# Algorithms and Complexity for Counting Configurations in Steiner Triple Systems

Daniel Heinlein<sup>\*</sup> and Patric R. J. Östergård Department of Communications and Networking Aalto University School of Electrical Engineering P.O. Box 15400, 00076 Aalto, Finland {daniel.heinlein,patric.ostergard}@aalto.fi

#### Abstract

Steiner triple systems form one of the most studied classes of combinatorial designs. Configurations, including subsystems, play a central role in the investigation of Steiner triple systems. With sporadic instances of small systems, ad-hoc algorithms for counting or listing configurations are typically fast enough for practical needs, but with many systems or large systems, the relevance of computational complexity and algorithms of low complexity is highlighted. General theoretical results as well as specific practical algorithms for important configurations are presented.

Keywords: algorithm, computational complexity, configuration, Steiner triple system, subsystem MSC: 05B07, 68Q25

## 1 Introduction

A Steiner triple system (STS) is an ordered pair  $(V, \mathcal{B})$ , where V is a set of points and  $\mathcal{B}$  is a set of 3-subsets of points, called *blocks* or *lines*, such that every 2-subset of points occurs in exactly one block. The size of the point set is the *order* of the Steiner triple system, and a Steiner triple system of order v is denoted by STS(v). It is well known that an STS(v) exists iff

$$v \equiv 1 \text{ or } 3 \pmod{6}. \tag{1}$$

<sup>\*</sup>Supported by the Academy of Finland, Grant 331044.

An STS(v) has v(v-1)/6 blocks and each point is in (v-1)/2 blocks. For more information about Steiner triple systems, see [5, 9].

A configuration in a  $(V, \mathcal{B})$  STS(v) is a set system  $(V', \mathcal{B}')$ , where  $\mathcal{B}' \subseteq \mathcal{B}$ and  $V' = \bigcup_{B \in \mathcal{B}'} B$ . For configurations, we adopt the convention of calling the elements of  $\mathcal{B}'$  lines. If each point in V' occurs in at least two lines, then the configuration is said to be *full*. A configuration that is an STS(v) is called an STS(v) subsystem, or a sub-STS(w), and is said to be proper if w < v and nontrivial if w > 3. A configuration with w lines such that each point is in three of the lines is a  $w_3$  configuration [16]. Double counting shows that the size of the point set of a  $w_3$  configuration is w.

The computational problem of finding configurations in designs is recurrent in design theory. For example, the problem of finding maximal arcs in projective planes of order 16, studied in [13], is about finding 2-(52,4,1) subdesigns in 2-(273,17,1) designs. Similar computational problems also occur in discrete geometry [3]. We shall here focus explicitly on configurations in Steiner triple systems, motivated by a need in [19] for algorithms to count configurations in many Steiner triple systems with orders that are large—even in the thousands. Earlier work in this area has mainly concerned subsystems of Steiner triple systems [7].

An STS(v) is said to be *isomorphic* to another STS(v) if there exists a bijection between the point sets that maps blocks onto blocks; such a bijection is called an *isomorphism*. An isomorphism of a Steiner triple system onto itself is an *automorphism* of the Steiner triple system. The automorphisms of a Steiner triple system form a group under composition, the *automorphism* group of the Steiner triple system. These concepts are defined analogously for configurations.

The paper is organized as follows. In Section 2, the time complexity of counting and listing configurations in Steiner triple systems is considered. With fixed (sets of) configurations, these problems are in **P**. Polynomial upper bounds on the time complexity are obtained by developing algorithms. The number of occurrences of all *n*-line configurations can be obtained as a function of the number of occurrences of all full *m*-line configurations with  $m \leq n$ . The conjecture that a subset of the full *m*-line configurations does not suffice has earlier been verified for  $n \leq 7$ , which is here extended to  $n \leq 8$ . Practical aspects are not addressed in the theoretical proofs, so Section 3 is devoted to practical counting algorithms for several specific small configurations. In particular, an approach is developed for constructing an exhaustive set of algorithms of a certain type. The algorithms are compared experimentally, and the winning algorithms are displayed for nine important configurations.

## 2 Counting Configurations

#### 2.1 Problem and Algorithms

The computational problem studied here is as follows, where C is any *fixed* set of configurations.

**Problem:**  $P(\mathcal{C})$ **Input:** A Steiner triple system S of order v**Output:** The number of occurrences of the configurations in S that are isomorphic to a configuration in C

The motivation for the work is that of *counting* configurations, but we will also address the problem of *listing* configurations in Steiner triple systems. The listed configurations can obviously simultaneously be counted, but the fastest (known) counting algorithm has in many cases smaller time complexity than the fastest (known) listing algorithm. For example, considering a configuration with just one line, an optimal algorithm simply lists all lines of the STS(v), which takes  $\Theta(v^2)$ , whereas counting is simply a matter of evaluating v(v-1)/6.

Indeed, for certain configurations the number of occurrences in an STS(v) only depends on v. Such configurations are called *constant*. A configuration that is not constant is said to be *variable*. Small configurations in STS(v)s are surveyed in [9, Ch. 13]. All configurations with three or fewer lines are constant and so are the members of five infinite families presented in [20]. A complete characterization of constant configurations is still missing.

