Abstract

Let X_t be the (reflecting) diffusion process generated by $L := \Delta + \nabla V$ on a complete connected Riemannian manifold M possibly with a boundary ∂M , where $V \in C^1(M)$ such that $\mu(dx) := e^{V(x)} dx$ is a probability measure. We estimate the convergence rate for the empirical measure $\mu_t := \frac{1}{t} \int_0^t \delta_{X_s} ds$ under the Wasserstein distance. As a typical example, when $M = \mathbb{R}^d$ and $V(x) = c_1 - c_2|x|^p$ for some constants $c_1 \in \mathbb{R}, c_2 > 0$ and $p > 1$, the explicit upper and lower bounds are present for the convergence rate, which are of sharp order when either $d < \frac{4(p-1)}{p}$ or $d \geq 4$ and $p \rightarrow \infty$.

AMS subject Classification: 60D05, 58J65.

Keywords: Empirical measure, diffusion process, Wasserstein distance, Riemannian manifold.

1 Introduction

Let M be a d -dimensional complete connected Riemannian manifold, possibly with a boundary ∂M . Let $V \in C^1(M)$ such that $Z_V := \int_M e^{V(x)} dx < \infty$, where $dx := \text{vol}(dx)$ stands for the Riemannian volume measure. Then $\mu(dx) := Z_V^{-1} e^{V(x)} dx$ is a probability measure, and the (reflecting if ∂M exists) diffusion process X_t generated by $L := \Delta + \nabla V$ is reversible with stationary distribution μ . When M is compact, the convergence rate of the empirical measure

$$\mu_t := \frac{1}{t} \int_0^t \delta_{X_s} ds, \quad t > 0$$

*Supported in part by NNSFC (11771326, 11831014, 11921001).

under the Wasserstein distance is investigated in [19]. More precisely, let ρ be the Riemannian distance on M , and let

$$\mathbb{W}_2(\mu_1, \mu_2) := \inf_{\pi \in \mathcal{C}(\mu_1, \mu_2)} \|\rho\|_{L^2(\pi)}$$

be the associated L^2 -Wasserstein distance for probability measures on M , where $\mathcal{C}(\mu_1, \mu_2)$ is the class of all couplings of μ_1 and μ_2 . For two positive functions ξ, η of t , we denote $\xi(t) \sim \eta(t)$ if $c^{-1} \leq \frac{\xi(t)}{\eta(t)} \leq c$ holds for some constant $c > 1$ and large $t > 0$. According to [19], for large $t > 0$ we have

$$\mathbb{E}[\mathbb{W}_2(\mu_t, \mu)^2] \sim \begin{cases} t^{-1}, & \text{if } d \leq 3, \\ t^{-1} \log t, & \text{if } d = 4, \\ t^{-\frac{2}{d-2}}, & \text{if } d \geq 5, \end{cases}$$

where the lower bound estimate on $\mathbb{E}[\mathbb{W}_2(\mu_t, \mu)^2]$ for $d = 4$ is only derived for a typical example that M is the 4-dimensional torus and $V = 0$. Moreover, when ∂M is either convex or empty, we have

$$(1.1) \quad \lim_{t \rightarrow \infty} t \mathbb{E}[\mathbb{W}_2(\mu_t, \mu)^2] = \sum_{i=1}^{\infty} \frac{2}{\lambda_i^2},$$

where $\{\lambda_i\}_{i \geq 1}$ are all non-trivial eigenvalues of $-L$ (with Neumann boundary condition if ∂M exists) listed in the increasing order counting multiplicities. See [17, 18] for further studies on the conditional empirical measure of the L -diffusion process with absorbing boundary.

In this note, we investigate the convergence rate of $\mathbb{E}[\mathbb{W}_2(\mu_t, \mu)^2]$ for non-compact Riemannian manifold M .

1.1 Upper bound estimate

We first present a result on the upper bound estimate of $\mathbb{E}^\nu[\mathbb{W}_2(\mu_t, \mu)^2]$, where \mathbb{E}^ν is the expectation for the diffusion process with initial distribution ν . When $\nu = \delta_x$ is a Dirac measure, we simply denote $\mathbb{E}^x = \mathbb{E}^{\delta_x}$.

Let $p_t(x, y)$ be the heat kernel of the (Neumann) Markov semigroup P_t generated by L . We will assume

$$(1.2) \quad \gamma(t) := \int_M p_t(x, x) \mu(dx) < \infty, \quad t > 0.$$

By [12, Theorem 3.3] (see also [14, Theorem 3.3.19]) and the spectral representation of heat kernel, (1.2) holds if and only if L has discrete spectrum such that all eigenvalues $\{\lambda_i\}_{i \geq 0}$ of $-L$ listed in the increasing order satisfy

$$\sum_{i=0}^{\infty} e^{-\lambda_i t} < \infty, \quad t > 0.$$

Since M is connected, the trivial eigenvalue $\lambda_0 = 0$ is simple, so that

$$(1.3) \quad \lambda_1 := \inf \{ \mu(|\nabla f|^2) : f \in C_b^1(M), \mu(f) = 0, \mu(f^2) = 1 \} > 0.$$

The first non-trivial eigenvalue λ_1 is called the spectral gap of L , and (1.3) is known as the Poincaré inequality.

In particular, (1.2) holds if P_t is ultracontractive, i.e.

$$\sup_{x,y \in M} p_t(x,y) = \|P_t\|_{L^1(\mu) \rightarrow L^\infty(\mu)} < \infty, \quad t > 0.$$

Since $\gamma(t)$ is decreasing in t , (1.2) implies

$$(1.4) \quad \beta(\varepsilon) := 1 + \int_\varepsilon^1 ds \int_s^1 \gamma(t) dt < \infty, \quad \varepsilon \in (0, 1].$$

Moreover, let

$$(1.5) \quad \alpha(\varepsilon) := \mathbb{E}^\mu[\rho(X_0, X_\varepsilon)^2] = \int_M \rho(x,y)^2 p_\varepsilon(x,y) \mu(dx) \mu(dy), \quad \varepsilon > 0.$$

Finally, for any $k \geq 1$, let $\mathcal{P}_k = \{\nu \in \mathcal{P} : \nu = h_\nu \mu, \|h_\nu\|_\infty \leq k\}$, where \mathcal{P} is the set of all probability measures on M .

Theorem 1.1. *Assume (1.2).*

(1) *For any $k \geq 1$,*

$$(1.6) \quad \limsup_{t \rightarrow \infty} \left\{ t \sup_{\nu \in \mathcal{P}_k} \mathbb{E}^\nu[\mathbb{W}_2(\mu_t, \mu)^2] \right\} \leq \sum_{i=1}^{\infty} \frac{8}{\lambda_i^2}.$$

If P_t is ultracontractive, then

$$(1.7) \quad \limsup_{t \rightarrow \infty} \left\{ t \mathbb{E}^\nu[\mathbb{W}_2(\mu_t, \mu)^2] \right\} \leq \sum_{i=1}^{\infty} \frac{8}{\lambda_i^2}$$

holds for $\nu \in \mathcal{P}$ satisfying

$$(1.8) \quad \int_0^1 ds \int_M \mathbb{E}^\nu[\rho(x, X_s)^2] \mu(dx) < \infty.$$

(2) *There exists a constant $c > 0$ such that*

$$(1.9) \quad \sup_{\nu \in \mathcal{P}_k} \mathbb{E}^\nu \mathbb{W}_2(\mu_t, \mu)^2 \leq ck \inf_{\varepsilon \in (0,1]} \{ \alpha(\varepsilon) + t^{-1} \beta(\varepsilon) \}, \quad t, k \geq 1.$$

If P_t is ultracontractive, then there exists a constant $c > 0$ such that for any $\nu \in \mathcal{P}$ and $t \geq 1$,

$$(1.10) \quad \mathbb{E}^\nu[\mathbb{W}_2(\mu_t, \mu)^2] \leq c \left\{ \frac{1}{t} \int_0^1 \mathbb{E}^\nu[\mu(\rho(X_s, \cdot)^2)] ds + \inf_{\varepsilon \in (0,1]} \{ \alpha(\varepsilon) + t^{-1} \beta(\varepsilon) \} \right\}.$$

Since the conditions (1.2), (1.5) and (1.8) are less explicit, for the convenience of applications we present the following consequence of Theorem 1.1.

