Accelerated expansion induced by Dark Matter with two charges

1 September 2021

ABSTRACT

The accelerated expansion of the universe has been established through observations of supernovae, the growth of structure, and the cosmic microwave background. The most popular explanation is Einsteins cosmological constant, or dynamic variations hereof. A recent paper demonstrated that if dark matter particles are endowed with a repulsive force proportional to the internal velocity dispersion of galaxies, then the corresponding acceleration of the universe may follow that of a cosmological constant fairly closely. However, no such long-range force is known to exist. A concrete example of such a force is derived here, by equipping the dark matter particles with two new dark charges. This result lends support to the possibility that the current acceleration of the universe may be explained without the need for a cosmological constant.

Key words: gravitation, acceleration of particles, dark matter, dark energy

INTRODUCTION

The acceleration of the Universe was first observed in SN1a data [\(Perlmutter et al. 1999](#page-4-0); [Riess et al. 1998](#page-4-1)) and has since been confirmed by a range of independent observations including growth of the large scale structure and the cosmic microwave background [\(Komatsu et al. 2011](#page-4-2); [Percival et al.](#page-4-3) [2010](#page-4-3); [Blake et al. 2011;](#page-3-0) [Larson et al. 2011](#page-4-4); [Hicken et al.](#page-4-5) [2009](#page-4-5); [Blake et al. 2012](#page-3-1)). Recent observational data is sufficiently abundant and precise, that one may start seeing indications that possibly not even dynamic versions of the cosmological constant provide a self-consistent explanation of all the data [\(Dainotti et al. 2021](#page-3-2); [Teng et al. 2021;](#page-4-6) [Krolewski et al. 2021](#page-4-7)). It is therefore relevant to investigate alternatives to (dynamics versions of) the cosmological constant. A large number of such models have been discussed over the years, see e.g. references in [\(Motta et al.](#page-4-8) [2021](#page-4-8)). Most of these proposals conform with the idea that [\(Peebles & Ratra 2003](#page-4-9)) " \ldots this cosmic repulsion is a gravitational effect of the negative gravitational mass density, not a new force law." A recent paper, however, challenged this view, by demonstrating that if a new inverse squaredistance force exists amongst the dark matter particles, then the resulting acceleration of the Universe is consistent with the acceleration that is induced by a cosmological constant [\(Loeve et al. 2021](#page-4-10)). In that paper the temporal evolution came about by letting the force depend on the internal velocity dispersion of the dark matter halos: since structure formation proceeds bottom-up, then the later structures will be more massive and have higher velocity dispersions

[\(Loeve et al. 2021](#page-4-10)). The main problem is, however, that no such long-range force is known to exist in nature.

This paper shows that such a force indeed may exist. Using established tools from spacetime algebra it is shown, that if one equips the dark matter particles with two new dark-charges, where the two forces are attractive and repulsive, respectively (likely because the carriers of the forces have even and odd spins) then the non-cancelled part of the forces has exactly the form needed to generate an accelerated universe without a cosmological constant.

2 ANGULAR MOMENTUM

To introduce the practical tool needed, namely spacetime algebra (STA), let us start by addressing how angular momentum can be made Lorentz invariant.

Even though both time and space separately are changed under a Lorentz transformation, then the timespace vector, (ct, \vec{r}) , is a proper 4-dimensional vector and hence has invariant length under a change of reference. Similarly, the energy-momentum vector, $(\varepsilon/c, \vec{p})$, is a proper 4vector.

This is starkly contrasted by the 3-dimensional angular momentum, $\vec{L} = \vec{r} \times \vec{p}$, where \vec{r} and \vec{p} are the 3dimensional distance and momentum. This object cannot be combined with anything to make a proper 4-dimensional vector. Similarly, the dynamic mass moment, $\vec{N} = ct\vec{p}$ – $\varepsilon \vec{x}/c$, cannot be combined with anything to make a proper 4-vector [\(Landau & Lifshitz 1975](#page-4-11)). Instead, there exists a rank-2 antisymmetric tensor, $M_{\mu\nu}$, which is the combina-

