# REFLECTIVE HYPERBOLIC 2-ELEMENTARY LATTICES, K3 SURFACES AND HYPERKAHLER MANIFOLDS

# VALERY ALEXEEV

ABSTRACT. We compute Coxeter diagrams of several "large" reflective 2-elementary even hyperbolic lattices and their maximal parabolic subdiagrams, and give some applications of these results to the theory of K3 surfaces and hyperkahler manifolds.

#### 1. Introduction

Even hyperbolic lattices L appear in the theory of K3 surfaces and hyperkahler manifolds in several ways:

- (1) As the Picard lattice  $S_X$  of a K3 surface X together with the intersection form, resp. as the Picard lattice  $S_X \subset H^2(X,\mathbb{Z})$  of a hyperkahler manifold X, with the Beauville-Bogomolov-Fujiki form. In this interpretation, the primitive isotropic vectors  $v \in S_X$ ,  $v^2 = 0$ , correspond to elliptic, resp. Lagrangian fibrations.
- (2) As the hyperbolic lattice  $\delta^{\perp}/\delta$  attached to a 0-cusp of the moduli space of lattice polarized K3 surfaces, resp. hyperkahler manifolds. In this interpretation, the isotropic vectors correspond to 1-cusps of the moduli space and to Type II degenerations. (Here,  $\delta$  is an isotropic vector in some lattice H of signature (2, n) for some n, defining a 0-cusp; then  $\delta^{\perp}/\delta$  has signature (1, n-1).)

Let L be such a lattice. Since we are mostly concerned with application to algebraic geometry, "hyperbolic" for us means signature (1, r-1). The isometry group O(L) contains two important normal subgroups  $W_2(L)$  and  $W_r(L)$  generated by reflections in the (-2)-vectors, resp. in all reflective vectors  $r \in L$  with  $r^2 < 0$ . They are described by the Coxeter diagrams  $\Gamma_2$ , resp.  $\Gamma_r$ . The lattice is called 2-reflective, resp. reflective if  $W_2(L)$ , resp.  $W_r(L)$  has finite index in O(L).

By the Torelli theorem, the automorphism group  $\operatorname{Aut}(X)$  of a K3 surface is commensurable to  $O(S_X)/W_2(S_X)$ , in particular  $\operatorname{Aut}(X)$  is finite iff  $S_X$  is 2-reflective. In some cases when  $S_X$  is not 2-reflective but is reflective, the Coxeter diagram  $\Gamma_r$  provides a nice description of the infinite group  $\operatorname{Aut}(X)$ , see Vinberg [Vin83] for a classical example. In the case of hyperkahler manifolds, similar results hold for the group  $\operatorname{Bir}(X)$  of birational automorphisms. In the second interpretation above, reflective lattices provide toroidal compactifications of the moduli spaces.

A simple but very powerful way to compute the Coxeter diagrams  $\Gamma_2$  and  $\Gamma_r$  is Vinberg's algorithm [Vin72, Vin75]. When the lattice is 2-reflective, resp. reflective, the algorithm completes in finitely many steps. Then the O(L)-orbits of primitive isotropic vectors correspond to the maximal parabolic subdiagrams.

In this paper we treat the case of 2-elementary lattices, i.e. the lattices with  $L^*/L \simeq \mathbb{Z}_2^a$ . By Nikulin [Nik79] an indefinite even 2-elementary lattice is uniquely determined by its signature and a triple of integers  $(r,a,\delta)$ , where r is its rank,  $a \equiv r \pmod 2$  is the  $\mathbb{Z}_2$ -rank, and  $\delta \in \{0,1\}$  is a certain invariant which we call coparity. In the case of K3 surfaces, these are the generic Picard lattices of K3 surfaces with a nonsymplectic involution.

In some sense 2-elementary lattices are one step up from unimodular lattices. For such lattices  $\Gamma_2$  is easily derived from  $\Gamma_r$ , even if one or both of these diagrams are infinite, cf. [Vin83, Prop. on p.2] or [AN06, Prop. 2.4]. In any case,  $\Gamma_r$  is usually dramatically smaller than  $\Gamma_2$ , so it is a good strategy to compute  $\Gamma_r$ .

