We determine the symmetry energy $S_{\text{sym}}(\rho)$ at the saturation density $\rho = \rho_0$, particularly for three quantities of $J \equiv S_{\text{sym}}(\rho_0)$, the sloop L , the curvature K_{sym} . The values are evaluated from the observational constraint $M_{\text{max}} \geq 2M_{\text{sun}}$ of neutron star and the experimental constraint on the neutron skin thickness r_{skin}^{208} . The experimental constraint is obtained by taking the weighted mean and its error for three reliable measurements of PREX, electric-dipole polarizability, pygmy strength. One result is $J = 28 - 34$ MeV, $L = 43 - 67$ MeV, $K_{\text{sym}} = (-150) - (-3)$ MeV based on both the observational constraint and the experimental constraint. The other is $J = 27 - 35$ MeV, $L = 43 - 67$ MeV, $K_{\text{sym}} = (-270) - (29)$ MeV based on the experimental constraint only. We also determine the relation between r_{skin}^{48} and r_{skin}^{208} with the correlation coefficient $R = 0.99$. Using the r_{skin}^{48} - r_{skin}^{208} relation, we transform the central value of PREX to the corresponding value for r_{skin}^{48} and predict a result of CREX.

I. INTRODUCTION

Many predictions on the symmetry energy $S_{\text{sym}}(\rho)$ have been made so far by taking several experimental and observational constraints on $S_{\text{sym}}(\rho)$ and their combinations. Among the constraints, we take reliable constraints, as shown below.

In neutron star (NS), the $S_{\text{sym}}(\rho)$ and its density (ρ) dependence influence strongly the nature within the star. For a pulsar in a binary system, detection of the general relativistic Shapiro delay allows us to determine the mass M of NS. In fact, the NS with $M = 1.97 \pm 0.04 M_{\text{sun}}$ is observed [1]. In $\rho = 2 - 3\rho_0$ for the saturation density ρ_0 , the strangeness changing weak decay replaces nucleons by hyperons. The decay makes the maximum mass M_{max} decrease, if the decay occurs really. In this paper, we assume the decay does not take place, because nucleon-hyperon and hyperon-hyperon interactions are still unknown. As an essential constraint on the equation of state (EoS) from astrophysics, we can take

$$M_{\text{max}} \geq 2M_{\text{sun}}. \quad (1)$$

Equation (1) is the most important observational constraint on

$$S_{\text{sym}}(\rho) = J + \frac{L(\rho - \rho_0)}{3\rho_0} + \frac{K_{\text{sym}}(\rho - \rho_0)^2}{18\rho_0^2} + \dots \quad (2)$$

For the $S_{\text{sym}}(\rho)$, at the present stage, a major aim is to determine $J \equiv S_{\text{sym}}(\rho_0)$, the sloop L and the curvature K_{sym} at $\rho = \rho_0$. The symmetry energy $S_{\text{sym}}(\rho)$ cannot be measured by experiment directly. In place of $S_{\text{sym}}(\rho)$, the neutron-skin thickness r_{skin} is measured to determine L , since a strong correlation between r_{skin}^{208} and L is well known [2, 3]. Meanwhile, for the correlation between

r_{skin}^{208} and J and the correlation between r_{skin}^{208} and K_{sym} , the correlation coefficient R is not shown.

In this paper, we consider reliable experiment constraints on the neutron-skin thickness r_{skin} for double magic nuclei, ^{208}Pb and ^{48}Ca . In this section, we concentrate on ^{208}Pb ; see Sec. II C for ^{48}Ca .

Horowitz, Pollock and Souder proposed a direct measurement for $r_{\text{skin}} = r_n - r_p$ [4]. The measurement is composed of parity-violating and elastic electron scattering; the neutron radius r_n is determined from the former experiment, whereas the proton radius r_p is from the latter. In fact, for r_{skin}^{208} , the Lead Radius EXperiment (PREX) provides $r_n = 5.78^{+0.16}_{-0.18}$ fm [5, 6]. This result leads to

$$r_{\text{skin}}^{208} = 0.33^{+0.16}_{-0.18} = 0.15 - 0.49 \text{ fm} \quad (3)$$

under $r_p^{208} = 5.45$ fm [7] determined from the elastic electron scattering. Now, the PREX-II and the ^{48}Ca Radius EXperiment (CREX) are ongoing at Jefferson Lab [5]. A result of PREX-II is predicted by taking the central value of the PREX result:

$$r_{\text{skin}}^{208}(\text{PREX II}) = 0.33 \pm 0.06 = 0.27 - 0.39 \text{ fm}; \quad (4)$$

note that 0.06 fm is the estimated error of PREX-II shown in the proposal of CREX [8].

