ABSTRACT: In this paper, island formation for entangling regions of finite size in the asymptotically flat eternal Schwarzschild black hole is considered. We check the complementarity property of entanglement entropy which was implicitly assumed in previous studies for semi-infinite regions. This check reveals the emergence of infrared anomalies after regularization of a Cauchy surface. A naive infrared regularization based on “mirror symmetry” is considered and its failure is shown. We introduce an improved regularization that gives a correct limit agreed with the semi-infinite results from previous studies. As the time evolution goes, the endpoints of a finite region compatible with the improved regularization become separated by a timelike interval. We call this phenomenon the “Cauchy surface breaking”. Shortly before the Cauchy surface breaking, finite size configurations generate asymmetric entanglement islands in contrast to the semi-infinite case. Depending on the size of the finite regions, qualitatively new behaviour arises, such as discontinuous evolution of the entanglement entropy and the absence of island formation. Finally, we show that the island prescription does not help us to solve the information paradox for certain finite size regions.

1 Introduction

Hawking radiation is a mysterious and important phenomenon which provides a window to the world of quantum effects emerging in gravity [1, 2]. Having attracted the attention of physicists for years, it remains one of the main fingerprints of the quantum nature of black holes. Black holes, being thermodynamic systems, hint to us that we should study the entropy of the emitted radiation in order to understand their nature. Years ago, Page showed [3, 4] that a detailed comparison of the thermodynamic entropy of black holes and the entropy of their radiation leads to the fact that the entanglement entropy of this radiation exhibits an unlimited growth which. In the end, the entanglement entropy exceeds the entropy of the black hole. This is in contradiction with the expected time dependence of the entanglement entropy visualized by the so-called Page curve, which should start to decrease after some characteristic time moment — the Page time. The descending part of the Page curve is difficult to interpret in a straightforward way, and recently a new mechanism called the “entanglement islands” [5–7] was introduced to explain the stoppage of the entanglement entropy growth. This mechanism arises when systems with dynamical gravitational degrees of freedom are considered, and the appearance of the entanglement islands is required for gravity to be consistent with the results of calculations performed using the replica trick. The conjecture of modifying the entanglement entropy in the presence of dynamical gravity has attracted a lot of attention in recent years [8–65]. The entanglement islands has been studied in two-dimensional gravity setups [5, 12, 14, 15, 24, 25, 28, 34, 51], in boundary CFT models [13, 19, 40, 46, 54, 56, 59, 62] and moving mirrors models [8–11, 32, 36, 37, 42, 49, 61].

In this paper, we study entanglement entropy and entanglement islands in the higher-dimensional Schwarzschild black hole following the setup proposed in [18]. In [18], the authors consider the s-wave approximation for fields defined on the background of the four-dimensional Schwarzschild black hole, effectively reducing the problem to a two-dimensional one while capturing the features of the higher-dimensional setup. This model explains how the unlimited growth of the entanglement entropy associated with semi-infinite regions “collecting” the Hawking radiation is stopped by emergence of the entanglement islands in the near-horizon zone of the Schwarzschild black hole. The variety of papers extending the results of [18] in the context of different models have appeared in recent years [22, 29, 30, 34, 35, 39, 41, 43, 45, 48, 50–52, 55, 57, 58, 60, 63–65].

In the framework of the s-wave approximation, we generalize the results of [18] and consider entangling regions with a finite extent (instead of the semi-infinite ones studied in [18]). This problem, seemingly simple in its formulation, reveals curious

Figure 1: Left: Penrose diagram for the eternal Schwarzschild black hole with the *schematic* plots of the entangling region $R \equiv R_- \cup R_+$ (orange) and its complement $\bar{R} \equiv [\mathbf{b}_-, \mathbf{b}_+]$ (dashed red). **Right:** The same as in the left diagram but with the regularized semi-infinite entangling region R .

features of the entanglement entropy in the two-sided Schwarzschild black hole. It is well known [25, 66] that for a pure bipartite quantum state, the entanglement entropies of each partition are equal to each other. This property is commonly used in the calculations of the entropy for semi-infinite regions. We explicitly check whether this “*complementarity property*” holds, i.e.

$$S(R) \stackrel{?}{=} S(\bar{R}), \quad (1.1)$$

(see Fig. 1 for the notation) and reveal, strictly speaking, its *violation*.

The complementarity property check involves the calculation of the entropy for semi-infinite regions, which can be done using the infrared (IR) regularization

$$S(R) = \lim_{\mathbf{q}_{\pm} \rightarrow i^0} S([\mathbf{q}_-, \mathbf{b}_-] \cup [\mathbf{b}_+, \mathbf{q}_+]), \quad (1.2)$$

see Fig. 1 for the configuration without islands. The regularized entangling region in the right wedge extends between the points \mathbf{b}_+ and \mathbf{q}_+ ; the left region starts at the point \mathbf{b}_- that is mirror-symmetric to \mathbf{b}_+ , i.e.

$$b_- = b_+, \quad t_{b_-} = -t_{b_+} + \frac{i\pi}{\kappa_h}, \quad (1.3)$$

where $\{b_{\pm}, t_{b_{\pm}}\}$ are Schwarzschild radial and time coordinates of the points \mathbf{b}_{\pm} .

In the same manner, one can also try to take the point \mathbf{q}_- as a mirror-symmetric

one to \mathbf{q}_+

$$q_- = q_+, \quad t_{q_-} = -t_{q_+} + \frac{i\pi}{\kappa_h}. \quad (1.4)$$

We call this regularization scheme the “*mirror-symmetric*” (MS) regularization, since the regularized regions are mirror-symmetric¹ to each other, see Fig. 13. As we demonstrate, this treatment is *not* actually a regularization at all, since it does not possess the desired limit at spacelike infinity i^0 .

Our calculations show that the regularization should be such that Schwarzschild radial and time coordinates of the points \mathbf{q}_- and \mathbf{q}_+ are equal (up to the imaginary term $\frac{i\pi}{\kappa_h}$ for the time coordinate), i.e.

$$q_- = q_+, \quad t_{q_-} = t_{q_+} + \frac{i\pi}{\kappa_h}. \quad (1.5)$$

Only this regularization provides the complementarity property up to a violation term

$$S(R) = S(\overline{R}) + \frac{c}{3} \log \frac{2}{\kappa_h \varepsilon}. \quad (1.6)$$

We call this scheme the “*asymmetric*” (AS) regularization, since the regularized regions in the Penrose diagram are not symmetric in any sense, see Fig. 7. We interpret the second term on the RHS of (1.6) as an *anomaly* related to IR modes that violates the exact complementarity property. This type of regularization has a limit which coincides with the results of [18] (up to the anomaly term (1.6)), but contains a subtlety: the finite entangling region in the left wedge cannot be located on a constant time hypersurface and, moreover, if the radial coordinates are kept fixed, its endpoints become separated by a timelike interval during time evolution, thus the initial hypersurface is no longer spacelike. We refer to this phenomenon as the “*Cauchy surface breaking*”.

The same complementarity property problem arises for configurations with entanglement islands. Calculations for such configurations in works of different authors have assumed the equality between $S(R \cup I)$ and $S(\overline{R \cup I})$. We elaborate on this by defining

$$S(R \cup I) = \lim_{\mathbf{q}_\pm \rightarrow i^0} S([\mathbf{q}_-, \mathbf{b}_-] \cup [\mathbf{b}_+, \mathbf{q}_+] \cup I) \quad (1.7)$$

(see Fig. 2 for the notation) and demonstrating that in the AS scheme, the following

¹By mirror symmetry we mean the reflection about the vertical axis of symmetry of the Penrose diagram for the two-sided Schwarzschild black hole.

Figure 2: **Left:** Penrose diagram for the eternal Schwarzschild black hole with the *schematic* plots of the semi-infinite entangling region $R \equiv R_- \cup R_+$ (orange), its complement $\overline{R_- \cup R_+ \cup I} \equiv [\mathbf{b}_-, \mathbf{a}_-] \cup [\mathbf{a}_+, \mathbf{b}_+]$ (dashed red) and the entanglement island $I \equiv [\mathbf{a}_-, \mathbf{a}_+]$ (magenta). **Right:** the same as in the left diagram but with the regularized entangling region R .

relation holds

$$S(R \cup I) = S(\overline{R \cup I}) + \frac{c}{3} \log \frac{2}{\kappa_h \varepsilon}, \quad (1.8)$$

i.e. once again, the same anomalous extra term (1.6) appears.

Regularization schemes (1.2) and (1.7) are related to the study of finite size effects in the behaviour of entanglement entropy. In accordance with the described regularization schemes, we consider two types of finite entangling regions with *fixed* radial coordinates of the points \mathbf{q}_\pm , and for both types we choose the points \mathbf{b}_\pm as in (1.3). Namely, the first and the second types of finite regions correspond to the choices of the points \mathbf{q}_\pm as in the mirror-symmetric (1.4) and asymmetric (1.5) regularizations. We call the finite regions of the first type *mirror-symmetric* (MS) (see Fig. 7), and of the second type — *asymmetric* (AS), (see Fig. 13). Note that the MS setup corresponds to finite configurations for the eternal black hole in two-dimensional AdS with flat reservoirs [47]. We should emphasize the difference between regularized and finite regions. We use the first ones to study the infrared behaviour of entanglement entropy and assume that the timelike coordinates are taken fixed while the radial ones go to spacelike infinity. In contrast, the radial coordinates of finite regions are fixed, and we study time evolution of their entropy. In particular, Cauchy surface breaking makes sense only for finite regions.

It is important to note that the finite size of entangling regions strongly affects the evolution picture, adding many qualitative features and influencing the behaviour of the entanglement entropy. The dynamics of the latter for finite size configurations is

very peculiar even beyond the island paradigm. Below we list our findings for finite size effects for the AS and MS entangling regions both with and without islands. They are as follows:

- **Finite entangling regions without islands:**

- The evolution of AS entangling regions suffers from a counterintuitive drawback — after some time, the entangling region in the left wedge is no longer spacelike, and we can say that the corresponding Cauchy surface breaks down. The time dependence of the entropy for these configurations corresponds to the semi-infinite case [18], with the only difference in the rapid decrease just before the Cauchy surface breaking.
- The time evolution of the entropy for MS entangling regions at relatively early times is given by a monotonic growth twice as fast as that of the entropy for the semi-infinite case [18]. The finite size effects lead to saturation of the entropy at late times when the fluxes of the radiation particles entering and leaving the region become equal.

- **Finite entangling regions with islands:**

- The existence of a new scale for AS entangling regions — the Cauchy surface breaking time — has important implications for entanglement islands as an effect inherent in late time evolution. It might happen that the breaking time occurs before the formation of the island, which makes the island formula of little use.
- At relatively early times, for AS entangling regions, a symmetric island configuration dominates. However, shortly before the Cauchy surface breaking, finite size effects come into play, making the entanglement island asymmetric in both spacelike and timelike directions. For sufficiently large regions at late times, the island saddle point dominates the matter contribution, thus stopping the growth of the entropy until the Cauchy surface breaking happens.
- For sufficiently large sizes of MS regions, entanglement islands exist only for a finite time due to the violation of extremization conditions for which they were found. Islands for MS regions are symmetric and lead to a monotonic growth of the entropy twice as slow as that for the same regions without islands. Since the lifetime of an island is finite, after its disappearance there is a discontinuous transition to the no-island configuration. This leads to

exceeding the allowed upper limit of the entropy, which we interpret as the information paradox for finite regions.

- For both AS and MS configurations, reducing the size of the entangling region can change the qualitative picture of the entropy evolution and forever make the entanglement entropy with an island subdominant. Moreover, for sufficiently small sizes, the island configuration is not generated at all.

Also, we discuss some universal modifications regarding the unitary evolution of the entropy of the Hawking radiation [3, 4] due to finite sizes of entangling regions in the context of the information paradox. For both AS and MS configurations, we show that in the limit $\mathbf{q}_{\pm} \rightarrow i^0$, the appropriate upper bound on the entropy [12, 18] is correctly reproduced. For sufficiently small regions, the introduction of islands is not required so that the entropy does not exceed this upper bound. However, for intermediate sizes of MS entangling regions, the entropy exceeds the upper bound for a finite time due to the discontinuous transition to the configuration without an island. Thus, one can assume that the introduction of an island for these regions does not lead to a satisfying resolution of the information paradox.

The paper is organized as follows. In Section 2, we present the setup for our further calculations. It contains a brief overview of the eternal Schwarzschild black hole geometry as well as a sketch of the results obtained in [18]. Section 3 is devoted to a discussion of the infrared regularizations and the complementarity property for semi-infinite entangling regions. In Section 4, we study the properties of the entanglement entropy for finite entangling regions. In Section 5, we discuss the information paradox for finite configurations. Section 6 gives a short summary and future perspectives. Appendix contains several long formulas.

2 Setup

Geometry

We start with the metric of the four-dimensional Schwarzschild black hole

$$ds^2 = -f(r)dt^2 + \frac{dr^2}{f(r)} + r^2 d\Omega_2^2, \quad f(r) = 1 - \frac{r_h}{r}, \quad (2.1)$$

where r_h corresponds to the horizon location, and $d\Omega_2^2$ is the spherical part of the metric. The surface gravity and the Hawking temperature of this black hole are defined as

$$\kappa_h = \frac{1}{2r_h}, \quad T = \frac{1}{4\pi r_h}. \quad (2.2)$$

Introducing Kruskal coordinates U and V corresponding to the right wedge of the eternal (two-sided) Schwarzschild black hole as²

$$\begin{aligned} U &= -\frac{1}{\kappa_h} e^{-\kappa_h u}, \quad u = t - r_*, \\ V &= \frac{1}{\kappa_h} e^{\kappa_h v}, \quad v = t + r_*, \end{aligned} \quad (2.3)$$

where u, v are retarded and advanced null coordinates, and $r_* = r_*(r)$ is the tortoise coordinate

$$r_*(r) = r + r_h \log\left(\frac{r - r_h}{r_h}\right), \quad (2.4)$$

the metric (2.1) of the Schwarzschild black hole can be rewritten in the form

$$ds^2 = -e^{2\rho(r)} dU dV + r^2 d\Omega^2, \quad (2.5)$$

where the conformal factor $\rho(r)$ is given by

$$e^{2\rho(r)} = \frac{r_h}{r} e^{-r/r_h}. \quad (2.6)$$

In what follows, we need a formula for the radial geodesic distance $d(\mathbf{x}, \mathbf{y})$ for the spherically symmetric two-dimensional part of the metric (2.5). If we consider (2.5) as the Weyl transformed version of the metric $ds^2 = -dU dV$ (neglecting the angular part) with the Weyl factor $e^{2\rho(r)}$, the square of the distance $d(\mathbf{x}, \mathbf{y})$ in the metric (2.5) can be derived as

$$d^2(\mathbf{x}, \mathbf{y}) = [U(\mathbf{x}) - U(\mathbf{y})] [V(\mathbf{y}) - V(\mathbf{x})] e^{\rho(\mathbf{x})} e^{\rho(\mathbf{y})}, \quad (2.7)$$

where by the bold letters we denote pairs of radial and time coordinates

$$\mathbf{x} = \{x, t_x\}. \quad (2.8)$$

²Sometimes we will refer to the global time defined as $U + V$.

