Write asymmetry of spin-orbit torque memory induced by in-plane magnetic fields

Baiqing Jiang, Dongyang Wu, Qianwen Zhao, Kaihua Lou, Yuelei Zhao, Yan Zhou, C. Tian, and Chong Bi

Abstract-Write asymmetry, the significantly different write current for high-to-low and low-to-high resistance switching because of natural stochastic behaviors of magnetization, is a fundamental issue in magnetic random-access memory (MRAM). For high-performance spin transfer torque (STT) MRAM, it can be eliminated by precisely controlling atomically thin magnetic multilayers or by introducing compensation techniques in circuitlevel designs, while for spin-orbit torque (SOT) MRAM, it has not been addressed. Here we systematically investigated the write asymmetry of SOT-MRAM as a function of applied magnetic fields (H) and demonstrated that the write currents are intrinsically asymmetric due to different SOT efficiencies for highto-low and low-to-high switching. Furthermore, we found that the SOT efficiency is very sensitive to the tilt angle between H and write current, which can be tuned through H to achieve symmetric SOT switching. These results provide an additional guideline for designing SOT devices and suggest that the write asymmetry can be eliminated by adjusting the introduced effective magnetic fields within a field-free SOT-MRAM architecture.

Index Terms-MRAM, SOT, STT, nonvolatile memory

I. INTRODUCTION

MRAM based on perpendicularly magnetized FM/IL/FM (FM: ferromagnetic layer; IL: ultrathin insulating layer) tunnel junctions (MTJs) has attracted intense attentions from both academia and industry [1]–[3] owing to its potential applications in the replacement of static random-access memory (SRAM) when SRAM approaches its scaling limit at the 7-nm technology node and beyond [4], [5]. In addition to the excellent scalability compared to SRAM, MRAM shows low-power consumption because of its nonvolatility that does not need static power to retain information. Based on write

mechanisms [6], MRAM can be classified into STT-MRAM and SOT-MRAM. The former uses the STT generated from the reference layer of MTJs to switch the storage layer [1], [3], while the latter uses the SOT generated by a neighboring SOT layer [7], [8]. In STT-MRAM, the critical switching current (I_c) as well as switching time varies when the resistance switches from high-to-low and low-to-high states, causing the significant write asymmetry [9]–[11]. This write asymmetry induces extra complexity during STT-MRAM production both in device- and circuit-level [11]–[13]. Combined with circuit compensation techniques, the write asymmetry of STT-MRAM can be eased by precisely controlling MTJ structures [1], [2].

Since SOT-MRAM is still in its infancy, most studies are focusing on the fundamental SOT phenomena such as field-free switching [14]–[18] and enhancement of SOT efficiency [19]– [24]. The write asymmetry issue has not been specifically raised so far even many works show asymmetric I_c like STT [8], [25]. In the SOT scheme, an external H collinear with write current must be applied to break the symmetry for deterministic switching [26]. However, in practical devices, the external H cannot be aligned with the write current exactly and a small angle between them is usually required for achieving full SOT switching [7]. This symmetry-breaking and field misalignment may lead to different switching processes or SOT efficiencies

for up-to-down $(\uparrow\downarrow)$ and down-to-up $(\downarrow\uparrow)$ switching (corresponding to the low-to-high and high-to-low resistance switching of MTJs, respectively).

Moreover, two different SOT switching mechanisms, coherent switching [26], [27] and domain expansion switching [28]–[30], may dominate the $\uparrow\downarrow$ and $\downarrow\uparrow$ switching processes, respectively, also resulting in the write asymmetry. It should be noted that, in the field-free SOT switching architectures, an effective in-plane magnetic field due to stray fields or interlayer coupling can be viewed as the external H and the write asymmetry should also exist. In this work, we directly address the write asymmetry issue in typical SOT structures and explore the underlying physical origins. Finally, we show that the write asymmetry of SOT-MRAM can be completely eliminated by adjusting the external H.

II. DEVICE FABRICATION

The samples for investigating SOT switching are reduced MTJ structures in the absence of reference layers, specifically, Ta 8/CoFeB 1.2/MgO 2 (nm) multilayers with a 3 nm TaO_x capping layer. All layers were deposited on a thermally oxidized Si/SiO₂ 300 nm substrate by magnetron sputtering with a base pressure about 4.5×10^{-9} Torr. The Ta and CoFeB layers were sputtered from the Ta and Co₂Fe₆B₂ targets (purity: 99.95%) through DC sputtering under an Ar pressure of 2 mTorr, respectively. The MgO layer was sputtered from an MgO target (99.99%) through RF sputtering under the Ar pressure of 1.1 mTorr. The as-deposited layers were then transferred to a 220 °C vacuum annealing chamber with the pressure better than 1×10^{-7} Torr for one hour to enhance perpendicular magnetic anisotropy (PMA). The samples were patterned into Hall bars with the width of 2 µm through standard photolithography and subsequent Ar ion milling. As illustrated in Fig. 1(a), the up and down magnetization states were detected by measuring anomalous Hall resistance $(R_{\rm H})$. The sensing current for measuring R_H is 25 µA. For current-driven SOT switching, a 1 ms current pulse (I_p) was applied first to switch

Fig. 3. (a) Perpendicularly magnetized R_H loops under an in-plane field $H = \pm 30$ Oe with $\beta = 0.24^\circ$. The shift of R_H loops corresponds to H^z_{eff} . (b) The measured χ as a function of H when $\beta = 0.24^\circ$.