In addition to the direct measurement mentioned above, there are two important indirect measurements for ^{208}Pb . One is measurements of $E1$ polarizability α_D and the other is measurements of pygmy dipole resonances. The high-resolution measurement of α_D was made for ^{208}Pb in RCNP [9]: The value is

$$r_{\text{skin}}^{208} = 0.156^{+0.025}_{-0.021} = 0.135 - 0.181 \text{ fm}. \quad (5)$$

In this experiment, the value of r_{skin} was measured directly without using the value of r_p . The r_{skin}^{208} is also derived from the experimental pygmy strength [10]: The value is

$$r_{\text{skin}}^{208} = 0.24 \pm 0.04 = 0.20 - 0.28 \text{ fm}. \quad (6)$$

* orion093g@gmail.com

We take the weighed mean and its error of the direct and the indirect measured values. The result is

$$r_{\text{skin}}^{208} = 0.18 \pm 0.02 = 0.16 - 0.20 \text{ fm}, \quad (7)$$

This is the most important experimental constraint on r_{skin}^{208} in the present state.

There are many EoSs that show the values of r_{skin}^{208} , J , L , K_{sym} . Chen *et al.* find that existing data on the r_{skin} of Sn isotopes yield an important constraint on L [11]. Combining these constraints with analyses of isospin diffusion and double neutron/proton ratio in heavy-ion collisions at intermediate energies, they predict $L = 58 \pm 18 = 40 - 76$ MeV. Hagen *et al.* calculated a value of r_p for ^{48}Ca , using the coupled-cluster calculation with the chiral interaction. Using the $r_p - J$ and $r_p - L$ correlations, they show $25.2 \lesssim J \lesssim 30.4$ MeV and $37.8 \lesssim L \lesssim 47.7$ MeV [12], where the theoretical errors of J and L mainly come from the systematic uncertainties of the employed Hamiltonians.

In this paper, we determine reliable ranges of J , L and K_{sym} , using the observational constraint (1) and the experimental constraint (7). One set of J , L and K_{sym} is based on both the observational and the experimental constraint, whereas the other set is on the experimental constraint only.

We derive the relation between r_{skin}^{48} and r_{skin}^{208} with the correlation coefficient $R = 0.99$. Using the r_{skin}^{48} - r_{skin}^{208} relation, we transform the central value of PREX to the corresponding values for r_{skin}^{48} and predict a result of CREX, since the proposed error of CREX is smaller than that of PREX-II [8]. We also transform measured values on r_{skin}^{48} to the corresponding results on r_{skin}^{208} . This transformation allows us to compare the transformed data with the original one (7) on r_{skin}^{208} .

We construct two Gogny EoSs, since the number of Gogny EoSs is much smaller than that of Skyrme EoSs.

Section II show our results. Section III is devoted to conclusion.

II. RESULTS

A. Approach to reliable ranges of J , L and K_{sym}

We first accumulate the 204 EoSs from Refs. [3, 11, 13–36] in which r_{skin}^{208} and/or L is presented, since a strong correlation between r_{skin}^{208} and L is shown. In the 204 EoSs of Table I, the number of Gogny EoSs is much smaller than that of Skyrme EoSs. We then construct two EoSs so that D1M* [16] and D1P [22] may become harder; the two EoSs are referred to as D1MK and D1PK, respectively. Eventually, we get the 206 EoSs, as shown in Table I.