2 Steen H. Hansen

tion of \vec{L} and \vec{N} , which has nice transformation properties under a Lorentz transformation. The properties of $M_{\mu\nu}$ are made most simple and explicit in the language of spacetime algebra [\(Hestenes 1966](#page-4-12), [2003](#page-4-13)), where the relevant object is written as

$$
\mathbf{M} = r \wedge p, \tag{1}
$$

where r and p are proper 4-dimensional vectors. The wedgeoperator, ∧, is the natural 4-dimensional antisymmetric generalization of the 3-dimensional cross-product, ×. A brief teaser to STA calculations will be given now, and then the technical details will be discussed correctly in the next section. The basis of STA calculations is to acknowledge that all observables exist in 4-dimensional Minkowski space. In STA there is one unique derivative, ∇ , which contains both timeand space-derivatives, and hence the only natural equation to write for M is

$$
\nabla \mathbf{M} = j_M \,,\tag{2}
$$

where j_M is some source. Forces appear in STA by contracting **M** with a proper 4-dimensional vector, w, to get $\mathbf{M} \cdot w$, which for instance gives Newtons gravitational law. The only thing missing is, that one needs observations to determine the constant in front of the force, which in this case is the gravitational constant, G.

3 SPACETIME ALGEBRA

After this brief teaser, the details of the algebra can now be introduced correctly. Spacetime algebra (STA) starts with Minkowski space, $\mathcal{M}_{1,3}$, using the metric signature $(+, -, -, -)$, and a chosen basis $\{\gamma_\mu\}_{\mu=0}^3$ of $\mathcal{M}_{1,3}$.

These four orthonormal vectors constitute the basis for 1-blades. The six antisymmetric products $\gamma_{\mu\nu} \equiv \gamma_{\mu} \gamma_{\nu}$ are called the 2-blades. The product is in general given by the sum of the dot and wedge products: $ab = a \cdot b + a \wedge b$ [\(Hestenes](#page-4-14) [2015](#page-4-14); [Doran & Lasenby 2007\)](#page-3-3). The four 3-blades, $\gamma_{\mu\nu\delta}$, are given by $\gamma_{\mu\nu\delta} = \gamma_{\mu}\gamma_{\nu}\gamma_{\delta}$. Finally one reaches the highest grade, the pseudoscalar $I \equiv \gamma_0 \gamma_1 \gamma_2 \gamma_3$, which represents the unit 4-volume in any basis, with the property that $I^2 = -1$.

The generalized angular momentum mentioned above is called a bi-vector. The bi-vectores are oriented plane segments, and examples also include the electromagnetic field F [\(Hestenes 2015](#page-4-14); [Doran & Lasenby 2007\)](#page-3-3). Vector-arrows are used above spatial 3-vectors like \vec{E} or \vec{p} , no-vector-arrows are used for proper 4-vectors like r and p , and boldface is used for bi-vectors like F and M.

One of the reasons for the success of STA is that the derivative $\nabla \mathbf{F} = \nabla \cdot \mathbf{F} + \nabla \wedge \mathbf{F}$ naturally contains both time and space derivation. When choosing a time-direction, γ_0 , one can decompose the derivative along a direction parallel to and perpendicular to $\gamma_0, \nabla = (\partial_0 - \vec{\nabla}) \gamma_0$, where $\vec{\nabla}$ is the frame-dependent relative 3-vector derivative. This choice of frame also allows one to connect a 4-vector w with its para-vector, $w_0 + \vec{w}$, via γ_0 [\(Doran & Lasenby 2007\)](#page-3-3), namely $w = (w_0 + \vec{w}) \gamma_0$. Furthermore, the right-multiplication by the timelike vector γ_0 isolates the relative quantities of that frame [\(Dressel et al. 2015](#page-3-4)), e.g. $r\gamma_0 = (ct + \vec{r})$.

4 ELECTROMAGNETISM IN STA

The case of electromagnetism in STA is well described in the literature [\(Hestenes 2015](#page-4-14); [Dressel et al. 2015\)](#page-3-4). The starting point may be taken with the bi-vector [\(Hansen 2021](#page-4-15))

$$
\mathbf{F} = \frac{q}{m} r \wedge p. \tag{3}
$$

When comparing to eq. [\(1\)](#page-1-0) one notes that the only difference is the exchange of mass by charge.

