SET-THEORETICAL SOLUTIONS TO THE ZAMOLODCHIKOV TETRAHEDRON EQUATION ON ASSOCIATIVE RINGS AND LIOUVILLE INTEGRABILITY

SERGEI IGONIN

Centre of Integrable Systems, P.G. Demidov Yaroslavl State University, Yaroslavl, Russia

ABSTRACT. This paper is devoted to tetrahedron maps, which are set-theoretical solutions to the Zamolodchikov tetrahedron equation. We construct a family of tetrahedron maps on associative rings.

We show that matrix tetrahedron maps presented in [arXiv:2110.05998] are a particular case of our construction. This provides an algebraic explanation of the fact that the matrix maps from [arXiv:2110.05998]

satisfy the tetrahedron equation.

Also, Liouville integrability is established for some of the constructed maps.

Mathematics Subject Classification 2020: 16T25, 81R12.

Keywords: Zamolodchikov tetrahedron equation, tetrahedron maps, associative rings, Liouville integrability

1. INTRODUCTION

This paper is devoted to tetrahedron maps, which are set-theoretical solutions to the Zamolodchikov tetrahedron equation [15, 16]. The tetrahedron equation belongs to fundamental equations of mathematical physics and has applications in many diverse branches of physics and mathematics, including statistical mechanics, quantum field theories, combinatorics, low-dimensional topology, and the theory of integrable systems (see, e.g., [1, 2, 6, 7, 10, 12] and references therein).

Presently, the relations of tetrahedron maps with integrable systems and with algebraic structures (including groups and rings) are a very active area of research (see, e.g., [3, 5, 7, 9, 12, 14]).

In this paper we construct tetrahedron maps on associative rings and study their properties. In particular, for any associative ring \mathcal{A} and any element $M \in \mathcal{A}$ we define the maps (4), (5) and prove that they satisfy the tetrahedron equation (1). The obtained tetrahedron maps (4), (5) are new, to our knowledge.

Also, we study the matrix tetrahedron maps (14), (15) constructed in [5]. The preprint [5] says that one can verify by a straightforward computation that (14), (15) satisfy the tetrahedron equation (1). In Theorem 2 we present an algebraic explanation of this fact.

Namely, in Theorem 2 we show that the maps (14), (15) are of the form (4) for $\mathcal{A} = \operatorname{Mat}_n(\mathbb{K})$ and some matrices $M \in \operatorname{Mat}_n(\mathbb{K})$. Here \mathbb{K} is a field, and $\operatorname{Mat}_n(\mathbb{K})$ is the associative ring of $n \times n$ matrices with entries from \mathbb{K} . Usually, \mathbb{K} is either \mathbb{R} or \mathbb{C} , but one can consider also arbitrary fields.

Proposition 1 recalls a well-known construction, which allows one to obtain a new tetrahedron map from a known one. Applying Proposition 1 to the maps (14), (15), we get new tetrahedron maps (16), (17). In Section 3 we prove Liouville integrability

• for the map (16) in the case $1 \le m \le n/2$ in Proposition 6,

• for the map (17) in the case $3n/2 \le \hat{m} \le 2n-1$ in Proposition 7.

The proofs of these results on Liouville integrability for (16), (17) are deduced from the proofs of similar results for (14), (15) taken from [5].

We use the standard notion of Liouville integrability for maps on manifolds (see, e.g., [4, 5, 8, 13] and references therein). This notion is presented in Definition 1.

Let W be a set. A *tetrahedron map* is a map

$$T: W^3 \to W^3, \qquad T(x, y, z) = (f(x, y, z), g(x, y, z), h(x, y, z)), \qquad x, y, z \in W$$

satisfying the (Zamolodchikov) tetrahedron equation

(1)
$$T^{123} \circ T^{145} \circ T^{246} \circ T^{356} = T^{356} \circ T^{246} \circ T^{145} \circ T^{123}.$$

Here $T^{ijk}: W^6 \to W^6$ for i, j, k = 1, ..., 6, i < j < k, is the map acting as T on the *i*th, *j*th, *k*th factors of the Cartesian product W^6 and acting as identity on the remaining factors. For instance,

$$T^{246}(x, y, z, r, s, t) = (x, f(y, r, t), z, g(y, r, t), s, h(y, r, t)), \qquad x, y, z, r, s, t \in W.$$

The statement of Proposition 1 is well known. A proof can be found, e.g., in [7].

