Properties of minimal charts and their applications VIII: charts of type (7)

Teruo NAGASE and Akiko SHIMA¹

Abstract

Let Γ be a chart, and we denote by Γ_m the union of all the edges of label m. A chart Γ is of type (7) if there exists a label m such that $w(\Gamma) = 7$, $w(\Gamma_m \cap \Gamma_{m+1}) = 7$ where w(G) is the number of white vertices in G. In this paper, we prove that there is no minimal chart of type (7).

Key Words and Phrases. surface link, chart, white vertex.

1 Introduction

Charts are oriented labeled graphs in a disk (see [1],[5], and see Section 2 for the precise definition of charts). From a chart, we can construct an oriented closed surface embedded in 4-space \mathbb{R}^4 (see [5, Chapter 14, Chapter 18 and Chapter 23]). A C-move is a local modification between two charts in a disk (see Section 2 for C-moves). A C-move between two charts induces an ambient isotopy between oriented closed surfaces corresponding to the two charts.

We will work in the PL category or smooth category. All submanifolds are assumed to be locally flat. In [16], we showed that there is no minimal chart with exactly five vertices (see Section 2 for the precise definition of minimal charts). Hasegawa proved that there exists a minimal chart with exactly six white vertices [2]. This chart represents a 2-twist spun trefoil. In [3] and [15], we investigated minimal charts with exactly four white vertices. In this paper, we investigate properties of minimal charts and need to prove that there is no minimal chart with exactly seven white vertices (see [6],[7], [8],[9], [10], [11], [12],[13]).

Let Γ be a chart. For each label m, we denote by Γ_m the union of all the edges of label m.

Now we define a type of a chart: Let Γ be a chart with at least one white vertex, and n_1, n_2, \ldots, n_k integers. The chart Γ is of $type\ (n_1, n_2, \ldots, n_k)$ if there exists a label m of Γ satisfying the following three conditions:

- (i) For each i = 1, 2, ..., k, the chart Γ contains exactly n_i white vertices in $\Gamma_{m+i-1} \cap \Gamma_{m+i}$.
- (ii) If i < 0 or i > k, then Γ_{m+i} does not contain any white vertices.

¹The second author is supported by JSPS KAKENHI Grant Number 21K03255.

(iii) Both of the two subgraphs Γ_m and Γ_{m+k} contain at least one white vertex.

If we want to emphasize the label m, then we say that Γ is of $type(m; n_1, n_2, \ldots, n_k)$. Note that $n_1 \geq 1$ and $n_k \geq 1$ by the condition (iii).

We proved in [7, Theorem 1.1] that if there exists a minimal n-chart Γ with exactly seven white vertices, then Γ is a chart of type (7), (5, 2), (4, 3), (3, 2, 2) or (2, 3, 2) (if necessary we change the label i by n - i for all label i). In [10], we showed that there is no minimal chart of type (3, 2, 2). In [11] and [12], there is no minimal chart of type (2, 3, 2). In this paper we shall show the following:

Theorem 1.1 There is no minimal chart of type (7).

In the future paper [13], we shall show there is no minimal chart of type (5,2),(4,3). Therefore we shall show that there is no minimal chart with exactly seven white vertices.

The paper is organized as follows. In Section 2, we define charts and minimal charts. In Section 3, we investigate a disk called a 2-angled disk whose boundary contains exactly two white vertices and consists of edges of label m. In Section 4, we review a lemma about a disk called a 3-angled disk whose boundary contains exactly three white vertices and consists of edges of label m. In Section 5, we investigate the graph Γ_m for a minimal chart Γ of type (m;7). In Section 6, we shall show that if Γ is a minimal chart of type (m;7), then there exist two connected components G_1 and G_2 of Γ_m (resp. Γ_{m+1}) such that G_1 contains five white vertices and G_2 contains two white vertices. In Section 7, we investigate a connected component of Γ_m with exactly five white vertices for a minimal chart Γ . In Section 8, we shall show that neither Γ_m nor Γ_{m+1} contains the graphs as shown in Fig. 12(a) and (d) for any minimal chart Γ of type (m;7). In Section 9, we review IO-Calculation (a property of numbers of inward arcs of label k and outward arcs of label k in a closed domain F with $\partial F \subset \Gamma_{k-1} \cup \Gamma_k \cup \Gamma_{k+1}$ for some label k). Moreover we shall show that neither Γ_m nor Γ_{m+1} contains the graph as shown in Fig. 12(f) for any minimal chart Γ of type (m; 7). From Section 10 to Section 14, we shall show that neither Γ_m nor Γ_{m+1} contains the graphs as shown in Fig. 12(i),(h),(e),(b),(c) for any minimal chart Γ of type (m;7). In Section 15, we shall prove Theorem 1.1.

2 Preliminaries

In this section, we introduce the definition of charts and its related words.

Let n be a positive integer. An n-chart (a braid chart of degree n [1] or a surface braid chart of degree n [5]) is an oriented labeled graph in the interior of a disk, which may be empty or have closed edges without vertices satisfying the following four conditions (see Fig. 1):

- (i) Every vertex has degree 1, 4, or 6.
- (ii) The labels of edges are in $\{1, 2, \dots, n-1\}$.
- (iii) In a small neighborhood of each vertex of degree 6, there are six short arcs, three consecutive arcs are oriented inward and the other three are outward, and these six are labeled i and i+1 alternately for some i, where the orientation and label of each arc are inherited from the edge containing the arc.
- (iv) For each vertex of degree 4, diagonal edges have the same label and are oriented coherently, and the labels i and j of the diagonals satisfy |i-j| > 1.

We call a vertex of degree 1 a *black vertex*, a vertex of degree 4 a *crossing*, and a vertex of degree 6 a *white vertex* respectively.

Among six short arcs in a small neighborhood of a white vertex, a central arc of each three consecutive arcs oriented inward (resp. outward) is called a *middle arc* at the white vertex (see Fig. 1(c)). For each white vertex v, there are two middle arcs at v in a small neighborhood of v. An edge is said to be *middle at* a white vertex v if it contains a middle arc at v.

Let e be an edge connecting v_1 and v_2 . If e is oriented from v_1 to v_2 , then we say that e is oriented outward at v_1 and inward at v_2

Figure 1: (a) A black vertex. (b) A crossing. (c) A white vertex. Each arc with three transversal short arcs is a middle arc at the white vertex.

Now *C-moves* are local modifications of charts as shown in Fig. 2 (cf. [1], [5] and [17]). Two charts are said to be *C-move equivalent* if there exists a finite sequence of C-moves which modifies one of the two charts to the other.

An edge in a chart is called a *free edge* if it has two black vertices.

For each chart Γ , let $w(\Gamma)$ and $f(\Gamma)$ be the number of white vertices, and the number of free edges respectively. The pair $(w(\Gamma), -f(\Gamma))$ is called a *complexity* of the chart (see [4]). A chart Γ is called a *minimal chart* if its complexity is minimal among the charts C-move equivalent to the chart Γ with respect to the lexicographic order of pairs of integers.

We showed the difference of a chart in a disk and in a 2-sphere (see [6, Lemma 2.1]). This lemma follows from that there exists a natural one-to-one correspondence between {charts in S^2 }/C-moves and {charts in D^2 }/C-

Figure 2: For the C-III move, the edge with the black vertex is not middle at a white vertex in the left figure.

moves, conjugations ([5, Chapter 23 and Chapter 25]). To make the argument simple, we assume that the charts lie on the 2-sphere instead of the disk.

Assumption 1 In this paper, all charts are contained in the 2-sphere S^2 .

We have the special point in the 2-sphere S^2 , called the point at infinity, denoted by ∞ . In this paper, all charts are contained in a disk such that the disk does not contain the point at infinity ∞ .

An edge in a chart is called a *terminal edge* if it has a white vertex and a black vertex.

Let Γ be a chart, and m a label of Γ . A hoop is a closed edge of Γ without vertices (hence without crossings, neither). A ring is a simple closed curve in Γ_m containing a crossing but not containing any white vertices. A hoop is said to be simple if one of the two complementary domains of the hoop does not contain any white vertices.

We can assume that all minimal charts Γ satisfy the following four conditions (see [6],[7],[8], [14]):

Assumption 2 If an edge of Γ contains a black vertex, then the edge is a free edge or a terminal edge. Moreover any terminal edge contains a middle arc.

Assumption 3 All free edges and simple hoops in Γ are moved into a small neighborhood U_{∞} of the point at infinity ∞ . Hence we assume that Γ does not contain free edges nor simple hoops, otherwise mentioned.

Figure 3: m is a label, and $\varepsilon \in \{+1, -1\}$.

Assumption 4 Each complementary domain of any ring and hoop must contain at least one white vertex.

Assumption 5 The point at infinity ∞ is moved in any complementary domain of Γ .

In this paper for a set X in a space we denote the interior of X, the boundary of X and the closure of X by Int X, ∂X and Cl(X) respectively.

Let α be a simple arc or an edge, and p,q the endpoints of α . We denote $\partial \alpha = \{p,q\}$.

3 2-angled disks

In this section, we investigate a disk called a 2-angled disk whose boundary contains exactly two white vertices and consists of edges of label m.

Let Γ be a chart, m a label of Γ , D a disk with $\partial D \subset \Gamma_m$, and k a positive integer. If ∂D contains exactly k white vertices, then D is called a k-angled disk of Γ_m . Note that the boundary ∂D may contain crossings.

Let Γ be a chart, and m a label of Γ . An edge of label m is called a *feeler* of a k-angled disk D of Γ_m if the edge intersects $N-\partial D$ where N is a regular neighborhood of ∂D in D.

Let X be a set in a chart Γ . Let

w(X) = the number of white vertices in X.

Let Γ be a chart. Suppose that an object consists of some edges of Γ , arcs in edges of Γ and arcs around white vertices. Then the object is called a *pseudo chart*.

Lemma 3.1 ([7, Corollary 5.8]) Let Γ be a minimal chart. Let D be a 2-angled disk of Γ_m with at most one feeler. If $w(\Gamma \cap \text{Int} D) = 0$, then a regular neighborhood of D contains one of two pseudo charts as shown in Fig. 3.

By Lemma 3.1, we have the following lemma:

Lemma 3.2 Let Γ be a minimal chart, and m a label of Γ . Let D be a 2-angled disk D of Γ_m with at most one feeler. If D satisfies one of the following two conditions, then $w(\Gamma \cap \operatorname{Int} D) \geq 1$.

- (a) D has one feeler.
- (b) D has no feeler, and the boundary ∂D is oriented clockwise or anticlockwise.

In our argument we often construct a chart Γ . On the construction of a chart Γ , for a white vertex $w \in \Gamma_m$ for some label m, among the three edges of Γ_m containing w, if one of the three edges is a terminal edge (see Fig. 4(a) and (b)), then we remove the terminal edge and put a black dot at the center of the white vertex as shown in Fig. 4(c). Namely Fig. 4(c) means Fig. 4(a) or Fig. 4(b). We call the vertex in Fig. 4(c) a BW-vertex with respect to Γ_m .

Figure 4: (a),(b) White vertices in terminal edges. (c),(d),(e) BW-vertices.

Lemma 3.3 ([10, Lemma 3.1]) In a minimal chart Γ , for each BW-vertex in Γ_m , the two edges of label m containing the BW-vertex are oriented inward or outward at the BW-vertex simultaneously if each of the two edges is not a terminal edge (see Fig. 4(d) and (e)).