The fact that the set of configurations C is fixed gives possibilities of simplifying proofs. For example, determining whether two configurations are isomorphic can be done in constant time. As the goal is to establish theoretical bounds, we do not make any attempts to develop practical algorithms in this section but defer such issues to Section 3.

It is straightforward to see that Problem  $P(\mathcal{C})$  is in **P**. Namely, if there are at most m lines in the configurations in  $\mathcal{C}$ , then we can explore all subsets of at most m lines of  $\mathcal{S}$  and there are  $\Theta(v^{2m})$  such subsets. However, it will turn out that this upper bound is weak, and better upper bounds—also in the context of listing—will be obtained. As  $\mathbf{P} \subseteq \mathbf{PSPACE}$ , the space complexity will also be polynomial in all cases and will not be considered here.

The concept of configurations generated by sets of points is central in the study of specific algorithms. We here use a framework considered for Steiner triple systems in [9, p. 99] and its references. Given a configuration with

point set V and line set  $\mathcal{B}$ , fix  $V_0 \subseteq V$  and let

$$V_{i+1} = V_i \cup \{z : \{x, y, z\} \in \mathcal{B}, x, y \in V_i\}.$$

For some finite j,  $V_{j+1} = V_j$  and then  $V_i = V_j$  for all i > j. The set  $V_j$  is the *closure* of  $V_0$ , and  $V_j$  is the point set of a subconfiguration, which is the smallest point-induced subconfiguration (subsystem, when  $(V, \mathcal{B})$  is a Steiner triple system) containing  $V_0$  and is said to be *generated* by  $V_0$ .

If  $|V_0| = 2$ , then  $V_0$  generates at most one line, a line in which the pair of points occurs. Similarly, if  $|V_0| = 3$  and  $V_0$  is a line, then no further lines are generated. But many types of configurations can be generated by  $V_0$  when  $|V_0| = 3$  and  $V_0$  is not a line.

**Theorem 1.** Let C be a collection of configurations that can be generated by m points. Then the time complexity of listing the configurations in an STS(v) isomorphic to a configuration in C is  $O(v^m)$ .

Proof. Consider a  $(V, \mathcal{B})$  STS(v). For each possible *m*-subset  $V'_0 \subseteq V$  and with  $\mathcal{B}'_0 = \emptyset$ , the following iterative extension procedure is carried out in all possible ways: given a point set  $V'_i$  and a line set  $\mathcal{B}'_i$ , let  $V'_{i+1} = V'_i \cup B$  and  $\mathcal{B}'_{i+1} = \mathcal{B}'_i \cup \{B\}$ , where  $B \in \mathcal{B} \setminus \mathcal{B}'_i$  and  $|B \cap V'_i| \geq 2$ . Whenever *i* equals the number of lines of a configuration in  $\mathcal{C}$ , an isomorphism test is carried out. If the outcome of that test is positive, then the configuration is listed if two additional tests are passed: (i) the *m*-subset  $V'_0$  is the lexicographically smallest one amongst the *m*-subsets from which the configuration can be generated, and (ii) the configuration has not already been listed in the branch of the search tree starting from  $V'_0$ . This makes sure that each configuration is listed exactly once. The number of lines in the configurations in  $\mathcal{C}$  sets a bound on the largest value of *i* to consider.

Using a precomputed data structure, which can be created in  $O(v^2)$  (cf. Section 3), the extension can be carried out in constant time. As the isomorphism test can also be carried out in constant time, the time complexity of the problem is bounded from above by the number of *m*-subsets of a *v*-set and is therefore  $O(v^m)$ .

Note that the core of the algorithm in the proof is essentially about canonical augmentation [23]—see also [21, Sect. 4.2.3]—which consists of (i) a parent test and (ii) an isomorphism test. The extension procedures in and before the proof of Theorem 1 are closely connected to the core of Miller's algorithm [24] for computing a canonical form of an STS(v) in  $O(v^{\log v+O(1)})$ . Further related studies include [7, 26]. Also note the similarity between the extension procedure and the algorithm in [3].

For listing algorithms, it is now a matter of determining the size of point sets needed to generate configurations.

#### 2.2 Small Configurations

An algorithm that solves Problem  $P(\mathcal{C})$  gives an upper bound on the time complexity. For some configurations, including the smallest nontrivial case of *Pasch* configurations, it is possible to prove that the upper bound given by Theorem 1 is actually exact. The Pasch configuration is depicted in Figure 1a; one possible set of generating points is here and in later pictures shown with bold circles. The labels in all pictures refer to the naming of variables in Section 3.

Figure 1: The Pasch and mitre configurations

**Theorem 2.** The time complexity of listing the Pasch configurations in an STS(v) is  $\Theta(v^3)$ .

*Proof.* The Pasch configuration can be generated by the 3 points indicated in Figure 1a. Then combine the upper bound given by Theorem 1 and the fact that there are STS(v)s with v(v-1)(v-3)/24 Pasch configurations [27].

**Theorem 3.** The time complexity of counting the number of occurrences of a given 4-line variable configuration in an STS(v) is  $O(v^3)$ .