Corollary 1.2. *Assume that $\partial M = \emptyset$ or ∂M is convex outside a compact set. Let $V = V_1 + V_2$ for some functions $V_1, V_2 \in C^1(M)$ such that*

$$(1.11) \quad \text{Ric}_{V_1} := \text{Ric} - \text{Hess}_{V_1} \geq -K, \quad \|\nabla V_2\|_\infty \leq K$$

holds for some constant $K > 0$, where Ric is the Ricci curvature and Hess denotes the Hessian tensor. For any $t, \varepsilon > 0$, let

$$\tilde{\gamma}(t) := \int_M \frac{\mu(dx)}{\mu(B(x, \sqrt{t}))}, \quad \tilde{\beta}(\varepsilon) := 1 + \int_\varepsilon^1 ds \int_s^1 \tilde{\gamma}(r) dr.$$

(1) *There exists a constant $c > 0$ such that*

$$(1.12) \quad \sup_{\nu \in \mathcal{P}_k} \mathbb{E}^\nu [\mathbb{W}_2(\mu_t, \mu)^2] \leq ck \inf_{\varepsilon \in (0,1]} \{\varepsilon + t^{-1} \tilde{\beta}(\varepsilon)\}, \quad t, k \geq 1.$$

(2) *If $\|P_t e^{\lambda \rho^2}\|_\infty < \infty$ for $\lambda, t > 0$, then for any $t \geq 1$ and $\nu \in \mathcal{P}$,*

$$(1.13) \quad \mathbb{E}^\nu [\mathbb{W}_2(\mu_t, \mu)^2] \leq c \left[t^{-1} \nu(|\nabla V|^2) + \inf_{\varepsilon \in (0,1]} \{\varepsilon + t^{-1} \tilde{\beta}(\varepsilon)\} \right].$$

1.2 Lower bound estimate

Consider the modified L^1 -Wasserstein distance

$$\tilde{W}_1(\mu_1, \mu_2) := \inf_{\pi \in \mathcal{C}(\mu_1, \mu_2)} \int_{M \times M} \{1 \wedge \rho(x, y)\} \pi(dx, dy) \leq \mathbb{W}_2(\mu_1, \mu_2).$$

We have the following result.

Theorem 1.3. (1) *In general, there exists a constant $c > 0$ such that*

$$(1.14) \quad \mathbb{E}^\mu [\tilde{W}_1(\mu_t, \mu)^2] \geq ct^{-1}, \quad t \geq 1.$$

If (1.3) holds, then

$$(1.15) \quad \liminf_{t \rightarrow \infty} \left\{ t \mathbb{E}^\nu [\tilde{W}_1(\mu_t, \mu)^2] \right\} > 0, \quad \nu \in \mathcal{P}.$$

(2) *Let ∂M be empty or convex, and let $d \geq 3$. If $\mu(|\nabla V|) < \infty$ and*

$$(1.16) \quad \text{Ric} \geq -K, \quad V \leq K$$

holds for some constant $K > 0$, then there exists a constant $c > 0$ such that

$$(1.17) \quad \inf_{\nu \in \mathcal{P}_k} \mathbb{E}^\nu [\tilde{W}_1(\mu_t, \mu)] \geq c(kt)^{-\frac{1}{d-2}}, \quad k, t \geq 1,$$

and moreover

$$(1.18) \quad \liminf_{t \rightarrow \infty} \left\{ t^{\frac{1}{d-2}} \mathbb{E}^\nu [\tilde{W}_1(\mu_t, \mu)] \right\} > 0, \quad d \geq 4, \nu \in \mathcal{P}.$$

(3) *Assume that P_t is ultracontractive, ∂M is either empty or convex, and $\text{Ric} - \text{Hess}_V \geq K$ for some constant $K \in \mathbb{R}$. Then*

$$(1.19) \quad \liminf_{t \rightarrow \infty} \inf_{\nu \in \mathcal{P}} \left\{ t^{-1} \mathbb{E}^\nu [W_2(\mu_t, \mu)^2] \right\} \geq \sum_{i=1}^{\infty} \frac{2}{\lambda_i^2}.$$

Remark 1.1. According to Theorem 1.1(1) and Theorem 1.3(3), when P_t is ultracontractive, ∂M is either empty or convex, and $\text{Ric} - \text{Hess}_V \geq K$ for some constant $K \in \mathbb{R}$, we have

$$\sum_{i=1}^{\infty} \frac{2}{\lambda_i^2} \leq \liminf_{t \rightarrow \infty} \left\{ t^{-1} \mathbb{E}^{\nu} [W_2(\mu_t, \mu)^2] \right\} \leq \limsup_{t \rightarrow \infty} \left\{ t^{-1} \mathbb{E}^{\nu} [W_2(\mu_t, \mu)^2] \right\} \leq \sum_{i=1}^{\infty} \frac{8}{\lambda_i^2}, \quad \nu \in \mathcal{P}.$$

Because of (1.1) derived in [19] in the compact setting, we may hope that the same limit formula holds for the present non-compact setting. In particular, for the one-dimensional Ornstein-Uhlenbeck process where $M = \mathbb{R}$, $V(x) = -\frac{1}{2}|x|^2$ and $\lambda_i = i$, $i \geq 1$, we would guess

$$\lim_{t \rightarrow \infty} \left\{ t \mathbb{E}^{\mu} [\mathbb{W}_2(\mu_t, \mu)^2] \right\} = \sum_{i=1}^{\infty} \frac{2}{i^2}.$$

However, there is essential difficulty to prove the exact upper bound estimate as the corresponding calculations in [19] heavily depend on the estimate $\|P_t\|_{L^1(\mu) \rightarrow L^\infty(\mu)} \leq ct^{-\frac{d}{2}}$ for some constant $c > 0$ and all $t \in (0, 1]$, which is available only when M is compact.

1.3 Example

To illustrate Corollary 1.2 and Theorem 1.3, we consider a class of specific models, where the convergence rate is sharp when $d < \frac{4p-1}{p}$ as both upper and lower bounds behave as t^{-1} , and is asymptotically sharp when $d \geq 4$ and $p \rightarrow \infty$ for which both upper and lower bounds are of order $t^{-\frac{2}{d-2}}$. The assertions will be proved in Section 4.

Example 1.4. Let $M = \mathbb{R}^d$ and $V(x) = -\kappa|x|^\alpha + W(x)$ for some constants $\kappa > 0, \alpha > 1$, and some function $W \in C^1(M)$ with $\|\nabla W\|_\infty < \infty$.

(1) There exists a constant $c > 0$ such that for any $t, k \geq 1$, we have

$$(1.20) \quad \sup_{\nu \in \mathcal{P}_k} \mathbb{E}^{\nu} [\mathbb{W}_2(\mu_t, \mu)^2] \leq \begin{cases} ckt^{-\frac{2(\alpha-1)}{(d-2)\alpha+2}}, & \text{if } 4(\alpha-1) < d\alpha, \\ ckt^{-1} \log(1+t), & \text{if } 4(\alpha-1) = d\alpha, \\ ckt^{-1}, & \text{if } 4(\alpha-1) > d\alpha. \end{cases}$$

(2) If $\alpha > 2$, then there exists a constant $c > 0$ such that for any $t \geq 1$,

$$(1.21) \quad \sup_{x \in \mathbb{R}^d} \frac{\mathbb{E}^x [\mathbb{W}_2(\mu_t, \mu)^2]}{1 + |x|^{2(\alpha-1)}} \leq \begin{cases} ct^{-\frac{2(\alpha-1)}{(d-2)\alpha+2}}, & \text{if } 4(\alpha-1) < d\alpha, \\ ct^{-1} \log(1+t), & \text{if } 4(\alpha-1) = d\alpha, \\ ct^{-1}, & \text{if } 4(\alpha-1) > d\alpha. \end{cases}$$

(3) For any probability measure ν , there exists a constant $c > 0$ such that for large $t > 0$,

$$\mathbb{E}^{\nu} [\mathbb{W}_2(\mu_t, \mu)^2] \geq \mathbb{E}^{\nu} [\tilde{\mathbb{W}}_1(\mu_t, \mu)^2] \geq ct^{-\frac{2}{2\nu(d-2)}}.$$

2 Proofs of Theorem 1.1 and Corollary 1.2

By the spectral representation, the heat kernel of P_t is formulated as

$$(2.1) \quad p_t(x, y) = 1 + \sum_{i=1}^{\infty} e^{-\lambda_i t} \phi_i(x) \phi_i(y), \quad t > 0, x, y \in M,$$

where $\{\phi_i\}_{i \geq 1}$ are the associated unit eigenfunctions with respect to the non-trivial eigenvalues $\{\lambda_i\}_{i \geq 1}$ of $-L$, with the Neumann boundary condition if ∂M exists.