The three graphs in Fig. 5 are examples of graphs in Γ_m for a chart Γ and a label m. We call a θ -curve, an oval, a skew θ -curve the three graphs as shown in Fig. 5(a),(b),(c) respectively.

Let Γ be a chart, and m a label of Γ . Let L be the closure of a connected component of the set obtained by taking out all the white vertices from Γ_m . If L contains at least one white vertex but does not contain any black vertex, then L is called an *internal edge of label* m. Note that an internal edge may contain a crossing of Γ .

Lemma 3.4 Let Γ be a minimal chart, and m a label of Γ . Let G be a θ -curve in Γ_m . Then there exist two connected components of $S^2 - G$ each of which contains at least one white vertex.

Figure 5: (a) A θ -curve. (b) An oval. (c) A skew θ -curve.

Figure 6: The light gray region is F_1 , and the dark gray region is F_2 .

Proof. Let w_1, w_2 be the white vertices in G, and e_1, e_2, e_3 the three internal edges of label m in G such that e_1 is middle at w_1 .

Let F_1, F_2 be the connected components of $S^2 - G$ with $\partial F_1 = e_1 \cup e_2$ and $\partial F_2 = e_1 \cup e_3$ (see Fig. 6). Then both of $Cl(F_1)$ and $Cl(F_2)$ are 2-angled disks without feelers.

Without loss of generality we can assume that e_1 is oriented from w_1 to w_2 . Since e_1 is middle at w_1 , the two edges e_2, e_3 are oriented from w_2 to w_1 (see Fig. 6). Thus ∂F_1 and ∂F_2 are oriented clockwise or anticlockwise. Hence by Lemma 3.2(b), we have $w(\Gamma \cap F_1) \geq 1$ and $w(\Gamma \cap F_2) \geq 1$.

Lemma 3.5 ([7, Lemma 6.7]) Let Γ be a minimal chart, and m a label of Γ . Let D be a 2-angled disk of Γ_m with two feelers such that ∂D is contained in an oval of label m. Then $w(\Gamma \cap \operatorname{Int} D) \geq 2$.

Lemma 3.6 Let Γ be a minimal chart, and m a label of Γ . Let D be a 2-angled disk of Γ_m without feelers, and w_1, w_2 the white vertices in ∂D . Let e_1, e_2 be the internal edges (possibly terminal edges) of label m at w_1, w_2 , respectively, such that $e_1 \not\subset D$ and $e_2 \not\subset D$. Suppose that the two edges e_1, e_2 are oriented inward (resp. outward) at w_1, w_2 , respectively (see Fig. 7(a) and (b)). Then we have the following.

- (a) $w(\Gamma \cap \text{Int}D) \geq 1$.
- (b) If D contains an oval of label m, then $w(\Gamma \cap \text{Int} D) \geq 3$.

Proof. Suppose that e_1, e_2 are oriented inward at w_1, w_2 , respectively.

We shall show Statement (a). Let e_3, e_4 be the internal edges in ∂D . Without loss of generality we can assume that e_3 is oriented from w_1 to w_2 . Since both of e_2 and e_3 are oriented inward at w_2 , the edge e_4 is oriented from w_2 to w_1 (see Fig. 7(c)). Hence by Lemma 3.2(b), we have $w(\Gamma \cap \text{Int} D) \geq 1$.

We shall show Statement (b). Suppose that the disk D contains an oval of label m, say G. Let E be the 2-angled disk of Γ_m in D with $\partial E \subset G$. There are three cases: (i) E has two feelers, (ii) E has one feeler, (iii) E has no feeler.

Case (i). Since ∂E is contained in the oval G, by Lemma 3.5 we have $w(\Gamma \cap \operatorname{Int} E) \geq 2$. Thus the condition $E \subset \operatorname{Int} D$ implies $w(\Gamma \cap \operatorname{Int} D) \geq 4 \geq 3$.

Figure 7: The gray region is the disk E.

Case (ii). By Lemma 3.2(a), we have $w(\Gamma \cap \text{Int} E) \geq 1$. Hence we have $w(\Gamma \cap \text{Int} D) \geq 3$.

Case (iii). We use the orientations as shown in Fig. 7(c). Let e'_1, e'_2 be internal edges (possibly terminal edges) of label $m \pm 1$ at w_1, w_2 , respectively, in D. Since the edges e_1, e_2 are oriented inward at w_1, w_2 , respectively,

(1) the edges e'_1, e'_2 are oriented outward at w_1, w_2 , respectively.

Moreover since e_4 , e_3 are oriented inward at w_1 , w_2 , respectively, neither e'_1 nor e'_2 is middle at w_1 or w_2 . Thus by Assumption 2,

(2) neither e'_1 nor e'_2 is a terminal edge.

Let w_3, w_4 be the white vertices in the oval G. Since the disk D contains the oval G, by Lemma 3.3 the two internal edges in ∂E are oriented inward at w_3 or oriented outward at w_3 . Without loss of generality we can assume that the two internal edges in ∂E are oriented inward at w_3 . Since E has no feeler, the disk D contains the pseudo chart as shown in Fig. 7(d).

If $w(\Gamma \cap (\operatorname{Int} D - E)) = 0$, then by (1) and (2) both of e'_1 and e'_2 contain w_4 . Hence the condition $w(\Gamma \cap (\operatorname{Int} D - E)) = 0$ implies that there exist two terminal edges of label $m \pm 1$ at w_3 . However this contradicts Assumption 2. Thus $w(\Gamma \cap (\operatorname{Int} D - E)) \geq 1$. Therefore $w(\Gamma \cap \operatorname{Int} D) \geq 3$.

Similarly, we can show Statement (a) and (b) for the case that e_1, e_2 are oriented outward at w_1, w_2 , respectively. Thus we complete the proof of Lemma 3.6.

4 3-angled disks

In this section, we review a lemma about a 3-angled disk.

Let Γ and Γ' be C-move equivalent charts. Suppose that a pseudo chart X of Γ is also a pseudo chart of Γ' . Then we say that Γ is modified to Γ' by

C-moves keeping X fixed. In Fig. 8, we give examples of C-moves keeping pseudo charts fixed.

Figure 8: C-moves keeping thicken figures fixed.

Let X be a set in a chart Γ . Let

c(X) = the number of crossings in X.

Let D be a k-angled disk of Γ_m for a minimal chart Γ . The pair of integers $(w(\Gamma \cap \text{Int}D), c(\Gamma \cap \partial D))$ is called the *local complexity with respect to* D, denoted by $\ell c(D; \Gamma)$. Let $\mathbb S$ be the set of all minimal charts each of which can be moved from Γ by C-moves in a regular neighborhood of D keeping ∂D fixed. The chart Γ is said to be *locally minimal with respect to* D if its local complexity with respect to D is minimal among the charts in $\mathbb S$ with respect to the lexicographic order.

Let Γ be a chart, and D a k-angled disk of Γ_m . If any feeler of D of label m is a terminal edge, then D is called a *special* k-angled disk.

Let Γ be a chart, D a disk, and G a pseudo chart with $G \subset D$. Let $r: D \to D$ be a reflection of D, and G^* the pseudo chart obtained from G by changing the orientations of all of the edges. Then the set $\{G, G^*, r(G), r(G^*)\}$ is called the RO-family of the pseudo chart G.

Lemma 4.1 ([8, Theorem 1.2]) Let Γ be a minimal chart. Let D be a special 3-angled disk of Γ_m such that Γ is locally minimal with respect to D. If $w(\Gamma \cap \operatorname{Int} D) = 0$, then a regular neighborhood of D contains one of the RO-families of the two pseudo charts as shown in Fig. 9.

Figure 9: The 3-angled disks without feelers. m is a label, $\varepsilon \in \{+1, -1\}$.

By Lemma 4.1, we have the following lemma:

Lemma 4.2 Let Γ be a minimal chart, and m a label of Γ . Let D be a special 3-angled disk D of Γ_m such that Γ is locally minimal chart with respect to D. If D satisfies one of the following two conditions, then $w(\Gamma \cap \operatorname{Int} D) \geq 1$.

- (a) D has at least one feeler.
- (b) D has no feeler, and the boundary ∂D is oriented clockwise or anticlockwise.

5 Types of Γ_m for a minimal chart of type (m;7)

In this section, we investigate the graph Γ_m for a minimal chart Γ of type (m;7).

Let Γ be a chart, and m a label of Γ . A *loop* is a simple closed curve in Γ_m with exactly one white vertex (possibly with crossings).

Lemma 5.1 ([10, Lemma 3.2]) Let Γ be a minimal chart, and m a label of Γ . Let G be a connected component of Γ_m . Then we have the following.

- (a) If 1 < w(G), then 2 < w(G).
- (b) If $1 \le w(G) \le 3$ and G does not contain any loop, then G is one of three graphs as shown in Fig. 5.

Let Γ be a chart, and m a label of Γ . Let G_1, G_2, \dots, G_k be all of the connected components of Γ_m each of which contains at least one white vertex. For $i = 1, 2, \dots, k$, we put $n_i = w(G_i)$. Without loss of generality we can assume $n_1 \geq n_2 \geq \dots \geq n_k$. Then we say that Γ_m is of type (n_1, n_2, \dots, n_k) .

Lemma 5.2 Let Γ be a minimal chart of type (m;7). Then Γ_m (resp. Γ_{m+1}) is of type (7), (5,2), (4,3), or (3,2,2).

Proof. If Γ_m is of type (n_1, n_2, \dots, n_k) , then by Lemma 5.1(a) we have $n_i \geq 2$ for $i = 1, 2, \dots, k$. Since Γ is of type (m; 7), we have $7 = w(\Gamma_m) = n_1 + n_2 + \dots + n_k$.

If k > 4, then

$$7 = n_1 + n_2 + \dots + n_k \ge n_1 + n_2 + n_3 + n_4 \ge 2 + 2 + 2 + 2 = 8.$$

This is a contradiction. Hence $1 \le k \le 3$.

If k = 1, then $n_1 = 7$. Hence Γ_m is of type (7). If k = 2, then $n_1 + n_2 = 7$, $n_1 \geq 2$ and $n_2 \geq 2$. Hence Γ_m is of type (5,2) or (4,3). If k = 3, then $n_1 + n_2 + n_3 = 7$, $n_1 \geq 2$, $n_2 \geq 2$ and $n_3 \geq 2$. Hence Γ_m is of type (3,2,2). Therefore Γ_m is of type (7), (5,2), (4,3) or (3,2,2).

Similarly we can show that Γ_{m+1} is of type (7), (5,2), (4,3) or (3,2,2).

Lemma 5.3 ([9, Theorem 1.1]) There is no loop in any minimal chart with exactly seven white vertices.

Lemma 5.4 Let Γ be a minimal chart of type (m;7). Then Γ_m (resp. Γ_{m+1}) is neither of type (4,3) nor of type (3,2,2).

Proof. Suppose that Γ_m is either of type (4,3) or of type (3,2,2). Then there exists a connected component G of Γ_m with w(G)=3. By Lemma 5.1(b) and Lemma 5.3, the graph G is a skew θ -curve. Let e_1 be the terminal edge in G. Let D_1, D_2 be the closures of connected components of $S^2 - G$ such that $D_1 \supset e_1$ and D_2 is a 2-angled disk. Without loss of generality, we can assume that Γ is locally minimal with respect to D_1 . Since D_1 is a special 3-angled disk with one feeler e_1 , by Lemma 4.2(a) we have

(1) $w(\Gamma \cap \operatorname{Int} D_1) \geq 1$.

Claim 1. $w(\Gamma \cap \operatorname{Int} D_2) \geq 1$.

