A superconducting quantum interference device (SQUID) comprising 0- and π -Josephson junctions (JJs), called π -SQUID, is studied by the resistively shunted junction model. The π -SQUID shows half-integer Shapiro-steps (SS) under microwave irradiation at the voltage $V = (\hbar/2e)\Omega(n/2)$, with angular frequency Ω and half-integer $n/2$ in addition to integer n . We show that the π -SQUID can be a π -qubit with spontaneous loop currents by which the half-integer SS are induced. Making the 0- and π -JJs equivalent is a key for the half-integer SS and realizing the π -qubit.

A superconducting quantum interference device (SQUID) shows steps in the current-voltage (I - V) curve under microwave irradiation. This feature called Shapiro-steps (SS) appears at the voltage $V = n(\hbar/2e)\Omega$ with an angular frequency of microwave Ω , integer n , the Planck constant $h = 2\pi\hbar$ and the elementary charge e .¹⁻³ Because the frequency of the microwave and the fundamental constants are precisely determined, the voltage can be defined in the order of 10^{-9} accuracy.^{4,5} The magnetic flux through the SQUID is quantized using $\Phi_0 \equiv h/(2e)$. When a magnetic field with the magnitude of $\Phi_0/2$, which is equivalent to the π -shift, is externally applied, the SS appear at half-integer multiples of $V = (n/2)(\hbar/2e)\Omega$ in addition to the integer multiples.¹³

In a Josephson junction (JJ) separated by a ferromagnet, i.e., superconductor/ferromagnet/superconductor (SFS) junction, the current-phase relation is shifted by π compared with the conventional JJ, and it is called π -JJ.⁶⁻⁹ In an SFS junction, SS can be induced by ferromagnetic resonance,¹⁰ and it is sensitive to a domain wall motion in the ferromagnet.^{11,12} Half-integer SS are also observed in the SFS junction with a thickness modulation¹⁴⁻¹⁷ and in the grain boundary of high- T_C cuprates.¹⁸ This phenomenon originates from the inductive coupling between a 0-JJ and a π -JJ.¹⁹⁻²¹ Such a SQUID, including the π -JJ, is called π -SQUID, which is realized using a high- T_C cuprate as well.^{22,23}

A solid-state qubit is a key to realize quantum computers,²⁴⁻²⁷ and decoupling from the environment is essential.²⁸ The π -SQUID is a potential candidate for a “quiet” qubit not using an external field;²⁹⁻³¹ it is called π -qubit. There are some proposals, such as two JJs with a 0-JJ and a metallic π -JJ,³⁰ and three JJs with two 0-JJs and one π -JJ.³¹ The Rabi-oscillation in a π -qubit comprising a SFS junction is observed.³² Because of the π -JJ, the π -qubit can form a quantum two-level system without an external magnetic field.

In this letter, we show that the π -qubit using the π -SQUID is characterized by the half-integer SS, which are optimized by making the 0- and π -JJs equivalent in terms of critical current and resistivity. Making two JJs in π -SQUID equivalent yields a π -qubit.

A schematic of the π -SQUID comprising 0- and π -JJs is shown in Fig. 1. It can be studied using the resistively shunted junction (RSJ) model composed of two parallel circuits of

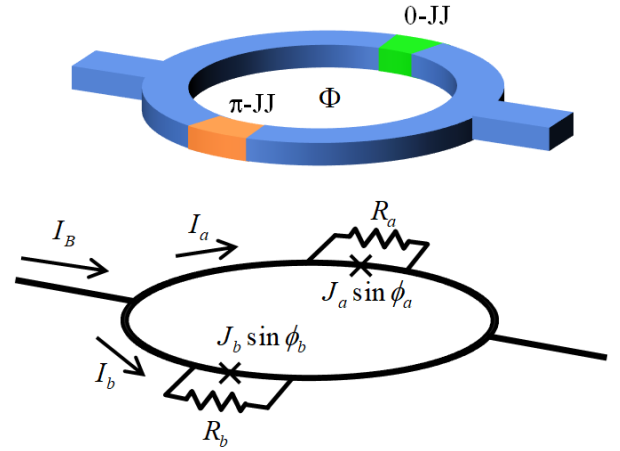

Fig. 1. Schematic of π -SQUID (upper) and the RSJ (lower) models.