For the 206 EoSs, both r_{skin}^{208} and L are obtained self-consistently; the starting r_{skin}^{208} - L relation is determined from the EoSs in which both r_{skin}^{208} and L are presented. The resulting relation

$$L = 620.39 r_{\text{skin}}^{208} - 57.963, \quad (8)$$

has a strong correlation, because of $R = 0.99$. The relation (8) allows us to deduce an empirical constraint on L from the experimental constraint (7). The empirical constraint is

$$L = 41 - 67 \text{ MeV}. \quad (9)$$

In Table I, 47 EoSs satisfy the observational constraint (1). The 47 EoSs are tabulated in Table III. Out of the 47 EoSs, the 23 (D1M*, Sly230a, D2, SLy4, BSk24, BSk21, SFHo, Sly2, SKb, DD-ME2, Sly9, D1PK, DD-ME1, HS(DD2), NL3 $\omega\rho$, APR(E0019), BSk23, SkI6, SkI4, FSUgold2.1, BSR2, SGI, D1AS) satisfy the empirical constraint (9) on L . The 23 yield

$$J = 28 - 34, \quad L = 43 - 67, \quad K_{\text{sym}} = (-150) - (-3) \quad (10)$$

in units of MeV. This is our result based on both the observational constraint (1) and the experimental constraint (7).

In Table I, 95 EoSs satisfy the empirical constraint (9) on L . These are (D1M*, BSk14, SLy230a, M3Y-P6, D2, SLy0, UNEDF0, Ly5, Sk χ m, E0015, SkM*, SLy4, Sly230b, BSk24, D280, BSk21, SV-L47, SFHo, IU-FSU, SLy6, Sly2, SKb, SLy5, SR3, es275, GSklII, SR2, D1P, SII, Ska25-B, SV-sym32-B, DD-ME2, rDD-ME2, M3Y-P7, SV-mas07, SQMC650, SkT3-B, SKRA, Ska35-B, KDE0v1, Sly9, D1PK, DD-ME1, E0024, HA, HS(DD2), SKRA-B, TW99, D1MK, Ducoin, SkT3, NL3 $\omega\rho$, DD, DD-F, SkT1-B, SLy4-B, SkT2, SkT1, SV-sym32, APR, E0019, BSk23, Ska35-T, SkM*-B, SkT2-B, SkT3-T, SV-sym32-T, Ska25-T, SQMC750-B, SQMC700, NRAPR, SkI6, FSUgold, MSL0, SkI4, FSU, FSUgold2.1, rFSUgold, KDE0v1-B, NRAPR-B, NL $\omega\rho$ (025), LNS, BSR2, SkT2-T, SkT1-T, GSkl, Ska25s20, SGI, Ska35s20, SkM*-T, SKRA-T, SkSM*, SLy4-T, BHF-1, D1AS, RAPR). The 95 yield

$$J = 27 - 35, \quad L = 43 - 67, \quad K_{\text{sym}} = (-270) - (29) \quad (11)$$

This is our result based on the experimental constraint (7). The resulting constraint on L is stronger than that of Chen *et al.*

Further explanation is shown below. We first make three comments on Table I.

1. For D1S, D1N, D1M, D1M*, D1MK, D1P, D1PK, we have calculated r_{skin}^{208} and r_{skin}^{48} with the Hartree-Fock-Bogoliubov method with the angular momentum projection [37]. For the Gogny EoSs, the effective nucleon-nucleon interaction can be described as

$$\begin{aligned} V(\vec{r}) &= \sum_{i=1,2} t_0^i (1 + x_0^i P_\sigma) \rho^{\alpha_i} \delta(\vec{r}) \\ &+ \sum_{i=1,2} (W_i + B_i P_\sigma - H_i P_\tau - M_i P_\sigma P_\tau) e^{-\frac{r^2}{\mu_i^2}} \\ &+ i W_0 (\sigma_1 + \sigma_2) [\vec{k}' \times \delta(\vec{r}) \vec{k}], \end{aligned} \quad (12)$$

where σ and τ are the Pauli spin and isospin operators, respectively, and the corresponding exchange operators P_σ and P_τ are defined as usual. See Table II for the parameter sets of D1MK and D1PK. As shown in Table I, the results of D1MK and D1PK for r_{skin}^{208} and r_{skin}^{48} are consistent with the experimental constraint (7) on r_{skin}^{208} and the experimental constraint (15) on r_{skin}^{48} . For matter, the energy density functional has been used.