We will use the following inequality due to [9, Theorem 2]

$$(2.2) \quad \mathbb{W}_2(f\mu, \mu)^2 \leq 4\mu(|\nabla(-L)^{-1}(f-1)|^2), \quad f \geq 0, \mu(f) = 1,$$

which is proved using an idea due to [2], see Theorem A.1 below for an extension to the upper bound on $\mathbb{W}_p(f_1\mu, f_2\mu)$. To apply (2.2), we consider the modified empirical measures

$$(2.3) \quad \mu_{\varepsilon, t} := f_{\varepsilon, t} \mu, \quad \varepsilon > 0, t > 0,$$

where, according to (2.1),

$$(2.4) \quad f_{\varepsilon, t} := \frac{1}{t} \int_0^t p_{\varepsilon}(X_s, \cdot) = 1 + \sum_{i=1}^{\infty} e^{-\lambda_i \varepsilon} \xi_i(t) \phi_i, \quad \xi_i(t) := \frac{1}{t} \int_0^t \phi_i(X_s) ds.$$

Proof of Theorem 1.1. (1) It suffices to prove for $\sum_{i=1}^{\infty} \lambda_i^{-2} < \infty$. In this case, by [19, (2.19)] whose proof works under the condition (1.2), we find a constant $c > 0$ such that

$$\sup_{\nu \in \mathcal{P}_k} \left| t \mathbb{E}^{\nu} [\mu(|(-L)^{-\frac{1}{2}}(f_{\varepsilon, t} - 1)|^2)] - \sum_{i=1}^{\infty} \frac{2}{\lambda_i^2 e^{2\varepsilon \lambda_i}} \right| \leq \frac{ck}{t} \sum_{i=1}^{\infty} \frac{1}{\lambda_i^2 e^{2\varepsilon \lambda_i}}.$$

This together with (2.2) yields

$$(2.5) \quad t \sup_{\nu \in \mathcal{P}_k} \mathbb{E}^{\nu} [\mathbb{W}_2(\mu_{\varepsilon, t}, \mu)^2] \leq \sum_{i=1}^{\infty} \frac{8}{\lambda_i^2} + \frac{ck}{t} \sum_{i=1}^{\infty} \frac{4}{\lambda_i^2}, \quad \varepsilon > 0.$$

To approximate μ_t using $\mu_{\varepsilon, t}$, for any $n \geq 1$ let

$$\mathbb{W}_{2,n}(\mu_1, \mu_2) := \inf_{\pi \in \mathcal{C}(\mu_1, \mu_2)} \left(\int_{M \times M} \{n \wedge \rho(x, y)^2\} \pi(dx, dy) \right)^{\frac{1}{2}}, \quad \mu_1, \mu_2 \in \mathcal{P}.$$

Given $\gamma \in \mathcal{P}$, let $(X_s^{\gamma})_{s \geq 0}$ be the (reflecting, if $\partial M \neq \emptyset$) diffusion process generated by L with initial distribution γ , and let γP_s denote the distribution of X_s^{γ} . By the continuity of the diffusion process and the dominated convergence theorem, we have

$$\limsup_{\varepsilon \downarrow 0} \mathbb{W}_{2,n}(\gamma P_{\varepsilon}, \gamma)^2 = 0, \quad n \geq 1, \gamma \in \mathcal{P}.$$

Observing that $\mu_{\varepsilon,t} = \mu_t P_\varepsilon$, we have

$$\limsup_{\varepsilon \downarrow 0} \mathbb{W}_{2,n}(\mu_{\varepsilon,t}, \mu_t)^2 = 0, \quad n \geq 1, t > 0.$$

Since $\mathbb{W}_{2,n}(\mu_{\varepsilon,t}, \mu_t)^2 \leq n$ and $\nu \leq k\mu$ for $\nu \in \mathcal{P}_k$, this and the dominated convergence theorem yield

$$\limsup_{\varepsilon \downarrow 0} \sup_{\nu \in \mathcal{P}_k} \mathbb{E}^\nu \mathbb{W}_{2,n}(\mu_{\varepsilon,t}, \mu_t)^2 \leq k \limsup_{\varepsilon \downarrow 0} \mathbb{E}^\mu \mathbb{W}_{2,n}(\mu_{\varepsilon,t}, \mu_t)^2 = 0, \quad n \geq 1, t > 0.$$

Combining this with (2.5) and applying the triangle inequality of $\mathbb{W}_{2,n}$, we derive

$$\begin{aligned} t \sup_{\nu \in \mathcal{P}_k} \mathbb{E}^\nu [\mathbb{W}_{2,n}(\mu_t, \mu)^2] &\leq t \limsup_{\varepsilon \downarrow 0} \sup_{\nu \in \mathcal{P}_k} \left\{ \mathbb{W}_{2,n}(\mu_{\varepsilon,t}, \mu_t) + \mathbb{W}_{2,n}(\mu_t, \mu) \right\}^2 \\ &\leq \sum_{i=1}^{\infty} \frac{8}{\lambda_i^2} + \frac{ck}{t} \sum_{i=1}^{\infty} \frac{4}{\lambda_i^2}, \quad n \geq 1, t > 0. \end{aligned}$$

Therefore, for any $t > 0$ we have

$$(2.6) \quad t \sup_{\nu \in \mathcal{P}_k} \mathbb{E}^\nu [\mathbb{W}_2(\mu_t, \mu)^2] = t \sup_{n \geq 1, \nu \in \mathcal{P}_k} \mathbb{E}^\nu [\mathbb{W}_{2,n}(\mu_t, \mu)^2] \leq \sum_{i=1}^{\infty} \frac{8}{\lambda_i^2} + \frac{ck}{t} \sum_{i=1}^{\infty} \frac{4}{\lambda_i^2},$$

which implies (1.6).

Next, when P_t is ultracontractive, we have

$$\delta(\varepsilon) := \sup_{t \geq \varepsilon, x, y \in M} p_t(x, y) < \infty, \quad \varepsilon > 0.$$

Then the distribution ν_ε of X_ε starting at ν is in the class $\mathcal{P}_{\delta(\varepsilon)}$. For any $\varepsilon \in (0, 1]$, let

$$\bar{\mu}_{\varepsilon,t} := \frac{1}{t} \int_\varepsilon^{t+\varepsilon} \delta_{X_s} ds.$$

By the Markov property and (2.6), we obtain

$$(2.7) \quad \limsup_{t \rightarrow \infty} \left\{ t \mathbb{E}^\nu [\mathbb{W}_2(\bar{\mu}_{\varepsilon,t}, \mu)^2] \right\} = \limsup_{t \rightarrow \infty} \left\{ t \mathbb{E}^{\nu_\varepsilon} [\mathbb{W}_2(\mu_t, \mu)^2] \right\} \leq \sum_{i=1}^{\infty} \frac{8}{\lambda_i^2}, \quad \varepsilon > 0.$$

On the other hand, since

$$\pi := \frac{1}{t} \int_0^\varepsilon \delta_{(X_s, X_{s+t})} ds + \frac{1}{t} \int_\varepsilon^t \delta_{(X_s, X_s)} ds \in \mathcal{C}(\mu_t, \bar{\mu}_{\varepsilon,t}),$$

and since the conditional distribution of X_{s+t} given X_s is bounded above by $\delta(1)\mu$ for $t \geq 1$, we have

$$t \mathbb{E}^\nu [\mathbb{W}_2(\mu_t, \bar{\mu}_{\varepsilon,t})^2] \leq t \mathbb{E}^\nu \int_{M \times M} \rho(x, y)^2 \pi(dx, dy)$$

$$= \int_0^\varepsilon \mathbb{E}^\nu[\rho(X_s, X_{s+t})^2] ds \leq \delta(1) \int_0^\varepsilon \mathbb{E}^\nu[\mu(\rho(X_s, \cdot)^2)] ds =: r_\varepsilon.$$