Proposition 1. Consider the permutation map

$$P^{13}: W^3 \to W^3, \qquad P^{13}(a_1, a_2, a_3) = (a_3, a_2, a_1), \qquad a_i \in W.$$

If a map $T: W^3 \to W^3$ satisfies the tetrahedron equation (1) then $\tilde{T} = P^{13} \circ T \circ P^{13}$ obeys this equation as well.

Proposition 2. For any associative ring \mathcal{A} , we have the tetrahedron maps

(2)
$$\mathbf{T}: (\mathcal{A})^3 \to (\mathcal{A})^3, \qquad \mathbf{T}(X, Y, Z) = (X, Y + XZ, Z),$$

(3)
$$\tilde{\mathbf{T}}: (\mathcal{A})^3 \to (\mathcal{A})^3, \qquad \tilde{\mathbf{T}}(X, Y, Z) = (X, Y + ZX, Z),$$

$$X, Y, Z \in \mathcal{A}$$

Proof. For the map (2) and any elements $A_1, A_2, A_3, A_4, A_5, A_6 \in \mathcal{A}$ we have

$$(\mathbf{T}^{123} \circ \mathbf{T}^{145} \circ \mathbf{T}^{246} \circ \mathbf{T}^{356}) (A_1, A_2, A_3, A_4, A_5, A_6) = = (\mathbf{T}^{123} \circ \mathbf{T}^{145} \circ \mathbf{T}^{246}) (A_1, A_2, A_3, A_4, A_5 + A_3 A_6, A_6) = = (\mathbf{T}^{123} \circ \mathbf{T}^{145}) (A_1, A_2, A_3, A_4 + A_2 A_6, A_5 + A_3 A_6, A_6) = = \mathbf{T}^{123} (A_1, A_2, A_3, A_4 + A_2 A_6 + A_1 (A_5 + A_3 A_6), A_5 + A_3 A_6, A_6) = = (A_1, A_2 + A_1 A_3, A_3, A_4 + A_2 A_6 + A_1 A_5 + A_1 A_3 A_6, A_5 + A_3 A_6, A_6),$$

$$(\mathbf{T}^{356} \circ \mathbf{T}^{246} \circ \mathbf{T}^{145} \circ \mathbf{T}^{123})(A_1, A_2, A_3, A_4, A_5, A_6) = = (\mathbf{T}^{356} \circ \mathbf{T}^{246} \circ \mathbf{T}^{145})(A_1, A_2 + A_1A_3, A_3, A_4, A_5, A_6) = = (\mathbf{T}^{356} \circ \mathbf{T}^{246})(A_1, A_2 + A_1A_3, A_3, A_4 + A_1A_5, A_5, A_6) = = \mathbf{T}^{356}(A_1, A_2 + A_1A_3, A_3, A_4 + A_1A_5 + (A_2 + A_1A_3)A_6, A_5, A_6) = = (A_1, A_2 + A_1A_3, A_3, A_4 + A_1A_5 + A_2A_6 + A_1A_3A_6, A_5 + A_3A_6, A_6).$$

Therefore, the map (2) satisfies the tetrahedron equation (1).

The map (3) is obtained from (2) by means of Proposition 1.

Theorem 1. Let \mathcal{A} be an associative ring. Let $M \in \mathcal{A}$. The maps

(4)
$$\mathbf{T}_M \colon (\mathcal{A})^3 \to (\mathcal{A})^3, \qquad \mathbf{T}_M(X, Y, Z) = (X, Y + XMZ, Z),$$

(5)
$$\tilde{\mathbf{T}}_M \colon (\mathcal{A})^3 \to (\mathcal{A})^3, \qquad \tilde{\mathbf{T}}_M(X, Y, Z) = (X, Y + ZMX, Z),$$

$$X, Y, Z \in \mathcal{A},$$

satisfy the tetrahedron equation.