*Proof.* For any of the 11 variable 4-line configurations, the number of occurrences can be derived from the number of occurrences of any single one of them [15]. In particular, using the number of Pasch configurations, the result follows from Theorem 2.  $\Box$ 

The case of 4-line configurations provides further examples with different time complexity for counting and listing. Namely, for all but the Pasch configuration, 4 to 8 points are needed for generation, which gives listing algorithms with time complexity  $O(v^4)$  to  $O(v^8)$ . In fact, the maximum number of occurrences of configurations [15] shows that the time complexity of listing is  $\Theta(v^4)$  to  $\Theta(v^8)$ . For example, the configuration that requires 8 points for generation consists of four disjoint lines.

The result in Theorem 3 may be extended by considering *n*-line configurations for any fixed n > 4 in an analogous way. Formulas for the relationship between the numbers of occurrences of variable 5-line and 6-line configurations can be found in [10] and [11], respectively. Actually, since we do not need exact formulas in our study of complexity, the following general result will suffice.

**Theorem 4** ([20]). The number of occurrences of any variable n-line configuration in an STS(v) is a constant (as a polynomial in v) plus a linear combination (with coefficients that are polynomials in v) of the numbers of occurrences of the full m-line configurations with  $m \leq n$ .

The only full 5-line configuration is the *mitre* configuration (Figure 1b).

**Theorem 5.** The time complexity of counting the number of occurrences of a given 5-line variable configuration in an STS(v) is  $O(v^3)$ .

*Proof.* The full *m*-line configurations with  $m \leq 5$  are the Pasch and the mitre configuration. The mitre configuration can be generated by 3 points—as indicated in Figure 1b—and therefore the number of occurrences can be obtained in  $O(v^3)$  by Theorem 1. As also the Pasch configurations can be counted in  $O(v^3)$  by Theorem 3, the result now follows from Theorem 4.  $\Box$ 

With an increasing number of lines, extending the results in Theorems 3 and 5 is rather straightforward but becomes more and more laborious. Moreover, for different configurations we will get different upper bounds on the time complexity, so the results cannot be stated in compact form. For example, for 6-line and 7-line configurations we get the following general result.

**Theorem 6.** The time complexity of counting the number of occurrences of a given 6-line or 7-line variable configuration in an STS(v) is  $O(v^4)$ .

*Proof.* There are 5 full 6-line configurations, which are depicted in Figure 2 with generating sets indicated. Consequently, by Theorem 4, the time complexity for counting the number of occurrences of a variable 6-line configuration is  $O(v^4)$ . For variable 7-line configurations, a similar argument applies as all full 7-line configurations have generating sets of size at most 4 (by Table 1, to be discussed later).

Clearly Theorem 6 is not tight in the sense that for some of the variable 6-line and 7-line configurations, the time complexity of counting is  $O(v^3)$ .

Figure 2: The full 6-line configurations

For a fixed  $n \geq 7$ , there are too many full *n*-line configurations to depict all of them here. However, computationally one can easily get rather extensive results. The number *N* of isomorphism classes of full *n*-line configurations for  $n \leq 12$  have been obtained earlier in [12]. We extend that work to  $n \leq 13$  in Table 1 and, for all those parameters, tabulate the distribution  $N_i$ based on the size *i* of the smallest generating set. Also, the distribution of automorphism group sizes, |Aut|, is shown.

It is an interesting open question whether all full configurations are really required in Theorem 4 or whether a subset of them would suffice. It is conjectured in [20] that Theorem 4 is indeed strict. For n = 4, 5, and 6, this follows from the formulas of [15], [10], and [11], respectively, and the case of n = 6 is handled explicitly in [20]. The conjecture has also been verified for n = 7 in an unpublished study [28].

An established approach [14] to study the aforementioned conjecture for small values of n is to investigate the number of occurrences of full m-line configurations for  $m \leq n$  in a set of (randomly chosen) STS(v)s for some fixed v. If there are r configurations to consider, we get for each STS(v) a vector of length r+1 with nonnegative integers (r counts and a constant, say 1). Forming a matrix with rows consisting of those vectors, we check whether the rank is r + 1 (for which we obviously need at least r + 1 vectors).

Table 1: Sizes of generating sets of full n-line configurations

In the current study, this approach is used to extend the earlier results to n = 8. Notice that the following theorem actually confirms the old results for  $n \leq 7$ , including the unpublished result [28] for n = 7.

**Theorem 7.** For  $n \leq 8$ , there is no full n-line configuration C whose number of occurrences in an STS(v) is a constant (as a function of v) plus a linear combination (with coefficients that are functions of v) of the numbers of occurrences of the full m-line configurations with  $m \leq n$  excluding C.

*Proof.* For n = 8, 623 distinct and randomly chosen STS(25)s were considered, and for each of these a vector of length 180 was determined as described earlier (there are 179 full *m*-line configurations with  $m \leq 8$ ). Calculations using **gap** show that the 623 × 180 matrix formed by these vectors has rank 180.

The 623 Steiner triple systems considered and the related vectors are published separately in [17].  $\hfill \Box$ 

See [1, 6, 14] for further results on configurations in designs in general and in Steiner triple systems in particular.