JJs.¹³)

$$I_j = \frac{V_j}{R_j} + J_j \sin \phi_j, \quad (1)$$

$$\frac{d\phi_j}{dt} = \frac{2\pi}{\Phi_0} V_j, \quad (2)$$

$$\phi_a - \phi_b = \frac{2\pi}{\Phi_0} (\Phi - \Phi_\pi), \quad (3)$$

$$\Phi = \Phi_{ex} + \frac{L}{2} (I_b - I_a), \quad (4)$$

$$I_a + I_b = I + I_{ac} \cos \Omega t \equiv I_B, \quad (5)$$

where $j = a, b$. Each junction comprises a resistor R_j and a Josephson current $J_j \sin \phi_j$, with current I_j , voltage V_j , and a phase difference ϕ_j at the j -JJ. In Eq. (4), the total flux through the SQUID is denoted by $\Phi = n \Phi_0$, which is the sum of an externally applied flux Φ_{ex} and the flux induced by a screening current. The additional flux $\Phi_\pi = \Phi_0/2$ is due to the π -JJ in π -SQUID and $\Phi_\pi = 0$ in the conventional one. Notably, we consider the overdamped case, i.e., with negligible capacitance. Considering the Josephson relation, Eq. (2), the equation of motion for phase differences ϕ_a and ϕ_b are given by,

$$\frac{d\phi_a}{d\tau} + \sin \phi_a + \frac{1}{\beta} (\phi_a - \phi_b) = \frac{1}{2} \left[i_B - \frac{4\pi}{\beta} \frac{\Phi_\pi - \Phi_{ex}}{\Phi_0} \right], \quad (6)$$

$$\frac{d\phi_b}{d\tau} + \sin\phi_b - \frac{1}{\alpha\beta}(\phi_a - \phi_b) = \frac{1}{2\alpha} \left[i_B + \frac{4\pi}{\beta} \frac{\Phi_\pi - \Phi_{ex}}{\Phi_0} \right]. \quad (7)$$

where $R_a J_a = R_b J_b \equiv RJ$, $\omega_0 \equiv 2\pi RJ/\Phi_0$, $\tau \equiv \omega_0 t$, $\beta \equiv 2\pi L J_a/\Phi_0$, $i \equiv I/J_a$, $i_{ac} \equiv I_{ac}/J_a$, and $i_B \equiv I_B/J_a$. As we will discuss later, one of the key parameters is $\alpha \equiv J_b/J_a$, which indicates the asymmetry of two JJs.

By numerically solving Eqs. (6) and (7) for $\Phi_{ex} = 0$, I - V curves with step structures are obtained as shown in Figs. 2 (a) and (b). In Fig. 2 (a) for $\beta = 1.0$ and $i_{ac} = 0.5$, I - V curves

Fig. 2. (a) I - V curves with $\Omega/\omega_0 = 0.1$, $\beta = 1.0$, and $i_{ac} = 0.5$, for $\alpha = 1.0$ (red upper triangles), $\alpha = 0.8$ (blue lower triangles), and $\alpha = 0.6$ (purple circles). For clarity, the latter two curves are vertically shifted by $i_{ac} = 0.2$ and 0.4 , respectively. (b) I - V curves with $\Omega/\omega_0 = 0.1$ and $\alpha = 1.0$, for $i_{ac} = 0.2$ and $\beta = 1.0$ (green circles), $i_{ac} = 0.2$ and $\beta = 1.0$ (red upper triangles), $i_{ac} = 0.5$, and $\beta = 0.2$ (black crosses). The first curve (green circles) is s vertically shifted by $i_{ac} = 0.2$ for clarity.

are plotted for $\alpha = 1.0$ (red upper triangles), $\alpha = 0.8$ (blue lower triangles), and $\alpha = 0.6$ (purple circles). For clarity, the latter two curves are vertically shifted by $i_{ac} = 0.2$ and 0.4 , respectively. The half-integer SS are suppressed by decreasing α , which is controlled by changing the ratio of junction areas, W_a and W_b . Making both Josephson coupling and resistance of two JJs equivalent is a key to observe the half-integer SS. In Fig. 2 (b) for $\alpha = 1$, I - V curves are plotted for $i_{ac} = 0.2$ and $\beta = 1.0$ (green circles), $i_{ac} = 0.5$ and $\beta = 1.0$ (red upper triangles), and $i_{ac} = 0.5$ and $\beta = 0.2$ (black crosses). The height

of half-integer SS is enhanced by increasing i_{ac} , whereas it is suppressed by decreasing β . When β is small by decreasing the SQUID loop, the half-integer Shapiro steps can be observed by increasing the i_{ac} . β is estimated as $\beta \sim 1$ for $2.5 \times 2.5 \mu\text{m}^2$ loop and $J_a \sim 70 \mu\text{A}$,¹³⁾ meaning $L \sim 4.7$ pH. It satisfies the criteria to overcome the thermal noise, i.e., L must be less than about 20 nH at 4.2 K.³⁾