Proof. On the associative ring \mathcal{A} one has the addition and multiplication operations, which we call the initial addition and multiplication on \mathcal{A} . Let us consider a new multiplication operation on \mathcal{A} defined as follows

$$P * Q := PMQ, \qquad P, Q \in \mathcal{A}.$$

Since the initial multiplication on \mathcal{A} is associative, the new multiplication (6) is associative as well.

Moreover, the set \mathcal{A} with the initial addition and the new multiplication (6) is an associative ring. Applying Proposition 2 to this ring, we get the tetrahedron maps

(7)
$$\mathbf{T}: (\mathcal{A})^3 \to (\mathcal{A})^3, \qquad \mathbf{T}(X, Y, Z) = (X, Y + X * Z, Z),$$

(8)
$$\widetilde{\mathbf{T}}: (\mathcal{A})^3 \to (\mathcal{A})^3, \qquad \widetilde{\mathbf{T}}(X, Y, Z) = (X, Y + Z * X, Z),$$

Taking into account formula (6), we see that the maps (4), (5) coincide with the tetrahedron maps (7), (8).

 $X, Y, Z \in \mathcal{A}.$

We denote by $\mathbb{Z}_{>0}$ the set of positive integers.

Corollary 1. Let $n \in \mathbb{Z}_{>0}$ and $M \in Mat_n(\mathbb{K})$. The maps

(9)
$$\mathbf{T}_{M}: \left(\operatorname{Mat}_{n}(\mathbb{K})\right)^{3} \to \left(\operatorname{Mat}_{n}(\mathbb{K})\right)^{3}, \qquad \mathbf{T}_{M}(X, Y, Z) = (X, Y + XMZ, Z),$$

(10)
$$\tilde{\mathbf{T}}_{M}: \left(\operatorname{Mat}_{n}(\mathbb{K})\right)^{3} \to \left(\operatorname{Mat}_{n}(\mathbb{K})\right)^{3}, \qquad \tilde{\mathbf{T}}_{M}(X, Y, Z) = (X, Y + ZMX, Z),$$

$$X, Y, Z \in \operatorname{Mat}_{n}(\mathbb{K}),$$

satisfy the tetrahedron equation.

Proof. This follows from Theorem 1 in the case $\mathcal{A} = \operatorname{Mat}_n(\mathbb{K})$.

Remark 1. Let $\hat{\mathcal{A}}$ be an associative ring with a unit $e \in \hat{\mathcal{A}}$. (That is, for any $x \in \hat{\mathcal{A}}$ we have xe = ex = x.) Let $K \in \hat{\mathcal{A}}$ be an invertible element. (That is, there is $K^{-1} \in \hat{\mathcal{A}}$ such that $KK^{-1} = K^{-1}K = e$.) The preprint [5] presents the following tetrahedron maps

(11)
$$\mathbb{T}_{K}:\left(\hat{\mathcal{A}}\right)^{3}\to\left(\hat{\mathcal{A}}\right)^{3},\qquad \mathbb{T}_{K}(X,Y,Z)=(X,\,YK+XZ,\,KZK^{-1}),$$

(12)
$$\tilde{\mathbb{T}}_{K}: (\hat{\mathcal{A}})^{3} \to (\hat{\mathcal{A}})^{3}, \qquad \tilde{\mathbb{T}}_{K}(X, Y, Z) = (KXK^{-1}, YK + ZX, Z), X, Y, Z \in \hat{\mathcal{A}}.$$

In the case K = e formulas (11), (12) coincide with (2), (3). Note that the maps (2), (3) are defined for any associative ring \mathcal{A} , which does not necessarily have a unit.