### **2.3** $w_3$ Configurations

For configurations with a large number of lines, a more general study is feasible only for specific types of configurations. We here consider  $w_3$  configurations, algorithms for which are needed in [19]. The number N of isomorphism classes of  $w_3$  configurations with small w can be found in [2, 16]. In Table 2 we list those values for  $7 \le n \le 16$ , and for each entry we give the same information as in Table 1.

The unique  $7_3$  and  $8_3$  configurations are the Fano plane and the Möbius–Kantor configuration, respectively, and are depicted in Figure 3, again with generating sets indicated.

We call an  $n_3$  configuration in a  $v_3$  configuration a subconfiguration and say that such a subconfiguration is proper if n < v.

**Theorem 8.** If a  $v_3$  configuration has a proper  $n_3$  subconfiguration, then it has a proper  $(n - v)_3$  subconfiguration.

*Proof.* Consider the configuration obtained by removing the points and lines of a proper  $n_3$  subconfiguration from the  $v_3$  configuration.

**Corollary 1.** If a  $v_3$  configuration has a proper  $n_3$  subconfiguration, then  $v \ge 14$ .

Table 2: Sizes of generating sets of  $w_3$  configurations

Figure 3: The  $7_3$  and  $8_3$  configurations

The smallest example of a  $v_3$  configuration with proper  $n_3$  subconfigurations is of type 14<sub>3</sub> and is unique as the 7<sub>3</sub> configuration is unique. This particular configuration occurs in the STS(21)s of Wilson type, as discussed in [18].

The size of the generating set of a  $v_3$  configuration with proper  $n_3$  and  $(v - n)_3$  subconfigurations equals the sum of the sizes of the generating sets of those subconfigurations. All configurations corresponding to the entries in column  $N_6$  of Table 2 can be explained in this way. This argument can be applied recursively.

**Theorem 9.** For any integer d, there is a  $w_3$  configuration whose smallest generating set has size greater than d.

*Proof.* Consider the  $(7m)_3$  configuration consisting of  $m 7_3$  subconfigurations. Each of the  $7_3$  subconfigurations requires 3 points for generation, so the minimum number of points in a generating set is 3m.

## **3** Practical Algorithms

There are two situations when fast practical algorithms for counting configurations in Steiner triple systems are needed: if there are many Steiner triple systems to consider, as in [8], or if the order of the Steiner triple systems is large, as in [19].

The main challenge in this work is that—as we are interested in averagecase performance—in a formal analysis one should know the distribution of all possible inputs. An experimental approach was taken here, and algorithms were evaluated using random Steiner triple systems. The algorithms were produced in an exhaustive manner that will be described later in this section. This falls within the paradigm of using algorithms to design algorithms [4]. Hopefully, the computational results will also inspire analytical studies of these algorithms.

In this section, we apply the following conventions. For a Steiner triple system  $(V, \mathcal{B})$ , we let  $V = \{0, 1, \ldots, v - 1\}$ . In  $(V, \mathcal{B})$ , we want to count the number of occurrences of a configuration  $(V', \mathcal{B}')$  with |V'| = w points,  $|\mathcal{B}'| = b$  lines, and a minimum generating set of size m.

We use two auxiliary functions  $B_2 : \{(x, y) \in V^2 : x \neq y\} \to V$  and  $B_3 : V^3 \to \{0, 1\}$  so that  $B_2(x, y) = z$  iff  $\{x, y, z\} \in \mathcal{B}$  and

$$B_3(x, y, z) = \begin{cases} 0, & \text{if } \{x, y, z\} \notin \mathcal{B}, \\ 1, & \text{if } \{x, y, z\} \in \mathcal{B}. \end{cases}$$

A precomputed array of size  $v^2$  can be used to evaluate both of these functions in constant time.

The configurations  $(V', \mathcal{B}')$  we focus on are the  $w_3$  configurations with  $w \leq 8$  and the full *n*-line configurations with  $n \leq 6$ , that is, the nine configurations depicted in this paper.

#### 3.1 Generating Sets, Up to Symmetry

The main idea in the algorithms to be considered is that they loop over values for elements in a generating set of size m. A configuration may have many such generating sets, but the number of generating sets to consider can be reduced by utilizing symmetries of the configuration, that is, its automorphism group  $\Gamma$ . Since the nesting of the loops in the algorithms imply an order on the elements of a generating set, we specifically consider representatives from the set  $\mathcal{M}$  of transversals of the action of  $\Gamma$  on the *ordered* generating sets.

The automorphism group of a configuration can also be utilized to derive conditions on its points, so that occurrences will not be counted multiple times. We denote the orbit of an element x under the action of G by  $G \cdot x$  and the stabilizer by  $\operatorname{Stab}_G(x)$ . Let  $Z = (z_1, z_2, \ldots, z_m)$  be an ordered generating set that is a permutation of an element  $M \in \mathcal{M}$ . For  $i \in \{1, 2, \ldots, m\}$ , we now compute  $O_i = \Gamma_{i-1} \cdot z_i$  and  $\Gamma_i = \operatorname{Stab}_{\Gamma_{i-1}}(z_i)$ , using  $\Gamma_0 = \Gamma$ . Whereas M gives the order of the **for** loops, Z shows where the conditions given by the symmetries will be taken into account. The value  $Q := |\Gamma_m|$  gives the number of times each configuration will be encountered.