Combining this with (1.8), (2.7), and applying the triangle inequality of \mathbb{W}_2 , we arrive at

$$\begin{aligned} & \limsup_{t \rightarrow \infty} \left\{ t \mathbb{E}^\nu[\mathbb{W}_2(\bar{\mu}_t, \mu)^2] \right\} \\ & \leq \lim_{\varepsilon \downarrow 0} \left((1 + r_\varepsilon^{\frac{1}{2}}) \limsup_{t \rightarrow \infty} \left\{ t \mathbb{E}^\nu[\mathbb{W}_2(\bar{\mu}_{\varepsilon,t}, \mu)^2] \right\} + (1 + r_\varepsilon^{-\frac{1}{2}}) r_\varepsilon \right) \\ & \leq \sum_{i=1}^{\infty} \frac{8}{\lambda_i^2}. \end{aligned}$$

(2) By (1.3), we have

$$(2.8) \quad \int_M |P_t f - \mu(f)|^2 d\mu \leq e^{-2\lambda_1 t} \int_M |f - \mu(f)|^2 d\mu, \quad t \geq 0, f \in L^2(\mu).$$

By (2.1)-(2.3), and noting that $L\phi_i = -\lambda_i\phi_i$ with $\{\phi_i\}_{i \geq 1}$ being orthonormal in $L^2(\mu)$, we obtain

$$(2.9) \quad \mathbb{W}_2(\mu_{\varepsilon,t}, \mu)^2 \leq 4\mu(|\nabla(-L)^{-1}(f_{\varepsilon,t} - 1)|^2) = 4 \sum_{i=1}^{\infty} \lambda_i^{-1} e^{-2\lambda_i \varepsilon} |\xi_i(t)|^2.$$

Below we prove the desired assertions respectively.

Since for $\nu \in \mathcal{P}_k$ we have $\mathbb{E}^\nu \leq k\mathbb{E}^\mu$, it suffices to prove for $\nu = \mu$. Since μ is P_t -invariant and $\mu(\phi_i^2) = 1$, we have

$$(2.10) \quad \mathbb{E}^\mu[\phi_i(X_{s_1})^2] = \mu(\phi_i^2) = 1.$$

Next, the Markov property yields

$$\mathbb{E}^\mu(\phi_i(X_{s_2}) | X_{s_1}) = P_{s_2-s_1} \phi_i(X_{s_1}) = e^{-\lambda_i(s_2-s_1)} \phi_i(X_{s_1}), \quad s_2 > s_1.$$

Combining this with (2.10) and the definition of $\xi_i(t)$, we obtain

$$\begin{aligned} \mathbb{E}^\mu |\xi_i(t)|^2 &= \frac{2}{t^2} \int_0^t ds_1 \int_{s_1}^t \mathbb{E}^\mu[\phi_i(X_{s_1}) \phi_i(X_{s_2})] ds_2 \\ &= \frac{2}{t^2} \int_0^t ds_1 \int_{s_1}^t \mathbb{E}^\mu[\phi_i(X_{s_1})^2] e^{-\lambda_i(s_2-s_1)} ds_2 \leq \frac{2}{t\lambda_i}. \end{aligned}$$

Substituting into (2.9) gives

$$(2.11) \quad \mathbb{E}^\mu[\mathbb{W}_2(\mu_{\varepsilon,t}, \mu)^2] \leq \frac{8}{t} \sum_{i=1}^{\infty} \lambda_i^{-2} e^{-2\lambda_i \varepsilon} = \frac{32}{t} \sum_{i=1}^{\infty} \int_\varepsilon^\infty ds \int_s^\infty e^{-2\lambda_i r} dr.$$

Noting that (2.8) and the semigroup property imply

$$p_{2t}(x, x) - 1 = \int_M |p_t(x, y) - 1|^2 \mu(dy) = \int_M |P_{\frac{t}{2}} p_{\frac{t}{2}}(x, \cdot)(y) - 1|^2 \mu(dy)$$

$$\leq e^{-\lambda_1 t} \int_M |p_{\frac{t}{2}}(x, y) - 1|^2 \mu(dy) = e^{-\lambda_1 t} \{p_t(x, x) - 1\},$$

we deduce from (2.1) that

$$\sum_{i=1}^{\infty} e^{-2\lambda_i t} = \int_M \{p_{2t}(x, x) - 1\} \mu(dx) \leq e^{-\lambda_1 t} \int_M \{p_t(x, x) - 1\} \mu(dx) \leq e^{-\lambda_1 t} \gamma(t).$$

Therefore, by (2.11) and that $\gamma(t)$ is decreasing in t , we find a constant $c_1 > 0$ such that

$$\begin{aligned} \mathbb{E}^\mu[\mathbb{W}_2(\mu_{\varepsilon, t}, \mu)^2] &\leq \frac{32}{t} \int_\varepsilon^\infty ds \int_s^\infty e^{-\lambda_1 t} \gamma(t) dt \\ (2.12) \quad &\leq \frac{32}{t} \int_\varepsilon^1 \left(\int_s^1 \gamma(t) dt + \gamma(1) \int_1^\infty e^{-\lambda_1 t} dt \right) ds + \frac{32\gamma(1)}{t} \int_1^\infty ds \int_s^\infty e^{-\lambda_1 r} dr \\ &\leq \frac{c_1}{t} \beta(\varepsilon), \quad \varepsilon \in (0, 1]. \end{aligned}$$

On the other hand, (2.3) and (2.9) imply that the measure

$$\pi(dx, dy) := \frac{1}{t} \int_0^t \{ \delta_{X_s}(dx) p_\varepsilon(X_s, y) \mu(dy) \} ds$$

is a coupling of μ_t and $\mu_{\varepsilon, t}$. Combining this with the fact that μ is P_t -invariant, we obtain

$$\mathbb{E}^\mu[\mathbb{W}_2(\mu_t, \mu_{\varepsilon, t})^2] \leq \frac{1}{t} \mathbb{E}^\mu \int_0^t ds \int_M \rho(X_s, y)^2 p_\varepsilon(X_s, y) \mu(dy) = \alpha(\varepsilon).$$

By (2.12) and the triangle inequality of \mathbb{W}_2 , this yields

$$\mathbb{E}^\mu[\mathbb{W}_2(\mu_t, \mu)^2] \leq 2 \inf_{\varepsilon \in (0, 1]} \{ \alpha(\varepsilon) + c_1 t^{-1} \beta(\varepsilon) \}.$$

Therefore, (1.9) holds for some constant $c > 0$ and $\nu = \mu$.

Finally, let P_t be ultracontractive. Then there exists a constant $c_1 > 0$ such that

$$(2.13) \quad \sup_{t \geq 1} p_t(x, y) \leq c_1, \quad x, y \in M.$$

So, the distribution of X_1 has a distribution $\nu_1 \leq c_1 \mu$. Let $\bar{\mu}_t = \frac{1}{t} \int_0^t \delta_{X_{1+s}} ds$. It is easy to see that

$$(2.14) \quad \pi := \frac{1}{t} \int_0^1 \delta_{(X_s, X_{s+t})} ds + \frac{1}{t} \int_1^t \delta_{(X_s, X_s)} ds \in \mathcal{C}(\mu_t, \bar{\mu}_t),$$

so that (2.13) yields

$$(2.15) \quad \mathbb{E}^\nu[\mathbb{W}_2(\mu_t, \bar{\mu}_t)^2] \leq \frac{1}{t} \mathbb{E}^\nu \int_0^1 |X_s - X_{s+t}|^2 ds \leq \frac{c_1}{t} \mathbb{E}^\nu \int_0^1 \mu(\rho(X_s, \cdot)^2) ds.$$

On the other hand, by the Markov property and (1.9), we find a constant $c_2 > 0$ such that

$$\mathbb{E}^\nu[\mathbb{W}_2(\bar{\mu}_t, \mu)^2] = \mathbb{E}^{\nu_1}[\mathbb{W}_2(\mu_t, \mu)^2] \leq c_2 \inf_{\varepsilon \in (0, 1]} \{ \alpha(\varepsilon) + t^{-1} \beta(\varepsilon) \}.$$

Combining this with (2.15) and using the triangle inequality of \mathbb{W}_2 , we prove (1.10) for some constant $c > 0$. \square