Proof of Claim 1. First, we shall show that Γ contains the graph as shown in Fig. 10. Let w_1 be the white vertex in e_1 . Let e_2, e_3 be the internal edges of label m at w_1 . Let w_2, w_3 be the white vertices different from w_1 in e_2, e_3 , respectively. Without loss of generality we can assume that the terminal edge e_1 is oriented inward at w_1 . By Assumption 2, both of e_2 and e_3 are oriented outward at w_1 . Thus the edges e_2, e_3 are oriented inward at w_2, w_3 , respectively (see Fig. 10).

Since the two white vertices w_2, w_3 are contained in ∂D_2 , by Lemma 3.6(a) we have $w(\Gamma \cap \text{Int} D_2) \geq 1$. Hence Claim 1 holds.

By (1) and Claim 1, each of $\operatorname{Int} D_1$ and $\operatorname{Int} D_2$ contains at least one white vertex. Let w_4, w_5 be white vertices in $\operatorname{Int} D_1$, $\operatorname{Int} D_2$, respectively. Since Γ is of type (m; 7), we have $w_4, w_5 \in \Gamma_m$. Let G_1, G_2 be the connected components of Γ_m with $w_4 \in G_1$ and $w_5 \in G_2$. Then Γ_m contains at least three connected components G, G_1, G_2 each of which contains a white vertex. Since Γ_m is of type (4, 3) or of type (3, 2, 2), the set Γ_m is of type (3, 2, 2). Thus the condition w(G) = 3 implies $w(G_1) = 2$ and $w(G_2) = 2$.

Claim 2. $w(\Gamma \cap \operatorname{Int} D_2) \geq 3$.

Proof of Claim 2. By Lemma 5.1(b) and Lemma 5.3, there are two cases: (i) G_2 is a θ -curve, (ii) G_2 is an oval.

Case (i). Let E_1, E_2 be the closures of the connected components of $D_2 - G_2$ which are 2-angled disks. Then by Lemma 3.4, one of E_1 and E_2 contains at least one white vertex in its interior. Thus $w(\Gamma \cap \text{Int} D_2) \geq 3$.

Case (ii). Since the 2-angled disk D_2 contains an oval G_2 of label m and since the two edges e_2, e_3 are oriented inward at w_2, w_3 , respectively (see Fig. 10), we have $w(\Gamma \cap \text{Int}D_2) \geq 3$ by Lemma 3.6(b). Hence Claim 2 holds.

Since Γ is of type (m;7), we have $w(\Gamma)=7$. Thus by Claim 2, we have

$$7 = w(\Gamma) \ge w(G) + w(G_1) + w(\Gamma \cap \text{Int}D_2) \ge 3 + 2 + 3 = 8.$$

Figure 10: The gray region is the disk D_1 .

This is a contradiction. Therefore Γ_m is neither of type (4,3) nor of type (3,2,2).

Similarly we can show that Γ_{m+1} is neither of type (4,3) nor of type (3,2,2). Hence we complete the proof of Lemma 5.4.

6 Rings

In this section, we shall show that if Γ is a minimal chart of type (m; 7), then both of Γ_m and Γ_{m+1} are of type (5, 2).

Lemma 6.1 Let Γ be a minimal chart of type (m;7). If Γ contains a ring or a non-simple hoop of label m-1 (resp. m+2), then Γ_m (resp. Γ_{m+1}) is of type (5,2).

Proof. Suppose that Γ contains a ring or a non-simple hoop of label m-1. Let C be the ring or the non-simple hoop. Let F_1, F_2 be the connected components of S^2-C . Then by Assumption 4, each of F_1 and F_2 contains at least one white vertex. Let w_i be the white vertex in F_i (i=1,2). Since Γ is of type (m;7), we have $w_1, w_2 \in \Gamma_m$. Let G_1, G_2 be the connected component of Γ_m with $w_i \in G_i$ (i=1,2). Since the curve C of label m-1 does not intersect Γ_m , the condition $w_i \in F_i$ (i=1,2) implies $G_i \subset F_i$. Thus the condition $F_1 \cap F_2 = \emptyset$ implies $G_1 \cap G_2 = \emptyset$. Hence Γ_m contains at least two connected components with white vertices. Thus by Lemma 5.2 and Lemma 5.4, the set Γ_m is of type (5,2).

Similarly we can show that if Γ contains a ring or a non-simple hoop of label m+2, then the set Γ_{m+1} is of type (5,2).

Lemma 6.2 ([8, Lemma 6.7]) Let Γ be a minimal chart of type $(m; n_1)$. Then there exists a ring or a non-simple hoop of label m-1 or m+2.

Lemma 6.3 Let Γ be a minimal chart of type (m;7). Then both of Γ_m and Γ_{m+1} are of type (5,2). Moreover we have the following.

(a) Let G be the connected component of Γ_m (resp. Γ_{m+1}) with w(G) = 5. Then there exists a connected component F of $S^2 - G$ with $w(\Gamma \cap F) = 2$.

Figure 11: $(k = m, \varepsilon = +1)$ or $(k = m + 1, \varepsilon = -1)$.

- (b) The other connected components of $S^2 G$ do not contain any white vertices.
- (c) The domain F contains an oval of label m (resp. m+1) as shown in Fig. 11.
- (d) $w(\Gamma \cap F') = 0$ or $w(\Gamma \cap F') = 2$ for each connected component F' of $S^2 G$.

Proof. Since Γ is of type (m;7), by Lemma 6.2 there exists a ring or a non-simple hoop of label m-1 or m+2.

Now suppose that there exists a ring or a non-simple hoop of label m-1. Then by Lemma 6.1 the set Γ_m is of type (5,2). Let G, G' be the connected components of Γ_m with w(G) = 5 and w(G') = 2. Then $G \cap G' = \emptyset$ implies that the graph G' is contained in a connected component F of $S^2 - G$. Thus $w(\Gamma \cap F) \geq 2$. If $w(\Gamma \cap F) > 2$, then

$$7 = w(\Gamma) \ge w(G) + w(\Gamma \cap F) > 5 + 2 = 7.$$

This is a contradiction. Hence $w(\Gamma \cap F) = 2$. Thus Statement (a) holds.

Similarly we can show Statement (b). Statement (d) follows from Statement (a) and (b).

We shall show Statement (c). By Lemma 5.1(b) and Lemma 5.3 there are two cases: (i) G' is a θ -curve, (ii) G' is an oval.

Case (i). By the similar way to the proof of Case (i) of Claim 2 in Lemma 5.4, we have $w(\Gamma \cap F) \geq 3$. This contradicts Statement (d). Hence Case (i) does not occur.

Case (ii). Let D be the 2-angled disk of Γ_m with $\partial D \subset G'$ and $D \subset F$. Thus the condition $w(\Gamma \cap F) = 2$ implies $w(\Gamma \cap \text{Int}D) = 0$. Hence by Lemma 3.1, a regular neighborhood of D contains one of two pseudo charts as shown in Fig. 3. Since Γ is of type (m;7), the two white vertices in ∂D are contained in $\Gamma_m \cap \Gamma_{m+1}$. Thus a regular neighborhood of D contains the pseudo chart as shown in Fig. 3(b) where $\varepsilon = +1$. Hence the domain F contains the pseudo chart as shown in Fig. 11 where k = m and $\varepsilon = +1$. Thus Statement (c) holds.

Moreover the disk D intersects two proper arcs of label m+2. Hence the chart Γ contains a ring of label m+2. Thus by Lemma 6.1, the set Γ_{m+1} is

of type (5,2). Similarly for the set Γ_{m+1} we can show the four statements in this lemma.

Similarly if there exists a ring or a non-simple hoop of label m+2, we can show this lemma. Hence we complete the proof of Lemma 6.3.

7 Connected components of Γ_m with exactly five white vertices

In this section, we investigate a connected component of Γ_m with exactly five white vertices for a minimal chart Γ .

Lemma 7.1 ([11, Lemma 3.4]) Let Γ be a minimal chart, and m a label of Γ . Let G be a connected component of Γ_m . If w(G) = 5 and G has no loop, then G is one of nine graphs as shown in Fig. 12.

Figure 12: (a),(b),(c) Graphs with three black vertices. (d),(e),(f) Graphs with one black vertex. (g),(h) Graphs with three black vertices. (i) A graph with one black vertex.

Lemma 7.2 Let Γ be a minimal chart, and m a label of Γ . Let G be a connected component of Γ_m with w(G) = 5. Then we have the following:

(a) If G is the graph as shown in Fig. 12(a) (resp. Fig. 12(b)), then G is one of the RO-family of the graph as shown in Fig. 13(a) (resp. Fig. 13(b)).

- (b) Suppose that G is the graph as shown in Fig. 12(c). If necessary we move the point at infinity ∞ , then G is one of the RO-family of the graph as shown in Fig. 13(c).
- (c) If G is the graph as shown in Fig. 12(d) (resp. Fig. 12(e), (g), (h)), then G is one of the RO-family of the graph as shown in Fig. 13(d) (resp. Fig. 13(e), (f), (g)).

Figure 13: Connected components of Γ_m with five white vertices.

Proof. We show only this lemma for the case that the graph G is one of the three graphs as shown in Fig. 12(b),(c),(g).

Suppose that G is the graph as shown in Fig. 12(b). We use the notations as shown in Fig. 14(a), where w_1, w_2, w_3 are BW-vertices, e_1, e_2, \dots, e_6 are the six internal edges of label m with $e_1 \cap e_2 \ni w_1$, $\partial e_3 = \{w_4, w_5\}$, $\partial e_4 = \{w_2, w_4\}$, $\partial e_5 = \{w_2, w_3\}$, $\partial e_6 = \{w_3, w_5\}$.

Without loss of generality we can assume that the terminal edge of label m at w_1 is oriented inward at w_1 . Then by Assumption 2, both of e_1 and e_2 are oriented outward at w_1 . Thus

(1) e_2 is oriented inward at w_5 .

If necessary we reflect the chart Γ , we can assume that the edge e_3 is oriented from w_4 to w_5 . Hence by (1), both of e_2 and e_3 are oriented inward at w_5 . Thus the edge e_6 is oriented from w_5 to w_3 . Hence by Lemma 3.3, the edge e_5 is oriented from w_2 to w_3 and the edge e_4 is oriented from w_2 to w_4 . Thus the graph G is the graph as shown in Fig. 13(b).

Suppose that G is the graph as shown in Fig. 12(c). We use the notations as shown in Fig. 14(b), where w_3, w_4, w_5 are BW-vertices, e_1, e_2, \dots, e_6 are the six internal edges of label m with $w_1 \in e_1 \cap e_2 \cap e_3$, $w_2 \in e_4 \cap e_5 \cap e_6$, $w_3 \in e_1 \cap e_4$, $w_4 \in e_2 \cap e_5$, $w_5 \in e_3 \cap e_6$.

If necessary we move the point at infinity ∞ by Assumption 5, we can assume that

(2) e_1 is middle at w_1 .

Moreover we can assume that the edge e_1 is oriented inward at w_1 . Then by (2), both of e_2 and e_3 are oriented outward at w_1 . Thus e_1 is oriented outward at w_3 , and e_2 , e_3 are oriented inward at w_4 , w_5 , respectively. Hence by Lemma 3.3, the edge e_4 is oriented outward at w_3 , and e_5 , e_6 are oriented inward at w_4 , w_5 , respectively. Thus the graph G is the graph as shown in Fig. 13(c).

