tau) \sin(\omega\tau),$$

with $\widehat{\Omega}'_{\tau}$ from (3.17).

3.2.1 Symmetry-breaking bifurcation of relative equilibria

Setting $\lambda = 0$ (3.9) we have $\widehat{\Omega}\tau = \frac{\pi}{2} + n\pi$, with $n \in \mathbb{Z}$, which gives time-delays $\tau = \tau_*$ where P_j has a zero root.

3.2.2 Symmetry breaking bifurcation from equilibria

We shall analyze bifurcation from equilibria where $\Omega(\tau) = 0$ as we did in the previous section for $\text{Fix}(\mathbf{S}_N)$. We know that for this case $\omega_M \tau = n\pi$ with $n \in \mathbb{N}_0$ and $\widehat{\Omega} = \omega_M$; we have two cases:

- When $\omega_M \tau = 2n\pi$ then $\cos(\omega_M \tau) = 1$
- When $\omega_M \tau = (2n+1)\pi$. We have $\cos(\omega_M \tau) = -1$ which violates (3.33), therefore bifurcations are not possible in W_j for this case.

3.2.3 Symmetry breaking bifurcation from relative equilibria

For this analysis we shall follow the steps described in section 3.1.3 for bifurcations in Fix(\mathbf{S}_N) and we will continue with the same example. We look for bifurcation points of the characteristic function P_j with $\mu = 1$, K = 1, $\omega_M = 1$ choosing N = 2. Using the S_n map as before, bifurcation points are shown in figure 14. In all cases $\delta(\omega(\tau^*)) \geq 0$. The first bifurcation appears at $\tau = \pi$, which is lower than the lowest bifurcation value in Fix(\mathbf{S}_N) in figure 13.

Figure 14: The S_n map for different curves $\widehat{\Omega}$ related to the characteristic function $P_j(\lambda, \tau)$ in (3.9). In every case $\delta(\omega(\tau^*)) \geq 0$, i.e., roots cross from the left to the right.

4 Phase-difference model

In [5, 8, 24] an alternative approach is used to model a fully connected PLL network using, the phase difference between any two nodes j and k which is defined as

$$\varphi^{(j,k)}(t) := \theta_j(t) - \theta_k(t-\tau). \tag{4.1}$$

From 3.1 we get

$$\ddot{\varphi}^{(i,j)} + \mu \dot{\varphi}^{(i,j)} + \frac{K\mu}{N-1} \left[\sum_{\substack{l=1\\l\neq i}}^{N} \sin\left(\varphi^{(i,l)} + \omega_M \tau\right) - \sum_{\substack{l=1\\l\neq j}}^{N} \sin\left(\varphi^{(j,l)}_{\tau} + \omega_M \tau\right) \right] = 0.$$
(4.2)

This phase-difference model has \mathbf{S}_N -symmetry as it is derived from the phase model of section 3, but not translational symmetry due to the definitions of phase differences.

If N > 2 then the phase difference model lives in $\varphi \in \mathbb{R}^{N(N-1)}$ and N(N-1) > N so that it is to be expected that the phase difference model has fictitious solutions which do not correspond to the phase model for $\theta \in \mathbb{R}^N$ from Section 3. If N = 2 and $\theta_1([-\tau, 0))$ and $\theta_2([-\tau, 0))$ are known we can compute $\varphi^{(1,2)}$ and $\varphi^{(2,1)}$ for $t = [-\tau, \infty)$, and then compute $\theta(t)$ for $\forall t$ using (4.3). But from solutions ($\varphi^{(1,2)}, \varphi^{(2,1)}$) we can not reconstruct (θ_1, θ_2) initial data, so any solution of the (θ_1, θ_2)-dynamics is a solution of ($\varphi^{(1,2)}, \varphi^{(2,1)}$)-dynamics, but not vice versa. Hence not all solutions of the ($\varphi^{(1,2)}, \varphi^{(2,1)}$)-dynamics give solutions of the original (θ_1, θ_2) dynamics. We demonstrate this issue by studying equilibria of the phase-difference model.

In Fix(\mathbf{S}_N) an N-node network modelled by (4.2) has a family of \mathbf{S}_N -invariant equilibria given by

$$\varphi^{(i,j)}(t) = C, \quad C \in \mathbb{R}, \tag{4.3}$$

which implies $\theta_i(t) - \theta_j(t-\tau) = \theta_j(t) - \theta_i(t-\tau) = C$ for all $i \neq j$. The solutions are relative periodic orbits (RPOs) of the θ -dynamics, i.e., satisfy

$$\theta_i(t) = \theta_i(t - 2\tau) + 2C$$

$$\theta_i(t) = \theta_j(t - \tau) + C.$$
(4.4)

If $C \equiv 0$ then $\theta(t)$ is 2τ -periodic with \mathbb{Z}_2 -spatio temporal symmetry, otherwise the RPOS have \mathbb{Z}_2 -spatio temporal symmetry in a suitable comoving frame.