Fig. 4. The extracted I_c for (a, c) $\uparrow \downarrow$ and (b, d) $\downarrow \uparrow$ switching with (a, b) positive and (c, d) negative β . The solid and dash lines represent the predicted values for the domain expansion switching and coherent switching, respectively. The parameters are $\varepsilon H_k = 0.15$ T, $\beta = 0.3^\circ$, $\delta M_s = 5 \times 10^4$ A/m, and $\theta_{SH} = 0.2$. the CoFeB layer and then the sensing current was applied to

detect the magnetization states [23].

III. SOT SWITCHING RESULTS AND DISCUSSION

The PMA was confirmed by measuring R_H versus H_z , where a square switching loop is clearly presented (Fig. 1(b)). The critical switching field (H_s^z) is about ± 5 Oe, which can be used to estimate the tilt angle (β) of H from film plane through $\Delta H_c \sin \beta = 2H_s^z$, where ΔH_c is defined in Fig. 1(c). Fig. 1(c) shows typical R_H versus H curve when $\beta = 0.7^\circ$, from which $H_k \approx 2.2$ kOe is extracted according to the field-driven coherent switching model [23], [26]. Fig. 1(d) presents ΔH_c as a function of β extracted from Fig. 1(c), where the excellent agreement of the simulated coherent switching behaviors with experimental results indicates that the field-driven coherent switching keeps well when $\beta \ge 0.2^\circ$.

Fig. 2(a) and Fig. 2(b) show typical current-induced SOT switching curves when $\beta = 0.24^{\circ}$, in which I_c for $\uparrow \downarrow (I_c^{\uparrow\downarrow})$ and $\downarrow \uparrow (I_c^{\downarrow\uparrow})$ switching can be extracted. For +H and -H, the switching loops are anticlockwise and clockwise, respectively, which are the typical characteristics of SOT switching [7], [8], [26]. The remarkable feature is that the $\uparrow \downarrow$ and $\downarrow \uparrow$ switching becomes asymmetric with increasing H (Fig. 2(b)). When H = 300 Oe, $I_c^{\uparrow\downarrow} = -0.31$ mA, two times larger than $I_c^{\downarrow\uparrow} = 0.14$ mA. The I_c difference becomes even larger when H = 600 Oe. Fig. 2(c) gives the SOT switching loops when $\beta = \pm 0.24^{\circ}$, which clearly shows that the asymmetric SOT switching strongly depends on the sign of β . For $\beta = 0.24^\circ$, $|I_c^{\uparrow\downarrow}| > |I_c^{\downarrow\uparrow}|$, while for $\beta = -0.24^\circ$, $|I_c^{\uparrow\downarrow}| < |I_c^{\downarrow\uparrow}|$.

To clearly demonstrate the asymmetric SOT switching, $\Delta I_c/|I_c|_{min}$ with $\Delta I_c = |I_c^{\uparrow\downarrow}| - |I_c^{\downarrow\uparrow}|$ as a function of H was plotted in Fig. 2(d), where $|I_c|_{min} = \text{Min} \{|I_c^{\uparrow\downarrow}|, |I_c^{\downarrow\uparrow}|\}$. When |H| > 400 Oe, ΔI_c is determined by the sign of β and $|\Delta I_c|/|I_c|_{min}$ exceeds 1000%, showing strongly asymmetric switching. Even for weak fields |H| < 100 Oe, $|\Delta I_c|/|I_c|_{min}$ can be larger than 100%. Remarkably, ΔI_c can approach 0 at certain fields (for example, H $\approx \pm 200$ Oe), which means that the asymmetric SOT switching can be eliminated by controlling H. It should be noted that, when $|\beta| < 0.24^\circ$, both field- and current-driven magnetization switching only show partial switching and I_c cannot be determined accurately.

We have also evaluated the SOT efficiency by measuring the SOT-induced effective perpendicular field (H_{eff}^z) [31], [32] to explore the physical origins of the asymmetric SOT switching. H_{eff}^z originates from SOT effects on the internal magnetization texture of Néel-type domain walls and directly represents SOT efficiency [31]. Fig. 3(a) shows R_H versus H_z loops with an additional in-plane magnetic field H (β = 0.24°), where the shift of R_H loops can be used to estimate H_{eff}^z . For the additional H = 30 Oe, the R_H loop shifts toward +H_z, indicating a negative H_{eff}^z generated by the -0.5 mA applied current. The negative H_{eff}^z will induce the magnetization switching to the down state when $|H_{eff}^z| > |H_s^z|$, in consistent with the SOT switching directions in Fig. 2(a).