The half-integer SS can be understood using the following approximation. In the first order of β , i_B is given by,

$$i_B \sim 4 \frac{\alpha}{1+\alpha} \left[\cos\left(\pi \frac{\Phi_{ex} - \Phi_\pi}{\Phi_0}\right) \sin\phi + \frac{\beta}{2} \frac{\alpha}{1+\alpha} \sin\left(\pi \frac{\Phi_{ex} - \Phi_\pi}{\Phi_0}\right)^2 \sin 2\phi \right], \quad (8)$$

where $\phi \equiv (\phi_a + \phi_b)/2$.²¹⁾ Notably, the second term in Eq.(8) including “ $\sin 2\phi$ ” is the origin of the half-integer SS. By applying a voltage $\tilde{V}(t) = V + V_1 \cos \Omega t$, $\phi = \phi(0) + at + b \sin \Omega t$ with $a = 2\pi V/\Phi_0$ and $b = 2\pi V_1/(\Phi_0 \Omega)$, i_B becomes,

$$i_B \sim 4 \frac{\alpha}{1+\alpha} \text{Im} \left[A e^{i\phi(0)} \sum_k J_k(b) e^{i(a+k\Omega)t} + \frac{\beta}{2} \frac{\alpha}{1+\alpha} B^2 e^{2i\phi(0)} \sum_{k'} J_{k'}(2b) e^{i(2a+k'\Omega)t} \right], \quad (9)$$

where $A \equiv \cos\left(\pi \frac{\Phi_{ex} + \Phi_\pi}{\Phi_0}\right)$, $B \equiv \sin\left(\pi \frac{\Phi_{ex} + \Phi_\pi}{\Phi_0}\right)$, and the k th order Bessel function $J_k(b)$. For the π -SQUID with $\Phi_{ex} = 0$, the first term in Eq. (9) is zero because $\Phi_\pi/\Phi_0 = 1/2$. When V satisfies $V/(\Omega\Phi_0/2\pi) = k'/2$, the SS with a half-integer $k'/2$ and an integer q ($k' = 2q$) appear with a DC-component, $2\beta[\alpha/(1+\alpha)]^2 J_{k'}(2b)$, for $\phi(0) = \pi/4$. Meanwhile, in the conventional SQUID with $\Phi_{ex} = 0$, the second term in Eq. (9) is zero because $\Phi_\pi/\Phi_0 = 0$. Only integer SS appear at voltages of integer multiples of $V/(\Omega\Phi_0/2\pi) = k$ with a DC-component, $4[\alpha/(1+\alpha)] J_k(b)$, for $\phi(0) = \pi/2$.

The half-integer SS are explained by the onset of spontaneous current, leading to a flip-flop between two fluxoid states of the π -SQUID synchronized to the alternating field.^{13,14)} It suggests that the present system can become a qubit. Equation (8) shows that the two potentials with ϕ and 2ϕ are convoluted similar to the sds -wave JJ.^{22,23,28)} The half-integer SS and π -qubit are the two sides of the same coin. The potential energy of the π -SQUID $U(\phi_a, \phi_b)$ with Eq. (3) is given by,

$$U(\phi_a, \phi_b) = \frac{\Phi_0}{2\pi} [-J_a \cos\phi_a - J_b \cos(\phi_b)] + \frac{1}{2L} \Phi^2, \quad (10)$$

$$\equiv \left(J_a \frac{\Phi_0}{2\pi} \right) f(x, y), \quad (11)$$

$$f(x, y) = -\sin(x+y) + \alpha \sin(x-y) + \frac{2}{\beta} y^2, \quad (12)$$

where $x \equiv \phi$, and $y \equiv (\pi/\Phi_0)\Phi$. The ground state is obtained by minimizing $f(x, y)$ with respect to y for a fixed x .

$$\left. \frac{\partial f(x, y)}{\partial y} \right|_{y=y_0} = -\cos(x+y_0) - \alpha \cos(x-y_0) + \frac{4}{\beta} y_0 = 0, \quad (13)$$

by which y_0 is determined as a function of x , i.e., $y_0 = y_0(x)$. Equation (13) means that $f(x, y)$ is minimized with respect to Φ_{ex} , since we study the π -SQUID with two JJs shown in Fig. 1. To avoid Φ_{ex} , the minimization with respect to Φ_{ex} can be substituted by another Josephson phase including one more

JJ in the π -SQUID, as discussed in the previous studies.^{28,31} Numerically solving Eq. (13), we find that $f(x, y_0(x))$ has the double minimum with respect to x as shown in Fig. 3. The

Fig. 3. The potential energy for $\beta = 1.0$ with $\alpha = 1.0$ (red upper triangles), $\alpha = 0.8$ (blue lower triangles), and $\alpha = 0.6$ (black circles).

right minimum corresponds to the current circulating state, whereas the left one has no circulating current. Similar to the previous case,³⁰ the barrier height is suppressed by decreasing α , which coincides with the suppression of the half-integer SS. When the barrier height was zero, the stable state is $x = \pi/2$, which may be realized by setting the phase-lock to $\phi_a = \phi_b$ using Eqs. (3) and (4). In this case, the spontaneous loop current $I_a - I_b = 0$. Then, the SS appear at voltages with integer multiples. The two minima correspond to the clockwise and anticlockwise loop currents in addition to the π -shift because of the π -JJ, meaning that the spontaneous loop current is induced. Then, ϕ_a and ϕ_b are not synchronized as discussed in Refs.¹³) and,¹⁴) because the loop current means the time-evolution of the phase difference in each junction.