In terms of (t, r) coordinates, one can explicitly rewrite (2.7) in the form

$$d^2(\mathbf{x}, \mathbf{y}) = \frac{2\sqrt{f(x)f(y)}}{\kappa_h^2} [\cosh \kappa_h(r_*(x) - r_*(y)) - \cosh \kappa_h(t_x - t_y)]. \quad (2.9)$$

The Kruskal coordinates covering the left wedge of the eternal Schwarzschild black hole are given by

$$\begin{aligned} U &= \frac{1}{\kappa_h} e^{-\kappa_h u}, \\ V &= -\frac{1}{\kappa_h} e^{\kappa_h v}. \end{aligned} \quad (2.10)$$

From the comparison of (2.3) and (2.10), we see that if we continue the timelike coordinate of the right wedge as $t \rightarrow t + \frac{i\pi}{\kappa_h}$, then we will find ourselves in the left wedge. This imaginary part implies the change of the Kruskal coordinates which corresponds to transition between the wedges.

We use the following notation for spacetime points

$$\begin{aligned} \mathbf{x}_+ &= \{x_+, t_{x_+}\}, \\ \mathbf{x}_- &= \left\{x_-, t_{x_-} + \frac{i\pi}{\kappa_h}\right\}, \end{aligned} \quad (2.11)$$

where the subscripts “+” and “−” denote the points in the right and the left wedges of the Penrose diagram for Schwarzschild spacetime, respectively.

Also, note there are two spacelike infinities i^0 in the Penrose diagram for the two-sided Schwarzschild black hole. For arbitrary spacetime points \mathbf{q}_\pm in the right and left wedges, we use a short-hand notation $\mathbf{q}_\pm \rightarrow i^0$ meaning the limits to different i^0 in the corresponding wedges. In this case, in the Schwarzschild patch (2.1), the radial coordinates of \mathbf{q}_\pm go to infinity: $q_\pm \rightarrow \infty$, while the timelike ones t_{q_\pm} are kept fixed.

Entanglement entropy

We study the entanglement entropy of massless conformal matter on the background (2.5). Generally speaking, the calculation of the entanglement entropy in a higher-dimensional curved spacetime is an extremely challenging problem, at least analytically. An important suggestion made in [18] is the consideration of the s-wave approximation of conformal four-dimensional matter, in which we neglect the spherical part of the metric (2.5) and effectively reduce the calculations to a two-dimensional problem. In this way, one

can consider the entanglement entropy of conformal matter in a two-dimensional metric and calculate it analytically. In this work, we will calculate the entanglement entropy of a system consisting of several finite intervals. In flat space, the entanglement entropy of a single interval between points x and y is given by

$$S = \frac{c}{3} \log \frac{|x - y|}{\varepsilon}, \quad (2.12)$$

while for a system of N intervals [67] we have

$$S = \frac{c}{3} \left(\sum_{i,j} \log \frac{|x_i - y_j|}{\varepsilon} - \sum_{i < j} \log \frac{|x_i - x_j|}{\varepsilon} - \sum_{i < j} \log \frac{|y_i - y_j|}{\varepsilon} \right), \quad (2.13)$$

where x_i and y_i are the left and right interval endpoints, and ε is the UV cutoff. The entanglement entropy in the curved spacetime (2.5) can be calculated using (2.9) and (2.13)

$$S_N = \frac{c}{3} \left(\sum_{i,j} \log \frac{d(\mathbf{x}_i, \mathbf{y}_j)}{\varepsilon} - \sum_{i < j} \log \frac{d(\mathbf{x}_i, \mathbf{x}_j)}{\varepsilon} - \sum_{i < j} \log \frac{d(\mathbf{y}_i, \mathbf{y}_j)}{\varepsilon} \right), \quad (2.14)$$

where \mathbf{x}_i and \mathbf{y}_i denote the left and right interval endpoints as in the flat space (2.13).

Entanglement islands in eternal Schwarzschild black hole

In the two-sided Schwarzschild black hole, we consider the Hartle-Hawking vacuum [68], for which the fluxes of outgoing and incoming radiation particles balance each other. The island mechanism can be schematically described as the appearance of an additional contribution from a region I to the entanglement entropy of an entangling region A . The region I is called the entanglement island and is located in spacetime according to certain rules [5, 7, 15, 69]. To calculate the entanglement entropy in such a system, one should consider the generalized entropy functional S_{gen} given by the so-called *island formula* [14, 15]

$$S_{\text{gen}}(A) = \min_{\partial I} \left\{ \text{ext}_{\partial I} \left[\frac{\text{Area}(\partial I)}{4G_N} + S_{\text{matter}}(A \cup I) \right] \right\}, \quad (2.15)$$

where ∂I denotes the boundary of the entanglement island I , G_N is Newton's constant and S_{matter} is the entanglement entropy of conformal matter. One has to extremize this functional over all possible island configurations and choose the minimal one after that.

In [18], authors considered two semi-infinite entangling regions R_+ and R_- (see Fig. 1), where R_+ is in the right wedge of the two-sided Schwarzschild black hole and extends from some point \mathbf{b}_+ ³

$$\mathbf{b}_+ = \{b, t_b\}, \quad (2.16)$$

to spacelike infinity i^0 . In turn, R_- is in the left wedge and extends from the point \mathbf{b}_-

$$\mathbf{b}_- = \left\{ b, -t_b + \frac{i\pi}{\kappa_h} \right\}, \quad (2.17)$$

to the corresponding spacelike infinity i^0 . The time coordinate in (2.17) is taken in accordance with the analytic continuation of the coordinates (2.1) to the left wedge.

As it was mentioned in Introduction, all previous papers on this topic have been based on the calculation of the entropy for finite complements of the entangling regions. In particular, given the region $R \equiv R_+ \cup R_-$ where the ‘‘Hawking quanta’’ are ‘‘collected’’ during the evolution, one can define the entanglement entropy of \bar{R} as

$$S(\bar{R}) \equiv S([\mathbf{b}_-, \mathbf{b}_+]). \quad (2.18)$$

The calculation of $S(\bar{R})$ is simple and leads to [18]

$$S(\bar{R}) = \frac{c}{6} \log \left[\frac{16r_h^2(b - r_h)}{\varepsilon^2 b} \cosh^2 \kappa_h t_b \right]. \quad (2.19)$$

In the limit when the boundaries of the entangling regions go to spacelike infinities i^0 (i.e. $b \rightarrow \infty$ at fixed t_b), this formula reduces to

$$\lim_{\mathbf{b}_\pm \rightarrow i^0} S(\bar{R}) = \frac{c}{3} \log \frac{2}{\varepsilon \kappa_h} + \frac{c}{3} \log \cosh \kappa_h t_b. \quad (2.20)$$

This is not what was expected, since in the limit of the vanishing region R , entangled particles of radiation are not collected, and the entanglement entropy should have been equal to zero. The first term on the RHS of (2.20) can be understood as the contribution to the entanglement entropy from the IR modes. This constant arises in further calculations and will be important for explaining of our results.

The entanglement entropy (2.19) at late times $t_b \gg r_h$ enters the unbounded linear

³The s-wave approximation works at $b \gg r_h$.

growth regime

$$S(\overline{R}) = \frac{c}{3} \kappa_h t_b, \quad (2.21)$$

that can be interpreted as a variation of the information paradox.

In [18], it was shown that with the introduction of entanglement islands this growth stops at some time moment, since the generalized entanglement entropy $S_{\text{gen}}(R)$ saturates. There is a symmetric island at late times with endpoints located in different wedges the horizon (see Fig. 2). These results were also obtained via the consideration of the complement of $R \cup I^4$

$$\min_{\partial I} \left\{ \text{ext}_{\partial I} \left[\frac{\text{Area}(\partial I)}{4G_N} + S_{\text{matter}}(\overline{R \cup I}) \right] \right\} \simeq \frac{2\pi r_h^2}{G_N} + \frac{c}{6} \left[\log \left(\frac{16r_h^3(b-r_h)^2}{b\varepsilon^4} \right) + \frac{b-r_h}{r_h} \right]. \quad (2.22)$$

This entropy does not increase at late times as opposed to the late-time result without the island (2.21), and thus, according to the island formula (2.15), the configuration with the island is preferred.

For clarity of comparison with different types of finite regions in the following sections, we introduce the notation for the semi-infinite region $R_+ \cup R_-$ used above as

$$R_\infty \equiv R_+ \cup R_- = (i^0, \mathbf{b}_-] \cup [\mathbf{b}_+, i^0). \quad (2.23)$$

3 Infrared regularization and complementarity property

In this section, we are going to clarify the subtle points mentioned above. For this purpose, we study the entanglement entropy of the semi-infinite entangling region R_∞ . In studies exploring the model [18], the entropy of R_∞ is calculated under the assumption that it is equal to the entanglement entropy of the R_∞ complement (since they lie on the same Cauchy surface Σ which defines a pure quantum state). We call this statement the *complementarity property*. It is natural to ask how to calculate it directly representing R_∞ as the limit of some finite region (i.e. pass from Fig. 1 (right) to Fig. 1 (left)). At first sight, this might seem obvious, however, such a consideration contains subtleties which will give us further understanding of finite entangling regions and their edge effects. Let us list the results that will be important for further analysis:

- Regions R_+ and R_- should be defined on a *certain* Cauchy surface Σ . According to the complementarity property, the entanglement entropy of a pure state on R_∞ should be equal to the entanglement entropy of the R_∞ complement. We

⁴In [18], the entropy (2.22) is obtained in the leading order expansion in cG/r_h^2 .

check explicitly whether this property holds for the infinite region R_∞ defined as the limit of a finite one.

- Representation of an infinite entangling region as the limit of a finite one raises the issue of how to take this limit *correctly*, namely, how to pick the points \mathbf{q}_- and \mathbf{q}_+ in Fig. 1 before sending them to spacelike infinity i^0 . A naive way to choose finite entangling intervals is to take the points $\mathbf{q}_+ = \{q, t_q\}$ in the right wedge and $\mathbf{q}_- = \left\{q, -t_q + \frac{i\pi}{\kappa_h}\right\}$ in the left one (i.e. choose a radially-symmetric configuration at the same global time). We show that such a choice does not satisfy the complementarity property.
- As a result, we obtain two qualitatively different types of entangling regions — MS and AS. The MS configurations *fail* the complementarity test, while the AS ones do *not*. In the next section, we show that the AS regions also demonstrate interesting properties.
- We obtain that the complementarity property for regularized configurations holds *up to a constant* which depends on the black hole temperature and the UV cutoff of the entanglement entropy. This is exactly the constant defined in (2.20) which corresponds to the entanglement entropy associated with the IR modes. The presence of such an infrared anomalous term and the importance of the proper Cauchy surface regularization are reminiscent of the appearance of anomalies in quantum field theory due to regularization.

3.1 Regularization of Cauchy surface

Before considering different types of entangling regions, let us introduce the regularization of a Cauchy surface Σ which extends between spacelike infinities in the left and right wedges (see Fig. 3). To regularize Σ , we take a finite spacelike interval $\Sigma_{\text{reg}} = [\mathbf{q}_-, \mathbf{q}_+]$ with the coordinates of the endpoints

$$\begin{aligned}\mathbf{q}_- &= \left\{q_-, t_{q_-} + \frac{i\pi}{\kappa_h}\right\}, \\ \mathbf{q}_+ &= \{q_+, t_{q_+}\}.\end{aligned}\tag{3.1}$$

Then, the entanglement entropy of conformal matter on the regularized Cauchy surface Σ_{reg} is given by

$$S(\Sigma_{\text{reg}}) = \frac{c}{6} \log \frac{d^2(\mathbf{q}_-, \mathbf{q}_+)}{\varepsilon^2},\tag{3.2}$$

which is, in general, divergent. However, if we take $q_- = q_+ \equiv q$ and $t_{q_-} = t_{q_+} \equiv t_q$, we obtain the following expression

$$S(\Sigma_{\text{reg}}) = \frac{c}{6} \log \frac{4f(q)}{\varepsilon^2 \kappa_h^2}. \quad (3.3)$$

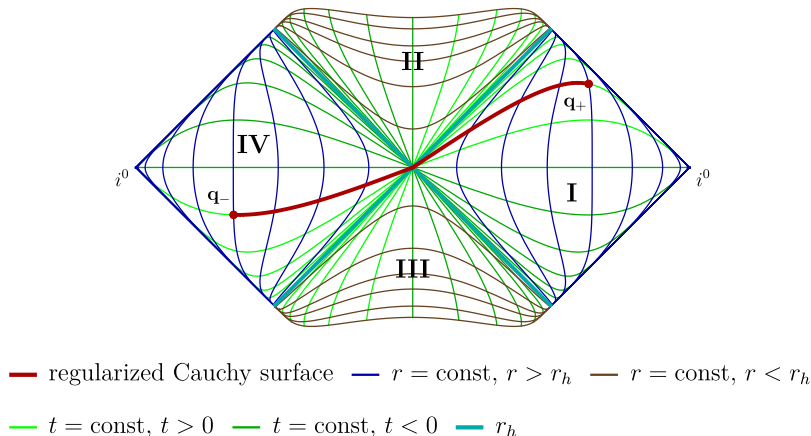

Figure 3: Penrose diagram for the eternal Schwarzschild black hole with the regularized Cauchy surface $\Sigma_{\text{reg}} \equiv [\mathbf{q}_-, \mathbf{q}_+]$, $\mathbf{q}_{\pm} \rightarrow i^0$.

The entanglement entropy of the whole Cauchy surface Σ is given by the limit $q \rightarrow \infty$ of (3.3) which we expect to be zero for a pure state. Taking into account that $f(q) \rightarrow 1$ as $q \rightarrow \infty$, we obtain

$$S(\Sigma) = \frac{c}{3} \log \frac{2}{\varepsilon \kappa_h}. \quad (3.4)$$

This is the same constant we have encountered in (2.20). As we have mentioned, this constant seems to be the contribution of the IR modes, and we should *renormalize* all the results by subtracting this constant from the final answers.

Now, let us check the complementarity property for certain configurations of entangling regions lying on the Cauchy surface Σ . For our future purposes, we consider:

- a semi-infinite interval (Fig. 4),
- a finite interval which lies arbitrarily in the left/right or both wedges of the Penrose diagram for Schwarzschild spacetime (Fig. 5),

- a union of two disjoint finite intervals one of which lies in the left wedge and the other in the right (Fig. 6).