Proof of Corollary 1.2. (1) By [16, Lemma 3.5.6] and comparing P_t with the semigroup generated by $\Delta + \nabla V_1$, see for instance [6, (2.8)], (1.11) implies that the Harnack inequality

$$(2.16) \quad (P_t f(x))^2 \leq \{P_t f^2(y)\} e^{C+Ct^{-1}\rho(x,y)^2}, \quad x, y \in M, t \in (0, 1]$$

holds for some constant $C > 0$. Therefore, by [15, Theorem 1.4.1] with $\Phi(r) = r^2$ and $\Psi(x, y) = C + Ct^{-1}\rho(x, y)^2$, we obtain

$$p_{2t}(x, x) = \sup_{\mu(f^2) \leq 1} (P_t f(x))^2 \leq \frac{1}{\int_M e^{-C-Ct^{-1}\rho(x,y)^2} \mu(dy)} \leq \frac{e^{3C}}{\mu(B(x, \sqrt{2t}))}, \quad t \in (0, 1], x \in M.$$

This implies

$$(2.17) \quad \gamma(t) \leq e^{3C} \tilde{\gamma}(t), \quad t \in (0, 2].$$

On the other hand, by (1.11) and Itô's formula due to [7], there exists constant $C_1 > 0$ such that

$$d\rho(x, X_t)^2 \leq \left[C_1(1 + \rho(x, X_t)^2) + |\nabla V(x)|^2 \right] dt + 2\sqrt{2}\rho(x, X_t) db_t,$$

where b_t is a one-dimensional Brownian motion. So, there exists a constant $C_2 > 0$ such that

$$(2.18) \quad \mathbb{E}^\nu[\rho(x, X_t)^2] \leq (C_1 + \nu(|\nabla V|^2))te^{C_1 t} \leq C_2(1 + \nu(|\nabla V|^2))t, \quad t \in [0, 1], x \in M.$$

Then there exists a constant $c > 0$ such that

$$\begin{aligned} \sup_{\nu \in \mathcal{P}_k} \int_M \mathbb{E}^\nu \rho(x, X_\varepsilon)^2 \mu(dx) &\leq k \int_M \mathbb{E}^\mu \rho(x, X_\varepsilon)^2 \mu(dx) \\ &\leq C_2 k(1 + \nu(|\nabla V|^2))\varepsilon \leq ck\varepsilon, \quad \varepsilon \in (0, 1], k \geq 1. \end{aligned}$$

Combining this with (2.17), we prove the first assertion by Theorem 1.1(2). The second assertion follows from (2.18) and Theorem 1.1(2), since P_t is ultracontractive provided $\|P_t e^{\lambda \rho^2}\|_\infty < \infty$ for $\lambda, t > 0$, see for instance [16, Theorem 3.5.5]. \square

3 Proof of Theorem 1.3

(1) We first prove that for any $0 \neq f \in L^2(\mu)$,

$$(3.1) \quad \lim_{t \rightarrow \infty} \frac{1}{t} \mathbb{E}^\mu \left[\left| \int_0^t f(X_s) ds \right|^2 \right] = 4 \int_0^\infty \mu((P_s f)^2) ds > 0.$$

As shown in [3, Lemma 2.8] that the Markov property and the symmetry of P_t in $L^2(\mu)$ imply

$$\begin{aligned} \frac{1}{t} \mathbb{E}^\mu \left[\left| \int_0^t f(X_s) ds \right|^2 \right] &= \frac{2}{t} \int_0^t ds_1 \int_{s_1}^t \mathbb{E}^\mu [f(X_{s_1}) P_{s_2-s_1} f(X_{s_1})] ds_2 \\ (3.2) \quad &= \frac{2}{t} \int_0^t ds_1 \int_{s_1}^t \mu((P_{\frac{s_2-s_1}{2}} f)^2) ds_2 = \frac{4}{t} \int_0^{t/2} \mu((P_s f)^2) ds \int_s^{t-s} dr \\ &= \frac{4}{t} \int_0^{t/2} (t-2s) \mu((P_s f)^2) ds, \quad t > 0, \end{aligned}$$

where we have used the variable transform $(s, r) = (\frac{s_2-s_1}{2}, \frac{s_1+s_2}{2})$. This implies (3.1). On the other hand, we take $0 \neq f \in L^2(\mu)$ with $\mu(f) = 0$ and $\|f\|_\infty \vee \|\nabla f\|_\infty \leq 1$. Then

$$t\mathbb{E}^\mu[\tilde{W}_1(\mu_t, \mu)^2] \geq \frac{1}{t}\mathbb{E}^\mu\left[\left|\int_0^t f(X_s)ds\right|^2\right].$$

Combining this with (3.1), we prove (1.14) for some constant $c > 0$.

If (1.3) holds, then

$$(3.3) \quad \|P_t f - \mu(f)\|_{L^2(\mu)} \leq e^{-\lambda_1 t} \|f - \mu(f)\|_{L^2(\mu)}, \quad t \geq 0, f \in L^2(\mu).$$

Let $\nu = h_\nu \mu \in \mathcal{P}$ with $h_\nu \in L^2(\mu)$. Similarly to (3.2), for any $f \in L^2(\mu)$ with $\mu(f) = 0$, we have

$$\begin{aligned} & \frac{1}{t} \left\{ \mathbb{E}^\nu \left[\left| \int_0^t f(X_s) ds \right|^2 \right] - \mathbb{E}^\mu \left[\left| \int_0^t f(X_s) ds \right|^2 \right] \right\} \\ &= \frac{1}{t} \int_M \{h_\nu(x) - 1\} \mathbb{E}^x \left[\left| \int_0^t f(X_s) ds \right|^2 \right] \mu(dx) \\ &= \frac{2}{t} \int_0^t ds_1 \int_{s_1}^t \mu(\{h_\nu - 1\} P_{s_1} \{f P_{s_2-s_1} f\}) ds_2 \\ &= \frac{2}{t} \int_0^t ds_1 \int_{s_1}^t \mu(\{P_{s_1}(h_\nu - 1)\} \cdot \{f P_{s_2-s_1} f\}) ds_2 \\ &\geq -\frac{2\|f\|_\infty}{t} \int_0^t ds_1 \int_{s_1}^t \|P_{s_1}(h_\nu - 1)\|_{L^2(\mu)} \|P_{s_2-s_1} f\|_{L^2(\mu)} ds_2. \end{aligned}$$

Taking $0 \neq f \in L^2(\mu)$ with $\mu(f) = 0$ and $\|f\|_\infty \vee \|\nabla f\|_\infty \leq 1$, by combining this with (3.1) and (3.3), we derive

$$(3.4) \quad \begin{aligned} \liminf_{t \rightarrow \infty} \left[t\mathbb{E}^\nu[\tilde{W}_1(\mu_t, \mu)^2] \right] &\geq \liminf_{t \rightarrow \infty} \left\{ \frac{1}{t} \mathbb{E}^\nu \left[\left| \int_0^t f(X_s) ds \right|^2 \right] \right\} \\ &\geq 4 \int_0^\infty \mu(|P_s f|^2) ds > 0, \quad \nu = h_\nu \mu \text{ with } h_\nu \in L^2(\mu). \end{aligned}$$

Next, let $\bar{\mu}_t = \frac{1}{t} \int_1^{t+1} \delta_{X_s} ds$, $t > 0$. By (2.14) we have

$$(3.5) \quad \tilde{W}_1(\bar{\mu}_t, \mu_t) \leq \int_{M \times M} 1_{\{x \neq y\}} \pi(dx, dy) = \frac{1}{t}.$$

Noting that for any $x \in M$ we have $\nu_x := p_1(x, \cdot)\mu$ with $p_1(x, \cdot) \in L^2(\mu)$, by the Markov property and (3.4), we obtain

$$\liminf_{t \rightarrow \infty} \left\{ t\mathbb{E}^x[\tilde{W}_1(\bar{\mu}_t, \mu)^2] \right\} = \liminf_{t \rightarrow \infty} \left[t\mathbb{E}^{\nu_x}[\tilde{W}_1(\mu_t, \mu)^2] \right] > 0.$$

Combining this with (3.5) and the triangle inequality leads to

$$\liminf_{t \rightarrow \infty} \left\{ t\mathbb{E}^x[\tilde{W}_1(\mu_t, \mu)^2] \right\} > 0, \quad x \in M.$$

Therefore, by Fatou's lemma, for any $\nu \in \mathcal{P}$ we have

$$\begin{aligned} \liminf_{t \rightarrow \infty} \left\{ t \mathbb{E}^\nu [\tilde{W}_1(\mu_t, \mu)^2] \right\} &= \liminf_{t \rightarrow \infty} \int_M \left\{ t \mathbb{E}^x [\tilde{W}_1(\mu_t, \mu)^2] \right\} \nu(dx) \\ &\geq \int_M \left(\liminf_{t \rightarrow \infty} \left\{ t \mathbb{E}^x [\tilde{W}_1(\mu_t, \mu)^2] \right\} \right) \nu(dx) > 0, \end{aligned}$$

which implies (1.15).