The θ -dynamics from (3.1) restricted to Fix(\mathbf{S}_N) is given by

$$\ddot{\theta}_i(t) + \mu \dot{\theta}_i - K\mu \sin(\theta_i(t-\tau) - \theta_i(t) - \omega_M \tau) = 0.$$
(4.5)

By substituting (4.3) into (4.5) we obtain the second-order ODE

$$\ddot{\theta}_i(t) + \mu \dot{\theta}_i(t) + K\mu \sin(C + \omega_M \tau) = 0, \qquad (4.6)$$

whose solution is

$$\theta_j(t) = -\frac{K}{\mu}\sin(C + \omega_M \tau)(\mu t - 1) - \frac{C_1}{\mu^2} + C_2 e^{-\mu t}, \qquad (4.7)$$

with C, C_1, C_2 arbitrary constants. From (4.4) we have for any $i \neq j$

$$\theta_i(t) - \theta_j(t-\tau) = K \sin((C+\omega_M \tau)\tau) + C_2 e^{-\mu t} (1-e^{\mu \tau}).$$

Hence, $C_2 = 0$ and so

$$C = -K\sin((C + \omega_M \tau)\tau),$$

and so $C = \Omega(\tau)\tau$ with $\Omega(\tau)$ from (3.3).

So although the N-node model from (4.2) admits an \mathbf{S}_N -invariant equilibrium $\varphi_{ij}(t) \equiv C$ for all $C \in \mathbb{R}$ only the choice $C = \Omega(\tau)\tau$ corresponds to an actual \mathbf{S}_N -invariant equilibrium of the phase model from section 3.

The matrix L from (2.7) related to the linearization around additional equilibria $\varphi^{(ij)}(t) = C$ of the phase-difference model (4.2) is for N = 2 given by

$$L = \begin{pmatrix} 0 & 1 & 0 & 0 \\ -K\mu\cos(C+\omega_M\tau) & -\mu & K\mu\cos(C+\omega_M\tau)e^{-\lambda\tau} & 0 \\ 0 & 0 & 0 & 1 \\ K\mu\cos(C+\omega_M\tau)e^{-\lambda\tau} & 0 & -K\mu\cos(C+\omega_M\tau) & -\mu \end{pmatrix}.$$

The characteristic matrix $\Delta(\lambda, \tau) := \lambda I - L$ can be uncoupled into blocks corresponding to isotypic components giving

$$\rho \triangle \rho^{-1} = \left(\begin{array}{c|c} \triangle_1 & 0 \\ \hline 0 & \triangle_2 \end{array} \right)$$

for some transformation $\rho \in Mat(4)$, and the characteristic functions $P(\lambda, \tau) = det(\Delta(\lambda, \tau))$ are

$$P_{1,2}(\lambda,\tau) = \lambda^2 + \mu\lambda + K\mu\cos(C + \omega_M\tau) \mp K\mu\cos(C + \omega_M\tau)e^{-\lambda\tau} = 0,$$

which upon substituting $C = \Omega(\tau)\tau$, give the characteristic functions for the phase model in (3.9) with N = 2, where $\Omega(\tau)\tau + \omega_M \tau = \widehat{\Omega}\tau$.

For a 3-node network using the phase differences model linearizing around the equilibrium point $\varphi^{(i,j)} = \Omega(\tau)\tau$ we obtain

$$\Delta(\lambda,\tau) = (\lambda^2 + \mu\lambda)^3 (\lambda^2 + \mu\lambda + K\mu\cos(\widehat{\Omega}\tau) - K\mu\cos(\widehat{\Omega}\tau)e^{-\lambda\tau})$$
$$(\lambda^2 + \mu\lambda + K\mu\cos(\widehat{\Omega}\tau) + \frac{K\mu}{2}\cos(\widehat{\Omega}\tau)e^{-\lambda\tau})^2 = 0,$$

and here is clear that the term $(\lambda^2 + \mu \lambda)^3$ does not correspond to actual solutions for the characteristic functions for the phase model in (3.9) with N = 3.

5 Discussion and conclusions

Due to the \mathbf{S}_N -symmetry of a second-order N-node oscillators network modeled using the full-phase variables the linearization along every \mathbf{S}_N -invariant equilibrium has N blocks, on of them corresponding to the fixed point space $\operatorname{Fix}(\mathbf{S}_N)$ and the others are identical and lead to eigenvalues of multiplicity N-1. This decomposition simplifies the bifurcation analysis considerably. Hopf bifurcation in the first block is symmetry-preserving, i.e. leads to bifurcation of synchronized periodic orbits which are periodic orbits in $\operatorname{Fix}(\mathbf{S}_N)$, Hopf bifurcation in the other blocks is symmetry-breaking and leads to bifurcation of non-synchronized or partially synchronized periodic orbits.

We presented this decomposition for second order oscillators, but networks of higher order oscillators, modelled accordingly, also have \mathbf{S}_N symmetry, therefore the above mentioned block decomposition also applies provided the time delay between the nodes are the same.

Note that the full-phase model is obtained from the phase-model by including the double-frequency term and passing into a comoving frame with velocity ω_M . The phase-difference model discussed in section 4 introduces fictitious solutions that may not correspond to real solutions to the phase model analyzed in section 3 even when the equilibrium point is chosen $as\Omega(\tau)\tau$ for N > 2.

We conclude that of the three models studied here, only the full phase model from section 2 represents better and without any approximations the dynamics of a fully connected N-node time-delay network.

While stability of bifurcations and periodic solutions for ODEs is a well established theory, the same problem for DDE's is more delicate, this will be the focus of future work.