3.2 Semi-infinite interval

First, let us check the complementarity property for a semi-infinite entangling region, spanning in the right wedge from the radial coordinate b to spatial infinity i^0 . Its complement extends from the spatial infinity in the left wedge to the point with the same radial coordinate b . Our goal is to represent the semi-infinite entangling region and its complement as the limits of several finite regions (see Fig. 4). One can consider this procedure as a regularization of spacelike infinities. The regularized entangling region is located between the points \mathbf{b}_+ and \mathbf{q}_+ (dark red curve in Fig. 4), namely

$$\begin{aligned}\mathbf{b}_+ &= \{b, t_b\}, \\ \mathbf{q}_+ &= \{q_+, t_{q_+}\}.\end{aligned}\tag{3.5}$$

The regularized complement lies between the point \mathbf{q}_- in the left wedge and the point \mathbf{b}_+ in the right wedge (light red curve in Fig. 4), where \mathbf{q}_- is given by

$$\mathbf{q}_- = \left\{ q_-, t_{q_-} + \frac{i\pi}{\kappa_h} \right\}.\tag{3.6}$$

The calculation of the entanglement entropy $S([\mathbf{b}_+, \mathbf{q}_+])$ for this entangling region by use of (2.14) gives

$$S([\mathbf{b}_+, \mathbf{q}_+]) = \frac{c}{6} \log \left[\frac{2\sqrt{f(b)f(q)}}{\kappa_h^2 \varepsilon^2} \left(\cosh \kappa_h (r_*(b) - r_*(q_+)) - \cosh \kappa_h (t_b - t_{q_+}) \right) \right].$$

For the large q_+ limit, it reduces to

$$S([\mathbf{b}_+, \mathbf{q}_+]) \Big|_{q_+ \rightarrow \infty} = \frac{c}{12} \log q_+ + \frac{c}{6} \kappa_h (q_+ - b) - \frac{c}{6} \log \kappa_h^2 \varepsilon^2 \sqrt{b},\tag{3.7}$$

with the similar result for the entanglement entropy $S([\mathbf{q}_-, \mathbf{b}_+])$ of the complement

$$S([\mathbf{q}_-, \mathbf{b}_+]) \Big|_{q_- \rightarrow \infty} = \frac{c}{12} \log q_- + \frac{c}{6} \kappa_h (q_- - b) - \frac{c}{6} \log \kappa_h^2 \varepsilon^2 \sqrt{b}.\tag{3.8}$$

Thus, if the IR regulators \mathbf{q}_\pm are taken such that their radial coordinates are equal, $q_- = q_+ \equiv q$, the complementarity property is satisfied in the form

$$\lim_{\mathbf{q}_\pm \rightarrow i^0} \left(S([\mathbf{q}_-, \mathbf{b}_+]) - S([\mathbf{b}_+, \mathbf{q}_+]) \right) \Big|_{q_- = q_+} = 0.\tag{3.9}$$

Figure 4: Penrose diagram for the eternal Schwarzschild black hole with the regularized semi-infinite configuration: the entangling region $[\mathbf{b}_+, \mathbf{q}_+]$ and its complement $[\mathbf{q}_-, \mathbf{b}_+]$, $\mathbf{q}_\pm \rightarrow i^0$.

Note that this result does *not* depend on the timelike coordinates of the regulators \mathbf{q}_\pm .

3.3 Finite interval

Now let us turn to the case when the entangling region R is given by a finite interval. We consider two different configurations. The first one is when the left endpoint \mathbf{b}_- is in the left wedge and the right endpoint \mathbf{y}_+ is in the right wedge. The second configuration corresponds to the endpoints both lying in the same wedge (in the right one for definiteness); in this case, we denote the left endpoint by \mathbf{b}_+ and the right one by \mathbf{y}_+ . The complement \bar{R} is, therefore, given by two semi-infinite intervals in each wedge extending to the corresponding spatial infinities i^0 . We proceed with a similar regularization of spacelike infinities in \bar{R} by introducing the points \mathbf{q}_- and \mathbf{q}_+ (see Fig. 5), as in the previous case. Explicitly, the coordinates of the mentioned points are defined as

$$\begin{aligned}
 \mathbf{y}_+ &= \{y, t_y\}, \\
 \mathbf{b}_+ &= \{b, t_b\}, \\
 \mathbf{b}_- &= \left\{ b, t_b + \frac{i\pi}{\kappa_h} \right\}, \\
 \mathbf{q}_+ &= \{q_+, t_{q_+}\}, \\
 \mathbf{q}_- &= \left\{ q_-, t_{q_-} + \frac{i\pi}{\kappa_h} \right\}.
 \end{aligned} \tag{3.10}$$

The entanglement entropy of the entangling region $R = [\mathbf{b}_\pm, \mathbf{y}_+]$ (i.e. for both choices of the left endpoint location) is given by

$$S(R) = \frac{c}{6} \log \left[\frac{2\sqrt{f(y)f(b)}}{\kappa_h^2 \varepsilon^2} \left(\cosh \kappa_h(r_*(b) - r_*(y)) \mp \cosh \kappa_h(t_b - t_y) \right) \right].$$

We compare this formula with the entanglement entropy of the regularized complement $\bar{R}_{\text{reg}} = [\mathbf{q}_-, \mathbf{b}_\pm] \cup [\mathbf{y}_+, \mathbf{q}_+]$

$$S(\bar{R}_{\text{reg}}) = \frac{c}{3} \log \frac{d(\mathbf{b}_\pm, \mathbf{a}_+)}{\varepsilon} + \frac{c}{3} \log \frac{d(\mathbf{q}_-, \mathbf{q}_+)}{\varepsilon} + \frac{c}{3} \log \left(\frac{d(\mathbf{a}_+, \mathbf{q}_+)d(\mathbf{b}_\pm, \mathbf{q}_-)}{d(\mathbf{a}_+, \mathbf{q}_-)d(\mathbf{b}_\pm, \mathbf{q}_+)} \right), \quad (3.11)$$

which in the limit $q_\pm \rightarrow \infty$, reduces to

$$S(\bar{R}_{\text{reg}})_{q_\pm \rightarrow \infty} = S(R) + \frac{c}{3} \log \frac{2}{\kappa_h \varepsilon} + F(q_+, q_-, t_{q_+}, t_{q_-}), \quad (3.12)$$

where

$$F(q_+, q_-, t_{q_+}, t_{q_-}) = \frac{c}{6} \log \left[\frac{\cosh \kappa_h(t_{q_+} - t_{q_-}) + \cosh \kappa_h(r_*(q_+) - r_*(q_-))}{2} \right]. \quad (3.13)$$

One can see that for a spatially symmetric regularization $q_+ = q_- \equiv q$ and for points \mathbf{q}_\pm lying on the same *time slice*, i.e. $t_{q_+} = t_{q_-} \equiv t_q$, we are left with

$$S(\bar{R}_{\text{reg}})_{q_\pm \rightarrow \infty} = S(R) + \frac{c}{3} \log \frac{2}{\kappa_h \varepsilon}, \quad (3.14)$$

which is exactly the complementarity property up to the anomaly (2.20). Also, the result does *not* depend on the wedge (left, right or both) in which the finite entangling region is located.

3.4 Multiple intervals

Having received some intuition, it is straightforward to consider two and more intervals. The simplest generalization is the configuration consisting of the union of two finite intervals $[\mathbf{a}_1, \mathbf{a}_2]$ (the left wedge) and $[\mathbf{a}_3, \mathbf{a}_4]$ (the right wedge) with arbitrary endpoint

Figure 5: Penrose diagram for the eternal Schwarzschild black hole with the regularized finite interval configuration: the finite interval $[\mathbf{b}_-, \mathbf{y}_+]$ and its complement $[\mathbf{q}_-, \mathbf{b}_-] \cup [\mathbf{y}_+, \mathbf{q}_+]$, $\mathbf{q}_\pm \rightarrow i^0$.

coordinates (see Fig. 6)

$$\begin{aligned}
\mathbf{a}_1 &= \left\{ a_1, t_{a_1} + \frac{i\pi}{\kappa_h} \right\}, \\
\mathbf{a}_2 &= \left\{ a_2, t_{a_2} + \frac{i\pi}{\kappa_h} \right\}, \\
\mathbf{a}_3 &= \{ a_3, t_{a_3} \}, \\
\mathbf{a}_4 &= \{ a_4, t_{a_4} \}.
\end{aligned} \tag{3.15}$$

Now, the entangling region R is defined as $R = [\mathbf{a}_1, \mathbf{a}_2] \cup [\mathbf{a}_3, \mathbf{a}_4]$ while the regularized complement $\bar{R}_{\text{reg}} = [\mathbf{q}_-, \mathbf{a}_1] \cup [\mathbf{a}_2, \mathbf{a}_3] \cup [\mathbf{a}_4, \mathbf{q}_+]$. The entanglement entropies of R and \bar{R}_{reg} are correspondingly given by

$$S(R) = \frac{c}{3} \log \left(\frac{d(\mathbf{a}_1, \mathbf{a}_2)d(\mathbf{a}_2, \mathbf{a}_3)d(\mathbf{a}_3, \mathbf{a}_4)d(\mathbf{a}_4, \mathbf{a}_1)}{\varepsilon^2 d(\mathbf{a}_1, \mathbf{a}_3)d(\mathbf{a}_2, \mathbf{a}_4)} \right) \tag{3.16}$$

and

$$\begin{aligned}
S(\bar{R}_{\text{reg}}) &= \frac{c}{3} \log \left(\frac{d(\mathbf{a}_1, \mathbf{a}_2)d(\mathbf{a}_2, \mathbf{a}_3)d(\mathbf{a}_3, \mathbf{a}_4)d(\mathbf{a}_4, \mathbf{a}_1)}{\varepsilon^2 d(\mathbf{a}_1, \mathbf{a}_3)d(\mathbf{a}_2, \mathbf{a}_4)} \right) + \frac{c}{3} \log \frac{d(\mathbf{q}_-, \mathbf{q}_+)}{\varepsilon} + \\
&+ \frac{c}{3} \log \left(\frac{d(\mathbf{a}_1, \mathbf{q}_-)d(\mathbf{a}_2, \mathbf{q}_+)d(\mathbf{a}_3, \mathbf{q}_-)d(\mathbf{a}_4, \mathbf{q}_+)}{d(\mathbf{a}_1, \mathbf{q}_+)d(\mathbf{a}_2, \mathbf{q}_-)d(\mathbf{a}_3, \mathbf{q}_+)d(\mathbf{a}_4, \mathbf{q}_-)} \right).
\end{aligned} \tag{3.17}$$

— interval — complement — $r = \text{const}, r > r_h$ — $r = \text{const}, r < r_h$
— $t = \text{const}, t > 0$ — $t = \text{const}, t < 0$ — r_h

Figure 6: Penrose diagram for the eternal Schwarzschild black hole with the regularized union of two finite intervals: the entangling region $[\mathbf{a}_1, \mathbf{a}_2] \cup [\mathbf{a}_3, \mathbf{a}_4]$ and its complement $[\mathbf{q}_-, \mathbf{a}_1] \cup [\mathbf{a}_2, \mathbf{a}_3] \cup [\mathbf{a}_4, \mathbf{q}_+]$, $\mathbf{q}_\pm \rightarrow i^0$.

After taking the large q_\pm , the latter takes the form

$$S(\bar{R}) \underset{q_\pm \rightarrow \infty}{=} S(R) + \frac{c}{3} \log \frac{2}{\kappa_h \varepsilon} + F(q_+, q_-, t_{q_+}, t_{q_-}). \quad (3.18)$$

Again, one can see that for a spatially symmetric regularization $q_- = q_+ \equiv q$ and the equal time slice choice $t_{q_-} = t_{q_+} \equiv t_q$, we obtain that the complementarity property is satisfied in the limit $\mathbf{q}_\pm \rightarrow i^0$ up to the constant (2.20).

It is straightforward to extend this calculation to the case when R consists of N intervals: $R = [\mathbf{a}_1, \mathbf{a}_2] \cup \dots \cup [\mathbf{a}_{N-1}, \mathbf{a}_N]$. Taking the IR regulators as in the previous cases, one can show that the entanglement entropy of the complement satisfies

$$S(\bar{R}_{\text{reg}}) = S(R) + \frac{c}{3} \log \frac{d(\mathbf{q}_-, \mathbf{q}_+)}{\varepsilon} + \frac{c}{3} \log \left(\frac{d(\mathbf{a}_1, \mathbf{q}_-) \dots d(\mathbf{a}_N, \mathbf{q}_+)}{d(\mathbf{a}_1, \mathbf{q}_+) \dots d(\mathbf{a}_N, \mathbf{q}_-)} \right). \quad (3.19)$$

In spatially symmetric equal time slice regularization, the third term on the RHS of (3.19) is identically zero, while the second term, which contains $d(\mathbf{q}_-, \mathbf{q}_+)$ and in general would be divergent, in our prescription, gives the constant contribution in the limit $\mathbf{q}_\pm \rightarrow i^0$ which is to be removed in the final formula.

3.5 Asymmetric & Mirror-symmetric regularizations

We have found that the representation of the entanglement entropy $S(R)$ of some entangling region R containing spacelike infinities in the left and right wedges as the limit of some finite regularized region has interesting properties. In such an entangling region, one should correctly regularize the semi-infinite intervals $[\mathbf{x}_+, i^0)$ and $(i^0, \mathbf{x}_-]$ by IR regulators \mathbf{q}_\pm such that the limits $\mathbf{q}_\pm \rightarrow i^0$ of $[\mathbf{q}_-, \mathbf{x}_-]$ and $[\mathbf{x}_+, \mathbf{q}_+]$ do not violate the complementarity property. To be more precise, these limits are well-defined and consistent with the complementarity property if

- The radial coordinates of the regularization points \mathbf{q}_\pm are taken equal: $q_- = q_+ \equiv q$. This is necessary for the limit $q \rightarrow \infty$ to exist.
- The regularization points \mathbf{q}_\pm lie on the same time slice $t_q = \text{const}$, i.e. the IR regulators are given by $\mathbf{q}_- = \left\{ q, t_q + \frac{i\pi}{\kappa_h} \right\}$ in the left wedge and $\mathbf{q}_+ = \{q, t_q\}$ in the right one.
- Final answers are renormalized by subtracting the constant $\frac{c}{3} \log \frac{2}{\varepsilon \kappa_h}$.

We combine these three conditions of regularizing spacelike infinities in the Schwarzschild two-sided geometry under the name “*asymmetric*” (AS) regularization.