(2) Let $d \geq 3$, and let ∂M be empty or convex. By (1.16), we have $\text{Ric} \geq -K$ for some constant $K > 0$. Then the Laplacian comparison theorem implies (see [4])

$$\Delta \rho(x, \cdot)(y) \leq \sqrt{K(d-1)} \coth \left[\sqrt{K/(d-1)} \rho(x, y) \right] \leq C \rho(x, y)^{-1}, \quad (x, y) \in \hat{M}$$

for some constant $C > 0$, where $\hat{M} := \{(x, y) : x, y \in M, x \neq y, x \notin \text{cut}(y)\}$, and $\text{cut}(y)$ is the cut-locus of y . So,

$$L\rho(x, \cdot)(y) \leq |\nabla V(y)| + C\{\rho(x, y) + \rho(x, y)^{-1}\}, \quad (x, y) \in \hat{M}.$$

Combining this with the Itô's formula due to [7], we obtain

$$d\rho(X_0, X_t) \leq \sqrt{2} db_t + \{|\nabla V(X_t)| + C\rho(X_0, X_t) + C\rho(X_0, X_t)^{-1}\} dt + dl_t,$$

where b_t is a one-dimensional Brownian motion, and l_t is the local time of X_t at the initial value X_0 , which is an increasing process supported on $\{t \geq 0 : X_t = X_0\}$. Thus, we find a constant $C_1 > 0$ such that

$$d\left\{ \frac{\rho(X_0, X_t)^2}{1 + \rho(X_0, X_t)^2} \right\} \leq C_1(1 + |\nabla V(X_t)|) dt + dM_t$$

for some martingale M_t . Since μ is P_t -invariant, this implies

$$\mathbb{E}^\mu \{ \rho(X_0, X_t) \wedge 1 \}^2 \leq C_2 \{ 1 + \mu(|\nabla V|) \} t, \quad t \geq 0, x \in M$$

for some constant $C_2 > 0$. Therefore, for any $N \in \mathbb{N}$ and $t_i := (i-1)t/N$, the probability measure

$$\tilde{\mu}_N := \frac{1}{N} \sum_{i=1}^N \delta_{X_{t_i}} = \frac{1}{t} \sum_{i=1}^N \int_{t_i}^{t_{i+1}} \delta_{X_{t_i}} ds$$

satisfies

$$\begin{aligned} \mathbb{E}^\mu \tilde{W}_1(\tilde{\mu}_N, \mu_t)^2 &\leq \frac{1}{t} \sum_{i=1}^N \int_{t_i}^{t_{i+1}} \mathbb{E}^\mu (\rho(X_{t_i}, X_s) \wedge 1)^2 ds \\ &\leq \frac{C_3}{t} \sum_{i=1}^N \int_{t_i}^{t_{i+1}} (s - t_i) ds \leq \frac{C_3 t}{N} \end{aligned}$$

for some constant $C_3 > 0$. So,

$$(3.6) \quad \sup_{\nu \in \mathcal{P}_k} \mathbb{E}^\nu [\tilde{W}_1(\tilde{\mu}_N, \mu_t)^2] \leq k \mathbb{E}^\mu [\tilde{W}_1(\tilde{\mu}_N, \mu_t)^2] \leq \frac{C_3 kt}{N}, \quad N, k \geq 1.$$

On the other hand, by $\text{Ric} \geq -K$ and $V \leq K$ in (1.16) and using the volume comparison theorem, we find a constant $C_4 > 1$ such that

$$\mu(B(x, r)) \leq C_4 r^d, \quad x \in M, r \in [0, 1],$$

where $B(x, r) := \{y \in M : \rho(x, y) \wedge 1 \leq r\}$. Since μ is a probability measure, this inequality holds for all $r > 0$. Therefore, by [8, Proposition 4.2], there exists a constant $C_5 > 0$ such that

$$\tilde{W}_1(\tilde{\mu}_N, \mu) \geq C_5 N^{-\frac{1}{d}}, \quad N \geq 1.$$

Combining this with (3.6) and using the triangle inequality for \tilde{W}_1 , we obtain

$$\sup_{\nu \in \mathcal{P}_k} \mathbb{E}^\nu [\tilde{W}_1(\mu_t, \mu)] \geq C_5 N^{-\frac{1}{d}} - \sqrt{C_3 kt} N^{-\frac{1}{2}}, \quad N, k \geq 1.$$

maximizing in $N \geq 1$, we find a constant $c > 0$ such that (1.17) holds.

Now, let $d \geq 4$. To prove (1.18) for general probability measure ν , we consider the shift empirical measure

$$\bar{\mu}_t := \frac{1}{t} \int_1^{t+1} \delta_{X_s} ds, \quad t \geq 1,$$

and the probability measures

$$\nu_x := \delta_x P_1 = p_1(x, \cdot) \mu, \quad \nu_{x,1} := \frac{1_{B(x,1)}}{\nu_x(B(x,1))} \nu_x, \quad x \in M.$$

By the Markov property, we obtain

$$\begin{aligned} \mathbb{E}^x [\tilde{W}_1(\bar{\mu}_t, \mu)] &= \mathbb{E}^{\nu_x} [\tilde{W}_1(\mu_t, \mu)] = \int_M \mathbb{E}^y [\tilde{W}_1(\mu_t, \mu)] p_1(x, y) \mu(dy) \\ &\geq \int_{B(x,1)} \mathbb{E}^y [\tilde{W}_1(\mu_t, \mu)] p_1(x, y) \mu(dy) = \nu_x(B(x,1)) \mathbb{E}^{\nu_{x,1}} [\tilde{W}_1(\bar{\mu}_t, \mu)]. \end{aligned}$$

Noting that $h(x) := \sup_{y \in B(x,1)} p_1(x, y) < \infty$, this and (1.17) yield

$$\mathbb{E}^x [\tilde{W}_1(\bar{\mu}_t, \mu)] \geq g(x) t^{-\frac{1}{d-2}}, \quad g(x) := c \nu_x(B(x,1)) h(x)^{-\frac{1}{d-2}}, \quad x \in M, t \geq 1.$$

Consequently, for any probability measure ν ,

$$\mathbb{E}^\nu [\tilde{W}_1(\bar{\mu}_t, \mu)] = \int_M \mathbb{E}^x [\tilde{W}_1(\bar{\mu}_t, \mu)] \nu(dx) \geq \nu(g) t^{-\frac{1}{d-2}}, \quad t \geq 1.$$

Combining this with (3.5) and noting that $d \geq 4$ implies $t^{-\frac{1}{d-2}} \geq t^{-\frac{1}{2}}$ for $t \geq 1$, we find a constant $c_\nu > 0$ such that when t is large enough,

$$\mathbb{E}^\nu [\tilde{W}_1(\mu_t, \mu)] \geq \mathbb{E}^\nu [\tilde{W}_1(\bar{\mu}_t, \mu) - \tilde{W}_1(\bar{\mu}_t, \mu_t)] \geq c(\nu) t^{-\frac{1}{d-2}}.$$

(3) According to [19, Theorem 2.1], for any $\varepsilon \in (0, 1]$ we have

$$(3.7) \quad \liminf_{t \rightarrow \infty} \left\{ t \inf_{x \in M} \mathbb{E}^x [\mathbb{W}_2(\mu_{\varepsilon, t}, \mu)^2] \right\} \geq \sum_{i=1}^{\infty} \frac{2}{\lambda_i^2 e^{2\varepsilon \lambda_i}}.$$

On the other hand, by [16, Theorem 3.3.2], the conditions that $\text{Ric} - \text{Hess}_V \geq K$ and ∂M is empty or convex imply

$$\mathbb{W}_2(\mu_{\varepsilon, t}, \mu)^2 \leq e^{-2\varepsilon K} \mathbb{W}_2(\mu_t, \mu)^2, \quad \varepsilon \geq 0.$$

Combining this with (3.7), we derive

$$\liminf_{t \rightarrow \infty} \left\{ t \inf_{x \in M} \mathbb{E}^x [\mathbb{W}_2(\mu_t, \mu)^2] \right\} \geq e^{2\varepsilon K} \sum_{i=1}^{\infty} \frac{2}{\lambda_i^2 e^{2\varepsilon \lambda_i}}, \quad \varepsilon \in (0, 1].$$

By letting $\varepsilon \downarrow 0$ we finish the proof.