As discussed in [5], in the case $\hat{\mathcal{A}} = \mathbb{C}$ the maps (11), (12) reduce to a tetrahedron map from Sergeev's classification [11].

Let

$$n \in \mathbb{Z}_{>0}, \qquad m \in \{1, \dots, n\}, \qquad \hat{m} \in \{n+1, \dots, 2n-1\}.$$

Below the elements of matrices $X, Z \in Mat_n(\mathbb{K})$ are denoted by $x_{k,l}$, $z_{k,l}$ for k, l = 1, ..., n, and we use the multiplication of a column by a row

(13)
$$\begin{pmatrix} x_{1,i} \\ x_{2,i} \\ \vdots \\ x_{n,i} \end{pmatrix} (z_{j,1} \ z_{j,2} \ \dots \ z_{j,n}) = \begin{pmatrix} x_{1,i}z_{j,1} & x_{1,i}z_{j,2} & \dots & x_{1,i}z_{j,n} \\ x_{2,i}z_{j,1} & x_{2,i}z_{j,2} & \dots & x_{2,i}z_{j,n} \\ \vdots & \vdots & \ddots & \vdots \\ x_{n,i}z_{j,1} & x_{n,i}z_{j,2} & \dots & x_{n,i}z_{j,n} \end{pmatrix} = X E_{i,j} Z, \quad i, j \in \{1, \dots, n\}.$$

Here $E_{i,j} \in Mat_n(\mathbb{K})$ is the $n \times n$ matrix with (i, j)-th entry equal to 1 and all other entries equal to zero.

The preprint [5] presents the following maps

$$\mathbb{T}_{n,m}: \left(\operatorname{Mat}_{n}(\mathbb{K}) \right)^{3} \to \left(\operatorname{Mat}_{n}(\mathbb{K}) \right)^{3}, \qquad m \in \{1, \dots, n\},$$
(14)
$$\mathbb{T}_{n,m}(X, Y, Z) = \left(X, Y + \sum_{i=1}^{m} \begin{pmatrix} x_{1,i} \\ x_{2,i} \\ \vdots \\ x_{n,i} \end{pmatrix} (z_{n-m+i,1} \ z_{n-m+i,2} \ \dots \ z_{n-m+i,n}), Z \right)$$

$$\mathbf{T}_{n,\hat{m}}: \left(\operatorname{Mat}_{n}(\mathbb{K}) \right)^{3} \to \left(\operatorname{Mat}_{n}(\mathbb{K}) \right)^{3}, \qquad \hat{m} \in \{n+1, \dots, 2n-1\},$$
(15)
$$\mathbf{T}_{n,\hat{m}}(X, Y, Z) = \left(X, Y + \sum_{i=1}^{2n-\hat{m}} \begin{pmatrix} x_{1,\hat{m}-n+i} \\ x_{2,\hat{m}-n+i} \\ \vdots \\ x_{n,\hat{m}-n+i} \end{pmatrix} (z_{i,1} \ z_{i,2} \ \dots \ z_{i,n}), Z \right),$$

$$X, Y, Z \in \operatorname{Mat}_{n}(\mathbb{K}).$$

The preprint [5] says that one can verify by a straightforward computation that the maps (14), (15) satisfy the tetrahedron equation. In Theorem 2 below we present an algebraic explanation of this fact.

Theorem 2. The map (14) is of the form (9) for $M = \sum_{i=1}^{m} E_{i,n-m+i}$. The map (15) is of the form (9) for $M = \sum_{i=1}^{2n-\hat{m}} E_{\hat{m}-n+i,i}$.

Therefore, Theorem 1 and Corollary 1 explain why (14), (15) obey the tetrahedron equation.

Proof. The statements follow from formula (13).