The simplest non-trivial equation is in this case given by

$$
\nabla \mathbf{F} = j_e \,,\tag{4}
$$

where the current, j_e , only contains an electric part in the absense of magnetic monopoles. By making the identification

$$
\mathbf{F} = \vec{E} + \vec{B} I,\tag{5}
$$

it is straight forward to derive the 4 Maxwells equations [\(Hestenes 2015](#page-4-14); [Dressel et al. 2015\)](#page-3-4), which include

$$
\vec{\nabla} \cdot \vec{E} = \frac{\rho_e}{\varepsilon_0}, \qquad (6)
$$

$$
\partial_0 \vec{B} + \vec{\nabla} \times \vec{E} = 0. \tag{7}
$$

Whereas **F** is a proper geometric object of electromagnetism, then the separation into \vec{E} and \vec{B} fields requires specification of a frame by the choice of γ_0 . At this point the connection with the tensor $F_{\mu\nu}$ can be made explicit by noticing [\(Dressel et al. 2015\)](#page-3-4)

$$
\mathbf{F} = (\mathbf{F} \cdot \gamma_0) \gamma_0 + (\mathbf{F} \wedge \gamma_0) \gamma_0
$$

= $\vec{E} + \vec{B} I$ (8)
= $F \cdot \gamma_0 + F \cdot \gamma_0 + F \cdot \gamma_0$

$$
= E_1 \gamma_{10} + E_2 \gamma_{20} + E_3 \gamma_{30}
$$

+ $B_1 \gamma_{32} + B_2 \gamma_{13} + B_3 \gamma_{21}$, (9)

where E_i and B_i are the components of the corresponding 3-vectors, and $\gamma_{\mu\nu}$ are the 2-blades as described in section [3.](#page-1-1)

It is important to emphasize, that eq. [\(4\)](#page-1-2) is not merely a matter of compact notation: it is instead the only logical extension beyond the most trivial equation in STA, $\nabla \mathbf{F} = 0$ (which leads to the four Maxwells equations without sources). The only thing remaining is to connect the bivector field to observables: the radial dependence is found from Gauss' law, eq. [\(6\)](#page-1-3), and the units of \vec{E} and \vec{B} are established through measurements.

5 APPEARANCE OF FORCES

In STA forces are derived by contracting the bi-vectors with a proper velocity vector, w , e.g. the Lorentz force is derived directly from $\mathbf{F} \cdot w$ [\(Dressel et al. 2015](#page-3-4))

$$
(\mathbf{F} \cdot w) \, q \frac{d\tau}{dt} \gamma_0 = q \vec{E} \cdot \vec{v} + q \left(\vec{E} + \vec{v} \times \vec{B} \right) , \qquad (10)
$$

where the first term on the r.h.s. is the rate of work, $d\varepsilon/d(ct)$, and the last parenthesis on the r.h.s. is the classical Lorentz force, where $\vec{w} = \gamma \vec{v}$. One notes that the γ here is the relativistic Lorentz factor, and should not be confused with the bases for Minkowski space, γ_{μ} .

Similarly the gravitational force appears from the contraction of M and a proper 4-velocity

$$
(\mathbf{M} \cdot w) m \frac{d\tau}{dt} \gamma_0 = -m \vec{N} \cdot \frac{\vec{v}}{c} + m \left(-\vec{N} - \frac{\vec{v}}{c} \times \vec{L} \right). \tag{11}
$$

The first term on the r.h.s. is similar to a rate of work, and the first term in the parenthesis leads to Newtons gravitational force [\(Hansen 2021](#page-4-16)).

When one considers gravitational forces, then there is an extra detail, which arises if the structure under consideration contains a dynamical term proportional to the velocity dispersion, σ^2 . This could for instance arise in a galaxy cluster where the galaxies and dark matter particles are orbiting in the local gravitational potential. In this case the potential is minus 2 times the kinetic energy according to the virial theorem [\(Binney & Tremaine 2008](#page-3-5)), $2T + U = 0$, and hence one can write the energy as

$$
\varepsilon = mc^2 - \frac{1}{2}m\sigma^2. \tag{12}
$$

The correction in eq. [\(12\)](#page-2-0) above is the first order correction. It is similar to the first order relativistic correction to the kinetic energy of a gas, where the difference between the relativistic and restenergies typically reads

$$
mc^2 \left(\frac{1}{\sqrt{1 - \frac{v^2}{c^2}}} - 1 \right) = \frac{3}{2}kT.
$$
 (13)

The fact that it is exactly this correction to the energy which is relevant, comes from the dynamic mass moment, N, as shown in [Hansen \(2021\)](#page-4-16). It is the expectation that the exact same expression can be derived from general relativity (GR) in a weak field limit, as the natural correction to the energymomentum tensor when one includes a structure with non-zero internal dispersion.