To get an exhaustive set of algorithms, for each  $M \in \mathcal{M}$ , we consider each of the m! possible choices of Z as permutations of M and each of the  $2^m$  possible choices of  $E = (e_1, e_2, \ldots, e_m)$ ,  $e_i \in \{\min, \max\}$ , where  $e_i$  tells whether the corresponding  $z_i$  should be minimum or maximum in the orbit  $O_i$ . As the isomorphism  $i \mapsto v - 1 - i$  does not change the average-case behavior,  $e_1$  can be fixed to min, which leaves  $2^{m-1}$  possible choices.

The following concrete example, which is split into two parts, demonstrates how one algorithm for the Fano plane is obtained.

**Example.** (Fano plane, Figure 3a) The lines  $\mathcal{B}'$  of the Fano plane in Figure 3a are {{a, b, e}, {a, c, g}, {a, d, f}, {b, c, f}, {b, d, g}, {c, d, e}, {e, f, g}}. Given a Steiner triple system, the goal is now to set the seven points a, b, c, d, e, f, g, which we regard as variables, such that ({a, b, c, d, e, f, g},  $\mathcal{B}'$ ) is a configuration of the system.

The Fano plane has w = 7 points, b = 7 lines, an automorphism group  $\Gamma$  of order  $|\Gamma| = 168$ , and a minimum generating set of size m = 3. It has 28 minimum generating sets, which are precisely the sets of three non-collinear

points, so there are  $28 \cdot 3! = 168$  sets of ordered minimum generating sets. Those 168 sets form one orbit under the action of  $\Gamma$ , and we can let  $\mathcal{M} = \{(a, b, c)\}$ . One possible choice is Z = (c, b, a) and  $E = (\min, \min, \min)$ .

We now get  $O_1 = \{ a, b, c, d, e, f, g \}$  (the automorphism group of the Fano plane is indeed point-transitive),  $|\Gamma_1| = 24$ ,  $O_2 = \{ a, b, d, e, f, g \}$ ,  $|\Gamma_2| = 4$ ,  $O_3 = \{ a, d, e, g \}$ , and  $|\Gamma_3| = Q = 1$ .

The constraints are then  $c = \min\{a, b, c, d, e, f, g\}$ ,  $b = \min\{a, b, d, e, f, g\}$ , and  $a = \min\{a, d, e, g\}$ , which can be simplified to c < b < a < d, e, g and b < f.

Note that if  $|\Gamma_i| = 1$  for some i < m, then  $|\Gamma_j| = 1$  and  $|O_j| = 1$ for j > i. The minimum and maximum of a 1-element set coincide, and we then get identical algorithms regardless of the values of  $e_j$  and  $z_j$  for j > i. Obviously, there are then no additional constraints on some for loop variables. This situation occurs especially for configurations with very small automorphism groups, such as the Crown configuration (automorphism group order 2). For comparison, we actually also included in our experiments all variants of algorithms where, for  $i \in \{1, 2, \ldots, m\}$ ,  $\Gamma_j$  and  $O_j$  are not determined for  $j \ge i$ . Then  $Q := |\Gamma_{i-1}|$  and some for loop variables do not have constraints. These variants are included later in the last column of Table 3 but are not further discussed here as they were not successful in the experimental evaluation.

#### 3.2 Algorithm for Constructing Counting Algorithms

We are now ready to discuss our approach for exhaustively constructing algorithms for counting  $(V', \mathcal{B}')$  configurations in  $(V, \mathcal{B})$ . For clarity, we only consider the case of generating sets of size 3, but the approach can be extended to arbitrary sizes of generating sets with further nesting of **for** loops (**continue** forces the next iteration of the **for** loop to take place). The missing part,  $\Omega$ , is explained later.

$r \leftarrow 0$	// A $_1$			
for $x_{\mathbf{F}_1} \leftarrow y_{\mathbf{F}_1}$ to $z_{\mathbf{F}_1}$ do	// F $_1$			
for $x_{\mathbf{F}_2} \leftarrow y_{\mathbf{F}_2}$ to $z_{\mathbf{F}_2}$ do	// F $_2$			
if $\mathbf{Check}(F_2) = 0$ continue	// C <sub>F2</sub>			
$x_{\mathbf{S}_1} \leftarrow B_2(x_{\mathbf{F}_1}, x_{\mathbf{F}_2})$	// S1			
if $\mathbf{Check}(S_1) = 0$ continue	// C <sub>S1</sub>			
for $x_{F_3} \leftarrow y_{F_3}$ to $z_{F_3}$ do	// F $_3$			
if $\mathbf{Check}(F_3) = 0$ continue	// C <sub>F3</sub>			
Ω				
$r \leftarrow r+1$	// A $_2$			
return $r/Q$	// $A_3$			

The comments in the right margin of the algorithm describe the type of action taken in the respective place.