Consider mirror-symmetric points \mathbf{q}_\pm , i.e. the conditions (1.4) are satisfied. We call such a choice the “*mirror-symmetric*” (MS) regularization. At first glance, this regularization seems more natural than the AS one. This is because, given the mirror symmetry (1.3) of the points \mathbf{b}_\pm , the regularized regions in the right and the left wedges are also mirror-symmetric, see Fig. 13. However, this regularization leads to a defect. Indeed, the function F (3.13) for MS regularization is

$$F_{\text{MS}}(q, q, t_q, -t_q) = \frac{c}{3} \log \cosh \kappa_h t_q. \quad (3.20)$$

Thus, the entropies of the entangling region and its complement, which includes spacelike infinities i^0 in both wedges, differ by a constant (2.20) and by a time-dependent function (3.20). As in AS regularization, the MS one uses the same prescription that the constant (2.20) is to be subtracted. Note that spacelike infinity i^0 does not correspond to a specific time — the points with arbitrary fixed times in the limit of infinite radial coordinates tend to i^0 . Therefore, the presence of the time dependence (3.20) in MS regularization leads to a significant discrepancy between the entropies of the region and its complement, as opposed to AS regularization.

For future purposes, let us introduce a short-hand notation which we call the “up-down” notation. We divide the interval endpoints \mathbf{x}_i into the “up” and “down” ones with respect to the horizontal line representing a hypersurface of the constant time $t = 0$ in the Penrose diagram for Schwarzschild spacetime. The “up” points are those which lie above this line (regardless of the wedge and the actual value of the time coordinate), and the “down” ones are those which lie below. Also note that in the right wedge, the Killing vector field ∂_t is directed from bottom to top, and in the left wedge — from top to bottom.

For clarity, let us write down the coordinates of arbitrary points $\mathbf{x}_\pm^{\text{up,down}}$ in the “up-down” notation

$$\begin{aligned} \mathbf{x}_+^{\text{up}} &= \{x, t_x\}, \\ \mathbf{x}_-^{\text{up}} &= \left\{x, -t_x + \frac{i\pi}{\kappa_h}\right\}, \\ \mathbf{x}_+^{\text{down}} &= \{x, -t_x\}, \\ \mathbf{x}_-^{\text{down}} &= \left\{x, t_x + \frac{i\pi}{\kappa_h}\right\}, \end{aligned} \tag{3.21}$$

where it is assumed that $t_x > 0$.

Now consider the entangling region R discussed in [18] and given by two semi-infinite intervals in each wedge which “collect” the Hawking radiation of the eternal Schwarzschild black hole. As we mentioned before, in [18] the entanglement entropy $S(R)$ was calculated with the use of the complementarity property: $S(R) = S(\bar{R})$. One can check explicitly that the calculation of the entanglement entropy $S(R)$ for the region R defined as the $\mathbf{q}_\pm \rightarrow i^0$ limit of the AS regularized configuration gives the same answer as in (2.19)

$$S(R) = \lim_{\mathbf{q}_\pm \rightarrow i^0} S([\mathbf{q}_-^{\text{down}}, \mathbf{b}_-^{\text{up}}] \cup [\mathbf{b}_+^{\text{up}}, \mathbf{q}_+^{\text{up}}]) = \frac{c}{6} \log \left(\frac{4f(b)}{\kappa_h^2} \cosh^2 \kappa_h t_b \right). \tag{3.22}$$

4 Entropy for finite entangling regions

Let us now turn to our main goal — the investigation of the entropy for finite regions affected by the presence of entanglement islands in the two-sided eternal Schwarzschild black hole. In Section 3, we made a statement that it is necessary to use AS regularization of spacelike infinities i^0 to be consistent with the complementarity property.

This statement specifies only an intermediate step in the calculation of the entropy for two *semi-infinite* regions in both wedges. At first sight, it seems that for *finite*

regions our previous results do not unambiguously specify the choice of their boundaries. However, as we show, the statement about AS regularization gives an intuition as to which finite regions are consistent with the results for the semi-infinite configuration obtained before [18]. In this section, we examine finite regions corresponding to both AS and MS schemes.

We consider the entropy of the following disjoint finite entangling region

$$R = [\mathbf{q}_-, \mathbf{b}_-] \cup [\mathbf{b}_+, \mathbf{q}_+], \quad (4.1)$$

where the first and the second finite parts are located in the left and the right wedges, respectively (see Fig. 7 and Fig. 13), and the coordinates of their boundaries are given by

$$\begin{aligned} \mathbf{b}_+ &= \{b_+, t_{b_+}\}, \\ \mathbf{q}_+ &= \{q_+, t_{q_+}\}, \\ \mathbf{b}_- &= \left\{b_-, t_{b_-} + \frac{i\pi}{\kappa_h}\right\}, \\ \mathbf{q}_- &= \left\{q_-, t_{q_-} + \frac{i\pi}{\kappa_h}\right\}. \end{aligned} \quad (4.2)$$

where, as in the previous section, $q_{\pm} > b_{\pm}$.

In [18], the boundaries of the semi-infinite regions \mathbf{b}_+ and \mathbf{b}_- have the time coordinates that are equal in absolute values but opposite in sign⁵, and the same radial coordinates, i.e.

$$t_{b_+} = -t_{b_-} \equiv t_b, \quad b_+ = b_- \equiv b. \quad (4.3)$$

This choice of the time coordinates makes the problem time-dependent in the case of semi-infinite intervals [12, 18]. Also, without loss of generality, we take \mathbf{q}_{\pm} radially symmetric

$$q_+ = q_- \equiv q, \quad (4.4)$$

and choose the time coordinates of the points \mathbf{b}_{\pm} , \mathbf{q}_{\pm} such that

$$|t_{q_+}| = |t_{q_-}| \equiv |t_b|, \quad (4.5)$$

with the following options for the choice of the relative sign:

⁵According to the notation introduced earlier, this means that \mathbf{b}_+ and \mathbf{b}_- are taken as the “up”-points.

- The first option is

$$t_{q_+} = t_{q_-}, \quad (4.6)$$

i.e. the points \mathbf{q}_+ and \mathbf{q}_- lie on the same time slice and correspond to AS regularization, see Fig. 7. Within the up-down notation, this corresponds to choosing the boundaries as $\mathbf{q}_-^{\text{down}}$ and \mathbf{q}_+^{up} ⁶

$$R_{\text{AS}} \equiv [\mathbf{q}_-^{\text{down}}, \mathbf{b}_-^{\text{up}}] \cup [\mathbf{b}_+^{\text{up}}, \mathbf{q}_+^{\text{up}}]. \quad (4.7)$$

We call this configuration the AS region. In Subsection 4.1, we will show that this is the case in which there is a correct limit for the entropy in the limit $\mathbf{q}_\pm \rightarrow i^0$. Also, notice that at some point, such a region becomes timelike which adds additional subtlety to the interpretation of this configuration.

- The second option is

$$t_{q_+} = -t_{q_-}, \quad (4.8)$$

see Fig. 13. This choice corresponds to MS regularization. Within the up-down notation, this corresponds to choosing the boundaries as \mathbf{q}_-^{up} and \mathbf{q}_+^{up}

$$R_{\text{MS}} \equiv [\mathbf{q}_-^{\text{up}}, \mathbf{b}_-^{\text{up}}] \cup [\mathbf{b}_+^{\text{up}}, \mathbf{q}_+^{\text{up}}]. \quad (4.9)$$

We denote this region as the MS region. In Subsection 4.2, we will show that in this case, the entropy in the limit $\mathbf{q}_\pm \rightarrow i^0$ does not correspond to the results for the semi-infinite setup [18].

So, after discussing the notation for entangling regions, it is appropriate to describe the island configuration which contributes to the generalized entanglement entropy. We restrict ourselves to the island given by a single interval and choose it similarly to [18]

$$I = [\mathbf{p}_-, \mathbf{a}_+], \quad (4.10)$$

with the boundary \mathbf{p}_- in the left wedge and the other boundary \mathbf{a}_+ in the right one (see Fig. 7 and Fig. 13), with the coordinates

$$\begin{aligned} \mathbf{a}_+ &= \{a, t_a\}, \\ \mathbf{p}_- &= \left\{ p, -t_p + \frac{i\pi}{\kappa_h} \right\}. \end{aligned} \quad (4.11)$$

⁶Since neither the left nor the right wedge is preferred, it does not really matter which one — right or left — has the “up”-point and which has the “down”-point. For clarity, we assume that the “down”-point is located in the left wedge.

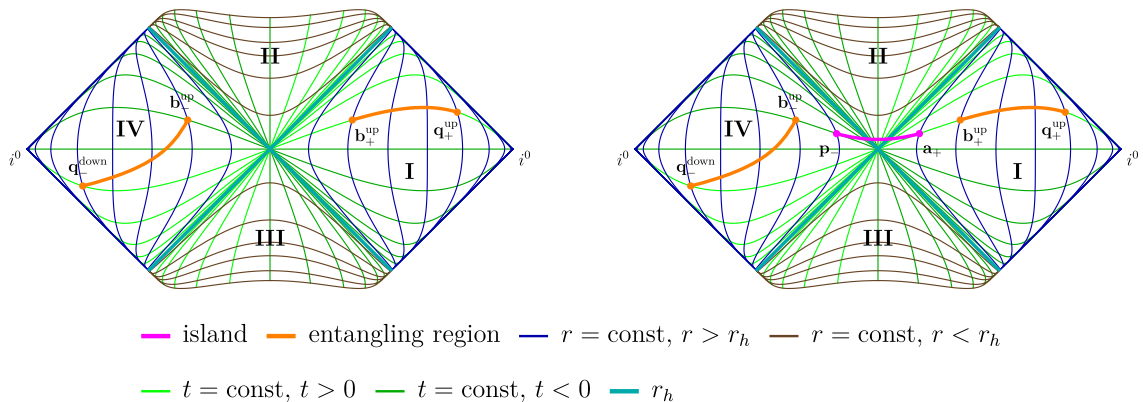

Figure 7: Left: Penrose diagram for the eternal Schwarzschild black hole with a finite AS entangling region $R_{\text{AS}} \equiv [\mathbf{q}_-^{\text{down}}, \mathbf{b}_-^{\text{up}}] \cup [\mathbf{b}_+^{\text{up}}, \mathbf{q}_+^{\text{up}}]$ (orange). **Right:** the same configuration with the island $I \equiv [\mathbf{p}_-, \mathbf{a}_+]$ (magenta).

In what follows, we show that for the entangling region R_{MS} , the island configuration reads: $a = p$, $t_a = t_p$, and that this is not the case for R_{AS} . We expect that at least for one of the types of entangling regions, the results for the semi-infinite case are reproduced for large sizes. We investigate the island configuration for different sizes of entangling regions, i.e. for different b and q .

Taking for our analysis the analytical formula for the entropy before extremization, expression in square brackets in (2.15), we find numerically the solutions (a, t_a, p, t_p) to the extremization equations for different sizes of finite entangling regions and investigate time dependence of the entropy with the island⁷. As discussed in Section 2, for semi-infinite intervals one can find a non-trivial symmetric island configuration at late times with endpoints located in different wedges in the near-horizon zone. We extend these results to the case when the entangling region is finite and, for generality, consider both R_{AS} and R_{MS} .

4.1 Asymmetric entangling regions

First, we consider the entanglement entropy for the finite entangling region R_{AS} (4.7) that corresponds to AS regularization (see Fig. 7). We show that for this region, the results for the semi-infinite one [18] are reproduced in the $\mathbf{q}_\pm \rightarrow i^0$ limit. We

⁷Our analytical analysis is somehow naive because we investigate the entropy for configurations with islands before extremization and not the extremization equations themselves. However, numerical analysis shows that this naive approach gives correct results.

also demonstrate that due to the non-constant time location of the region R_{AS} , such phenomena as Cauchy surface breaking and an asymmetric island arise.

No island

The entanglement entropy for R_{AS} (4.7) is given by (2.14)

$$S(R_{\text{AS}}) = \frac{c}{3} \log \left(\frac{d(\mathbf{b}_+^{\text{up}}, \mathbf{b}_-^{\text{up}}) d(\mathbf{q}_-^{\text{down}}, \mathbf{b}_-^{\text{up}}) d(\mathbf{b}_+^{\text{up}}, \mathbf{q}_+^{\text{up}}) d(\mathbf{q}_-^{\text{down}}, \mathbf{q}_+^{\text{up}})}{d(\mathbf{b}_-^{\text{up}}, \mathbf{q}_+^{\text{up}}) d(\mathbf{q}_-^{\text{down}}, \mathbf{b}_+^{\text{up}})} \right), \quad (4.12)$$

which, after substitution of coordinates, can be written down explicitly as

$$S(R_{\text{SE}}) = \frac{c}{6} \log \left(\frac{16f(b)f(q) \cosh^2 \kappa_h t_b}{\kappa_h^4 \varepsilon^4} \right) + \frac{c}{6} \log \left[\frac{(\cosh \kappa_h (r_*(q) - r_*(b)) - \cosh 2\kappa_h t_b) (\cosh \kappa_h (r_*(q) - r_*(b)) - 1)}{(\cosh \kappa_h (r_*(q) - r_*(b)) + \cosh 2\kappa_h t_b) (\cosh \kappa_h (r_*(q) - r_*(b)) + 1)} \right]. \quad (4.13)$$

The limit $\mathbf{q}_\pm \rightarrow i^0$ in AS regularization gives the same answer for the entropy (4.13) as in (2.19)

$$\lim_{\mathbf{q}_\pm \rightarrow i^0} S(R_{\text{AS}}) = S(R_\infty). \quad (4.14)$$

For the finite region R_{AS} , one inevitably meets a problem that there is an *upper bound* on time t_b . This happens because during time evolution, the interval at some point becomes timelike. Indeed, consider the square of the distance between $\mathbf{q}_-^{\text{down}}$ and \mathbf{b}_-^{up}

$$d^2(\mathbf{q}_-^{\text{down}}, \mathbf{b}_-^{\text{up}}) \propto \cosh \kappa_h (r_*(q) - r_*(b)) - \cosh 2\kappa_h t_b. \quad (4.15)$$

As we see, it gets negative after the time t_b^{break} that is given by

$$t_b^{\text{break}} = \frac{r_*(q) - r_*(b)}{2}. \quad (4.16)$$

As time evolution goes, the point \mathbf{b}_-^{up} moves forward in time along the flow of the Killing vector ∂_t , and the point $\mathbf{q}_-^{\text{down}}$ moves backward (see Fig. 7), such that at $t_b > t_b^{\text{break}}$ the interval between them is precisely timelike. This means that the Cauchy surface, which is a spacelike hypersurface spanned between spacelike infinities i^0 and includes the points $\mathbf{b}_\pm, \mathbf{q}_\pm$, at time t_b^{break} ceases to be such. We conclude that at $t_b > t_b^{\text{break}}$, the problem becomes ill-defined since there is no longer a Cauchy surface on which a pure quantum state is defined. Also, from (4.16) it follows that a larger finite region R_{AS} corresponds to a larger t_b^{break} . For an infinite region, which corresponds to $q \rightarrow \infty$ (and $r_*(q) \rightarrow \infty$), this time is infinite: $t_b^{\text{break}} \rightarrow \infty$, and the problem of Cauchy surface

Figure 8: No-island entropy evolution for the finite entangling region R_{AS} with $q = 25$ (darker magenta), $q = 100$ (red) and for the semi-infinite one R_∞ (blue dashed). For all cases we take $b = 5$. Note that the curves have the same slope before the breaking time t_b^{break} (4.16) (different for each q).

breaking disappears.