Suppose that G is the graph as shown in Fig. 12(g). We use the notations as shown in Fig. 14(c), where w_1, w_4, w_5 are BW-vertices, e_1, e_2, \dots, e_6 are the six internal edges of label m with $e_1 \cap e_2 \ni w_1, w_2, \partial e_3 = \{w_2, w_3\}, \partial e_4 = \{w_3, w_4\}, \partial e_5 = \{w_4, w_5\}, \partial e_6 = \{w_3, w_5\}.$

Without loss of generality we can assume that the terminal edge of label m at w_1 is oriented inward at w_1 . Then by Assumption 2, both of e_1, e_2 are oriented from w_1 to w_2 . Thus the edge e_3 is oriented from w_2 to w_3 .

For the edge e_4 , there are two cases: (i) e_4 is oriented from w_3 to w_4 , (ii) e_4 is oriented from w_4 to w_3 .

Case (i). By Lemma 3.3, the edge e_5 is oriented from w_5 to w_4 and the edge e_6 is oriented from w_5 to w_3 . Thus G is the graph as shown in Fig. 13(f).

Case (ii). By Lemma 3.3, the edge e_5 is oriented from w_4 to w_5 and the edge e_6 is oriented from w_3 to w_5 . Thus by reflecting the chart Γ , the graph G is the graph as shown in Fig. 13(f).

Figure 14: (a) w_1, w_2, w_3 are BW-vertices. (b) w_3, w_4, w_5 are BW-vertices. (c) w_1, w_4, w_5 are BW-vertices.

8 Cases of the graphs as shown in Fig. 12(a) and (d)

In this section, we shall show that neither Γ_m nor Γ_{m+1} contains the graphs as shown in Fig. 12(a) and (d) for any minimal chart Γ of type (m; 7).

Lemma 8.1 Let Γ be a minimal chart of type (m;7). Let D be a 2-angled disk of Γ_m without feelers, and w_1, w_2 the white vertices in ∂D . Let e_1, e_2 be the internal edges (possibly terminal edges) of label m at w_1, w_2 , respectively,

such that $e_1 \not\subset D$ and $e_2 \not\subset D$. Then one of e_1, e_2 is oriented inward at w_1 or w_2 , and the other is oriented outward at w_1 or w_2 .

Proof. Since Γ is of type (m;7), by Lemma 6.3 the set Γ_m is of type (5,2). Thus the boundary ∂D is contained in a connected component G of Γ_m with w(G) = 5 or w(G) = 2.

If w(G) = 2, then by Lemma 6.3(c) the graph G is an oval as shown in Fig. 11 where k = m and $\varepsilon = +1$. Hence both of e_1, e_2 are terminal edges, and one of e_1, e_2 is oriented inward at w_1 or w_2 , and the other is oriented inward at w_1 or w_2 .

Now suppose w(G) = 5. If e_1, e_2 are oriented inward at w_1, w_2 , respectively, then by Lemma 3.6(a) we have $w(\Gamma \cap \text{Int}D) \geq 1$. Hence by Lemma 6.3, the disk D contains an oval of label m as shown in Fig. 11 where k = m and $\varepsilon = +1$. Thus by Lemma 3.6(b), we have $w(\Gamma \cap \text{Int}D) \geq 3$. This contradicts Lemma 6.3(d). Therefore one of e_1, e_2 is oriented outward at w_1 or w_2 .

Similarly if e_1, e_2 are oriented outward at w_1, w_2 , respectively, then we have the same contradiction. Therefore one of e_1, e_2 is oriented inward at w_1 or w_2 .

Lemma 8.2 Let Γ be a minimal chart of type (m;7). Then neither Γ_m nor Γ_{m+1} contains the graph as shown in Fig. 12(a).

Proof. Suppose that Γ_m contains the graph as shown in Fig. 12(a), say G. By Lemma 7.2(a), the graph G is one of the RO-family of the graph as shown in Fig. 13(a). Without loss of generality we can assume that G is the graph as shown in Fig. 13(a).

Let D be the 2-angled disk of Γ_m without feelers with $\partial D \subset G$, and w_1, w_2 the two white vertices in ∂D . Let e_1, e_2 be the internal edges of label m at w_1, w_2 , respectively, with $e_1 \not\subset \partial D$ and $e_2 \not\subset \partial D$. Then the two edges e_1, e_2 are oriented inward at w_1, w_2 , respectively (see Fig. 15(a)). However this contradicts Lemma 8.1. Therefore Γ_m does not contain the graph as shown in Fig. 12(a).

Similarly we can show that Γ_{m+1} does not contain the graph as shown in Fig. 12(a).

Lemma 8.3 Let Γ be a minimal chart of type (m;7). Then neither Γ_m nor Γ_{m+1} contains the graph as shown in Fig. 12(d).

Proof. Suppose that Γ_m contains the graph as shown in Fig. 12(d), say G. By Lemma 7.2(c), the graph G is one of the RO-family of the graph as shown in Fig. 13(d). Without loss of generality we can assume that G is the graph as shown in Fig. 13(d). We use the notations as shown in Fig 15(b), where e_1, e_2 are internal edges of label m with $\partial e_1 = \{w_1, w_3\}$ and $\partial e_2 = \{w_2, w_4\}$.

Figure 15: (a) The graph as shown in Fig. 12(a). (b) The graph as shown in Fig. 12(d).

Let D be the 2-angled disks of Γ_m without feelers with $\partial D \ni w_1, w_2$. Then the two edges e_1, e_2 are oriented outward at w_1, w_2 , respectively (see Fig. 15(b)). However this contradicts Lemma 8.1. Therefore Γ_m does not contain the graph as shown in Fig. 12(d).

Similarly we can show that Γ_{m+1} does not contain the graph as shown in Fig. 12(d).

9 IO-Calculation

In this section, we shall show that neither Γ_m nor Γ_{m+1} contains the graph as shown in Fig. 12(f) for any minimal chart Γ of type (m; 7).

Let Γ be a chart, and v a vertex. Let α be a short arc of Γ in a small neighborhood of v such that v is an endpoint of α . If the arc α is oriented to v, then α is called an inward arc, and otherwise α is called an outward arc.

Let Γ be an n-chart. Let F be a closed domain with $\partial F \subset \Gamma_{k-1} \cup \Gamma_k \cup \Gamma_{k+1}$ for some label k of Γ , where $\Gamma_0 = \emptyset$ and $\Gamma_n = \emptyset$. By Condition (iii) for charts, in a small neighborhood of each white vertex, there are three inward arcs and three outward arcs. Also in a small neighborhood of each black vertex, there exists only one inward arc or one outward arc. We often use the following fact, when we fix (inward or outward) arcs near white vertices and black vertices:

(*) The number of inward arcs contained in $F \cap \Gamma_k$ is equal to the number of outward arcs in $F \cap \Gamma_k$.

When we use this fact, we say that we use *IO-Calculation with respect to* Γ_k in F. For example, in a minimal chart Γ , consider the pseudo chart as shown in Fig. 16 where

- (1) v_1, v_2, \dots, v_5 are five white vertices in $\Gamma_{k-1} \cap \Gamma_k$,
- (2) D_1 is a 3-angled disk of Γ_{k-1} without feelers with $\partial D_1 \ni v_1, v_2, v_3$,
- (3) D_1 contains an oval G of label k-1 with $G \ni v_4, v_5$,

Figure 16: The gray region is F.

(4) e_1, e_2, e_3 are internal edges (possibly terminal edges) of label k at v_1, v_2, v_3 , respectively.

Let D_2 be the 2-angled disk of Γ_{k-1} in D_1 with $\partial D_2 \subset G$. Set $F = Cl(D_1 - D_2)$. If none of e_1, e_2, e_3 are middle at v_1, v_2, v_3 , respectively, then we can show that $w(\Gamma \cap \operatorname{Int} F) \geq 1$. Suppose $w(\Gamma \cap \operatorname{Int} F) = 0$. By Assumption 2,

(5) none of edges e_1, e_2, e_3 are terminal edges.

Let e'_4, e''_4, e'_5, e''_5 be internal edges (possibly terminal edges) of label k such that e'_4, e''_4 are oriented inward at v_4 and e'_5, e''_5 are oriented outward at v_5 . Since none of edges e'_4, e''_4, e'_5, e''_5 are middle at v_4 or v_5 , by Assumption 2

(6) none of edges e'_4, e''_4, e'_5, e''_5 are terminal edges.

If the edges e_1, e_2, e_3 are oriented inward at v_1, v_2, v_3 , respectively, then by (5) and (6) the number of inward arcs in $F \cap \Gamma_k$ is five, but the number of outward arcs in $F \cap \Gamma_k$ is two. This contradicts the fact (*). Similarly for the other cases we have the same contradiction. Thus $w(\Gamma \cap \text{Int} F) \geq 1$. Instead of the above argument, we just say that if none of e_1, e_2, e_3 are middle at v_1, v_2, v_3 , respectively, then

we have $w(\Gamma \cap \operatorname{Int} F) \geq 1$ by IO-Calculation with respect to Γ_k in F.

Lemma 9.1 Let Γ be a minimal chart of type (m;7). Then there does not exist a 3-angled disk D of Γ_m without feelers such that ∂D is oriented clockwise or anticlockwise.

Proof. Suppose that there exists a 3-angled disk D of Γ_m without feelers such that ∂D is oriented clockwise or anticlockwise. Without loss of generality, we can assume that Γ is locally minimal with respect to D. Then by Lemma 4.2(b) we have $w(\Gamma \cap \operatorname{Int} D) \geq 1$.

Let G be the connected component of Γ_m with $G \supset \partial D$. Since Γ is of type (m;7), by Lemma 6.3 the graph Γ_m is of type (5,2). Thus we have

w(G) = 5. Hence by Lemma 6.3, the condition $w(\Gamma \cap \text{Int}D) \ge 1$ implies that the disk D contains an oval of label m as shown in Fig. 11 where k = m and $\varepsilon = +1$.

Let w_1, w_2, w_3 be the white vertices in ∂D , and e_1, e_2, e_3 internal edges (possibly terminal edges) of label m+1 at w_1, w_2, w_3 , respectively, in D. Let D' be the 2-angled disk of Γ_m in D without feelers. Since ∂D is oriented clockwise or anticlockwise, none of e_1, e_2, e_3 are middle at w_1, w_2, w_3 , respectively. Thus considering as $D_1 = D$, $D_2 = D'$, F = Cl(D - D') and k = m+1 in the example of IO-Calculation in this section, we have $w(\Gamma \cap (\operatorname{Int} D - D')) \geq 1$. Hence $w(\Gamma \cap \operatorname{Int} D) \geq 3$. This contradicts Lemma 6.3(d). Therefore there does not exist a 3-angled disk D of Γ_m without feelers such that ∂D is oriented clockwise or anticlockwise.

Lemma 9.2 Let Γ be a minimal chart of type (m;7). Then neither Γ_m nor Γ_{m+1} contains the graph as shown in Fig. 12(f).

Proof. Suppose that Γ_m contains the graph as shown in Fig. 12(f). We use the notations as shown in Fig. 17(a), where w_1 is the BW-vertex, and $e'_1, e''_1, e'_2, e''_2, e''_3, e''_3, e_4$ are seven internal edges of label m with $e'_1 \cap e''_1 \ni w_1$, $e'_1 \cap e'_2 \cap e''_2 \ni w_2$, $e''_1 \cap e'_3 \cap e''_3 \ni w_3$, and $\partial e_4 = \{w_4, w_5\}$. Let D_1, D_2 be the 3-angled disks of Γ_m without feelers with $\partial D_1 = e'_3 \cup e''_3 \cup e_4$ and $\partial D_2 = e'_2 \cup e''_2 \cup e_4$.