2. Dutra *et al.* proposed a series of criteria derived from macroscopic properties of nuclear matter in the vicinity of nuclear saturation density derived by the liquid drop model, experiments with giant resonances and heavy-ion collisions, and selected 16 EoSs from 240 Skyrme EoSs by using a series of criteria [29]. The 16 EoSs (GSkI, GSkII, KDE0v1, LNS, MSL0, NRAPR, Ska25s20, Ska35s20, SKRA, SkT1, SkT2, SkT3, Skxs20, SQMC650, SQMC700, SV-sym32) are in Table I.
3. Out of the 240 Skyrme EoSs, Tsang *et al.* selected 12 EoSs (KDE0v1, NRAPR, Ska25, Ska35, SKRA, SkT1, SkT2, SkT3, SQMC750, SV-sym32, SLy4, SkM*) and fitted them to nuclear binding energies, charge radii and single-particle energies [14]. The fitted set is identified with the label “-T” from the original set. Brown and Schwenk fitted the original set so that the effective mass m^*/m can be 0.9 in neutron matter at $\rho = 0.10 \text{ fm}^{-3}$ [30]. This set is identified with the label by “-B”. The three sets are in Table I.

Figure 1 shows r_{skin}^{208} dependence of J , L , K , K_{sym} for 206 EoSs of Table I, where K and K_{sym} are the incompressibility and the symmetry-energy incompressibility, respectively. The dotted lines denote Eq. (8) for the r_{skin}^{208} - L and

$$J = 48.287 r_{\text{skin}}^{208} + 23.091. \quad (13)$$

for the r_{skin}^{208} - J relation. The r_{skin}^{208} - L relation ($R = 0.99$) is much stronger than the r_{skin}^{208} - J relation ($R = 0.74$), the r_{skin}^{208} - K relation ($R = 0.30$), and the r_{skin}^{208} - K_{sym} relation ($R = 0.84$).

The M - R relation of NS is shown in Fig. 2 for D1MK and D1PK, where R is a radius of NS. In our calculations, the beta-equilibrium is taken into account. Below the subnuclear density $n < 0.1 \text{ fm}^{-3}$, we use the BPS EoS [38]. D1PK satisfies the observable constraint (1). Meanwhile, the maximum mass $M_{\text{max}} = 1.94 M_{\odot}$ of D1MK is slightly smaller than the observable constraint (1), but is in the $M = 1.97 \pm 0.04 M_{\odot}$ of Ref. [1].

Horowitz mentioned some observational constraints and the lower limit of R determined from PREX [39]; his mention is illustrated in Fig. 2. Bauswein *et al.* suggested that if $1.6 M_{\odot}$ stars have radii less than the indicated lower limit, the NS in GW170817 would collapse to soon to a black hole and not eject material enough to power

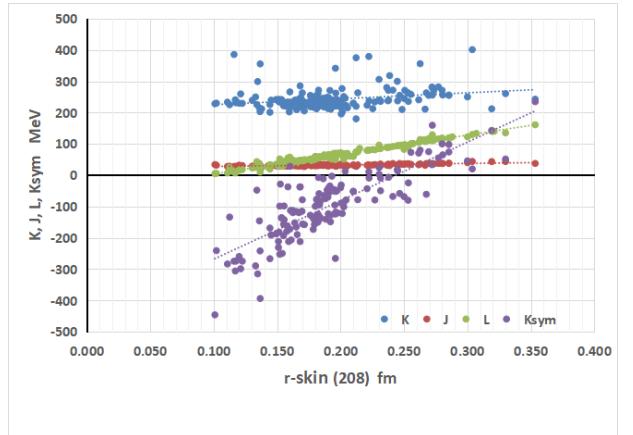

FIG. 1. Properties of 206 EoSs (dotts) as a function of r_{skin}^{208} . The dotted lines stand for Eq. (8) for the r_{skin}^{208} -Land Eq. (13) for the r_{skin}^{208} - J .

the observed Kilonova. When the maximum mass of a NS is above the red dotted line, Metzger *et al.* argued that the compact remnant in GW170817 lives too long and provides too much energy to the kilonova. Finally the GW170817 limit on the radius of a $1.4 M_{\odot}$ is from the limit on the gravitational deformability, whereas the limit on the EoS at low density from PREX is plotted as a minimum radius of a $0.5 M_{\odot}$ NS. Such low mass NSs have low central densities comparable to nuclear density. As an interesting result, D1PK satisfies all of the observation constraints mentioned above and the lower bound of R determined from PREX. D1MK almost satisfies the observation constraints mentioned above and the lower bound of R determined from PREX.