- $A_i$  Actions on the accumulator r for counting configurations (i = 1: initializing; i = 2: increasing; i = 3: final division as each configuration is seen Q times)
- $C_i$  Checks after setting variable  $x_i$
- $D_B$  Checks regarding existence of line B
- $\mathbf{F}_i$  for loop for variable  $x_{\mathbf{F}_i}$
- $S_i$  Fixing variable  $x_{S_i}$

The variables  $x_i$  contain the points of the configurations; these are either inside  $(x_{\mathbf{F}_i}, m \text{ variables})$  or outside  $(x_{\mathbf{S}_i}, w - m \text{ variables})$  a generating set. After fixing any point, there is a corresponding check  $C_i$ , to be discussed later. After fixing a point  $x_{\mathbf{F}_k}$  in a **for** loop (and the related check), all variables in the closure of  $\{x_{\mathbf{F}_1}, \ldots, x_{\mathbf{F}_k}\}$  that have not been set so far are set (rows  $\mathbf{S}_i$ ). In  $\mathsf{D}_B$ , existence of lines needed for completing the configuration is checked; there are b - w + m such lines.

Let us next elaborate on the main details.

- 1. In the **for** loops, the values of  $y_{\mathbf{F}_i}$  and  $z_{\mathbf{F}_i}$  are set based on constraints on elements being minimum or maximum in orbits, as discussed in Section 3.1. With no restrictions, we would have  $y_{\mathbf{F}_i} = 0$  and  $z_{\mathbf{F}_i} = v-1$ ; these can be somewhat increased and decreased, respectively, when we have a lower bound on the number of elements that are smaller or larger, respectively.
- 2. In the test **Check(X)**, we incorporate further tests of elements being minimum or maximum in orbits. Some of the tests are included in the

for loops, as discussed in Item 1; any other inequalities that can be tested are included here. Whenever a point outside the generating set is fixed, all such tests are carried out here. Moreover, we need to make sure that a point that is fixed differs form the points that have been fixed earlier. The situation that a point is not new may occur both in a for loop and when fixing a point in  $S_i$ .

3. Whenever a variable is fixed, we check existence of the lines B of the configuration that have not been involved so far in determining new points or lines  $D_B$  but whose points are fixed. Indeed, an early test makes sense since the probability of existence of a particular line in a random STS is 1/(v-2).

The missing part in the algorithm,  $\Omega$ , is now as follows. For each variable  $x_{\mathbf{S}_i}$  that has not yet been set, we have a code line of type  $\mathbf{S}_i$  to assign a value to  $x_{\mathbf{S}_i}$ . Then we have a code line of type  $\mathbf{C}_{\mathbf{S}_i}$  to test whether all constraints are fulfilled and whether  $x_{\mathbf{S}_i}$  differs from all points that have been fixed earlier. Finally, we have one code line of type  $\mathbf{D}_B$  for each line in the configuration that consists of fixed points but did not occur in a code line of type  $\mathbf{S}_i$  or  $\mathbf{D}_B$  so far.

Note that there may be several ways of building up a configuration from a generating set, and we consider all possible such ways in the construction of algorithms.

We can now finish the example for Fano planes that we started in Section 3.1.

**Example (cont).** Based on the calculations earlier in the example, in particular the constraints c < b < a < d, e, g and b < f, we get the following overall structure of the algorithm, where the parts  $\Omega_1$  and  $\Omega_2$  are yet to be determined:

```
r \leftarrow 0<br/>for a \leftarrow 2 to v - 4 do<br/>for b \leftarrow 1 to a - 1 do<br/>\begin{bmatrix} \Omega_1 \\ \text{for } c \leftarrow 0 \text{ to } b - 1 \text{ do} \\ \Omega_2 \\ r \leftarrow r + 1 \end{bmatrix}<br/>return r
```

Next, we will discuss the remaining w - m = 4 variables d, e, f, g. The

sets of new points in  $\Omega_1$  and  $\Omega_2$  are  $G_1 = \{e\}$  and  $G_2 = \{d, f, g\}$ , respectively. We here consider one feasible ordering of the elements of  $G_1$  and  $G_2$ : (e) and (g, d, f), respectively.

In  $\Omega_1$ , there is only one way of setting e, namely  $\{a, b, e\}$ , and the only constraint is a < e. This also ensures distinctness of all points so far, so for  $\Omega_1$  we get

 $e \leftarrow B_2(b, a)$ if  $e \le a$  continue

In  $\Omega_2$ , one choice for setting g, d, and f is  $\{a, c, g\}$ ,  $\{c, d, e\}$ , and  $\{e, f, g\}$ , respectively. This choice implies that the remaining lines to check are  $\{a, d, f\}$ ,  $\{b, c, f\}$ , and  $\{b, d, g\}$ .

For the loop variable c we need to ensure that c < b. The tests related to g, d, and f are a < g, a < d, and b < f, respectively. These are also sufficient, as it can be verified that all points obtained in this way are necessarily distinct (for example,  $g \neq e$  as  $\{a, c, g\}$  and  $\{a, b, e\}$  are distinct lines through a and  $d \neq e$  as  $\{c, d, e\}$  is a line). Altogether, for  $\Omega_2$  we have