Fig. 3(b) gives the measured SOT efficiency ($\chi = H_{eff}^{z}/|J|$) as a function of H, where J is the applied current density. Both the saturation field (corresponding to the effective Dzyaloshinskii-Moriya interaction (DMI) field (H_{DMI})) and χ agree well with previous reports [32]. Interestingly, χ shows different field dependence for opposite currents in the linear range when H approaches 0 Oe. For +0.5 mA, the slope of χ in the linear range (|H| < 150 Oe) is about 0.14×10^{-11} m²/A and the estimated H_{DMI} \approx 240 Oe, while for -0.5 mA, the slope in the linear range (|H| < 60 Oe) is about -0.54×10^{-11} m²/A and H_{DMI} ≈ 100 Oe. Moreover, the saturation value of χ also shows a slight difference for opposite currents. We have also measured χ when $\beta = -0.24^{\circ}$ and observed a reversal χ behavior for ± 0.5 mA, indicating that the significantly different χ dependence is due to β .

This remarkable current direction dependence of SOT efficiency has not been reported before probably because χ was assumed to be the same for $\pm I$ [32]. Moreover, the strong β -dependence of χ may explain the significant χ change in the wedged samples (< 0.001 nm) [32] where β changes slightly compared to the uniformly deposited samples even the thickness variation may be less than one atomic layer in a single wedged device [17], [32]. According to the 1D domain wall model, $\chi = (\hbar \pi \xi_{DL}/4e\mu_0 M_s t_{FM}) \cos \Phi$, where ζ_{DL} , M_s , t_{FM} , and Φ , are the damping-like SOT, the saturation magnetization and the thickness of the ferromagnetic layer, and the tilt angle of domain wall moment, respectively. When H << H_{DMI}, cos Φ

 \approx H/H_{DMI}, it is reasonable that a larger χ slope corresponds to a smaller H_{DMI}, as observed in Fig. 3(b). However, the saturation value, $\chi_{sat} = \hbar \pi \xi_{DL} / 4e \mu_0 M_s t_{FM}$, varying with current direction cannot be fully understood within the 1D domain wall model [31], indicating that the detailed dynamics of the internal magnetization texture during SOT-driven domain wall motion should be considered.

Fig. 4 shows the measured I_c as a function of H. The solid lines guide I_c for the magnetization switching induced by the domain expansion, which are determined from the measured χ by using $H_{eff}^z = H_s^z$ [33]. Overall, I_c increases sharply with reducing H and gradually decreases when |H| > 100 Oe, in contrast to the coherent switching where I_c shows a linear dependence on H [27]. For $+\beta$, a positive I_c (for example, in the upper left corner of Fig. 4(a) is always smaller than the value of a negative I_c (in the bottom right corner of Fig. 4(a)) in the field range of |H| > 240 Oe, in consistent with the χ measurements (Fig. 3(b)), where H_{eff}^{z} for +I is larger than that for -I when $|H| > H_{DMI} \approx 240$ Oe). These results confirms that the SOT switching strongly correlates with the measured χ and thus is dominated by the domain expansion. By considering χ is very sensitive to β , the symmetric switching can be achieved by precisely controlling H and film roughness to make $|\chi(+I)| =$ $|\chi(-I)|$.

Notably, I_c occasionally shows extremely large values which has a linear dependence on H, as predicted by the coherent switching [27]. With the involvement of β , I_c of the coherent switching can be developed as,

$$I_{c} = \left(\frac{e^{\delta \mathcal{E}M_{S}H_{k}t_{FM}S}}{h\theta_{SH}}\right) \sqrt{1 + 2\sqrt{2}(sin\beta - cos\beta)h_{x}} + (2.5 - 3sin\beta cos\beta)h_{x}^{2},$$

where θ_{SH} is the effective spin Hall angle, *S* is the cross-
sectional area of the SOT layer, $h_{x} = H/\mathcal{E}H_{k}, 0 \le \delta, \varepsilon \le 1$ are
the factors for describing the residual M_{s} and H_{k} due to Joule
heating respectively. The deck lines in Fig. 4 represent L for

heating, respectively. The dash lines in Fig. 4 represent I_c for the coherent switching. The overlap with the occasional large values indicates that the coherent switching can also happen randomly, which will induce the additional write asymmetry.

IV. CONCLUSION

We have addressed the asymmetric switching issue in the prototype SOT-MRAM devices by varying the applied external field. It is found that the SOT efficiencies are intrinsically different for the up-to-down and down-to-up switching, which makes the corresponding SOT switching asymmetric in principle. The combination of the measured SOT efficiency and critical SOT switching current further reveals that the magnetization switching is dominated by the domain expansion. These results provide basic guidelines for designing symmetric SOT switching devices. Furthermore, we expect that the asymmetric SOT switching mechanism still functions in the nano-sized SOT devices since the width of domain walls is only several nanometers and the magnetization switching is still dominated by the domain expansion.