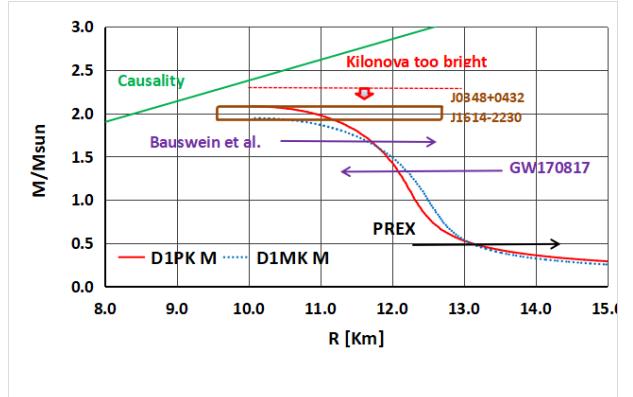

FIG. 2. M - R relation for D1MK and D1PK. D1PK is shown by the solid line, and D1MK is by the dashed line. See the text for the observation constraints shown and the lower limit of R determined from PREX.

B. Relation between r_{skin}^{48} and r_{skin}^{208}

For the 206 EoSs in Table I, we determine the relation between r_{skin}^{208} and r_{skin}^{48} self-consistently, where the

starting r_{skin}^{208} - r_{skin}^{48} relation is determined from the EoSs in which both r_{skin}^{208} and r_{skin}^{48} are presented. The result reads

$$r_{\text{skin}}^{48} = 0.5547 r_{\text{skin}}^{208} + 0.0718; \quad (14)$$

see Fig. 3. The correlation is quite strong, because of $R = 0.99$.

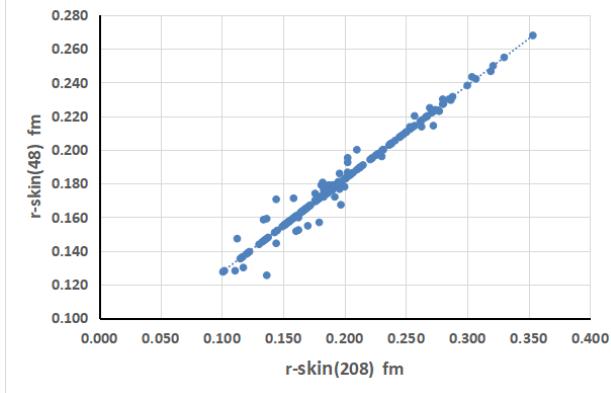

FIG. 3. Relation between r_{skin}^{208} and r_{skin}^{48} . The dotted line stands for Eq. (14), while dots correspond to 206 EoSs. Two vertical lines denote the experimental constraint (7) on r_{skin}^{208} , while two horizontal line correspond to the experimental constraint (15) on r_{skin}^{48} .

C. Prediction of CREX

The high-resolution measurement of α_D was applied for ^{48}Ca in RCNP [40]: The value is

$$r_{\text{skin}}^{48} = 0.17 \pm 0.03 = 0.14 - 0.20 \text{ fm}. \quad (15)$$

Very lately, Tanaka *et al.* have determined

$$r_{\text{skin}}^{48} = 0.146 \pm 0.048 \text{ fm} \quad (16)$$

by measuring interaction cross sections for ^{48}Ca scattering on a C target in RIKEN [41]. Before the measurement of Ref. [41], we predicted the interaction cross section and the r_{skin}^{48} , using D1S [42]. The predicted value $r_{\text{skin}}^{48} = 0.159$ fm is in Eq. (16), and the predicted interaction cross section agrees with the measured one..