Without loss of generality we can assume that the terminal edge of label m at w_1 is oriented inward at w_1 . Then by Assumption 2, both of e'_1, e''_1 are oriented outward at w_1 (see Fig. 17(a)). For the edge e'_1 , there are two cases: (i) e'_1 is middle at w_2 , (ii) e'_1 is not middle at w_2 .

- Case (i). By Condition (iii) of the definition of a chart, both of e'_2, e''_2 are oriented outward at w_2 . If necessary we reflect the chart Γ , we can assume that
 - (1) the edge e_4 is oriented from w_4 to w_5 .

Since both of e_2'' , e_4 are oriented inward at w_5 ,

(2) the edge e_3'' is oriented from w_5 to w_3 .

Moreover, since both of e_1'' , e_3'' are oriented inward at w_3 , the edge e_3' is oriented from w_3 to w_4 (see Fig. 17(b)). Hence by (1) and (2), the boundary ∂D_1 is oriented clockwise or anticlockwise. This contradicts Lemma 9.1. Hence Case (i) does not occur.

Case (ii). One of e'_2 , e''_2 is oriented inward at w_2 , and the other is oriented outward at w_2 . If necessary we reflect the chart Γ , we can assume that the edge e'_2 is oriented inward at w_2 , and the edge e''_2 is oriented outward at w_2 . Looking at the 3-angled disk D_2 , by Lemma 9.1 the edge e''_3 is oriented from w_4 to w_5 . By the same way to Case (i), the edge e''_3 is oriented from w_5 to w_3 , and the edge e'_3 is oriented from w_3 to w_4 (see Fig. 17(c)). Thus

Figure 17: The graphs as shown in Fig. 12(f). The light gray region is the disk D_1 . The dark gray region is the disk D_2 .

the boundary ∂D_1 is oriented clockwise or anticlockwise. This contradicts Lemma 9.1. Hence Case (ii) does not occur.

Therefore the both cases do not occur. Hence Γ_m does not contain the graph as shown in Fig. 12(f).

Similarly we can show that Γ_{m+1} does not contain the graph as shown in Fig. 12(f).

10 Lenses

In this section, we shall show that neither Γ_m nor Γ_{m+1} contains the graph as shown in Fig. 12(i) for any minimal chart Γ of type (m; 7).

Let Γ be a chart. Let D be a disk such that

- (1) the boundary ∂D consists of an internal edge e_1 of label m and an internal edge e_2 of label m+1, and
- (2) any edge containing a white vertex in e_1 does not intersect the open disk IntD.

Note that ∂D may contain crossings. Let w_1 and w_2 be the white vertices in e_1 . If the disk D satisfies one of the following conditions, then D is called a lens of type (m, m + 1) (see Fig. 18):

- (i) Neither e_1 nor e_2 contains a middle arc.
- (ii) One of the two edges e_1 and e_2 contains middle arcs at both white vertices w_1 and w_2 simultaneously.

Lemma 10.1 ([7, Corollary 1.3]) There is no lens in any minimal chart with at most seven white vertices.

Lemma 10.2 Let Γ be a minimal chart of type (m;7). Then there does not exist a 2-angled disk D of Γ_m without feelers such that ∂D is oriented clockwise or anticlockwise.

Figure 18: Lenses.

Proof. Suppose that there exists a 2-angled disk D of Γ_m without feelers such that ∂D is oriented clockwise or anticlockwise.

Let w_1, w_2 be the white vertices in ∂D , and e_1, e_2 internal edges (possibly terminal edges) of label m at w_1, w_2 , respectively, with $e_1 \not\subset D$ and $e_2 \not\subset D$. By Lemma 8.1, one of e_1, e_2 is oriented inward at w_1 or w_2 , and the other is oriented outward at w_1 or w_2 . Without loss of generality we can assume that e_1 is oriented inward at w_1 , and e_2 is oriented outward at w_2 . Let e'_1, e'_2 be internal edges (possibly terminal edges) of label m+1 at w_1, w_2 , respectively, in D. Then

(1) e'_1 is oriented outward at w_1 , and e'_2 is oriented inward at w_2 .

Let G be the connected component of Γ_m with $G \supset \partial D$. Since Γ_m is of type (5,2) by Lemma 6.3, we have w(G) = 5 or w(G) = 2.

If w(G) = 2, then by Lemma 6.3(c) the graph G is an oval of label m and the two internal edges in ∂D are oriented from w_1 to w_2 or are oriented from w_2 to w_1 (see Fig. 11). This contradicts that ∂D is oriented clockwise or anticlockwise. Thus w(G) = 5.

Since ∂D is oriented clockwise or anticlockwise, by Lemma 3.2(b) the interior of D contains at least one white vertex. Thus by Lemma 6.3, the condition w(G) = 5 implies that the disk D contains an oval G' of label m as shown in Fig. 11 where k = m and $\varepsilon = +1$ (see Fig. 19(a)). Moreover by Lemma 6.3(d), we have $w(\Gamma \cap \text{Int} D) = 2$. Let D' be the 2-angled disk of Γ_m in D with $\partial D' \subset G'$. Then the condition $w(\Gamma \cap \text{Int} D) = 2$ implies

(2)
$$w(\Gamma \cap (\operatorname{Int} D - D')) = 0.$$

We use the notations as shown in Fig. 19(a), where w_3, w_4 are white vertices in the oval G', e'_3, e''_3 are internal edges (possibly terminal edges) of label m+1 oriented inward at w_3 , and e'_4, e''_4 are internal edges (possibly terminal edges) of label m+1 oriented outward at w_4 . By Assumption 2,

(3) none of e'_3, e''_3, e'_4, e''_4 are terminal edges.

Since ∂D is oriented clockwise or anticlockwise, neither e'_1 nor e'_2 contains a middle arc at w_1 or w_2 . Thus by Assumption 2,

(4) neither e'_1 nor e'_2 is a terminal edge.

Hence by (1),(2),(3) and (4), we have $e_1'=e_3'$ or $e_1'=e_3''$ or $e_1'=e_2'$. Thus

Figure 19: The gray regions are lenses.

(5)
$$e'_1 = e'_3$$
, $e'_2 = e'_4$, and $e''_3 = e''_4$ (see Fig. 19(b)), or

(6)
$$e_1' = e_3''$$
, $e_2' = e_4''$, and $e_3' = e_4'$ (see Fig. 19(c)), or

(7)
$$e'_1 = e''_2$$
, $e'_3 = e'_4$, and $e''_3 = e''_4$ (see Fig. 19(d)).

For each case, there exists a lens of type (m, m + 1). This contradicts Lemma 10.1. Therefore there does not exist a 2-angled disk D of Γ_m without feelers such that ∂D is oriented clockwise or anticlockwise.

Lemma 10.3 Let Γ be a minimal chart of type (m;7). Then neither Γ_m nor Γ_{m+1} contains the graph as shown in Fig. 12(i).

Proof. Suppose that Γ_m contains the graph as shown in Fig. 12(i). We use the notations as shown in Fig. 20(a), where e_1, e_2, e_3, e_4 are internal edges of label m with $\partial e_1 = \partial e_2 = \{w_1, w_2\}, \partial e_3 = \{w_1, w_3\}, \partial e_4 = \{w_2, w_3\}.$

Let D_1, D_2 be the 2-angled disk and the 3-angled disk of Γ_m without feelers with $\partial D_1 = e_1 \cup e_2$ and $\partial D_2 = e_1 \cup e_3 \cup e_4$. Without loss of generality we can assume that

(1) the edge e_1 is oriented from w_1 to w_2 .

If the edge e_2 is oriented from w_2 to w_1 , then the boundary ∂D_1 is oriented clockwise or anticlockwise. This contradicts Lemma 10.2. Thus

(2) the edge e_2 is oriented from w_1 to w_2 .

By (1) and (2), the both edges e_1 and e_2 are oriented outward at w_1 . Hence the edge e_3 is oriented inward at w_1 . Thus the edge e_3 is oriented from w_3 to w_1 . Similarly by (1) and (2), the edge e_4 is oriented from w_2

Figure 20: The graphs as shown in Fig. 12(i). The light gray region is the disk D_1 . The dark gray region is the disk D_2 .

to w_3 . Thus the boundary ∂D_2 is oriented clockwise or anticlockwise (see Fig. 20(b)). This contradicts Lemma 9.1. Therefore Γ_m does not contain the graph as shown in Fig. 12(i).

Similarly we can show that Γ_{m+1} does not contain the graph as shown in Fig. 12(i).

11 Case of the graph as shown in Fig. 12(h)

In this section, we shall show that neither Γ_m nor Γ_{m+1} contains the graph as shown in Fig. 12(h) for any minimal chart Γ of type (m; 7).

Lemma 11.1 Let Γ be a minimal chart of type (m;7). Then there does not exist a special 2-angled disk of Γ_m with exactly one feeler.

Proof. Suppose that there exists a special 2-angled disk D of Γ_m with exactly one feeler. Let e_1 be the feeler of D, and w_1 the white vertex in e_1 . Let e'_1, e''_1 be internal edges (possibly terminal edges) of label m+1 at w_1 in D. Without loss of generality we can assume that the terminal edge e_1 is oriented inward at w_1 . Then by Assumption 2,

- (1) e'_1, e''_1 are oriented inward at w_1 ,
- (2) neither e'_1 nor e''_1 is a terminal edge.

Since the 2-angled disk D has exactly one feeler, by Lemma 6.3

(3) the boundary ∂D is contained in a connected component of Γ_m with exactly five white vertices.

Since the 2-angled disk D has one feeler e_1 , by Lemma 3.2(a) we have $w(\Gamma \cap \text{Int}D) \geq 1$. Thus by (3) and Lemma 6.3, the disk D contains an oval G of label m as shown in Fig. 11 where k = m and $\varepsilon = +1$ (see Fig. 21).

Let D' be the 2-angled disk of Γ_m in D with $\partial D' \subset G$. We use the notations as shown in Fig. 21, where w_2 is a white vertex in G, and e'_2, e''_2 are internal edges (possibly terminal edges) of label m+1 oriented inward at w_2 . By Assumption 2, neither e'_2 nor e''_2 is a terminal edge. Hence by

Figure 21: The gray region is the disk D'.

(1) and (2), there are four internal edges e'_1, e''_1, e'_2, e''_2 of label m+1 oriented inward at w_1, w_1, w_2, w_2 , respectively, in D. Thus by IO-Calculation with respect to Γ_{m+1} in Cl(D-D'), we have $w(\Gamma \cap (\operatorname{Int} D - D')) \geq 1$. Hence $w(\Gamma \cap \operatorname{Int} D) \geq 3$. This contradicts Lemma 6.3(d). Therefore there does not exist a special 2-angled disk of Γ_m with exactly feeler.

Lemma 11.2 Let Γ be a minimal chart of type (m;7). Then neither Γ_m nor Γ_{m+1} contains the graph as shown in Fig. 12(h).

Proof. Suppose that Γ_m contains the graph as shown in Fig. 12(h), say G. By Lemma 7.2(c), the graph G is one of the RO-family of the graph as shown in Fig. 13(g). Without loss of generality we can assume that the graph G is the graph as shown in Fig. 13(g).

Let D_1, D_2 be the 2-angled disks of Γ_m with $D_1 \cap D_2 = \emptyset$, $\partial D_1 \subset G$, $\partial D_2 \subset G$. Then by Lemma 11.1, both of D_1 and D_2 have no feelers. Thus the chart Γ contains the pseudo chart as shown in Fig. 22.