Proposition 3. Let $n \in \mathbb{Z}_{>0}$, $m \in \{1, \ldots, n\}$, $\hat{m} \in \{n+1, \ldots, 2n-1\}$. One has the following tetrahedron maps

$$\tilde{\mathbb{T}}_{n,m}: \left(\operatorname{Mat}_{n}(\mathbb{K})\right)^{3} \to \left(\operatorname{Mat}_{n}(\mathbb{K})\right)^{3}, \qquad m \in \{1, \dots, n\},$$
(16)
$$\tilde{\mathbb{T}}_{n,m}(X, Y, Z) = \left(X, Y + \sum_{i=1}^{m} \begin{pmatrix} z_{1,i} \\ z_{2,i} \\ \vdots \\ z_{n,i} \end{pmatrix} (x_{n-m+i,1} \ x_{n-m+i,2} \ \dots \ x_{n-m+i,n}), Z \right)$$

$$\tilde{\mathbf{T}}_{n,\hat{m}}: \left(\operatorname{Mat}_{n}(\mathbb{K})\right)^{3} \to \left(\operatorname{Mat}_{n}(\mathbb{K})\right)^{3}, \qquad \hat{m} \in \{n+1, \dots, 2n-1\},$$
(17)
$$\tilde{\mathbf{T}}_{n,\hat{m}}(X, Y, Z) = \left(X, Y + \sum_{i=1}^{2n-m} \begin{pmatrix} z_{1,m-n+i} \\ z_{2,m-n+i} \\ \vdots \\ z_{n,m-n+i} \end{pmatrix} (x_{i,1} \ x_{i,2} \ \dots \ x_{i,n}), Z \right),$$

$$X, Y, Z \in \operatorname{Mat}_{n}(\mathbb{K}).$$

Proof. The maps (16), (17) are obtained from (14), (15) by means of Proposition 1.

3. LIOUVILLE INTEGRABILITY

In Definition 1 we recall the standard notion of Liouville integrability for maps on manifolds (see, e.g., [4, 5, 8, 13] and references therein).

Definition 1. Let $k \in \mathbb{Z}_{>0}$. Let **M** be a k-dimensional manifold with (local) coordinates $\mathbf{x}_1, \ldots, \mathbf{x}_k$. A (smooth or analytic) map $F: \mathbf{M} \to \mathbf{M}$ is said to be *Liouville integrable* (or *completely integrable*) if one has the following objects on the manifold **M**.

• A Poisson bracket $\{,\}$ which is invariant under the map F and is of constant rank 2r for some positive integer $r \leq k/2$ (i.e., the $k \times k$ matrix with the entries $\{\mathbf{x}_i, \mathbf{x}_j\}$ is of constant rank 2r). The invariance of the bracket means the following. For any functions q, h on \mathbf{M} one has

(18)
$$\{g,h\} \circ F = \{g \circ F, h \circ F\}.$$

,

To prove that the bracket is invariant, it is sufficient to check property (18) for $g = \mathbf{x}_i$, $h = \mathbf{x}_j$, $i, j = 1, \ldots, k$.

In our examples considered below the manifold has a system of coordinates $\mathbf{x}_1, \ldots, \mathbf{x}_k$ such that for any $i, j = 1, \ldots, k$ the function $\{\mathbf{x}_i, \mathbf{x}_j\}$ is constant. Then, in order to prove that the bracket is invariant under F, it is sufficient to show that $\{\mathbf{x}_i \circ F, \mathbf{x}_j \circ F\} = \{\mathbf{x}_i, \mathbf{x}_j\}$ for all i, j.

• If 2r < k then one needs also k - 2r functions

$$C_s, \qquad s = 1, \dots, k - 2r$$

which are invariant under F (i.e., $C_s \circ F = C_s$) and are Casimir functions (i.e., $\{C_s, g\} = 0$ for any function g).

• One has r functions

 $I_l, \qquad l=1,\ldots,r,$

which are invariant under F and are in involution with respect to the Poisson bracket (i.e., $\{I_{l_1}, I_{l_2}\} = 0$ for all $l_1, l_2 = 1, \ldots, r$).

• The functions (19), (20) must be functionally independent.