It is useful to compare the present model with the previous one, in which a metallic transport is assumed in the π -JJ.³⁰ The Josephson current of the metallic junction assigned to the junction- b is given by,

$$J_b = \frac{\sin \phi_b}{\sqrt{1 - T \sin^2(\phi_b/2)}}, \quad (14)$$

with transmittance T ($0 \leq T \leq 1$).^{33–35}) This case also shows the half-integer SS as shown in Fig. 4, although its magnitude becomes small when T approaches 1, where the magnitude of the metallic junction becomes large and dominates the current. Even in such a metallic case, the half-integer SS can be observed by increasing the i_{ac} .

The potential energy corresponding to Eq. (12) is given by,

$$g(x, y) = -\sin(x + y) + \frac{4\alpha}{T} \sqrt{1 - \frac{T}{2} [1 + \sin(x - y)]} + \frac{2}{\beta} y^2. \quad (15)$$

The ground state is obtained by minimizing $g(x, y)$ with re-

Fig. 4. T -dependence of I - V curve with $\Omega/\omega_0 = 0.1$, $\alpha = 1.0$, and $\beta = 1.0$. Each line is obtained for $T = 0.2$ and $i_{ac} = 0.5$ (red upper triangles), $T = 0.5$ and $i_{ac} = 0.5$ (blue lower triangles), and $T = 0.5$ and $i_{ac} = 1.0$ (black crosses).

spect to y for a fixed x .

$$\left. \frac{\partial g(x, y)}{\partial y} \right|_{y=y_0} = -\cos(x + y_0) - \frac{\alpha \cos(x - y_0)}{\sqrt{1 + \frac{T}{2} [1 + \sin(x - y_0)]}} + \frac{4}{\beta} y_0 = 0. \quad (16)$$

Numerically solving Eq. (16), we find that $g(x, y_0(x))$ exhibits the double minimum with respect to x as shown in Fig. 5. Because the magnitude of potential highly depends on T , $g(x, y_0(x)) \times T$ is plotted instead of $g(x, y_0(x))$ for clarity. The rather insulating case with $\alpha = 0.6$, which corresponds

Fig. 5. Potential energy for $\alpha = 0.6$ and $\beta = 1.0$ with $T = 0.8$ (black circles), $T = 0.5$ (blue lower triangles), and $T = 0.2$ (red upper triangles).

to the black circles in Fig. 3, shows the shallow minimum, whereas the double minimum becomes clear by increasing T ; this would contradict to the suppression of the half-integer SS in Fig. 4, i.e., red upper triangles and blue lower triangles. However, it is caused by a large magnitude of potential in the metallic junction. In fact, the half-integer SS are revived by

increasing i_{ac} .

In this paper, we assumed that the Josephson critical current densities j_i ($i = a, b$) defined by $j_i \equiv J_i/A_i$ with junction area A_i are common between junctions- a and b , i.e., $j_b/j_a = 1$. Even in the case of $j_b/j_a \neq 1$, the half-integer SSs can remain for $0.7 \lesssim j_b/j_a \lesssim 1.3$. We can consider another type of SQUID including two 0-JJs and one π -JJ, which is experimentally realized.³²⁾ In this case, the π -JJ is used as a π -phase shifter. The condition is quite similar to the SQUID with an external flux studied by Vanneste et al.¹³⁾ We can expect the half-integer SSs in such a geometry as well.

So far, we have focused on the overdamped JJs to clarify the close relation between the half-integer SSs and the π -qubit. From a viewpoint of qubit application and/or operation, on the other hand, we need to include the capacitance in Eq. (1) and should estimate the coherence time of qubit. In fact, Kato et al., discussed a long coherence time in a π -qubit.³⁶⁾ Although the coherence time of qubit is a crucial factor, it goes beyond our aim in this paper. We will examine the coherence time of π -SQUID by considering a capacitance and thermal fluctuations in the near future.

In summary, the half-integer SS in π -SQUID comprising 0- and π -JJs have been studied using the RSJ model. We have shown that the π -SQUID can be a π -qubit with spontaneous loop currents, by which the half-integer SS are induced, meaning that the half-integer SS and the π -qubit are the two sides of the same coin. Making the 0- and π -JJs equivalent is a key for the half-integer Shapiro steps and realizing the π -qubit.