The data (16) has almost the same accuracy as the high-resolution measurement Eq. (15). We then calculate the weighed mean and its error of Eq. (15) and Eq (16): The result is

$$r_{\text{skin}}^{48} = 0.16 \pm 0.03 = 0.13 - 0.19 \text{ fm}. \quad (17)$$

This is the most important constraint on r_{skin}^{48} at the present stage. The coupled-cluster result $0.12 \lesssim r_{\text{skin}}^{48} \lesssim 0.15$ fm with the chiral interaction [12] is consistent with the experimental constraint (17).

In the proposal of CREX [8], the estimated error is 0.02 fm. Using Eq. (14), we transform the central value 0.33 fm of PREX to the corresponding value

$r_{\text{skin}}^{48} = 0.47$ fm. Therefore, we may predict a result of CREX as

$$r_{\text{skin}}^{48}(\text{CREX}) = 0.47 \pm 0.02 = 0.45 - 0.49 \text{ fm}. \quad (18)$$

This is too large in comparison with the present indirect result (17). This implies that the central value is large. We predict a CREX result by taking the central value of Eq. (17). This is

$$r_{\text{skin}}^{48} = 0.16 \pm 0.02 = 0.14 - 0.18 \text{ fm}; \quad (19)$$

note that 0.02 fm is the estimated error of CREX [8].

D. Comparison between data r_{skin}^{48} and data r_{skin}^{208}

Applying the r_{skin}^{208} - r_{skin}^{48} relation (14) for the experimental constraint (17) on r_{skin}^{48} , we can get

$$r_{\text{skin}}^{208} = 0.15 - 0.18 \text{ fm}. \quad (20)$$

The indirect range (20) is slightly smaller than the original one (7) on r_{skin}^{208} . We then take the weighted mean and its error from the original and indirect ranges: The result is

$$r_{\text{skin}}^{208} = 0.18 \pm 0.02 = 0.16 - 0.20 \text{ fm}. \quad (21)$$

The final result (21) agrees with the original one (7) including PREX.

III. CONCLUSION

We have determined two reliable ranges of J , L and K_{sym} by taking the observational constraint (1) and the experimental constraint (7). One is $J = 28 - 34$ MeV, $L = 43 - 67$ MeV, $K_{\text{sym}} = (-150) - (-3)$ MeV of Eq. (10) based on both the observational constraint (1) and the experimental constraint (7). The other is $J = 27 - 35$ MeV, $L = 43 - 67$ MeV, $K_{\text{sym}} = (-270) - (29)$ MeV of Eq. (11) based on the experimental constraint (7) only.

In addition, we have determined the r_{skin}^{208} - r_{skin}^{48} relation (14) with the correlation coefficient $R = 0.99$. In the proposal of CREX, the estimated error 0.02 fm of CREX is smaller than 0.06 fm of PREX-II. We then transform the central value $r_{\text{skin}}^{208} = 0.33$ fm of PREX to the corresponding value $r_{\text{skin}}^{48} = 0.47$ fm, using the the relation (14). We get $r_{\text{skin}}^{48} = 0.47 \pm 0.02 = 0.45 - 0.49$ fm as a prediction of CREX. However, it is too large compared with the range (17) measured for r_{skin}^{48} . Taking the central value 0.16 fm of the range (17), we predict a result of CREX as $r_{\text{skin}}^{48}(\text{CREX}) = 0.16 \pm 0.02 = 0.14 - 0.18$ fm of Eq. (19).

In the 204EoSs of Table I, the number of Gogny EoSs is much smaller than that of Skyrme EoSs. We have then constructed two Gogny EoSs, D1MK and D1PK. As for J , L , K_{sym} , the values of D1MK and D1PK are in the reliable range of Eq (10). For r_{skin}^{208} and r_{skin}^{48} , the values of D1MK and D1PK are consistent with the experimental

constraints (7) and (17). D1PK satisfies all of the observational constraint Eq. (1), the experimental constraint (7) on r_{skin}^{208} , and the experimental constraints Eq. (17)

ACKNOWLEDGEMENTS