Since the graph G is the graph as shown in Fig. 12(h), the set $S^2 - G$ consists of three connected component of $S^2 - G$. Two of three are $Int D_1$ and $Int D_2$. Let F be the last connected component of $S^2 - G$.

We use the notations as shown in Fig. 22, where $e'_1, e''_1, e'_2, e''_2, e''_3, e''_3$ are six internal edges (possibly terminal edges) of label m+1 oriented inward at $w_1, w_1, w_2, w_2, w_3, w_3$, respectively. Since none of them are middle at w_1, w_2 or w_3 , by Assumption 2 none of them are terminal edges. Hence by IO-Calculation with respect to Γ_{m+1} in Cl(F), we have $w(\Gamma \cap F) \geq 1$. Thus by Lemma 6.3, the domain F contains an oval G' of label m as shown in Fig. 11, where k = m and $\varepsilon = +1$.

Let D_3 be the 2-angled disk of Γ_m without feelers whose boundary is contained in G'. Again by IO-Calculation with respect to Γ_{m+1} in $Cl(F-D_3)$, we have $w(\Gamma \cap (F-D_3)) \geq 1$. Hence $w(\Gamma \cap F) \geq 3$. This contradicts Lemma 6.3(d). Therefore Γ_m does not contain the graph as shown in Fig. 12(h).

Similarly we can show that Γ_{m+1} does not contain the graph as shown in Fig. 12(h).

Figure 22: The six edges $e'_1, e''_1, e'_2, e''_2, e''_3, e''_3$ are oriented inward at $w_1, w_1, w_2, w_2, w_3, w_3$, respectively.

12 Case of the graph as shown in Fig. 12(e)

In this section, we shall show that neither Γ_m nor Γ_{m+1} contains the graph as shown in Fig. 12(e) for any minimal chart Γ of type (m; 7).

Lemma 12.1 Let Γ be a minimal chart of type (m;7). Then any special 3-angled disk of Γ_m has no feelers.

Proof. Suppose that there exists a special 3-angled disk D of Γ_m with at least one feeler. By Lemma 4.2(a), we have $w(\Gamma \cap \text{IntD}) \geq 1$. Thus by Lemma 6.3, the disk D contains the oval G of label m as shown in Fig. 11 where k=m and $\varepsilon=+1$ (see Fig. 23(a)). We use the notations as shown in Fig. 23(a), where

- (1) D' is the 2-angled disk of Γ_m in D,
- (2) e'_1, e''_1 are internal edges (possibly terminal edges) of label m+1 oriented inward at w_1 .

By Assumption 2,

(3) none of e'_1, e''_1, e'_2, e''_2 are terminal edges.

Since D has at least one feeler, we can assume that the white vertex w_3 is contained in the feeler e_3 (see Fig. 23(a)). Moreover we can assume that the terminal edge e_3 is oriented inward at w_3 . Then by Assumption 2,

- (4) both of e'_3, e''_3 are oriented inward at w_3 ,
- (5) neither e_3' nor e_3'' is a terminal edge, and
- (6) the two internal edges e, e' of label m are oriented outward at w_3 .

If the 3-angled disk D has three feelers, then there exists a connected component of Γ_m with exactly three white vertices and three terminal edges. This contradicts Lemma 5.1(b). Thus there are two cases: (i) D has one feeler (see Fig. 23(b)), (ii) D has two feelers (see Fig. 23(c)).

Case (i). If necessary we reflect the chart Γ , we can assume that the edge e'' of label m is oriented from w_4 to w_5 . Thus by (6) the edge e_5 is oriented

Figure 23: (a) A 3-angled disk. (b) A 3-angled disk with one feeler. (c) A 3-angled disk with two feelers.

inward at w_5 (see Fig. 23(b)). Since $e'_1, e''_1, e'_3, e''_3, e_5$ are oriented inward at w_1, w_1, w_3, w_5 , respectively by (2) and (4), and since none of e'_1, e''_1, e'_3, e''_3 are terminal edges by (3) and (5), we have $w(\Gamma \cap (\text{Int}D - D')) \geq 1$ by IO-Calculation with respect to Γ_{m+1} in Cl(D - D'). Hence $w(\Gamma \cap \text{Int}D) \geq 3$. This contradicts Lemma 6.3(d). Thus Case (i) does not occur.

Case (ii). Without loss of generality we can assume that the white vertex w_4 is contained in a feeler e_4 . Since the edge e is oriented inward at w_4 by (6), the edge e'' is oriented inward at w_4 by Assumption 2. Thus the edge e'' is oriented outward at w_5 (see Fig. 23(c)). Since the edge e' is oriented inward at w_5 by (6), the edge e_5 is not middle at w_5 . Hence by Assumption 2,

(7) the edge e_5 is not a terminal edge.

Let e'_4, e''_4 be internal edges (possibly terminal edges) of label m+1 at w_4 in D. By Assumption 2, none of e'_4, e''_4 are terminal edges. Thus by (3), (5) and (7), none of the nine edges $e'_1, e''_1, e'_2, e''_2, e''_3, e''_3, e'_4, e''_4, e_5$ are terminal edges. Hence we have $w(\Gamma \cap (\operatorname{Int} D - D')) \geq 1$ by IO-Calculation with respect to Γ_{m+1} in Cl(D-D'). Thus $w(\Gamma \cap \operatorname{Int} D) \geq 3$. This contradicts Lemma 6.3(d). Hence Case (ii) does not occur.

Therefore the both cases do not occur. Hence any special 3-angled disk of Γ_m has no feelers.

Lemma 12.2 Let Γ be a minimal chart of type (m;7). Then neither Γ_m nor Γ_{m+1} contains the graph as shown in Fig. 12(e).

Proof. Suppose that Γ_m contains the graph as shown in Fig. 12(e), say G. By Lemma 7.2(c), the graph G is one of the RO-family of the graph as shown in Fig. 13(e). Without loss of generality we can assume that the graph G is the graph as shown in Fig. 13(e).

We use the notations as shown in Fig. 24(a), where w_5 is the BW-vertex, and e_1, e_2, \dots, e_7 are seven internal edges of label m with $\partial e_1 = \partial e_2 = \{w_1, w_2\}, \partial e_3 = \{w_1, w_3\}, \partial e_4 = \{w_2, w_4\}, e_5 \cap e_6 \ni w_5, \partial e_7 = \{w_3, w_4\}, \text{ and } w_5 \in \mathbb{R}^n$

(1) the edge e_3 is oriented inward at w_1 .

Claim. The chart Γ contains the pseudo chart as shown in Fig. 24(b).

Proof of Claim. First we show that both of the edges e_1, e_2 are oriented outward at w_1 . Since $e_1 \cup e_2$ bounds a 2-angled disk without feelers, by Lemma 10.2 either both of the edges e_1, e_2 are oriented inward at w_1 or are oriented outward at w_1 . If both of the edges e_1, e_2 are oriented inward at w_1 , then by (1) there are three edges e_1, e_2, e_3 of label m oriented inward at w_1 . This contradicts the definition of a chart. Hence both of the edges e_1, e_2 are oriented outward at w_1 .

Since both of the edges e_1, e_2 are oriented inward at w_2 , the edge e_4 is oriented from w_2 to w_4 .

Let D_1 be the 3-angled disk of Γ_m with at most one feeler and $\partial D_1 = e_5 \cup e_6 \cup e_7$ (see Fig. 24(a)). By Lemma 12.1, the 3-angled disk D_1 has no feelers. Hence the chart Γ contains the pseudo chart as shown in Fig. 24(b). Thus Claim holds.

Let D_2 be the 5-angled disk of Γ_m with one feeler such that $\partial D_2 = e_1 \cup e_3 \cup e_4 \cup e_5 \cup e_6$. Let D_3 be the 4-angled disk of Γ_m without feelers such that $\partial D_3 = e_2 \cup e_3 \cup e_4 \cup e_7$. We use the notations as shown in Fig. 24(b), where

- (2) e'_1, e'_4, e'_5, e''_5 are internal edges (possibly terminal edges) of label m+1 oriented inward at w_1, w_4, w_5, w_5 in D_2 , respectively,
- (3) e'_2, e'_3, e''_4 are internal edges (possibly terminal edges) of label m+1 oriented outward at w_2, w_3, w_4 in D_3 , respectively.

Since none of the six edges $e'_1, e'_5, e''_5, e'_2, e'_3, e''_4$ are middle at $w_1, w_5, w_5, w_2, w_3, w_4$, respectively, by Assumption 2 none of the six edges are terminal edges. Thus by applying IO-Calculation with respect to Γ_{m+1} in D_2 and D_3 , we have $w(\Gamma \cap \text{Int}D_2) \geq 1$ and $w(\Gamma \cap \text{Int}D_3) \geq 1$ by (2) and (3). However by Lemma 6.3(b), $w(\Gamma \cap \text{Int}D_2) = 0$ or $w(\Gamma \cap \text{Int}D_3) = 0$. This is a contradiction. Therefore Γ_m does not contain the graph as shown in Fig. 12(e).

Similarly we can show that Γ_{m+1} does not contain the graph as shown in Fig. 12(e).

Figure 24: (a) The gray region is the disk D_1 . (b) The gray region is the disk D_2 .

13 Case of the graph as shown in Fig. 12(b)

In this section, we shall show that neither Γ_m nor Γ_{m+1} contains the graph as shown in Fig. 12(b) for any minimal chart Γ of type (m; 7).

Lemma 13.1 Let Γ be a minimal chart of type (m;7). Let D be a special 4-angled (or 5-angled) disk of Γ_m with exactly two feelers e_1, e_2 . Let w_1, w_2 be the white vertices in e_1, e_2 , respectively. Then one of e_1 and e_2 is oriented inward at w_1 or w_2 and the other is oriented outward at w_1 or w_2 .

Proof. Suppose that both of e_1, e_2 are oriented inward at w_1, w_2 , respectively. Let e'_1, e''_1, e'_2, e''_2 be internal edges (possibly terminal edges) of label m+1 in D at w_1, w_1, w_2, w_2 , respectively. By Assumption 2, the four edges e'_1, e''_1, e'_2, e''_2 are oriented inward at w_1, w_1, w_2, w_2 , respectively (see Fig 25), and none of e'_1, e''_1, e'_2, e''_2 are terminal edges. Hence by IO-Calculation with respect to Γ_{m+1} in D, we have $w(\Gamma \cap \text{Int}D) \geq 1$. Thus by Lemma 6.3, the disk D contains an oval of label m as shown in Fig. 11, where k = m and $\varepsilon = +1$.

Let D' be the 2-angled disk of Γ_m in D without feelers. By IO-Calculation with respect to Γ_{m+1} in Cl(D-D'), we have $w(\Gamma \cap (\operatorname{Int} D - D')) \geq 1$. Hence $w(\Gamma \cap \operatorname{Int} D) \geq 3$. This contradicts Lemma 6.3(d). Therefore one of e_1, e_2 is oriented outward at w_1 or w_2 .

Similarly we can show that one of e_1, e_2 is oriented inward at w_1 or w_2 . Hence we complete the proof of Lemma 13.1.

Lemma 13.2 Let Γ be a minimal chart of type (m;7). Then there does not exist a special 5-angled disk of Γ_m with exactly three feelers.

Proof. Let D be a special 5-angled disk of Γ_m , and w_1, w_2, \dots, w_5 the five white vertices lying on ∂D in this order. Let e_1, e_2, \dots, e_5 be the five internal edges of label m in ∂D with $\partial e_i = \{w_i, w_{i+1}\}$ (i = 1, 2, 3, 4) and $\partial e_5 = \{w_5, w_1\}$.