For intermediate times $r_h \ll t_b \ll t_b^{\text{break}}$, the entanglement entropy for R_{AS} given by (4.13) grows linearly

$$S(R_{AS}) \simeq \frac{c}{3} \kappa_h t_b. \quad (4.17)$$

The entanglement entropy for a finite AS region follows the same curve as for the semi-infinite one, without strong dependence on b and q . Only just before the breaking time t_b^{break} (4.16), the entropy decreases and after t_b^{break} , it is not well-defined (see Fig. 8).

Inclusion of island

Now let us turn to the island configuration for R_{AS} . For the semi-infinite entangling region [18], the island is symmetric while for the finite region R_{AS} , the interval $[\mathbf{b}_+^{\text{up}}, \mathbf{q}_+^{\text{up}}]$ in the right wedge is not symmetric⁸ with respect to the interval $[\mathbf{q}_-^{\text{down}}, \mathbf{b}_-^{\text{up}}]$ in the left one, see Fig. 7. This makes the problem more complicated, meaning that the coordinates of the island boundaries \mathbf{a}_+ and \mathbf{p}_- in different wedges are not supposed to depend on each other.

According to the island formula (2.15), the entropy for a non-trivial island configuration before the extremization procedure has the form

$$S_I(R_{AS}) = \frac{\text{Area}(\partial I)}{4G} + S_{\text{matter}}(R_{AS} \cup I). \quad (4.18)$$

⁸Again, by “symmetric configurations” we mean those whose parts are mirrored with respect to the vertical axis of symmetry of the Penrose diagram for the eternal Schwarzschild black hole.

The area of the island boundary is

$$\frac{\text{Area}(\partial I)}{4G} = \frac{\pi(a^2 + p^2)}{G}. \quad (4.19)$$

The second term on the RHS of (4.18) is the entanglement entropy of the union of the entangling region (4.7) and the island (4.10). It is given by

$$S_{\text{matter}}(R_{\text{AS}} \cup I) = \mathcal{Y}(a, p, b, q, t_a, t_p, t_b), \quad (4.20)$$

where \mathcal{Y} is the function of the time and radial coordinates of $R_{\text{AS}} \cup I$. Due to its cumbersome form, the explicit expression for \mathcal{Y} (A.2) is presented in Appendix A.

The limit $\mathbf{q}_{\pm} \rightarrow i^0$ of the entropy before extremization (4.18) in AS regularization scheme coincides with the results for the semi-infinite regions [18]

$$\lim_{\mathbf{q}_{\pm} \rightarrow i^0} S_I(R_{\text{AS}}) = S_I(R_{\infty}). \quad (4.21)$$

According to the island prescription (2.15), the entanglement entropy (4.18) is to be extremized with respect to the parameters (a, t_a, p, t_p) ⁹.

For a moment, let us discuss the formula (4.20) to obtain some intuition about different regimes of the island dynamics. Consider the term which is not symmetric under the exchange $a \leftrightarrow p, t_a \leftrightarrow t_p$

$$\frac{c}{6} \log \left[\frac{(\cosh \kappa_h(r_*(q) - r_*(a)) + \cosh \kappa_h(t_a - t_b)) (\cosh \kappa_h(r_*(q) - r_*(p)) + \cosh \kappa_h(t_p + t_b))}{(\cosh \kappa_h(r_*(q) - r_*(a)) - \cosh \kappa_h(t_a - t_b)) (\cosh \kappa_h(r_*(q) - r_*(p)) - \cosh \kappa_h(t_p + t_b))} \right]. \quad (4.22)$$

This term does not significantly contributes to the entanglement entropy at relatively early times, by which we mean

$$\cosh \kappa_h(r_*(q) - r_*(p)) \gg \cosh \kappa_h(t_p + t_b), \quad (4.23)$$

$$\cosh \kappa_h(r_*(q) - r_*(a)) \gg \cosh \kappa_h(t_a - t_b). \quad (4.24)$$

Thus, it is reasonable to assume a symmetric island configuration $a \simeq p, t_a \simeq t_p$. Under this condition, the extremization procedure for (4.18) actually does not differ from that

⁹As we mentioned in Section 4.1, for the no-island configuration (4.7) there is an upper bound on time (4.16), since at $t_b > t_b^{\text{break}}$, the points $\mathbf{b}_{-}^{\text{up}}$ and $\mathbf{q}_{-}^{\text{down}}$ are timelike-separated. With the inclusion of the island, it might be possible that a similar condition arises for the boundaries of the region R_{AS} and the island. Numerical analysis shows that this happens after t_b^{break} .

Figure 9: Left: entanglement entropy evolution for the region R_{AS} (red), and for the same region with the island (green). **Right:** entanglement entropy $S_I(R_{AS})$ in a different scale. For both plots, $b = 5$ and $q = 300$. Notice the abrupt decrease near $t_b^{\text{break}} = 150$ (4.16) caused by the finite size of the configuration.

for the semi-infinite region, where at late times

$$\cosh \kappa_h(t_a + t_b) \gg \cosh \kappa_h(r_*(a) - r_*(b)), \quad (4.25)$$

one can obtain an analytical estimate of the island location.

In fact, the condition (4.25) determines the moment, denoted by t_b^{isl} , when the island configuration appears. Due to the existence of the upper bound on time t_b^{break} (4.16), there is an additional restriction on the ratio between t_b^{isl} and t_b^{break} — the interval cannot become timelike faster than the island appears. If the condition

$$t_b^{\text{isl}} \ll t_b^{\text{break}} \quad (4.26)$$

is satisfied, which is expected for sufficiently large sizes of AS finite regions, then the “early time” extremization gives the same solution as in [18]

$$\begin{aligned} t_a &= t_p = t_b, \\ a &= p, \\ a - r_h &\ll r_h. \end{aligned} \quad (4.27)$$

For the island configuration (4.27), long before the breaking time t_b^{break} , one can write

Figure 10: **Left:** entanglement entropy evolution for the region R_{AS} with $q = 150$ (red), and for the same region with the island I (green). **Right:** the same, but with $q = 60$. For both cases, we take $b = 5$. Notice that the entropy with the island I is not preferred by (2.15) over that for the no-island configuration.

down the analytical expression for the extremized entropy with the island¹⁰

$$\begin{aligned}
S_I(R_{AS}) \simeq & \frac{2\pi r_h^2}{G} + \frac{c}{6} \left[\log \left(\frac{16r_h^3(b-r_h)^2}{b\varepsilon^4} \right) + \frac{b-r_h}{r_h} \right] \\
& + \frac{c}{6} \log \frac{4f(q)}{\kappa_h^2 \varepsilon^2} - \frac{c}{3} e^{2\kappa_h t_b - \kappa_h(r_*(q) - r_*(b))},
\end{aligned} \tag{4.28}$$

see Appendix A for the details of derivation of (4.28). The entropy (4.28) differs from that with an island (2.22) for the semi-infinite regions R_∞ by the last two terms related to finite size effects. In the limit $\mathbf{q}_\pm \rightarrow i^0$ of (4.28) in AS regularization, the entropy (2.22) is reproduced.

By numerical extremization of the island configuration, we confirm that at late times, the term (4.22) gets significant, such that shortly before the breaking time t_b^{break} , the extremization over a and t_a does not change much, but the extremization over p and t_p introduces a *non-symmetric* island configuration. In this case, the formula (4.28) for the entropy is no longer valid.

We have found the extremum of the generalized entropy functional (2.15) numerically and determined the finite size effects inherent to entanglement evolution of AS regions:

- Time dependence of the entanglement entropy affected by the island is depicted in Fig. 9 and 10. In Fig. 9, we present the evolution of the entropy for a large

¹⁰The formula (4.28) is valid at times t_b long before the breaking time t_b^{break} (4.16), therefore, $e^{\kappa_h(r_*(q) - r_*(b))} \gg e^{2\kappa_h t_b}$. So, exponential growth with time in (4.28) is significantly suppressed.

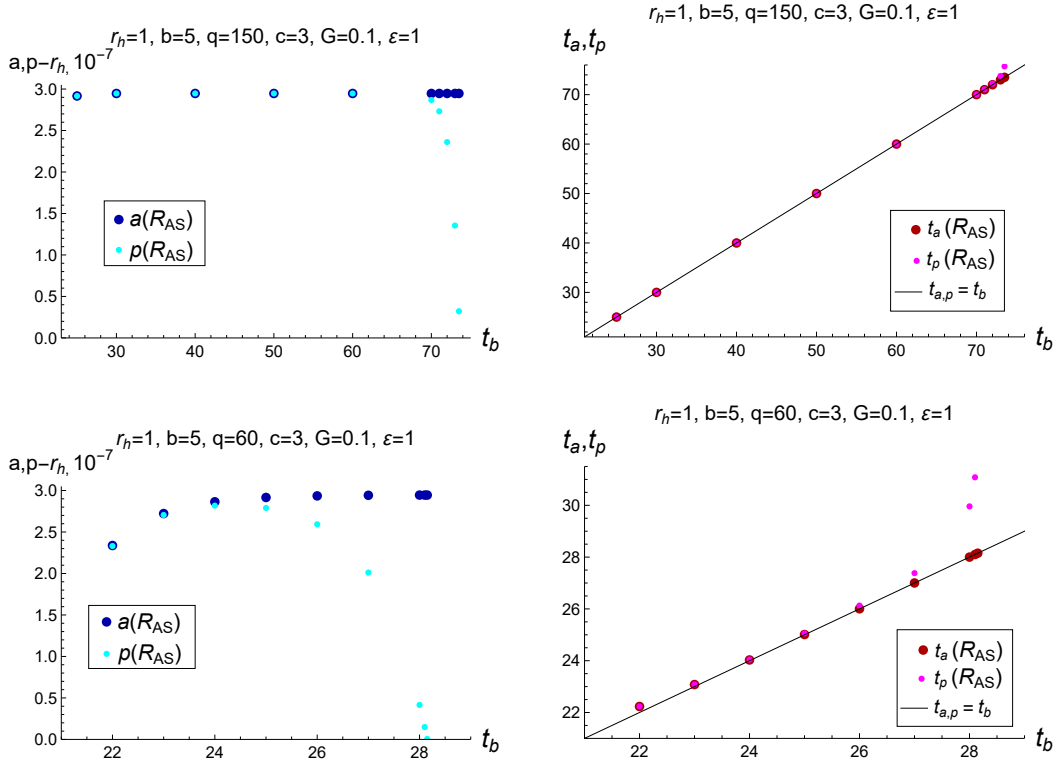

Figure 11: Left: evolution of the radial island coordinates a (darker blue), p (cyan) corresponding to the finite size entangling region R_{AS} . **Right:** evolution of the time island coordinates t_a (darker red), t_p (magenta) corresponding to the same region. Notice that near the breaking time t_b^{break} (4.16) one can observe spatial asymmetry $a \neq p$ and time assymetry $t_a \neq t_p$.

Figure 12: Time evolution of the entanglement entropy for $R_{AS} \cup I$ with $b = 5$ (green), $b = 15$ (light green) and $b = 18$ (cyan). For all cases, we take $q = 150$.

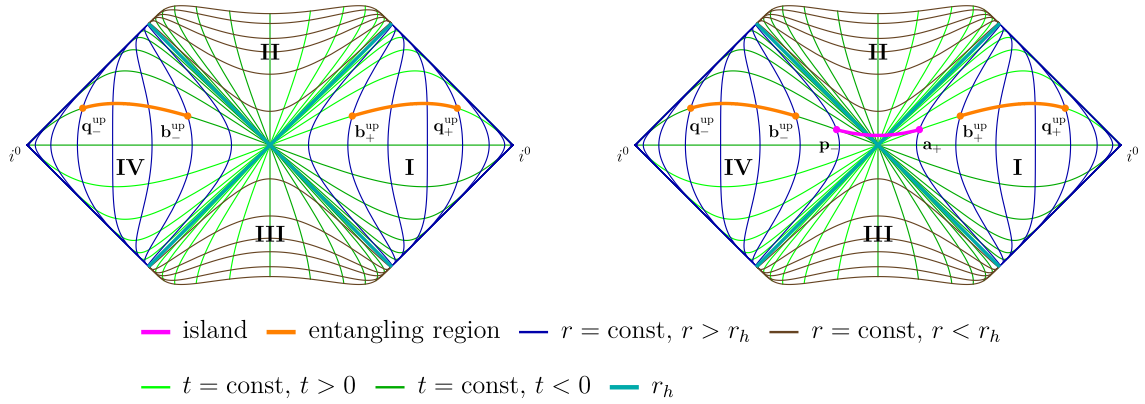

Figure 13: **Left:** Penrose diagram for the eternal Schwarzschild black hole with the mirror-symmetric entangling region $R_{\text{MS}} \equiv [\mathbf{q}_-^{\text{up}}, \mathbf{b}_-^{\text{up}}] \cup [\mathbf{b}_+^{\text{up}}, \mathbf{q}_+^{\text{up}}]$. **Right:** the same configuration with the island $I \equiv [\mathbf{p}_-, \mathbf{a}_+]$.

but still finite entangling region. Initially, the entropy follows the “canonical” picture of the linear growth (red curve). Then, the transition to the dominant island configuration happens (green curve), and the entropy, remaining approximately constant (4.28) for some time, slightly decreases just before the breaking time t_b^{break} .

- For a smaller region (Fig. 10), the picture is qualitatively different. Again, at early and intermediate times, the entropy grows approximately like in the semi-infinite case [18]. However, the island contribution is never dominant, so the whole evolution is determined only by the entanglement entropy of the matter in the entangling region.
- At early times (if the island appears), we observe the mirror-symmetric regime (4.27), while shortly before the breaking time t_b^{break} , we see significant deviation from the space and time symmetry between the island boundaries lying in different wedges (see Fig. 11).
- When reducing the size of the entangling region R_{AS} , the lifetime of the island decreases. At fixed b and decreasing q , t_b^{isl} does not change significantly, while t_b^{break} decreases (see Fig. 9 and 10). At fixed q and increasing b , t_b^{isl} increases, and t_b^{break} decreases (see Fig. 12). For sufficiently large b and small q , an island does not appear at all.