From this extra term there will be a correction to the normal Newtonian force, which is proportional to the velocity dispersion squared [\(Hansen 2021](#page-4-16)). This correction can be of the order 10^{-5} for a galaxy cluster of mass $M_{\text{cluster}} = 10^{15} M_{\odot}$, and of the order 10^{-9} for a dwarf galaxy of mass $M_{\text{dwarf}} = 10^9 M_{\odot}$.

6 A NEW REPULSIVE FORCE FOR DARK MATTER PARTICLES

Having seen how the Lorentz force of electromagnetism and Newtons gravitational law appear naturally from the bivectors \bf{F} and \bf{M} , in eqs. $(3, 1)$ $(3, 1)$, it is straight forward to generalize to new forces. Let us imagine that the dark matter particles are equipped with a new charge, q_r . The index, r, refers to repulsive, and one imagines that a quantum field theoretical description of the force-carrier is that of a spin-1 particle, such that equal charges repel each other. At this point let us consider an asymmetric creation of dark matter, such that all dark matter particles carry the same charge.

A new bi-vector is defined, $\mathbf{D}_r = \vec{D}_r + \vec{C}_r I$, (compare with the case of electromagnetism in eqs. $(5, 3)$ $(5, 3)$) where the D refers to the dark matter particle

$$
\mathbf{D}_r = \frac{q_r}{m} r \wedge p. \tag{14}
$$

From the dynamical equation

$$
\nabla \mathbf{D}_r = j_d, \tag{15}
$$

where j_d is a source term, one gets 4 equations, of which one is $\nabla \cdot \mathbf{D}_r = \rho_d/\varepsilon_d$, where ρ_d is the number density of the dark matter particle. ε_d is similar to the vacuum permittivity, ε_0 , of electromagnetism. Integrating this equation (just like Gauss' law) one gets that the field \vec{D}_r is inverse squaredistance. The corresponding forces are found from $\mathbf{D}_r \cdot w$, of which the main term gives a force

$$
\frac{dp}{d\tau}\gamma_0 = q_r (\mathbf{D}_r \cdot w)
$$

$$
\approx q_r \gamma \vec{D}_r.
$$
 (16)

The magnitude of the force must be determined from observations, in the same way that one measures G for the gravitational force, and ε_0 for the Coulomb force.

There is one very important detail, namely the sign of the minor correction in eq. [\(12\)](#page-2-0). Since the structure was already created through gravity, the correction will come with a negative sign (as in eq. (12)) because the particles have repulsive forces: the particles try to push each other apart, and are therefore in a slightly higher energy-state than they would prefer.

7 A NEW ATTRACTIVE FORCE FOR THE DARK MATTER PARTICLES

The dark matter particle is now also equipped with a second charge, q_a . The index a indicates that this is an *attractive* force, and hence one imagines it is generated by an even-spin force carrier. Everything repeats itself from section [6,](#page-2-1) except for two details: that one is using q_a and ε_a , and that the minor correction from eq. [\(12\)](#page-2-0) will come with the opposite sign: the particles are attracted to each other, and are hence in a lower energy state by being close together. This sign difference will be very important in the next section. The force again turns out to be inverse square-distance, however, it will be attractive. The magnitude of the force, expressed through ε_a to make the connection with ε_0 of electromagnetism explicit, must be determined from measurements.

8 TWO COMBINED FORCES

In the discussion above, there is nothing indicating the magnitude of the forces: both were inverse distance-square forces, and their magnitude could be virtually anything.

If each dark matter particle happens to be equipped with both charges, and for some reason the magnitude of the two forces happen to be identical, $q_a^2/\varepsilon_a = q_r^2/\varepsilon_r$, then the main force terms will cancel, where the main terms correspond to the first terms on the r.h.s. of eq. [\(12\)](#page-2-0). This is because the one force was (constructed to be) attractive and the other repulsive, but with equal strengths. However, the minor corrections (the last term in eq. [\(12\)](#page-2-0)) have opposite signs, and the combined force will therefore be non-zero. The resulting combined force is repulsive and of the form

$$
\frac{q_r^2}{\varepsilon_r} \left(1 - \frac{1}{2}\frac{\sigma^2}{c^2}\right) \frac{\hat{r}}{r^2} - \frac{q_a^2}{\varepsilon_a} \left(1 + \frac{1}{2}\frac{\sigma^2}{c^2}\right) \frac{\hat{r}}{r^2} = \frac{q_a^2}{\varepsilon_a} \frac{\sigma^2}{c^2} \frac{\hat{r}}{r^2}, (17)
$$

where the dispersion has been normalized to the speed of light.