4 Proof of Example 1.4

(1) Taking $V_1 \in C^\infty(\mathbb{R}^d)$ such that $V_1(x) = -\kappa|x|^\alpha$ for $|x| \geq 1$, and writing $V_2 = V + W - V_1$, we see that (1.11) holds for some constant $K \in \mathbb{R}$. By Corollary 1.2, it suffices to estimate $\tilde{\gamma}(t)$. For any $x \in \mathbb{R}^d$ with $|x| \geq 1$, and any $t \in (0, 1]$, let $x_t = \frac{x}{|x|}(|x| - \frac{1}{2}\sqrt{t})$. We find a constant $c_1 > 0$ and some point $z \in B(x, \sqrt{t})$ such that

$$(4.1) \quad \mu(B(x, \sqrt{t})) \geq \int_{B(x_t, \frac{1}{4}\sqrt{t})} e^{-\kappa|y|^\alpha + W(y)} dy \geq c_1 t^{\frac{d}{2}} e^{-\kappa(|x| - \frac{1}{4}t^{\frac{1}{2}})^\alpha + W(z)}.$$

Since $|x| \geq 1$, $t \in (0, 1]$ and $\alpha > 1$, we find a constant $c_2 > 0$ such that

$$(4.2) \quad \begin{aligned} |x|^\alpha - (|x| - t^{\frac{1}{2}}/4)^\alpha &= \alpha \int_{|x| - \frac{1}{4}t^{\frac{1}{2}}}^{|x|} r^{\alpha-1} dr \\ &\geq \frac{\alpha t^{\frac{1}{2}}}{4} \left(\frac{|x|}{2} \right)^{\alpha-1} \geq c_2 |x|^{\alpha-1} t^{\frac{1}{2}}. \end{aligned}$$

Moreover,

$$|W(z) - W(x)| \leq \|\nabla W\|_\infty |x - z| \leq \|\nabla W\|_\infty, \quad t \in (0, 1], z \in B(x, t^{\frac{1}{2}}).$$

Combining this with (4.1) and (4.2), we find a $c_3 > 0$ such that

$$\mu(B(x, \sqrt{t})) \geq c_3 t^{\frac{d}{2}} e^{-\kappa|x|^\alpha + c_2|x|^{\alpha-1}t^{\frac{1}{2}} + W(x)}, \quad t \in [0, 1], x \in \mathbb{R}^d.$$

Noting that $-\kappa|x|^\alpha + 2|W(x)|$ is bounded from above, we find constants $c_4, c_5 > 0$ such that

$$\int_{|x| \geq 1} \frac{\mu(dx)}{\mu(B(x, \sqrt{t}))} \leq c_4 t^{-\frac{d}{2}} \int_1^\infty r^{d-1} e^{-c_2 r^{\alpha-1} t^{\frac{1}{2}}} dr \leq c_5 t^{-\frac{d}{2} - \frac{d}{2(\alpha-1)}} = c_5 t^{-\frac{\alpha d}{2(\alpha-1)}}, \quad t \in (0, 1].$$

On the other hand, there exists a constant $c_6 > 0$ such that $\mu(B(x, r)) \geq c_6 r^d$ for $|x| < 1$ and $r \in (0, 1]$. In conclusion, there exists a constant $c_7 > 0$ such that

$$\tilde{\gamma}(t) := \int_{\mathbb{R}^d} \frac{\mu(dx)}{\mu(B(x, \sqrt{t}))} \leq c_5 t^{-\frac{\alpha d}{2(\alpha-1)}} + c_6^{-1} t^{-\frac{d}{2}} \leq c_7 t^{-\frac{\alpha d}{2(\alpha-1)}}, \quad t \in (0, 1].$$

Thus, there exists a constant $c_8 > 0$ such that for any $\varepsilon \in (0, 1]$,

$$\tilde{\beta}(\varepsilon) \leq 1 + c_6 \int_{\varepsilon}^1 ds \int_s^1 t^{-\frac{d\alpha}{2(\alpha-1)}} dt \leq \begin{cases} c_8 \varepsilon^{2-\frac{d\alpha}{2(\alpha-1)}}, & \text{if } 2 < \frac{d\alpha}{2(\alpha-1)}, \\ c_8 \log(1 + \varepsilon^{-1}), & \text{if } 2 = \frac{d\alpha}{2(\alpha-1)}, \\ c_8, & \text{if } 2 > \frac{d\alpha}{2(\alpha-1)}. \end{cases}$$

By taking $\varepsilon = t^{-\frac{2(\alpha-1)}{(d-2)\alpha+2}}$ if $4(\alpha-1) < d\alpha$, $\varepsilon = t^{-1}$ if $4(\alpha-1) = d\alpha$, and $\varepsilon \downarrow 0$ if $4(\alpha-1) > d\alpha$, we derive

$$(4.3) \quad \inf_{\varepsilon \in (0, 1]} \{\varepsilon + t^{-1} \tilde{\beta}(\varepsilon)\} \leq \begin{cases} ct^{-\frac{2(\alpha-1)}{(d-2)\alpha+2}}, & \text{if } 4(\alpha-1) < d\alpha, \\ ct^{-1} \log(1+t), & \text{if } 4(\alpha-1) = d\alpha, \\ ct^{-1}, & \text{if } 4(\alpha-1) > d\alpha \end{cases}$$

for some constant $c > 0$. Therefore, (1.20) follows from Corollary 1.2(1).

(2) Next, by [10, Corollary 3.3], when $\alpha > 2$ the Markov semigroup P_t^0 generated by $\Delta - \kappa \nabla |\cdot|^\alpha$ is ultracontractive with

$$(4.4) \quad \|P_t^0\|_{L^1(\mu_0) \rightarrow L^\infty(\mu_0)} \leq e^{c_1(1+t^{-\alpha/(\alpha-2)})}, \quad t > 0$$

for some constant $c_1 > 0$, where $\mu_0(dx) := Z^{-1} e^{-\kappa|x|^\alpha} dx$ is probability measure with normalized constant $Z > 0$. According to the correspondence between the ultracontractivity and the log-Sobolev inequality, see [5], (4.4) holds if and only if there exists a constant $c_2 > 0$ such that

$$\mu_0(f^2 \log f^2) \leq r \mu_0(|\nabla f|^2) + c_2(1 + r^{-\frac{\alpha}{\alpha-2}}), \quad r > 0, \mu_0(f^2) = 1.$$

Replacing f by $f e^{\frac{W}{2}}$ and using $\|\nabla W\|_\infty < \infty$ which implies $\mu(e^{cW}) < \infty$ for any $c > 0$ due to $\alpha > 1$, we find constants c_3 such that

$$\begin{aligned} \mu(f^2 \log f^2) &\leq \mu(f^2 W) + 2r \mu(|\nabla f|^2) + 2\|\nabla W\|_\infty^2 + c_2(1 + r^{-\frac{\alpha}{\alpha-2}}) \\ &\leq \frac{1}{2} \mu(f^2 \log f^2) + \frac{1}{2} \log \mu(e^{2W}) + 2r \mu(|\nabla f|^2) + 2\|\nabla W\|_\infty^2 + c_2(1 + r^{-\frac{\alpha}{\alpha-2}}) \\ &\leq \frac{1}{2} \mu(f^2 \log f^2) + 2r \mu(|\nabla f|^2) + c_3(1 + r^{-\frac{\alpha}{\alpha-2}}), \quad r > 0, \mu(f^2) = 1, \end{aligned}$$

where in the second line we have used the Young inequality [1, Lemma 2.4]

$$\mu(f^2 g) \leq \mu(f^2 \log f^2) + \log \mu(e^g), \quad \mu(f^2) = 1, g \in L^1(f^2 \mu).$$

Hence, for some constant $c_4 > 0$ we have

$$\mu(f^2 \log f^2) \leq r \mu(|\nabla f|^2) + c_4(1 + r^{-\frac{\alpha}{\alpha-2}}), \quad r > 0, \mu(f^2) = 1.$$

By the above mentioned correspondence of the log-Sobolev inequality and semigroup estimate, this implies

$$\|P_t\|_{L^1(\mu)\rightarrow L^\infty(\mu)} \leq e^{c_5(1+t^{-\alpha/(\alpha-2)}), \quad t > 0$$

for some constant $c_5 > 0$. In particular, this and $\mu(e^{\lambda|\cdot|^2}) < \infty$ imply $\|P_t e^{\lambda|\cdot|^2}\|_\infty < \infty$ for $t, \lambda > 0$, so that by Corollary 1.2(2), (1.21) follows from (4.3) and the fact that $|\nabla V(x)|^2 \leq c'(1 + |x|^{2(\alpha-1)})$ holds for some constant $c' > 0$.