4.2 Mirror-symmetric entangling regions

As we saw in the previous section, one has to consider finite regions R_{AS} to reproduce the results obtained in [18]. In this section, we consider the entanglement entropy of Hawking radiation using the island formula (2.15) for finite MS entangling regions R_{MS} (4.9) (see Fig. 13). We show that for such regions, the results for the semi-infinite ones [18] are not reproduced in the $\mathbf{q}_{\pm} \rightarrow i^0$ limit.

As we mentioned in Subsection 3.5, the region R_{MS} seems more natural than R_{AS} because its parts in the right and left wedges are mirror-symmetric (see Fig. 13). Therefore, the boundaries of the parts of the entangling region R_{MS} located in the same wedge can have the same Schwarzschild time coordinates. From a three-dimensional purely spatial point of view, one can imagine each part of R_{MS} as a domain between two concentric spheres with radii b and q . Outgoing Hawking modes pass through this domain in finite time and then escape to infinity.

Even though R_{MS} does not give the correct limit $\mathbf{q}_{\pm} \rightarrow i^0$, it can still be used to test the island formula (2.15), capturing the interplay between gravity and entanglement and being well understood from the “naive” and “physical” points of view.

No island

Let us consider the entanglement entropy of Hawking radiation collected in the finite region (4.9) depicted in Fig. 13

$$S(R_{\text{MS}}) = \frac{c}{6} \log \left(\frac{16f(b)f(q)}{\kappa_h^4 \varepsilon^4} \cosh^4 \kappa_h t_b \right) + \frac{c}{3} \log \left(\frac{\cosh \kappa_h (r_*(q) - r_*(b)) - 1}{\cosh \kappa_h (r_*(q) - r_*(b)) + \cosh 2\kappa_h t_b} \right). \quad (4.29)$$

One can see that in the limit $\mathbf{q}_{\pm} \rightarrow i^0$, the entropy (4.29) does not reproduce the answer (2.19). Indeed, due to (3.20)

$$\lim_{\mathbf{q}_{\pm} \rightarrow i^0} S(R_{\text{MS}}) = S(R_{\infty}) + \frac{c}{3} \log \cosh \kappa_h t_b. \quad (4.30)$$

At relatively early times, when

$$\cosh 2\kappa_h t_b \ll \cosh \kappa_h (r_*(q) - r_*(b)), \quad (4.31)$$

but $t_b \gg r_h$, the entropy (4.29) without islands increases monotonically as

$$S(R_{\text{MS}}) \simeq \frac{2c}{3} \kappa_h t_b. \quad (4.32)$$

We observe the linear growth twice as fast as for R_∞ and R_{AS} , see (2.21) and (4.17). This behaviour and the incorrect limit (4.30) arise due to the fact that the distance between the boundaries \mathbf{q}_- and \mathbf{q}_+ is now time-dependent since they lie on different time slices. Also, provided that $t_b = t_q$, this time dependence is exactly the same as that of the distance between \mathbf{b}_- and \mathbf{b}_+ which doubles the coefficient in (4.32).

At late times, when the inequality (4.31) holds in the opposite direction, the entropy without islands (4.29) saturates at the value independent of time

$$S(R_{\text{MS}}) \simeq \frac{c}{6} \log \frac{f(b)f(q)}{\kappa_h^4 \varepsilon^4} + \frac{c}{3} \log (\cosh \kappa_h(r_*(q) - r_*(b)) - 1). \quad (4.33)$$

If $q \gg b$, we get from (4.33)

$$S(R_{\text{MS}}) \simeq \frac{c}{3} \kappa_h(r_*(q) - r_*(b)). \quad (4.34)$$

This saturation can be interpreted as follows. As soon as the “first”¹¹ particle of radiation from the black hole reaches the sphere of smaller radius b , the entropy starts to increase monotonically because more and more particles reach the domain between the spheres with radii b and q . As this particle reaches the sphere of radius q , the fluxes of incoming and outgoing particles become equal. Therefore, the entropy without islands saturates at some finite value.

Unlike the configuration R_{AS} (4.7), which has an upper bound on time, the configuration R_{MS} (4.9) does not have such a problem since the points $\mathbf{b}_\pm, \mathbf{q}_\pm$ in both right and left wedges move forward in time. The comparison of the entropies for R_∞ (2.19) and R_{MS} (4.29) is demonstrated in Fig. 14.

Inclusion of island

Let us describe the island configuration for the finite region R_{MS} . In contrast to the region R_{AS} considered in Subsection 4.1, the interval $[\mathbf{b}_+^{\text{up}}, \mathbf{q}_+^{\text{up}}] \in R_{\text{MS}}$ in the right wedge is mirror-symmetric to the interval $[\mathbf{q}_-^{\text{up}}, \mathbf{b}_-^{\text{up}}] \in R_{\text{MS}}$ in the left one (see Fig. 13). Moreover, one can show that the entropy $S(R_{\text{MS}} \cup I)$ is symmetric under the permutation $a \leftrightarrow p, t_a \leftrightarrow t_p$ of the coordinates of the island boundaries (4.11). Therefore, we take a mirror-symmetric ansatz for I_{MS} , as in [18], i.e.

$$I_{\text{MS}} : \quad p = a, \quad t_p = t_a. \quad (4.35)$$

¹¹Of course, the eternal black hole radiates permanently, so the “first” particle of radiation means that one emitted after a certain moment, which we choose as $t = 0$.

Figure 14: No-island entropy evolution for the finite region R_{MS} with $q = 25$ (darker magenta), $q = 100$ (red), and for the semi-infinite one R_∞ (blue dashed). For all cases, we take $b = 5$. The monotonic growth for the no-island entropy $S(R_{\text{MS}})$ is twice as fast compared to $S(R_\infty)$.

The generalized entropy before extremization is

$$S_I(R_{\text{MS}}) = \frac{\text{Area}(\partial I_{\text{MS}})}{4G} + S_{\text{matter}}(R_{\text{MS}} \cup I_{\text{MS}}). \quad (4.36)$$

The area term remains the same as in (4.19). The entanglement entropy $S_{\text{matter}}(R_{\text{MS}} \cup I_{\text{MS}})$ reads

$$S_{\text{matter}}(R_{\text{MS}} \cup I_{\text{MS}}) = \mathcal{X}(a, b, q, t_a, t_b). \quad (4.37)$$

The explicit form of \mathcal{X} (A.10) is given in Appendix A.

The entropy (4.36) is extremized with respect to a and t_a . In the limit $\mathbf{q}_\pm \rightarrow i^0$, the entropy before extremization (4.36) does not reduce to that for the semi-infinite regions [18]. Indeed, again due to (3.20)

$$\lim_{q \rightarrow \infty} S_I(R_{\text{MS}}) = S_I(R_\infty) + \frac{c}{3} \log \cosh \kappa_h t_b. \quad (4.38)$$

Let us consider relatively early times in the sense that

$$\cosh \kappa_h (r_*(q) - r_*(a)) \gg \cosh \kappa_h (t_a \pm t_b), \quad (4.39)$$

$$\cosh \kappa_h (r_*(q) - r_*(b)) \gg \cosh 2\kappa_h t_b. \quad (4.40)$$

Under these conditions, the entropy $S_I(R_{\text{MS}})$ takes the form

$$S_I(R_{\text{MS}}) \simeq \frac{2\pi a^2}{G} + \frac{c}{6} \log \left[\frac{64f(a)f(b)}{\kappa_h^6} \cosh^2 \kappa_h t_a \cosh^4 \kappa_h t_b \right] \\ + \frac{c}{3} \log \left[\frac{\cosh \kappa_h (r_*(a) - r_*(b)) - \cosh \kappa_h (t_a - t_b)}{\cosh \kappa_h (r_*(a) - r_*(b)) + \cosh \kappa_h (t_a + t_b)} \right]. \quad (4.41)$$

The extremization procedure for (4.41) is the same as in [18]. So, if along with (4.39) and (4.40) the condition (4.25) is satisfied, i.e.

$$\cosh \kappa_h (r_*(b) - r_*(a)) \ll \cosh \kappa_h (t_a + t_b) \ll \cosh \kappa_h (r_*(q) - r_*(a)), \quad (4.42)$$

then there is the following island solution

$$t_a = t_b, \quad (4.43) \\ a - r_h \ll r_h.$$

An approximate analytical expression for the entropy with an island (4.43) is given by

$$S_I(R_{\text{MS}}) \simeq \frac{2\pi r_h^2}{G} + \frac{c}{6} \left[\log \left(\frac{16r_h^3(b - r_h)^2}{b\varepsilon^4} \right) + \frac{b - r_h}{r_h} \right] \\ + \frac{c}{6} \log \left(\frac{4f(q) \cosh^2 \kappa_h t_b}{\kappa_h^2 \varepsilon^2} \right) - \frac{c}{3} e^{2\kappa_h t_b - \kappa_h (r_*(q) - r_*(b))}. \quad (4.44)$$

See Appendix A for the details of the derivation of (4.44). Note that the exponential growth associated with finite size effects is suppressed due to the condition (4.40), so the entropy with the island $S_I(R_{\text{MS}})$ grows only linearly.

The monotonic growth of the entropy (4.44) *with* the island is the same as for the entropy *without* it (2.19) for the semi-infinite regions R_∞ , and twice as slow compared to the entropy *without* the island (4.32) for the region R_{MS} . The qualitative picture can be explained as follows. Both entangled particles in a pair are trapped by the entangling region and the black hole interior when the outgoing Hawking mode is in the region R_{MS} . When the outgoing particle leaves this region, only the interior one is trapped by the island. So, there is the same growth as for the semi-infinite regions without islands (2.19) with the only difference that the interior modes are trapped instead of the outgoing ones for R_∞ .

Now consider the late time approximation, when the inequalities (4.39) and (4.40)

Figure 15: Entanglement entropy evolution for the finite size entangling region R_{MS} with $q = 300$, and for the infinite region R_∞ . For both cases we take $b = 5$. **Left:** the no-island entropy $S(R_{MS})$ (red), the entropy with the island $S_I(R_{MS})$ (green) for the same region R_{MS} ; the no-island entropy $S(R_\infty)$ (blue dotted) and the entanglement entropy $S_I(R_\infty)$ with the island (darker cyan) for the infinite region R_∞ . One can see that there is discrepancy between the entropies for the finite and infinite regions. **Right:** one can see that after the disappearance of the island for the region R_{MS} (green), there is an instantaneous transition to the no-island entropy (red).

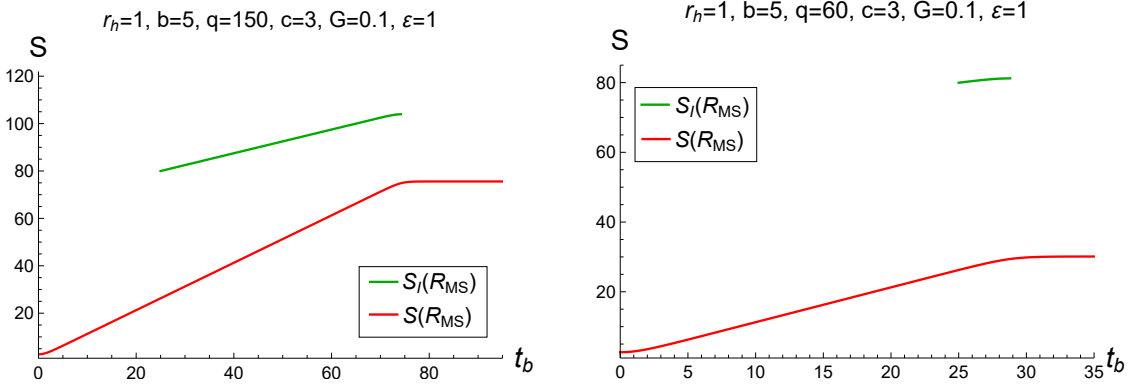

Figure 16: Left: entanglement entropy evolution for the region R_{MS} with $q = 150$ (red), and for the same region with the island I (green). **Right:** the same, but with $q = 60$. For both cases, we take $b = 5$. Notice that the entropy with the island I is not preferred by (2.15) over that for the no-island configuration R_{MS} .

hold in the opposite direction, i.e.

$$\begin{aligned} \cosh \kappa_h(t_a + t_b) &\gg \cosh \kappa_h(r_*(q) - r_*(a)), \\ \cosh 2\kappa_h t_b &\gg \cosh \kappa_h(r_*(q) - r_*(b)). \end{aligned} \quad (4.45)$$

Under these conditions, the entropy $S_I(R_{\text{MS}})$ is given by

$$S_I(R_{\text{MS}}) \simeq \frac{2\pi a^2}{G} + \frac{c}{3} \kappa_h t_a + \frac{c}{6} \log \frac{4f(a)f(b)f(q)}{\kappa_h^6} + \frac{c}{3} \log \left[\frac{(\cosh \kappa_h(r_*(a) - r_*(b)) - \cosh \kappa_h(t_a - t_b)) (\cosh \kappa_h(r_*(b) - r_*(q)) - 1)}{\cosh \kappa_h(r_*(q) - r_*(a)) - \cosh \kappa_h(t_a - t_b)} \right]. \quad (4.46)$$

The entropy (4.46) grows monotonically with time t_a . It is obvious that there is no extremum over t_a , so the island exists only for finite time and, moreover, only if the two inequalities (4.42) hold simultaneously. One can see from (4.42) that by reducing the size of the finite region — by decreasing q or increasing b — it is possible to ensure that the inequalities cease to hold.

So, what features can be observed for the island dynamics when we consider R_{MS} ? Let us enumerate them and compare with the results obtained for R_{AS} :

- First of all, the breaking time does not make sense for R_{MS} — the interval is always spacelike. No-island entropy at large times is saturated at the value independent of time. The island, if it arises at all, exists for a finite time and disappears due to the violation of the extremization conditions (4.42). Numerical analysis shows (see Fig. 15 and Fig. 16) that the no-island entropy reaches the saturation at the time approximately equal to the moment of the disappearance of the island.
- The comparison of the entropies for R_{MS} and R_∞ shows that R_{MS} leads to a wrong entropy evolution in the large q limit, see Fig. 15 (left). Fig. 14 demonstrates that the monotonic growth for the no-island entropy $S(R_{\text{MS}})$ is twice as fast as for $S(R_\infty)$. The entropy with an island for the region R_{MS} grows monotonically with time, unlike R_∞ and R_{AS} .
- For large q , one can observe significant changes in the qualitative behaviour of the entropy for R_{MS} compared to R_{AS} . In Fig. 15 (right), after the disappearance of the island there is a discontinuous transition from the entropy with an island to the no-island entropy. In the next section, we will show that this behaviour causes the entanglement entropy to exceed the allowed upper bound. However, same as for R_{AS} , starting from relatively small values of q , the island never dominates, and the whole evolution corresponds to the no-island configuration (see Fig. 16).
- The island geometry for R_{MS} coincides with the one for R_∞ except for the moment when the island disappears (see Fig. 17).