Figure 25: (a) A 4-angled disk with two feelers. (b) A 5-angled disk with two feelers.

Suppose that D has exactly three feelers e, e', e''. Since D is special, all of e, e', e'' are terminal edges. Without loss of generality we can assume that $w_1 \in e, w_2 \in e'$, and

(1) one of w_3, w_4, w_5 is contained in the feeler e''.

Moreover we can assume that the terminal edge e is oriented inward at w_1 . Then by Assumption 2, the terminal edge e is middle at w_1 . Thus both of e_1 and e_5 are oriented outward at w_1 . Hence e_1 is oriented inward at w_2 . Thus by Assumption 2, the terminal edge e' is oriented outward at w_2 , and

(2) e_2 is oriented inward at w_2 .

Hence we have the pseudo chart as shown in Fig. 26(a), where

(3) e'_1, e''_1 are internal edges (possibly terminal edges) of label m+1 oriented inward at w_1 .

Thus by Assumption 2,

(4) neither e'_1 nor e''_1 is a terminal edge.

By (1), there are three cases: (i) $w_3 \in e''$ (see Fig. 26(b)), (ii) $w_4 \in e''$ (see Fig. 26(c)), (iii) $w_5 \in e''$.

Case (i). By (2) and Assumption 2, the terminal edge e'' is middle at w_3 and oriented inward at w_3 . Hence

(5) there exist internal edges e'_3, e''_3 (not terminal edges) of label m+1 in D oriented inward at w_3 .

Moreover the edge e_3 is oriented from w_3 to w_4 .

If necessary we reflect the chart Γ , we can assume that the edge e_4 is oriented from w_4 to w_5 . Since e_5 is oriented from w_1 to w_5 (see Fig. 26(a)), both of e_4 and e_5 are oriented inward at w_5 . Thus there exists an internal edge e'_5 (possibly terminal edge) of label m+1 in D oriented inward at w_5 (see Fig. 26(b)). Hence by (3) and (5), the five edges $e'_1, e''_1, e'_3, e''_3, e'_5$ are

Figure 26: (a) The white vertices w_1, w_2 are contained in feelers e, e'. (b),(c) 5-angled disks with three feelers.

oriented inward at w_1, w_1, w_3, w_3, w_5 , respectively. Since none of e'_1, e''_1, e'_3, e''_3 are terminal edges by (4) and (5), we have $w(\Gamma \cap \text{Int} D) \geq 1$ by IO-Calculation with respect to Γ_{m+1} in D. Hence by Lemma 6.3, the disk D contains an oval of label m as shown in Fig. 11, where k = m and $\varepsilon = +1$.

Let D' be the 2-angeled disk of Γ_m in D without feelers. By IO-Calculation with respect to Γ_{m+1} in Cl(D-D'), we have $w(\Gamma \cap (\operatorname{Int} D - D')) \geq 1$. Thus $w(\Gamma \cap \operatorname{Int} D) \geq 3$. This contradicts Lemma 6.3(d). Hence Case (i) does not occur.

Case (ii). If necessary we change the orientation of all the edges and we reflect the chart Γ , we can assume that the terminal edge e'' is oriented inward at w_4 . Thus by Assumption 2,

(6) there exist internal edges e'_4, e''_4 (not terminal edges) of label m+1 in D oriented inward at w_4 , and

both of e_3, e_4 are oriented outward at w_4 . Since e_5 is oriented from w_1 to w_5 (see Fig. 26(a)), both of e_4 and e_5 are oriented inward at w_5 . Thus there exists an internal edge e'_5 (possibly terminal edge) of label m+1 in D oriented inward at w_5 (see Fig. 26(c)). Hence by (3) and (6), the five edges $e'_1, e''_1, e'_4, e''_4, e''_5$ are oriented inward at w_1, w_1, w_4, w_4, w_5 , respectively. Since none of e'_1, e''_1, e'_4, e''_4 are terminal edges by (4) and (6), we can show that $w(\Gamma \cap \text{Int} D) \geq 3$ by the similar way of the proof of Case (i). This contradicts Lemma 6.3(d). Thus Case (ii) does not occur.

Case (iii). We can show that Case (iii) does not occur by the similar way of the proof of Case (i).

Therefore all the three cases do not occur. Hence there does not exist a special 5-angled disk of Γ_m with exactly three feelers.

Lemma 13.3 Let Γ be a minimal chart of type (m;7). Then neither Γ_m nor Γ_{m+1} contains the graph as shown in Fig. 12(b).

Proof. Suppose that Γ_m contains the graph as shown in Fig. 12(b), say G. By Lemma 7.2(a), the graph G is one of the RO-family of the graph as shown

in Fig. 13(b). Without loss of generality we can assume that the graph G is the graph as shown in Fig. 13(b).

We use the notations as shown in Fig. 13(b) and Fig. 14(a), where w_1, w_2, w_3 are BW-vertices, and e_2, e_4 are internal edges of label m with $\partial e_2 = \{w_1, w_5\}$ and $\partial e_4 = \{w_2, w_4\}$. Let e, e', e'' be the terminal edges of label m at w_1, w_2, w_3 , respectively. Then

(1) e, e' are oriented inward at w_1, w_2 , respectively.

Now the graph G divides S^2 into three disks. Let D_1, D_2, D_3 be the three disks such that D_1 is a 3-angled disk, D_2 is a 4-angled disk, D_3 is a 5-angled disk. By Lemma 12.1, the 3-angled disk D_1 has no feeler. Thus the terminal edge e is contained in D_3 . Hence looking at the 5-angled disk D_3 , by Lemma 13.2 we have $e' \not\subset D_3$ or $e'' \not\subset D_3$. Hence $e' \subset D_2$ or $e'' \subset D_2$. Thus there are three cases: (i) $e' \subset D_2$, $e'' \subset D_3$ (see Fig. 27(a)), (ii) $e' \subset D_3$, $e'' \subset D_2$, (iii) $e' \cup e'' \subset D_2$ (see Fig. 27(b)).

Case (i). We use the notations as shown in Fig. 27(a), where

- (2) e'_2, e''_2 are internal edges (possibly terminal edges) of label m+1 oriented inward at w_2 in D_2 ,
- (3) e'_3, e''_3, e'_5 are internal edges (possibly terminal edges) of label m+1 oriented outward at w_3, w_3, w_5 in D_3 , respectively, and

none of $e'_2, e''_3, e''_3, e''_3$ are middle at w_2, w_2, w_3, w_3, w_5 , respectively. Thus by Assumption 2,

(4) none of the five edges $e'_2, e''_2, e''_3, e''_3, e''_5$ are terminal edges.

By Lemma 6.3(b), either $w(\Gamma \cap \text{Int}D_2) = 0$ or $w(\Gamma \cap \text{Int}D_3) = 0$. If $w(\Gamma \cap \text{Int}D_2) = 0$, then by (2) and (4), we have $e'_2 \ni w_4$ and $e''_2 \ni w_5$. Thus $e'_2 \cup e_4$ bounds a lens in D_2 . This contradicts Lemma 10.1. If $w(\Gamma \cap \text{Int}D_3) = 0$, then by (3) and (4), we have $e'_3 \ni w_4$ and $e''_3 \cap e'_5 \ni w_1$. Thus $e'_5 \cup e_2$ bounds a lens in D_3 . This contradicts Lemma 10.1. Hence Case (i) does not occur.

Case (ii). By (1), the two terminal edges e and e' are oriented inward at w_1, w_2 , respectively. This contradicts Lemma 13.1. Thus Case (ii) does not occur.

Case (iii). We use the notations as shown in Fig. 27(b), where

(5) e'_3, e''_3, e'_4, e''_5 are internal edges (possibly terminal edges) of label m+1 oriented outward at w_3, w_3, w_4, w_5 in D_2 , respectively, and

none of the four edges are middle at w_3, w_4, w_5 , respectively. Thus by Assumption 2, none of the four edges are terminal edges. Hence we have $w(\Gamma \cap \text{Int}D_2) \geq 1$ by IO-Calculation with respect to Γ_{m+1} in D_2 . Thus by Lemma 6.3, the disk D_2 contains an oval of label m as shown in Fig. 11, where k = m and $\varepsilon = +1$.

Let D be the 2-angled disk of Γ_m in D_2 without feelers. By IO-Calculation with respect to Γ_{m+1} in $Cl(D_2 - D)$, we have $w(\Gamma \cap (\operatorname{Int} D_2 - D)) \geq 1$. Thus

Figure 27: The gray regions are the disk D_2 .

 $w(\Gamma \cap \text{Int}D_2) \geq 3$. This contradicts Lemma 6.3(d). Hence Case (iii) does not occur.

Therefore all of the three cases do not occur. Hence Γ_m does not contain the graph as shown in Fig. 12(b).

Similarly we can show that Γ_{m+1} does not contain the graph as shown in Fig. 12(b).

14 Case of the graph as shown in Fig. 12(c)

In this section, we shall show that neither Γ_m nor Γ_{m+1} contains the graph as shown in Fig. 12(c) for any minimal chart Γ of type (m; 7).

Lemma 14.1 Let Γ be a minimal chart of type (m;7). Then neither Γ_m nor Γ_{m+1} contains the graph as shown in Fig. 12(c).

Proof. Suppose that Γ_m contains the graph as shown in Fig. 12(c), say G. By Lemma 7.2(b), if necessary we move the point at infinity ∞ , then the graph G is one of the RO-family of the graph as shown in Fig. 13(c). Without loss of generality we can assume that the graph G is the graph as shown in Fig. 13(c).

We use the notations as shown in Fig. 14(b), where w_3, w_4, w_5 are BW-vertices. Now the graph G divides S^2 into three disks. Let D_1, D_2, D_3 be the three disks which are 4-angled disks with $\partial D_1 \ni w_3, w_4, \partial D_2 \ni w_3, w_5, \partial D_3 \ni w_4, w_5$. Let e, e', e'' be the terminal edges of label m at w_3, w_4, w_5 , respectively. Then e', e'' are oriented outward at w_4, w_5 , respectively (see Fig. 13(c)). Since D_3 is a special 4-angled disk, by Lemma 13.1 we have $e' \not\subset D_3$ or $e'' \not\subset D_3$. Without loss of generality we can assume that

(1)
$$e' \not\subset D_3$$
 (i.e. $e' \subset D_1$).

For the edge e, there are two cases: (i) $e \subset D_1$ (see Fig. 28(a)), (ii) $e \subset D_2$ (see Fig. 28(b) and (c)).

Case (i). We use the notations as shown in Fig. 28(a), where

(2) e'_1, e'_2, e'_3, e''_3 are internal edges (possibly terminal edges) of label m+1 oriented inward at w_1, w_2, w_3, w_3 in D_1 , respectively, and

none of the four edges are middle at w_1, w_2, w_3, w_3 , respectively. Thus by Assumption 2, none of the four edges are terminal edges. Hence we have $w(\Gamma \cap \text{Int}D_1) \geq 1$ by IO-Calculation with respect to Γ_{m+1} in D_1 . Thus by Lemma 6.3, the disk D_1 contains an oval of label m as shown in Fig. 11, where k = m and $\varepsilon = +1$.

Let D be the 2-angeled disk of Γ_m in D_1 without feelers. By IO-Calculation with respect to Γ_{m+1} in $Cl(D_1 - D)$, we have $w(\Gamma \cap (\operatorname{Int} D_1 - D)) \geq 1$. Thus $w(\Gamma \cap \operatorname{Int} D_1) \geq 3$. This contradicts Lemma 6.3(d). Hence Case (i) does not occur.