 $\begin{array}{l} \mathbf{g} \leftarrow B_2(\mathbf{c}, \mathbf{a}) \\ \text{if } \mathbf{g} \leq \mathbf{a} \text{ continue} \\ \mathbf{d} \leftarrow B_2(\mathbf{e}, \mathbf{c}) \\ \text{if } \mathbf{d} \leq \mathbf{a} \text{ continue} \\ \text{if } B_3(\mathbf{b}, \mathbf{d}, \mathbf{g}) = 0 \text{ continue} \\ \mathbf{f} \leftarrow B_2(\mathbf{g}, \mathbf{e}) \\ \text{if } \mathbf{f} \leq \mathbf{b} \text{ continue} \\ \text{if } B_3(\mathbf{a}, \mathbf{d}, \mathbf{f}) = 0 \text{ continue} \\ \text{if } B_3(\mathbf{b}, \mathbf{c}, \mathbf{f}) = 0 \text{ continue} \end{array}$ 

We then get the following complete algorithm.

```
r \leftarrow 0
for a \leftarrow 2 to v - 4 do
    for b \leftarrow 1 to a - 1 do
         e \leftarrow B_2(b, a)
         if e < a continue
         for c \leftarrow 0 to b - 1 do
              g \leftarrow B_2(c, a)
              if g \leq a continue
              d \leftarrow B_2(e, c)
              if d \leq a continue
              if B_3(\mathbf{b}, \mathbf{d}, \mathbf{g}) = 0 continue
              f \leftarrow B_2(g, e)
              if f < b continue
              if B_3(a, d, f) = 0 continue
              if B_3(b, c, f) = 0 continue
              r \leftarrow r+1
```

return r

Algorithm 1: 7<sub>3</sub>-configuration (Fano plane) (Figure 3a)

#### 3.3 Experimental Evaluation

We constructed all possible algorithms with the approach discussed earlier and carried out an experimental evaluation. The authors are well aware of the challenges involved in such work. Above all, the performance of the algorithms depends on issues that are difficult or impossible to control, related to compilers and microprocessors. In particular, the programs contain many if statements and can be demanding for the technique of speculative execution used commonly by modern CPUs [22].

Table 3 summarizes the main details for the generation process of algorithms for all configurations in consideration here. The column "Name" is the name of the configuration, and  $b, w, m, |\Gamma|, |\mathcal{M}_s|, |\mathcal{M}|, \text{ and } |\mathcal{M}/\Gamma|$  are the number of lines, points, elements in a generating set of minimum size, automorphisms, minimum generating sets, minimum ordered generating sets, and orbits of minimum ordered generating sets under the action of the automorphism group  $\Gamma$ , respectively. The last column A gives the number of distinct algorithms generated.

For each configuration, we evaluated each of the A algorithms on random Steiner triple systems constructed by Stinson's hill-climbing algorithm [25]. This evaluation took part in three phases.

Name	b	w	m	$ \Gamma $	$ \mathcal{M}_s $	$ \mathcal{M} $	$ \mathcal{M}/\Gamma $	A
Pasch	4	6	3	24	16	96	4	296
Mitre	5	7	3	12	30	180	15	1272
Fano-line	6	7	3	24	28	168	7	2020
Crown	6	8	3	2	46	276	138	7348
Hexagon	6	8	3	12	48	288	24	2912
Prism	6	9	4	12	75	1800	150	60872
Grid	6	9	4	72	81	1944	27	34752
Fano	7	7	3	168	28	168	1	828
Möbius–Kantor	8	8	3	48	48	288	6	9216

Table 3: Details for the generated algorithms

In the first phase, for each configuration, we considered as many random Steiner triple systems of order v = 93 as could be considered in 0.5 seconds (at least one though). In the second phase, this was repeated for the max{100,  $[0.01 \cdot A]$ } algorithms with the smallest average time per configuration from the first phase. Moreover, in the second phase, 60 seconds was used for each algorithm and the order v = 121 was considered. Finally, in the third phase, this was repeated for the five algorithms with the smallest average time per configuration from the second phase with 600 seconds time and v = 151.

All computations were performed on 2.30-GHz Intel Xeon Gold 6140 CPUs using the programming language C++ compiled with the GNU Compiler Collection.

The fastest algorithm per configuration is determined as the algorithm with smallest average time in Phase 3. It turned out that these fastest algorithms are among the two best in Phase 2 and among the five best in Phase 1 for all configurations. The difference in average time between the fastest and second fastest algorithms in Phase 3, normalized to the fastest, was less than 3.2% for all configurations that were considered.

We conclude the paper by listing the nine algorithms obtained in the aforementioned manner as Algorithm 1 to 9; Algorithm 1 is given in the example in Section 3.2. Any scholar needing such algorithms should be able to implement them easily in any programming language.

```
\begin{array}{c} r \leftarrow 0 \\ \text{for } \mathbf{a} \leftarrow 0 \text{ to } v - 6 \text{ do} \\ \\ & \begin{bmatrix} \text{for } \mathbf{b} \leftarrow \mathbf{a} + 1 \text{ to } v - 2 \text{ do} \\ \mathbf{e} \leftarrow B_2(\mathbf{b}, \mathbf{a}) \\ \text{if } \mathbf{e} \leq \mathbf{a} \text{ continue} \\ \text{for } \mathbf{f} \leftarrow \max\{\mathbf{b}, \mathbf{e}\} + 1 \text{ to } v - 1 \text{ do} \\ & \mathbf{c} \leftarrow B_2(\mathbf{f}, \mathbf{a}) \\ \text{if } \mathbf{f} \leq \mathbf{c} \lor \mathbf{c} \leq \mathbf{a} \text{ continue} \\ & \mathbf{d} \leftarrow B_2(\mathbf{f}, \mathbf{e}) \\ & \text{if } \mathbf{d} \leq \mathbf{a} \text{ continue} \\ & \text{if } B_3(\mathbf{b}, \mathbf{c}, \mathbf{d}) = 0 \text{ continue} \\ & r \leftarrow r + 1 \\ \end{bmatrix} \\ \mathbf{return } r \end{array}
```