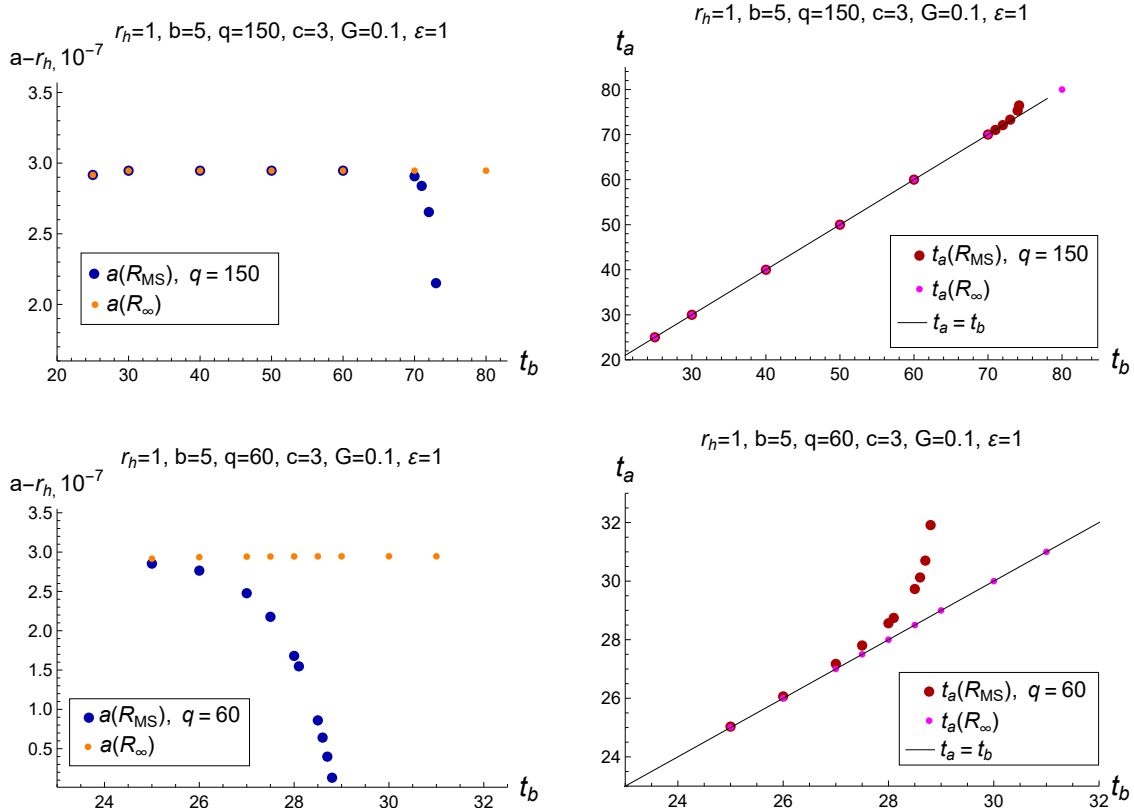

Figure 17: **Left:** evolution of the radial island coordinate a corresponding to the finite size entangling region R_{MS} (blue), and to the semi-infinite region R_∞ (orange). **Right:** evolution of the time island coordinate t_a corresponding to R_{MS} (magenta), and to R_∞ (pink). Just before the island disappearance, one can observe that the coordinates for the finite region R_{MS} cease to coincide with the coordinates of the infinite one R_∞ .

- Finally, as for R_{AS} , the lifetime of the island decreases with decreasing size of the region R_{MS} . Fig. 15 and Fig. 16 show this effect at a fixed b and decreasing q . Fig. 18 demonstrates the same for a fixed q and increasing b . For sufficiently large b and small q , the island does not appear at all.

Figure 18: Time evolution of the entanglement entropy for $R_{\text{MS}} \cup I_{\text{MS}}$ with $b = 5$ (green), $b = 15$ (light green) and $b = 22$ (cyan).

5 Information paradox for finite regions

In this section, we discuss an analogue of the Page behaviour [3, 4] for finite regions in the two-sided Schwarzschild eternal black hole corresponding to the unitary evolution of the Hawking radiation entropy. We obtain an upper bound for the entanglement entropy of finite regions in a given setup. It is crucial for the formulation of the information paradox for time-dependent entanglement entropy of Hawking radiation for finite regions. Namely, we say that there is the information paradox if the entanglement entropy for finite regions exceeds the upper bound that follows from the general properties of entanglement and purity of a state of a complete system including black hole and its radiation.

As a warm-up, let us remind the calculation of the upper bound for the entanglement entropy in the usual case of semi-infinite regions in which radiation is collected.¹² If the degrees of freedom of the black hole (BH) and its radiation (Rad) constitute a pure state, then according to the complementarity property, the fine-grained entropies, or the von Neumann entropies, of the black hole and the radiation should be equal

$$S(BH) = S(Rad). \quad (5.1)$$

Fine-grained entropy of the black hole should be bounded above by coarse-grained

¹²For a comprehensive review of this topic see [25].

(thermodynamic) entropy of the black hole

$$S(BH) \leq S_{\text{coarse}}(BH). \quad (5.2)$$

For the two-sided black hole, the coarse-grained entropy is twice the Bekenstein-Hawking entropy [12, 18]

$$S_{\text{coarse}}(BH) = 2S_{\text{Bekenstein-Hawking}} = \frac{2\pi r_h^2}{G}. \quad (5.3)$$

Thus, due to (5.1), (5.2) and (5.3) there is an upper bound on the entanglement entropy of Hawking radiation

$$S(\text{Rad}) \leq \frac{2\pi r_h^2}{G}. \quad (5.4)$$

For such a setup, the total Hilbert space, defined on some Cauchy surface, is partitioned into two parts: one is associated with the black hole degrees of freedom, and the other — with the radiation

$$\mathcal{H}_{\text{tot}} = \mathcal{H}_{BH} \otimes \mathcal{H}_{\text{Rad}}. \quad (5.5)$$

We consider a semi-infinite region Rad on the Cauchy surface, in which all radiation from the black hole horizon to spacelike infinity is collected (see the region $R_+ \cup R_-$ on the left Fig. 1). In our notation (2.23), it gives $\text{Rad} = R_\infty$.

Let us consider a finite region R (4.1) collecting radiation from the two-sided black hole (see the region $R_+ \cup R_-$ in Fig. 1 (right)). This means that the radiation from the boundaries \mathbf{q}_\pm of the region R to spacelike infinities in both wedges is not taken into account. We denote a semi-infinite region with unaccounted radiation as

$$C = C_+ \cup C_-, \quad (5.6)$$

where C_+ and C_- are located in the right and the left wedges, respectively. For the region Rad , we obtain

$$\text{Rad} = R \cup C. \quad (5.7)$$

The total Hilbert space (5.5) is, therefore, partitioned into three parts

$$\mathcal{H}_{\text{tot}} = \mathcal{H}_{BH} \otimes \mathcal{H}_R \otimes \mathcal{H}_C, \quad (5.8)$$

which can be rewritten as three bipartitions¹³

$$\mathcal{H}_{\text{tot}} = \mathcal{H}_R \otimes \mathcal{H}_{BH \cup C} = \mathcal{H}_{BH} \otimes \mathcal{H}_{R \cup C} = \mathcal{H}_C \otimes \mathcal{H}_{BH \cup R}. \quad (5.9)$$

Let us assume that we are given a pure state on the total space \mathcal{H}_{tot} . From the complementarity property for pure states, we have the following relations for bipartitions (5.9)

$$S(BH) = S(R \cup C), \quad S(R) = S(BH \cup C), \quad S(C) = S(BH \cup R). \quad (5.10)$$

The strong subadditivity property [66] for tripartitions like (5.8) gives the inequality

$$S(BH \cup R \cup C) + S(R) \leq S(BH \cup R) + S(R \cup C), \quad (5.11)$$

which, along with the conditions (5.10) and the entropy of the total pure state on $BH \cup R \cup C$ being zero, takes the form

$$S(R) \leq S(BH) + S(C). \quad (5.12)$$

From (5.2), (5.3) and (5.12), one gets an upper bound for the entanglement entropy of a finite region R

$$S(R) \leq \frac{2\pi r_h^2}{G} + S(C). \quad (5.13)$$

So, we have to know the entropy $S(C)$ for semi-infinite regions.

Note that for a semi-infinite region [18], the entropy with an island (2.22), in addition to $2\pi r_h^2/G$, contains other positive terms, which are small compared to the area term under the condition $r_h^2/G \gg c$. Therefore, one can say that the inequality (5.4) for a semi-infinite region is satisfied only approximately. If the entropy for finite regions exceeds the upper bound (5.13) by the value of the same order of magnitude as that for the semi-infinite region [18], we say that the inequality (5.13) also holds approximately.

So far, we have not specified the finite region R . The choice of the points \mathbf{q}_\pm , common for the regions R and C , is important for the calculation the entropy $S(C)$. In Section 4, we considered two different cases, R_{AS} (4.7) and R_{MS} (4.9). Denote the region C for the first choice as C_{AS} (corresponding to $\mathbf{q}_+^{\text{up}}, \mathbf{q}_-^{\text{down}}$), and for the second one as C_{MS} (corresponding to $\mathbf{q}_+^{\text{up}}, \mathbf{q}_-^{\text{up}}$). As in Section 4, we consider the conditions (4.3), (4.4) and (4.5) to be satisfied for the coordinates of the boundaries of the finite region.

¹³Here $\mathcal{H}_{X \cup Y} \equiv \mathcal{H}_X \otimes \mathcal{H}_Y$.

Asymmetric finite entangling region

Consider the no-island entropy for the region C_{AS} . Using AS regularization (see Subsection 3.5), one can show that

$$S(C_{\text{AS}}) = \frac{c}{6} \log \frac{4f(q)}{\kappa_h^2 \varepsilon^2}. \quad (5.14)$$

The entropy (5.14) does not depend on time. If there is an island for the semi-infinite region C_{AS} , then the entropy with the island will be greater than (5.14) due to the area term of order r_h^2/G ¹⁴. So, according to the island formula, the no-island entropy (5.14) dominates at all times. From (5.13), we get an upper bound for the entanglement entropy of Hawking radiation for a finite region R_{AS}

$$S(R_{\text{AS}}) \leq \frac{2\pi r_h^2}{G} + \frac{c}{6} \log \frac{4f(q)}{\kappa_h^2 \varepsilon^2}. \quad (5.15)$$

In Subsection 4.1, it was shown that the entropy with an island (4.28) just before the breaking time (4.16) has the largest value that the entropy can take during the evolution. Therefore, we use the entropy (4.28) as the LHS of the inequality (5.15) to check its validity. The entropy (4.28) differs from that for the semi-infinite region (2.22) by the second term on the RHS of (5.15) and by a negligible correction due to a finite size effect. Therefore, we say that the inequality (5.15) is satisfied approximately in the sense indicated above for all finite sizes of the region R_{AS} .

For small size regions (see Fig. 10), the no-island entropy dominates at all times and does not exceed the entropy with an island. Therefore, for small sizes, the island is not required for the inequality (5.15) to hold. The entropy (4.28) in the limit $\mathbf{q}_{\pm} \rightarrow i^0$ reduces to the entropy for the semi-infinite region, so the inequality (5.4) for semi-infinite regions is reproduced.

Mirror-symmetric finite entangling region

Let us consider the entropy for the region C_{MS} associated with R_{MS} . We show that this case, unlike the previous one, contains some subtleties. The entropy of the semi-infinite region C_{MS} is considered in [18]. Therefore, the no-island entropy dominating at early

¹⁴Remind that we assume the condition $r_h^2/G \gg c$.

times and the entropy with an island dominating at large times are

$$S(C_{\text{MS}}) = \begin{cases} \frac{c}{6} \log \left(\frac{4f(q) \cosh^2 \kappa_h t_q}{\kappa_h^2 \varepsilon^2} \right), & \text{no-island,} \\ \frac{2\pi r_h^2}{G} + \frac{c}{6} \left[\log \left(\frac{16r_h^3 (q - r_h)^2}{\varepsilon^4 q} \right) + \frac{q - r_h}{r_h} \right], & \text{with island.} \end{cases} \quad (5.16)$$

From (5.13), we get an upper bound for the entanglement entropy of Hawking radiation for a finite region R_{MS} for fixed q and relatively early times t_q as

$$S(R_{\text{MS}}) \leq \frac{2\pi r_h^2}{G} + \frac{c}{6} \log \left(\frac{4f(q) \cosh^2 \kappa_h t_q}{\kappa_h^2 \varepsilon^2} \right), \quad (5.17)$$

and for sufficiently large t_q as

$$S(R_{\text{MS}}) \leq \frac{4\pi r_h^2}{G} + \frac{c}{6} \left[\log \left(\frac{16r_h^3 (q - r_h)^2}{\varepsilon^4 q} \right) + \frac{q - r_h}{r_h} \right]. \quad (5.18)$$

Under the condition $t_b = t_q$, the time dependence for the entropy of both regions R_{MS} and C_{MS} is determined by the same time coordinate t_b . However, t_b is different for the formation of islands. Indeed, in Subsection 4.2 it was found that the condition for the formation of an island for a finite region R_{MS} is the fulfillment of the inequalities (4.42). While the formation of an island for the region C_{MS} requires the large time condition [18] in the form

$$\cosh \kappa_h (t_b + t_a^C) \gg \cosh \kappa_h (r_*(q) - r_*(a^C)), \quad (5.19)$$

where a^C, t_a^C are the coordinates of the island boundaries associated with the region C_{MS} . From the comparison of the conditions (4.42) and (5.19), one can observe that the islands associated with the regions R_{MS} and C_{MS} cannot exist simultaneously. It is important that first there is an island for region R_{MS} (if the region is large enough for an island to arise), and only some time after it disappears, an island for region C_{MS} occurs.

For large q , after the disappearance of the island for R_{MS} , one can show¹⁵ that the island for C_{MS} does not appear for a relatively long time. Therefore, the upper bound is given by an inequality (5.17), and the entropy $S(R_{\text{MS}})$ on the LHS is the no-island entropy. However, the no-island entropy $S(R_{\text{MS}})$ grows twice as fast (4.32)

¹⁵Indeed, the entropy $S_I(C_{\text{MS}})$ with an island (5.16) takes relatively large value for large q due to the term proportional to q/r_h , so it starts to dominate only for very late times, when the no-island entropy $S(C_{\text{MS}})$ reaches this large value.