In this section we assume that \mathbb{K} is either \mathbb{R} or \mathbb{C} . Then the set $(\operatorname{Mat}_n(\mathbb{K}))^3$ is a manifold. The elements of matrices $X, Y, Z \in (\operatorname{Mat}_n(\mathbb{K}))^3$ are denoted by $x_{i,j}, y_{i,j}, z_{i,j}$ for $i, j = 1, \ldots, n$. Then

(21)
$$x_{i,j}, y_{i,j}, z_{i,j}, \quad i, j = 1, \dots, n,$$

can be regarded as coordinates on the $3n^2$ -dimensional manifold $(\operatorname{Mat}_n(\mathbb{K}))^3$. Clearly, the functions $x_{i,j}$, $z_{i,j}$ are invariant under the maps (14), (15), (16), (17).

Propositions 4, 5 below are proved in the preprint [5]. To clarify the main ideas, we present the proofs from [5].

Proposition 4 ([5]). Let $n, m \in \mathbb{Z}_{>0}$ such that $1 \le m \le n/2$. Then the map (14) is Liouville integrable.

Proof. On the manifold $(\operatorname{Mat}_n(\mathbb{K}))^3$ we consider the Poisson bracket defined as follows. The bracket of two coordinates from the list (21) is nonzero only for

(22)
$$\{y_{p,j}, z_{p,j}\} = -\{z_{p,j}, y_{p,j}\} = 1, \qquad p = 1, \dots, n - m, \qquad j = 1, \dots, n, \\ \{y_{n-m+q,j}, x_{j,m+q}\} = -\{x_{j,m+q}, y_{n-m+q,j}\} = 1, \qquad q = 1, \dots, m, \qquad j = 1, \dots, n$$

This Poisson bracket is of rank $2n^2$. The n^2 functions

(23)
$$z_{n-m+q,j}, x_{j,q}, x_{j,2m+s}, q = 1, \dots, m, s = 1, \dots, n-2m, j = 1, \dots, n,$$

are Casimir functions, since they do not appear in (22). The rank of the bracket plus the number of the Casimir functions (23) equals the dimension of the manifold.

The n^2 functions

(24)
$$z_{p,j}, \quad x_{j,m+q}, \quad p = 1, \dots, n-m, \quad q = 1, \dots, m, \quad j = 1, \dots, n,$$

are in involution with respect to the Poisson bracket, as one has $\{x_{i,j}, x_{i',j'}\} = \{z_{i,j}, z_{i',j'}\} = \{x_{i,j}, z_{i',j'}\} = 0$ for all i, j, i', j' = 1, ..., n. The functions (23), (24) are functionally independent and are invariant under the map (14).

Let us show that the bracket (22) is invariant as well. In (14) we have

(25)
$$\hat{X} = X, \qquad \hat{Y} = Y + \sum_{i=1}^{m} \begin{pmatrix} x_{1,i} \\ x_{2,i} \\ \vdots \\ x_{n,i} \end{pmatrix} (z_{n-m+i,1} \ z_{n-m+i,2} \ \dots \ z_{n-m+i,n}), \qquad \hat{Z} = Z.$$

The elements of matrices $\hat{X}, \hat{Y}, \hat{Z} \in (\operatorname{Mat}_n(\mathbb{K}))^3$ are denoted by $\hat{x}_{i,j}, \hat{y}_{i,j}, \hat{z}_{i,j}$ for $i, j = 1, \ldots, n$. The functions

(26)
$$x_{1,i}, x_{2,i}, \ldots, x_{n,i}, z_{n-m+i,1}, z_{n-m+i,2}, \ldots, z_{n-m+i,n}, i = 1, \ldots, m,$$

which appear in (25), belong to the list of the Casimir functions (23). Therefore, formulas (22), (25) yield