**Algorithm 2:** Pasch configuration (Figure 1a)

```
\begin{array}{c|c} r \leftarrow 0 \\ \text{for } \mathbf{a} \leftarrow 0 \text{ to } v - 3 \text{ do} \\ \hline \\ \text{for } \mathbf{c} \leftarrow \mathbf{a} + 1 \text{ to } v - 2 \text{ do} \\ \text{for } \mathbf{c} \leftarrow \mathbf{a} + 1 \text{ to } v - 2 \text{ do} \\ \text{for } \mathbf{e} \leftarrow B_2(\mathbf{c}, \mathbf{a}) \\ \text{for } \mathbf{e} \leftarrow \max\{\mathbf{c}, \mathbf{f}\} + 1 \text{ to } v - 1 \text{ do} \\ \hline \\ \mathbf{g} \leftarrow B_2(\mathbf{g}, \mathbf{a}) \\ \text{if } \mathbf{e} \leq \mathbf{b} \text{ continue} \\ \text{d} \leftarrow B_2(\mathbf{g}, \mathbf{c}) \\ \text{if } \mathbf{e} \leq \mathbf{d} \text{ continue} \\ \text{if } B_3(\mathbf{b}, \mathbf{d}, \mathbf{e}) = 0 \text{ continue} \\ r \leftarrow r + 1 \end{array}
```

return r

**Algorithm 3:** Mitre configuration (Figure 1b)

```
r \leftarrow 0
for c \leftarrow 2 to v - 2 do
for c \leftarrow 2 to v - 2 do
for e \leftarrow 0 to c - 2 do
b \leftarrow B_2(c, e)
for f \leftarrow e + 1 to c - 1 do
if f = b continue
g \leftarrow B_2(f, b)
if g \le c continue
d \leftarrow B_2(e, g)
if B_3(c, d, f) = 0 continue
a \leftarrow B_2(f, e)
if B_3(a, c, g) = 0 continue
r \leftarrow r + 1
return r
```

**Algorithm 4:** Fano–line configuration (Figure 2a)

```
\begin{array}{c|c} r \leftarrow 0 \\ \text{for } \mathbf{f} \leftarrow 0 \text{ to } v - 2 \text{ do} \\ \hline \\ \text{for } \mathbf{e} \leftarrow 0 \text{ to } v - 1 \text{ do} \\ \text{if } \mathbf{e} = \mathbf{f} \text{ continue} \\ \mathbf{h} \leftarrow B_2(\mathbf{f}, \mathbf{e}) \\ \text{for } \mathbf{g} \leftarrow \mathbf{f} + 1 \text{ to } v - 1 \text{ do} \\ \text{if } \mathbf{g} \in \{\mathbf{e}, \mathbf{h}\} \text{ continue} \\ \mathbf{d} \leftarrow B_2(\mathbf{e}, \mathbf{g}) \\ \mathbf{b} \leftarrow B_2(\mathbf{f}, \mathbf{d}) \\ \mathbf{c} \leftarrow B_2(\mathbf{h}, \mathbf{g}) \\ \text{if } \mathbf{c} = \mathbf{b} \text{ continue} \\ \mathbf{a} \leftarrow B_2(\mathbf{f}, \mathbf{g}) \\ \text{if } B_3(\mathbf{a}, \mathbf{b}, \mathbf{c}) = 0 \text{ continue} \\ r \leftarrow r + 1 \end{array}
```

return r

**Algorithm 5:** Crown configuration (Figure 2e)

Algorithm 6: Hexagon configura-

**Algorithm 7:** Prism configuration (Figure 2c)

**Algorithm 8:** Grid configuration (Figure 2b)

```
r \leftarrow 0
for a \leftarrow 1 to v - 6 do
        for b \leftarrow a + 1 to v - 1 do
                 g \leftarrow B_2(b, a)
                   \  \  \, if \ g \leq a \ continue \\
                  for c \leftarrow 0 to a - 1 do
                          \mathtt{d} \leftarrow B_2(\mathtt{c}, \mathtt{a})
                          if d \le a continue
                           \mathtt{h} \leftarrow B_2(\mathtt{c}, \mathtt{b})
                           if h \leq a continue
                           \mathsf{e} \leftarrow B_2(\mathsf{d}, \mathsf{b})
                           if e \leq c continue
                           if B_3(\mathbf{e}, \mathbf{g}, \mathbf{h}) = 0 continue
                           \mathtt{f} \leftarrow B_2(\mathtt{e}, \mathtt{a})
                            \  \  \, {\tt if} \  {\tt f} \le {\tt a} \  \  \, {\tt continue} \\
                           if B_3(c, f, g) = 0 continue
                           if B_3(d, f, h) = 0 continue
                           r \leftarrow r + 1
```

```
return r
```