Figure 19: Left: Time evolution of the no-island entropy $S(R_{\text{MS}})$ (red), the entropy with the island $S_I(R_{\text{MS}})$ (green) and the upper bound (5.17) (blue) for the finite size entangling regions R_{MS} with $q = 300$. **Right:** the same, but with $q = 350$. For both cases, we take $b = 5$. After the disappearance of the island, there is a discontinuous transition to the no-island entropy $S(R_{\text{MS}})$, that during finite time (between two vertical shaded lines) is larger than the upper bound. One can see that as q increases, the difference between $S(R_{\text{MS}})$ and the upper bound increases, while the difference between $S_I(R_{\text{MS}})$ and the upper bound does not change significantly.

as the time-dependent term on the RHS for inequality (5.17). So, this inequality may no longer be true. This is indeed the case for large q , as shown in Fig. 19. After the disappearance of the island for R_{MS} there is a discontinuous transition to the saturation value (4.34) of no-island configuration. Therefore, the entropy $S(R_{\text{MS}})$ for a finite time is significantly larger than the upper bound.

In Fig. 19, the entropy with an island $S_I(R_{\text{MS}})$ is slightly larger than the upper bound, and difference between them does not change significantly when q varies.¹⁶ While after the disappearance of the island, the difference between the no-island entropy $S(R_{\text{MS}})$ and the upper bound grows with increasing q due to increasing saturation value (4.34). Thus, we say that the inequality (5.17) is satisfied approximately for the entropy with an island $S_I(R_{\text{MS}})$ and is violated during a finite time after the disappearance of the island.

As for R_{AS} , for relatively small size of the region R_{AS} (see Fig. 16), the no-island entropy dominates at all times and does not exceed the entropy with an island. Therefore, for a small region the inequalities (5.17) and (5.18) are satisfied at all times without the introduction of the island.

¹⁶Indeed, the difference between $S_I(R_{\text{MS}})$ (4.44) and the RHS of (5.17) is approximately the same as the difference between the entropy with an island (2.22) for a semi-infinite region and the area term $2\pi r_h^2/G$ and does not change greatly with q .

Consider the entropy of the region C_{MS} at the limit $\mathbf{q}_{\pm} \rightarrow i^0$. From (5.19), it seems that in this limit there is no late time regime. Therefore, we assume that the island for C_{MS} appears only in the asymptotic time and the no-island entropy dominates at all finite times. Then, the upper bound for the entropy $S(R_{\text{MS}})$ is given by the inequality (5.17). Using the mirror-symmetric regularization scheme, we obtain from (5.17) at $\mathbf{q}_{\pm} \rightarrow i^0$

$$\lim_{\mathbf{q} \rightarrow i^0} S(R_{\text{MS}}) \leq \frac{2\pi r_h^2}{G} + \frac{c}{6} \log \cosh^2 \kappa_h t_b. \quad (5.20)$$

The LHS of (5.20) for both no-island and island configurations, see (4.30) and (4.38), contains the entropy of semi-infinite regions $S(R_{\infty})$ plus a term equal to the time-dependent term on the RHS of (5.20). Therefore, this time-dependent term cancels on the left and on the right of (5.20), and for the region R_{MS} at the limit $\mathbf{q}_{\pm} \rightarrow i^0$, the upper bound for semi-infinite regions (5.4) is also reproduced. Note that this statement does not contradict our previous one that for large but finite q the entropy exceeds the upper bound. It is because at $\mathbf{q}_{\pm} \rightarrow i^0$ a discontinuous transition as in Fig. 19 does not occur at any finite times.

Let us list and emphasize the results of this section:

- For a two-sided eternal black hole, we obtained an upper bound (5.13) for the entanglement entropy of the Hawking radiation collected in an arbitrary finite region R . The upper bound is determined by the thermodynamic entropy of the two-sided black hole and the entanglement entropy of the semi-infinite region C with radiation unaccounted for in this setup. An upper bound depends on the specific type of finite region R . We considered two types of finite regions — region R_{AS} with finite lifetime and region R_{MS} between two concentric spheres at constant time.
- For both choices of a finite region R for a size so small that the entropy with an island are not dominant for the entire evolution, the entropy does not exceed an upper bound. Thus, small regions do not require the introduction of an island to avoid exceeding the upper bound. Also, for both regions at $\mathbf{q}_{\pm} \rightarrow i^0$, the upper bound condition for a semi-infinite region is reproduced, and in this case the introduction of islands is necessary.
- For sufficiently large regions R_{AS} , the presence of an island leads to the fact that the entropy does not exceed the upper bound. However, for large region R_{MS} due to the discontinuous transition from the island entropy to the no-island entropy

after the disappearance of the island, the entropy exceeds the upper bound for a finite time (see Fig. 19). Thus, the introduction of an island for large regions R_{MS} does not solve the information paradox.

6 Conclusions & Future prospects

In this paper, we address the properties of the entanglement entropy of Hawking radiation on the background of the eternal Schwarzschild black hole in the case of entangling regions of finite size. Not only this knowledge itself is necessary for IR regularizations in the context of the information paradox, but it is also vital for spacetimes with finite observable domains. Among them are de Sitter (dS) and Schwarzschild-de Sitter (SdS) solutions where a physical observer is bounded within the cosmological horizon. Therefore, only finite entangling regions are of physical significance in these spacetimes, and we are going to generalise the results of this paper on dS and SdS cases in the forthcoming paper.

We have established different ways of choosing finite entangling regions in Schwarzschild spacetime and demonstrated that only the asymmetric regularization is consistent with the complementarity property of the entanglement entropy. However, the corresponding Cauchy surface is no longer “immortal” and has a finite lifetime depending on the size of the entangling region. In this case, one gets a typical Hawking paradox: a linear growth of the entropy with time and the excess of the Bekenstein-Hawking entropy — with the only qualitative difference that right before the breaking time the entropy falls extremely fast.

Also, we have derived the constraints on the entanglement entropy for different choices of entangling regions. It turns out that the upper bound on the entropy for a finite region depends on the size of this region and on the location of its endpoints.

Accounting for the entanglement islands proves to be consistent with the unitarity of entropy evolution in the case of the asymmetric regularization. It preserves the conservation of information, thus, no paradoxes arise. However, the entanglement entropy might violate the upper bound inequalities for other choices of the entangling regions even in the presence of the islands.

Appendix

A Explicit formulas for entanglement entropy with island

In this appendix, we present explicit formulas for the matter contribution to the generalized entropy (2.15).

Asymmetric region

The entanglement entropy of conformal matter for $R_{\text{AS}} \cup I$ is

$$S_{\text{matter}}(R_{\text{AS}} \cup I) = \mathcal{Y}(a, p, b, q, t_a, t_p, t_b), \quad (\text{A.1})$$

where $\mathcal{Y}(a, p, b, q, t_a, t_p, t_b)$ is explicitly given by

$$\begin{aligned} \mathcal{Y}(a, p, b, q, t_a, t_p, t_b) = & \frac{c}{6} \log \left[\frac{(\cosh \kappa_h(r_*(b) - r_*(q)) - \cosh 2\kappa_h t_b)(\cosh \kappa_h(r_*(b) - r_*(q)) - 1)}{(\cosh \kappa_h(r_*(b) - r_*(q)) + \cosh 2\kappa_h t_b)(\cosh \kappa_h(r_*(b) - r_*(q)) + 1)} \right] \\ & + \frac{c}{6} \log \left[\frac{(\cosh \kappa_h(r_*(a) - r_*(b)) - \cosh \kappa_h(t_a - t_b))(\cosh \kappa_h(r_*(p) - r_*(b)) - \cosh \kappa_h(t_p - t_b))}{(\cosh \kappa_h(r_*(a) - r_*(b)) + \cosh \kappa_h(t_a + t_b))(\cosh \kappa_h(r_*(p) - r_*(b)) + \cosh \kappa_h(t_p + t_b))} \right] \\ & + \frac{c}{6} \log \left[\frac{(\cosh \kappa_h(r_*(a) - r_*(q)) + \cosh \kappa_h(t_a - t_b))(\cosh \kappa_h(r_*(p) - r_*(q)) + \cosh \kappa_h(t_p + t_b))}{(\cosh \kappa_h(r_*(a) - r_*(q)) - \cosh \kappa_h(t_a - t_b))(\cosh \kappa_h(r_*(p) - r_*(q)) - \cosh \kappa_h(t_p + t_b))} \right] \\ & + \frac{c}{6} \log \left[\frac{32\sqrt{f(a)f(p)f(b)f(q)}}{\kappa_h^6 \varepsilon^6} \cosh^2 \kappa_h t_b (\cosh \kappa_h(r_*(a) - r_*(p)) + \cosh \kappa_h(t_a + t_p)) \right]. \end{aligned} \quad (\text{A.2})$$

Let us obtain an approximate analytical expression for the entropy (A.2) at times long before the breaking time, when a symmetric island (4.27) with boundaries near the horizon emerges, i.e. when

$$\cosh \kappa_h(r_*(b) - r_*(a)) \ll \cosh 2\kappa_h t_b \ll \cosh \kappa_h(r_*(q) - r_*(b)). \quad (\text{A.3})$$

Note that inequality

$$\cosh 2\kappa_h t_b \ll \cosh \kappa_h(r_*(q) - r_*(a)) \quad (\text{A.4})$$

follows from (A.3) due to $r_*(b) \gg r_*(a)$ in near-horizon zone.

The entropy (A.2) under the condition of a symmetric island (4.27) is

$$\begin{aligned}
\mathcal{Y}(a, a, b, q, t_b, t_b, t_b) &= \frac{c}{6} \log \left[\frac{(\cosh \kappa_h(r_*(b) - r_*(q)) - \cosh 2\kappa_h t_b)(\cosh \kappa_h(r_*(b) - r_*(q)) - 1)}{(\cosh \kappa_h(r_*(b) - r_*(q)) + \cosh 2\kappa_h t_b)(\cosh \kappa_h(r_*(b) - r_*(q)) + 1)} \right] \\
&+ \frac{c}{6} \log \left[\frac{(\cosh \kappa_h(r_*(a) - r_*(q)) + \cosh 2\kappa_h t_b)(\cosh \kappa_h(r_*(a) - r_*(q)) + 1)}{(\cosh \kappa_h(r_*(a) - r_*(q)) - \cosh 2\kappa_h t_b)(\cosh \kappa_h(r_*(a) - r_*(q)) - 1)} \right] \\
&+ \frac{c}{6} \log \left[\frac{64f(a)f(b)f(q)}{\kappa_h^6 \varepsilon^6} \cosh^4 \kappa_h t_b \right] + \frac{c}{3} \log \left[\frac{\cosh \kappa_h(r_*(a) - r_*(b)) - 1}{\cosh \kappa_h(r_*(a) - r_*(b)) + \cosh 2\kappa_h t_b} \right].
\end{aligned} \tag{A.5}$$

It can be seen that under the conditions (A.3) and (A.4) the entropy (A.5) simplifies as¹⁷

$$\begin{aligned}
\mathcal{Y} &\simeq \frac{c}{6} \log \left[\frac{4f(a)f(b)f(q)}{\kappa_h^6 \varepsilon^6} \right] + \frac{c}{3} \kappa_h(r_*(b) - r_*(a)) - \frac{2c}{3} e^{-\kappa_h(r_*(b) - r_*(a))} - \frac{c}{3} e^{-2\kappa_h t_b + \kappa_h(r_*(b) - r_*(a))} \\
&- \frac{c}{3} \left[e^{2\kappa_h t_b - \kappa_h(r_*(q) - r_*(b))} + 2e^{-\kappa_h(r_*(q) - r_*(b))} - e^{2\kappa_h t_b - \kappa_h(r_*(q) - r_*(a))} - 2e^{-\kappa_h(r_*(q) - r_*(a))} \right].
\end{aligned} \tag{A.6}$$

All exponential terms in the considered approximations are negligible. We take into account only the largest exponential term related to the effect of the finite size of the entangling region. It is possible to find an analytic expression for the entropy (A.6) without an explicit form of the radial coordinate of the island boundary $a = r_h + X$ in the leading order in X/r_h due to the near-horizon zone condition. Taking into account the above, from (A.6) one can obtain

$$\mathcal{Y} \simeq \frac{c}{6} \left[\log \left(\frac{16r_h^3(b - r_h)^2}{b\varepsilon^4} \right) + \frac{b - r_h}{r_h} \right] + \frac{c}{6} \log \left(\frac{4f(q)}{\kappa_h^2 \varepsilon^2} \right) - \frac{c}{3} e^{2\kappa_h t_b - \kappa_h(r_*(q) - r_*(b))}. \tag{A.7}$$

Area term (4.19) in the leading order of X/r_h is

$$\frac{\text{Area}(\partial I)}{4G} \simeq \frac{2\pi r_h^2}{G}. \tag{A.8}$$

Mirror-symmetric region

The entanglement entropy of conformal matter for $R_{\text{MS}} \cup I_{\text{MS}}$ has the following form

$$S_{\text{matter}}(R_{\text{MS}} \cup I_{\text{MS}}) = \mathcal{X}(a, b, q, t_a, t_b), \tag{A.9}$$

¹⁷In (A.6), we use that $\cosh x \simeq \frac{1}{2}e^x$ at $x \gg 1$.

where $\mathcal{X}(a, b, q, t_a, t_b)$ is

$$\begin{aligned}
\mathcal{X}(a, b, q, t_a, t_b) &= \frac{c}{6} \log \left[\frac{64f(a)f(b)f(q)}{\kappa_h^6 \varepsilon^6} \cosh^2 \kappa_h t_a \cosh^4 \kappa_h t_b \right] \\
&+ \frac{c}{3} \log \left[\frac{(\cosh \kappa_h(r_*(b) - r_*(a)) - \cosh \kappa_h(t_a - t_b)) (\cosh \kappa_h(r_*(q) - r_*(a)) + \cosh \kappa_h(t_a + t_b))}{(\cosh \kappa_h(r_*(b) - r_*(a)) + \cosh \kappa_h(t_a + t_b)) (\cosh \kappa_h(r_*(q) - r_*(a)) - \cosh \kappa_h(t_a - t_b))} \right] \\
&+ \frac{c}{3} \log \left[\frac{\cosh \kappa_h(r_*(b) - r_*(q)) - 1}{\cosh \kappa_h(r_*(b) - r_*(q)) + \cosh 2\kappa_h t_b} \right].
\end{aligned} \tag{A.10}$$

Let us obtain an approximate analytical expression for the entropy (A.10) under conditions (4.42), when there is an island (4.43) in the near-horizon zone. Doing similar calculations as for the derivation of (A.7), in the leading order in X/r_h one can obtain for $\mathcal{X}(a, b, q, t_a, t_b)$

$$\mathcal{X} \simeq \frac{c}{6} \left[\log \left(\frac{16r_h^3(b - r_h)^2}{b\varepsilon^4} \right) + \frac{b - r_h}{r_h} \right] + \frac{c}{6} \log \left(\frac{4f(q) \cosh^2 \kappa_h t_b}{\kappa_h^2 \varepsilon^2} \right) - \frac{c}{3} e^{2\kappa_h t_b - \kappa_h(r_*(q) - r_*(b))}. \tag{A.11}$$

The area term in the leading order in X/r_h for region R_{MS} coincides with (A.8).