$$\{ \hat{x}_{i,j}, \hat{x}_{i',j'} \} = \{ x_{i,j}, x_{i',j'} \}, \quad \{ \hat{y}_{i,j}, \hat{y}_{i',j'} \} = \{ y_{i,j}, y_{i',j'} \}, \quad \{ \hat{z}_{i,j}, \hat{z}_{i',j'} \} = \{ z_{i,j}, z_{i',j'} \}, \\ \{ \hat{x}_{i,j}, \hat{y}_{i',j'} \} = \{ x_{i,j}, y_{i',j'} \}, \quad \{ \hat{x}_{i,j}, \hat{z}_{i',j'} \} = \{ x_{i,j}, z_{i',j'} \}, \quad \{ \hat{y}_{i,j}, \hat{z}_{i',j'} \} = \{ y_{i,j}, z_{i',j'} \}, \\ i, j, i', j' = 1, \dots, n,$$

which implies that the Poisson bracket is invariant under the map (14).

Therefore, the map (14) in the case $1 \le m \le n/2$ is Liouville integrable.

Example 1. Let n = 2 and m = 1. Then the map (14) reads

$$\mathbb{T}_{2,1}: \left(\operatorname{Mat}_{2}(\mathbb{K}) \right)^{3} \to \left(\operatorname{Mat}_{2}(\mathbb{K}) \right)^{3},$$
$$\mathbb{T}_{2,1}(X, Y, Z) = \left(X, Y + \begin{pmatrix} x_{11}z_{21} & x_{11}z_{22} \\ x_{21}z_{21} & x_{21}z_{22} \end{pmatrix}, Z \right),$$
$$X = \begin{pmatrix} x_{11} & x_{12} \\ x_{21} & x_{22} \end{pmatrix}, \qquad Y = \begin{pmatrix} y_{11} & y_{12} \\ y_{21} & y_{22} \end{pmatrix}, \qquad Z = \begin{pmatrix} z_{11} & z_{12} \\ z_{21} & z_{22} \end{pmatrix}.$$

One has the coordinates $x_{ij}, y_{ij}, z_{ij}, i, j \in \{1, 2\}$, on the 12-dimensional manifold $(\operatorname{Mat}_2(\mathbb{K}))^3$.

The Poisson bracket (22) reads

(27)
$$\{y_{11}, z_{11}\} = -\{z_{11}, y_{11}\} = 1, \qquad \{y_{12}, z_{12}\} = -\{z_{12}, y_{12}\} = 1, \\ \{y_{21}, x_{12}\} = -\{x_{12}, y_{21}\} = 1, \qquad \{y_{22}, x_{12}\} = -\{x_{12}, y_{22}\} = 1,$$

and is of rank 8. The Casimir functions (23) are z_{21} , z_{22} , x_{11} , x_{21} . The functions (24) are z_{11} , z_{12} , x_{12} , x_{22} , and they are in involution with respect to the bracket (27).

Example 2. Now let n = 5 and m = 2. Then the map (14) is

$$\mathbb{T}_{5,2} \colon \left(\operatorname{Mat}_{5}(\mathbb{K}) \right)^{3} \to \left(\operatorname{Mat}_{5}(\mathbb{K}) \right)^{3},$$

$$\mathbb{T}_{5,2}(X,Y,Z) = \left(X, Y + \begin{pmatrix} x_{11}z_{41} + x_{12}z_{51} & \dots & x_{11}z_{45} + x_{12}z_{55} \\ \vdots & \ddots & \vdots \\ x_{51}z_{41} + x_{52}z_{51} & \dots & x_{51}z_{45} + x_{52}z_{55} \end{pmatrix}, Z \right),$$

$$X = \begin{pmatrix} x_{11} & \dots & x_{15} \\ \vdots & \ddots & \vdots \\ x_{51} & \dots & x_{55} \end{pmatrix}, \qquad Y = \begin{pmatrix} y_{11} & \dots & y_{15} \\ \vdots & \ddots & \vdots \\ y_{51} & \dots & y_{55} \end{pmatrix}, \qquad Z = \begin{pmatrix} z_{11} & \dots & z_{15} \\ \vdots & \ddots & \vdots \\ z_{51} & \dots & z_{55} \end{pmatrix}.$$

One has the coordinates $x_{ij}, y_{ij}, z_{ij}, i, j \in \{1, \ldots, 5\}$, on the 75-dimensional manifold $(\operatorname{Mat}_5(\mathbb{K}))^3$.