Case (ii). Now $e'' \subset D_3$. Because if $e'' \subset D_2$ (see Fig. 28(b)), then we can show $w(\Gamma \cap \text{Int}D_2) \geq 3$ by the similar way of the proof of Case (i). This contradicts Lemma 6.3(d). Hence we have $e'' \subset D_3$ (see Fig. 28(c)).

We use the notations as shown in Fig. 28(c), where

(3) $e_1'', e_2'', e_3', e_3''$ are internal edges (possibly terminal edges) of label m+1 oriented inward at w_1, w_2, w_3, w_3 in D_2 , respectively, and

none of the four edges are middle at w_1, w_2, w_3, w_3 , respectively. Thus by Assumption 2, none of the four edges are terminal edges. Hence we can show that $w(\Gamma \cap \text{Int}D_2) \geq 3$ by the similar way of the proof of Case (i). This contradicts Lemma 6.3(d). Hence Case (ii) does not occur.

Therefore the two cases do not occur. Hence Γ_m does not contain the graph as shown in Fig. 12(c).

Similarly we can show that Γ_{m+1} does not contain the graph as shown in Fig. 12(c).

Proposition 14.2 If there exists a minimal chart Γ of type (m;7), then both of Γ_m and Γ_{m+1} contain graphs as shown in Fig. 12(g).

Proof. By Lemma 6.3, both of Γ_m and Γ_{m+1} are of type (5, 2). By Lemma 5.3 and Lemma 7.1, each of Γ_m and Γ_{m+1} contains one of nine graphs as shown in Fig. 12. By the eight lemmata (Lemma 8.2, Lemma 8.3, Lemma 9.2, Lemma 10.3, Lemma 11.2, Lemma 12.2, Lemma 13.3, Lemma 14.1), both of Γ_m and Γ_{m+1} contain graphs as shown in Fig. 12(g).

Figure 28: (a) The gray region is the disk D_1 . (b),(c) The gray regions are the disk D_2 .

15 Proof of Main Theorem

In this section we shall prove Main Theorem (Theorem 1.1).

Lemma 15.1 Let Γ be a minimal chart of type (m;7). Then Γ contains one of the RO-family of the pseudo chart as shown in Fig. 29(a). Moreover the edge e_3 is middle at w_2 , but not middle at w_3 .

Proof. By Proposition 14.2, the graph Γ_m contains the graph as shown in Fig. 12(g), say G. By Lemma 7.2(c), the graph G is one of the RO-family of the graph as shown in Fig. 13(f). Without loss of generality we can assume that the graph G is the graph as shown in Fig. 13(f).

Let D_1, D_2 be the 2-angled disk of Γ_m and the 3-angled disk of Γ_m with $\partial D_1 \subset G$, $\partial D_2 \subset G$ and $D_1 \cap D_2 = \emptyset$. Since D_1 is a special 2-angled disk with at most one feeler, the disk D_1 has no feelers by Lemma 11.1. Since D_2 is a special 3-angled disk, the disk D_2 has no feelers by Lemma 12.1. Hence Γ contains the pseudo chart as shown in Fig. 29(b).

We use the notations as shown in Fig. 29(b), where

(1) $e'_2, e''_2, e'_3, e'_4, e''_4$ are internal edges (possibly terminal edges) of label m+1 oriented outward at w_2, w_2, w_3, w_4, w_4 , respectively.

Moreover, none of the five edges are middle at w_2, w_2, w_3, w_4, w_4 , respectively. Thus by Assumption 2,

(2) none of the five edges $e'_2, e''_2, e''_3, e'_4, e''_4$ are terminal edges.

Claim. $w(\Gamma \cap (S^2 - (D_1 \cup D_2))) \ge 1$.

Proof of Claim. Suppose $w(\Gamma \cap (S^2 - (D_1 \cup D_2))) = 0$. By (2), the edge e_3' is not a terminal edge. Thus for the edge e_3' , there are four cases: (i) $e_3' = e_1'$, (ii) $e_3' = e_1''$, (iii) e_3' is a loop, (iv) $e_3' \ni w_5$.

Case (i). The annulus $Cl(S^2 - (D_1 \cup D_2))$ is divided by $e_3 \cup e_3'$ into two regions. Let E be one of the two regions with $E \supset e_2'$. Then we have $w(\Gamma \cap Int E) \geq 1$ by IO-Calculation with respect to Γ_{m+1} in E. Hence

$$0 = w(\Gamma \cap (S^2 - (D_1 \cup D_2))) \ge w(\Gamma \cap \operatorname{Int} E) \ge 1.$$

This is a contradiction. Hence Case (i) does not occur.

Case (ii). The condition $e_3' = e_1''$ implies $e_1' = e_2'$. Thus $e_1' \cup e_1$ bounds a lens. This contradicts Lemma 10.1. Hence Case (ii) does not occur.

Case (iii). By Lemma 5.3, Case (iii) does not occur.

Case (iv). The annulus $Cl(S^2 - (D_1 \cup D_2))$ is divided by e'_3 into two regions. Let E be one of the two regions with $E \supset e'_4$. Then we have $w(\Gamma \cap \operatorname{Int} E) \geq 1$ by IO-Calculation with respect to Γ_{m+1} in E. Thus we have the same contradiction by the similar way of Case (i). Hence Case (iv) does not occur.

Therefore all the four cases do not occur. Hence Claim holds. \Box

By Claim and Lemma 6.3(c), the region $S^2 - (D_1 \cup D_2)$ contains an oval of label m as shown in Fig. 11, where k = m and $\varepsilon = +1$. Moreover by Lemma 6.3, we have

(3)
$$w(\Gamma \cap \operatorname{Int} D_1) = 0$$
 and $w(\Gamma \cap \operatorname{Int} D_2) = 0$.

Thus by Lemma 3.1, a regular neighborhood of D_1 contains the pseudo chart as shown in Fig. 3(b). Furthermore, by Lemma 4.1, a regular neighborhood of D_2 contains one of the RO-family of the pseudo chart as shown in Fig. 9(b). Therefore Γ contains the pseudo chart as shown in Fig. 29(a).

Proof of Main Theorem (Theorem 1.1). Suppose that there exists a minimal chart Γ of type (m;7). Then by Lemma 15.1, the chart Γ contains one of the RO-family of the pseudo chart as shown in Fig. 29(a), where

(1) e_3'' is an internal edge of label m+1 middle at w_4 with $\partial e_3'' = \{w_3, w_4\}$.

By Proposition 14.2, the graph Γ_{m+1} contains the graph as shown in Fig. 12(g). Moreover by Lemma 6.3, the graph Γ_{m+1} contains an oval of label m+1 as shown in Fig. 11, where k=m+1 and $\varepsilon=-1$. By the similar way of the proof of Lemma 15.1, the chart Γ contains the graph as shown in Fig. 30(a), and

- (2) e is an internal edge of label m+1 middle at v_2 with $\partial e = \{v_2, v_3\}$,
- (3) there exists an internal edge e' of label m with $\partial e' = \{v_3, v_4\}$ or $\partial e' = \{v_3, v_5\}$,
- (4) there exists a disk D such that ∂D consists of the edge e' and an internal edge of label m+1 and $\mathrm{Int}D$ does not intersect any edge at v_3,v_4 or v_5 .

Figure 29: The graphs as shown in Fig. 12(g).

Claim 1. $e_3'' = e$, $w_3 = v_3$ and $w_4 = v_2$.

Proof of Claim 1. First we show $e_3'' = e$. Since Γ_{m+1} contains exactly five terminal edges (see Fig. 30(a)) and since the five white vertices w_1, w_2, w_5, w_6, w_7 are contained in terminal edges of label m+1 (see Fig. 29(a)), the two white vertices w_3, w_4 are not contained in any terminal edge of label m+1. Thus $\{w_3, w_4\} = \{v_2, v_3\}$ and $e_3'' = e$.

Since the edges e_3'' and e are middle at w_4, v_2 , respectively, by (1) and (2), we have $w_4 = v_2$. This implies $w_3 = v_3$. Hence Claim 1 holds.

Let C, C' be the simple closed curves in Γ_{m+1} with $v_1, v_2 \in C$ and $v_3, v_4, v_5 \in C'$ (see Fig. 30(a)).

Claim 2. $C = e'_4 \cup e''_4 \ni w_4, e'''_3 = e''_2 \text{ and } C' = e'_3 \cup e'''_3 \cup e'_2 \ni w_2, w_3.$ Proof of Claim 2. By Claim 1, we have $w_4 = v_2 \in C$ and $w_3 = v_3 \in C'.$ Hence $w_4 \in C$ and $w_3 \in C'.$ Thus $C = e'_4 \cup e''_4$ and $C' \supset e'_3 \cup e'''_3.$

Next we shall show $w_2 \in C'$. Since $\partial e' = \{v_3, v_4\}$ or $\partial e' = \{v_3, v_5\}$ by (3), we have $\partial e' \subset C'$.

Since $e_3'' = e$ by Claim 1, we have $e_3 = e'$ (see Fig. 29(a) and Fig. 30(a)). Thus $\partial e' = \partial e_3 = \{w_2, w_3\}$. Hence the condition $\partial e' \subset C'$ implies $w_2 \in C'$.

Thus $C' \supset e'_2 \cup e''_2$. Hence $e'''_3 = e'_2$ or $e'''_3 = e''_2$. Thus by (4), we have $e'''_3 = e''_2$ and $C' = e'_3 \cup e''_3 \cup e'_2$. Therefore Claim 2 holds.

Now the simple closed curve C contains the two white vertices v_1 and $v_2 = w_4$. For the white vertex v_1 , there are three cases: (i) $v_1 = w_1$, (ii) $v_1 = w_5$, (iii) $v_1 = w_6$.

Case (i). Let D_1, D_2 be the 2-angled disk of Γ_m and the 3-angled disk of Γ_m with $w_1, w_2 \in \partial D_1$, $w_3, w_4, w_5 \in \partial D_2$ and $D_1 \cap D_2 = \emptyset$. Then the annulus $Cl(S^2 - (D_1 \cup D_2))$ is divided by $e'_4 \cup e_3$ into two disks. Let E be

Figure 30: (a) The graph as shown in Fig. 12(g) and an oval. (b) The gray region is a lens.

one of the two disks with $E \supset e_2'$. Then $w(\Gamma \cap \text{Int} E) \geq 1$ by IO-Calculation with respect to Γ_{m+1} in E. Hence E contains the oval of label m.

Let D' be the 2-angled disk of Γ_m in E. Then we can show $w(\Gamma \cap (S^2 - (D_1 \cup D_2))) \ge 3$ by using IO-Calculation with respect to Γ_{m+1} in IntE - D'. This contradicts Lemma 6.3(d). Hence Case (i) does not occur.

Case (ii). The edges e'_4, e''_4 contain the white vertex w_5 . Thus $e''_4 \cup e_5$ bounds a lens. This contradicts Lemma 10.1. Hence Case (ii) does not occur.

Case (iii). The edges e'_4 , e''_4 contain the white vertex w_6 . By Claim 2, we have $e'''_3 = e''_2$. Hence the two edges e'_2 , e'_3 contain the white vertex w_1 (see Fig. 30(b)). Thus $e'_2 \cup e_1$ bounds a lens. This contradicts Lemma 10.1. Hence Case (iii) does not occur.

Therefore all the three cases do not occur. Hence there does not exist a minimal chart of type (m;7). Thus we complete the proof of Main Theorem (Theorem 1.1).