(3) By [11, Corollary 1.4], the Poincaré inequality (1.3) holds for some constant $\lambda_1 > 0$. Moreover, it is trivial that the condition (1.16) holds for some constant $K \geq 0$. So, the desired lower bound estimate is implied by Theorem 1.3.

A Upper bound estimate on $\mathbb{W}_p(f_1\mu, f_2\mu)$

For $p \geq 1$, let \mathbb{W}_p be the L^p -Wasserstein distance induced by ρ , i.e.

$$\mathbb{W}_p(\mu_1, \mu_2) = \inf_{\pi \in \mathcal{C}(\mu_1, \mu_2)} \|\rho\|_{L^p(\pi)}.$$

According to [9, Theorem 2], for any probability density f of μ , we have

$$(A.1) \quad \mathbb{W}_p(f\mu, \mu)^p \leq p^p \mu(|\nabla(-L)^{-1}(f-1)|^p).$$

The idea of the proof goes back to [2], in which the following estimate is presented for probability density functions f_1, f_2 :

$$(A.2) \quad \mathbb{W}_2(f_1\mu_1, f_2\mu_2)^2 \leq \int_M \frac{|\nabla(-L)^{-1}(f_2 - f_1)|^2}{\mathcal{M}(f_1, f_2)} d\mu,$$

where $\mathcal{M}(a, b) := 1_{\{a \wedge b > 0\}} \frac{\log a - \log b}{a - b}$ for $a \neq b$, and $\mathcal{M}(a, a) = 1_{\{a > 0\}} a^{-1}$. In general, for $p \geq 1$, denote $\mathcal{M}_p = \mathcal{M}$ if $p = 2$, and when $p \neq 2$ let

$$\mathcal{M}_p(a, b) = 1_{\{a \wedge b > 0\}} \frac{a^{2-p} - b^{2-p}}{(2-p)(a-b)} \text{ for } a \neq b, \quad \mathcal{M}_p(a, a) = 1_{\{a > 0\}} a^{1-p}.$$

In this Appendix, we extend estimates (A.1) and (A.2) as follows, which might be useful for further studies.

Theorem A.1. *For any probability density functions f_1 and f_2 with respect to μ such that $f_1 \vee f_2 > 0$,*

$$\mathbb{W}_p(f_1 \mu, f_2 \mu)^p \leq \min \left\{ p^p 2^{p-1} \int_M \frac{|\nabla(-L)^{-1}(f_2 - f_1)|^p}{(f_1 + f_2)^{p-1}} d\mu, p^p \int_M \frac{|\nabla(-L)^{-1}(f_2 - f_1)|^p}{f_1^{p-1}} d\mu, \int_M \frac{|\nabla(-L)^{-1}(f_2 - f_1)|^2}{\mathcal{M}_p(f_1, f_2)} d\mu \right\}.$$

Proof. It suffices to prove for $p > 1$. Let $\text{Lip}_b(M)$ be the set of bounded Lipschitz continuous functions on M . Consider the Hamilton-Jacobi semigroup $(Q_t)_{t>0}$ on $\text{Lip}_b(M)$:

$$Q_t \phi := \inf_{x \in M} \left\{ \phi(x) + \frac{1}{pt^{p-1}} \rho(x, \cdot)^p \right\}, \quad t > 0, \phi \in \text{Lip}_b(M).$$

Then for any $\phi \in \text{Lip}_b(M)$, $Q_0 \phi := \lim_{t \downarrow 0} Q_t \phi = \phi$, $\|\nabla Q_t \phi\|_\infty$ is locally bounded in $t \geq 0$, and $Q_t \phi$ solves the Hamilton-Jacobi equation

$$(A.3) \quad \frac{d}{dt} Q_t \phi = -\frac{p-1}{p} |\nabla Q_t \phi|^{\frac{p}{p-1}}, \quad t > 0.$$

Let $q = \frac{p}{p-1}$. For any $f \in C_b^1(M)$, and any increasing function $\theta \in C^1((0, 1))$ such that $\theta_0 := \lim_{s \rightarrow 0} \theta_s = 0, \theta_1 := \lim_{s \rightarrow 1} \theta_s = 1$, by (A.3) and the integration by parts formula, we obtain

$$\begin{aligned} \mu_1(Q_1 f) - \mu_2(f) &= \int_0^1 \left\{ \frac{d}{ds} \mu([f_1 + \theta_s(f_2 - f_1)] Q_s f) \right\} ds \\ &= \int_0^1 ds \int_M \left\{ \theta'_s(f_2 - f_1) Q_s f - \frac{f_1 + \theta_s(f_2 - f_1)}{q} |\nabla Q_s f|^q \right\} d\mu \\ &= \int_0^1 ds \int_M \left\{ \theta'_s \langle \nabla(-L)^{-1}(f_2 - f_1), \nabla Q_s f \rangle - \frac{f_1 + \theta_s(f_2 - f_1)}{q} |\nabla Q_s f|^q \right\} d\mu \\ &\leq \frac{1}{p} \int_M |\nabla(-L)^{-1}(f_2 - f_1)|^p d\mu \int_0^1 \frac{|\theta'_s|^p}{[f_1 + \theta_s(f_2 - f_1)]^{p-1}} ds, \end{aligned}$$

where the last step is due to Young's inequality $ab \leq a^p/p + b^q/q$ for $a, b \geq 0$. By Kantorovich duality formula

$$\frac{1}{p} \mathbb{W}_p(\mu_1, \mu_2)^p = \sup_{f \in C_b^1(M)} \left\{ \mu_1(Q_1 f) - \mu_2(f) \right\},$$

and noting that

$$\begin{aligned}
f_1 + \theta_s(f_2 - f_1) &= f_1 + f_2 - \theta_s f_1 - (1 - \theta_s)f_2 \\
&= (f_1 + f_2) \left(1 - \frac{\theta_s f_1}{f_1 + f_2} - \frac{(1 - \theta_s)f_2}{f_1 + f_2} \right) \\
&\geq (f_1 + f_2) \min\{1 - \theta_s, \theta_s\},
\end{aligned}$$

we derive

$$(A.4) \quad \mathbb{W}_p(\mu_1, \mu_2)^p \leq \int_0^1 \frac{|\theta'_s|^p}{\min\{\theta_s, 1 - \theta_s\}^{p-1}} ds \int_M \frac{|\nabla(-L)^{-1}(f_1 - f_2)|^p}{(f_1 + f_2)^{p-1}} d\mu.$$

By taking

$$\theta_s = 1_{[0, \frac{1}{2}]}(s) 2^{p-1} s^p + 1_{(\frac{1}{2}, 1]}(s) \{1 - 2^{p-1}(1 - s)^p\},$$

which satisfies

$$\theta'_s = p 2^{p-1} \min\{s, 1 - s\}^{p-1}, \quad \min\{\theta_s, 1 - \theta_s\} = 2^{p-1} \min\{s, 1 - s\}^p,$$

we deduce from (A.4) that

$$\mathbb{W}_p(f_1\mu, f_2\mu)^p \leq p^p 2^{p-1} \int_M \frac{|(-L)^{-\frac{1}{2}}(f_2 - f_1)|^p}{(f_1 + f_2)^{p-1}} d\mu.$$

Next, (A.4) with $\theta_s = 1 - (1 - s)^p$ implies

$$\mathbb{W}_p(f_1\mu, f_2\mu)^p \leq p^p \int_M \frac{|(-L)^{-\frac{1}{2}}(f_2 - f_1)|^p}{f_1^{p-1}} d\mu.$$

Finally, with $\theta_s = s$ we deduce from (A.4) that

$$\mathbb{W}_p(f_1\mu, f_2\mu)^p \leq \int_M \frac{|(-L)^{-\frac{1}{2}}(f_2 - f_1)|^2}{\mathcal{M}_p(f_1, f_2)} d\mu.$$

Then the proof is finished. □