The Poisson bracket (22) reads

(28)
$$\{y_{1,j}, z_{1,j}\} = -\{z_{1,j}, y_{1,j}\} = \{y_{2,j}, z_{2,j}\} = -\{z_{2,j}, y_{2,j}\} = \{y_{3,j}, z_{3,j}\} = -\{z_{3,j}, y_{3,j}\} = 1, \{y_{4,j}, x_{j,3}\} = -\{x_{j,3}, y_{4,j}\} = \{y_{5,j}, x_{j,4}\} = -\{x_{j,4}, y_{5,j}\} = 1,$$
 $j = 1, \dots, 5,$

and is of rank 50. The Casimir functions (23) are $z_{4,j}$, $z_{5,j}$, $x_{j,1}$, $x_{j,2}$, $x_{j,5}$, $j = 1, \ldots, 5$. The functions (24) are $z_{1,j}$, $z_{2,j}$, $z_{3,j}$, $x_{j,3}$, $x_{j,4}$, and they are in involution with respect to the bracket (28).

Proposition 5 ([5]). Let $n, \hat{m} \in \mathbb{Z}_{>0}$ such that $3n/2 \leq \hat{m} \leq 2n-1$. Then the map (15) is Liouville integrable.

Proof. Now on the manifold $(\operatorname{Mat}_n(\mathbb{K}))^3$ we consider the following Poisson bracket. The bracket of two coordinates from the list (21) is nonzero only for

(29)
$$\begin{cases} \{y_{p,j}, z_{2n-\hat{m}+p,j}\} = -\{z_{2n-\hat{m}+p,j}, y_{p,j}\} = 1, & p = 1, \dots, \hat{m} - n, & j = 1, \dots, n, \\ \{y_{\hat{m}-n+q,j}, x_{j,q}\} = -\{x_{j,q}, y_{n-\hat{m}+q,j}\} = 1, & q = 1, \dots, 2n - \hat{m}, & j = 1, \dots, n. \end{cases}$$

This bracket is of rank $2n^2$. The n^2 functions

(30)
$$z_{q,j}, \quad x_{j,2n-\hat{m}+p}, \quad q = 1, \dots, 2n - \hat{m}, \quad p = 1, \dots, \hat{m} - n, \quad j = 1, \dots, n,$$

are Casimir functions, as they do not appear in (29). The rank of the bracket plus the number of the Casimir functions (30) equals the dimension of the manifold.

The n^2 functions

(31) $z_{2n-\hat{m}+p,j}, x_{j,q}, p = 1, \dots, \hat{m} - n, q = 1, \dots, 2n - \hat{m}, j = 1, \dots, n,$

are in involution with respect to the bracket, since we have $\{x_{i,j}, x_{i',j'}\} = \{z_{i,j}, z_{i',j'}\} = \{x_{i,j}, z_{i',j'}\} = 0$ for all $i, j, i', j' = 1, \ldots, n$. The functions (30), (31) are functionally independent and are invariant under the map (15).

Similarly to the proof of Proposition 4, one shows that the bracket (29) is invariant as well. Hence the map (15) in the case $3n/2 \le \hat{m} \le 2n-1$ is Liouville integrable.

Proposition 6. Let $n, m \in \mathbb{Z}_{>0}$ such that $1 \le m \le n/2$. Then the map (16) is Liouville integrable.

Proof. To obtain a proof for Proposition 6, it is sufficient to interchange $x_{i,j}$ with $z_{i,j}$ in the proof of Proposition 4.

Proposition 7. Let $n, \hat{m} \in \mathbb{Z}_{>0}$ such that $3n/2 \leq \hat{m} \leq 2n-1$. Then the map (17) is Liouville integrable.

Proof. To obtain a proof for Proposition 7, it is sufficient to interchange $x_{i,j}$ with $z_{i,j}$ in the proof of Proposition 5.