This form is exactly of the shape needed for the suggestion of [Loeve et al. \(2021](#page-4-10))

$$
\kappa \frac{\sigma^2}{c^2} G m_1 m_2 \frac{\hat{r}}{r^2} \,. \tag{18}
$$

By comparing the two expressions above, one sees that the combination of the dark matter charge and their strength, must be equal to the gravitational force times a constant κ , which according to [Loeve et al. \(2021](#page-4-10)) should be of the order $\kappa \sim 10^6 - 10^8$.

9 OBSERVATIONAL CONSTRAINTS

A standard comparison of the strength of forces gives that the gravitational attraction between 2 protons is about 36 orders of magnitude smaller than the electromagnetic repulsion. One notices that a force only 6-8 orders of magnitude stronger than gravity is needed, which means 28-30 orders of magnitude weaker than electromagnetism. Since the above calculations were imagined in an asymmetric dark matter model (all dark matter particles are created with the same charge), then that can be imagined as a charge which is 14-15 orders of magnitude smaller than the electric charge.

Since all main forces cancel between the attractive and repulsive forces, this implies that the evolution of the universe will be entirely unaffected by the charges themselves. The only difference is that in the late universe, when the dispersions in galaxies starts being significant, there will be an overall repulsive force, which may accelerate the expansion of the universe.

Dark charges and the corresponding dark radiation have been discussed for many years [\(Ackerman et al. 2009](#page-3-6)). Impressively many models have been considered, some with massive dark photons (which is not relevant for the model considered here), some models with massless dark (or hidden) photons, with symmetric and asymmetric dark matter, milicharged dark matter, and naturally a very large number of models where there is some kind of interaction between the dark and visible sectors. Most of the constraints are highly model dependent and cannot be reviewed here, instead the reader is referred to the references in the reviews [\(Battaglieri et al. 2017](#page-3-7); [Fabbrichesi et al. 2020\)](#page-3-8).

The calculations above are entirely classical, in the sense that STA only allows one to derive Maxwells equations and the Lorentz force. In order to perform a quantum field theoretical derivation of the forces, one would have to define and calculate the relevant Feynman diagrams. It is the expectation that in the exact same way as QED generalized classical electromagnetism, a similar quantum field theoretical generalization would allow one to derive the dark forces described above. In this connection it will be particularly interesting how one at the quantum level will make the two different forces (mediated by different spin particles) cancel. Naturally this point is beyond the scope of the classical derivation presented above.

Any quantum field contributes zero-point energy, which might add a contribution to the cosmological constant which is many orders of magnitude larger than observationally acceptable [\(Weinberg 1989\)](#page-4-17). This goes very much counter to the suggestion of this paper, namely to avoid the need for a cosmological constant. The new dark charges proposed above are only likely to worsen this situation, and the present paper does in no way attempt to solve this issue.

One significant concern mentioned in [Loeve et al.](#page-4-10) [\(2021](#page-4-10)) is the stability of structures like galaxies and dwarf galaxies: if the force would be a standard "electromagneticlike" force, then there would be large forces internally in a dwarf galaxy, which would rip the structure apart. In the present model all these large internal forces are exactly cancelled, and hence that concern is completely avoided. In order to test if this model is indeed able to explain the observed accelating universe, it will be necessary to perform a numerical simulation, where the acceleration is accurately calculated in each time-step, from the actual velocity dispersions. Such a calculation is very likely to result in a temporal evolution, which is not an exact match to the evolution of a (dynamic versions of a) cosmological constant. The resulting observables can then be compared with accurate data from supernovae, growth of structures, and the cosmic microwave background, and in this way the models can be compared, testet and potentially observationally rejected.

10 CONCLUSION

Using the framework of spacetime algebra it is shown that when equipping the dark matter particles with two different charges (attractive and repulsive, respectively) with identical strengths, then the non-cancelled part of the long-range forces is proportional to velocity dispersion squared. This is an example of a force which was recently suggested to be able to accelerate the expansion of the universe without the need for a cosmological constant. The magnitude of the strength is about 30 orders of magnitude smaller than electromagnetism, and hence perfectly allowed observationally.