To begin with, there are only finitely many reflective 2-elementary lattices. Indeed,  $a \leq r$ , and by Esselmann [Ess96] a reflective lattice satisfies  $r \leq 20$  or r = 22. For lattices with  $r + a \leq 18$  the Coxeter diagrams  $\Gamma_r$  were computed by Nikulin in [AN06, Table 1]. For r + a = 20 we computed them in [AE22]. The latter paper also contains a description of the isotropic vectors for  $r + a \leq 20$ .

For K3 surfaces over  $\mathbb C$  the Picard lattice satisfies  $r+a\leq 22$ . The initial motivation for this paper was to classify the reflective diagrams  $\Gamma_r$  with r+a=22 and to compute the maximal parabolic subdiagrams in them.

The diagrams for (11, 11, 1), (12, 10, 1), (13, 9, 1), (14, 8, 0) and (14, 8, 1) are relatively small and we give them in Figure 3. The others are too large to draw directly. However, it turns out that they are remarkably symmetric and can be described in a way similar to the papers [VK78, Vin83] of Vinberg and Kaplinskaja.

**Theorem 1.1.** The 2-elementary lattices (17,5,1), (18,4,1) and (19,3,1) are not reflective. The other even 2-elementary lattices on the line r + a = 22 are reflective.

**Definition 1.2.** Let G be a graph and  $n \geq 2$  be an integer. Define the edge n-fold graph  $G^{(n)}$  by subdividing each edge of G into n edges and inserting n-1 intermediate vertices. Thus,  $G^{(n)}$  has  $n|E_G|$  edges and  $|V_G| + (n-1)|E_G|$  vertices.

We note that the vertices of  $G^{(2)}$  are in a natural bijection with the set of vertices and edges of G.

**Definition 1.3.** We say that a diagram  $\Gamma$  is built on top of a simple graph H if it contains a subdiagram of the main roots isomorphic to H, and the additional roots are defined in terms of the main roots by some specified rules. For the 2-elementary lattices of this paper the main roots are the (-2)-roots  $\alpha$  in L of divisibility 1, i.e. satisfying  $\alpha \cdot L = \mathbb{Z}$ . For the lattices in Theorem 1.4 the following is also true: if a main root  $\alpha$  and an additional root  $\beta$  are connected then  $\alpha \cdot \beta = 2$ .

**Theorem 1.4.** For n = 3, 4, 5, 6 the Coxeter diagram  $\Gamma_r$  of the even 2-elementary lattice (10+n, 12-n, 1) is built on top of  $G^{(2)}$ , where  $G = K_n$  is the complete graph on n vertices. The diagram  $\Gamma_r$  for (18, 4, 0) is built on top of  $G^{(2)}$ , where  $G = K_{4,4}$  is the complete bipartite graph on 8 vertices, and that of (14, 8, 0) on top of  $G^{(2)}$  for  $G = D_4$ . In all cases one has  $\operatorname{Aut} \Gamma_r = \operatorname{Aut} G$  and  $O^+(S) = \operatorname{Aut} G \ltimes W_r$ .

In some cases, e.g. (11,11,1), (18,4,0), (20,2,1), the diagrams were previously known. We add the computations of the maximal parabolic diagrams, which are not easy to extract from the literature.

We also investigated the remaining finitely many possibly reflective 2-elementary lattices. Some of these lattices appear as the Picard lattices of hyperkahler manifolds of  $K3^{[2]}$ -type. Indeed if X is a K3 surface then  $S(\operatorname{Hilb}^n X) = \langle 2-2n \rangle \oplus S_X$ . In particular, if  $S_X$  is 2-elementary then  $S(\operatorname{Hilb}^2 X) = \langle -2 \rangle \oplus S_X$  is also 2-elementary. The lattice  $(15,9,1) = \langle -2 \rangle \oplus (14,8,1)$  below provides such an example with a very interesting automorphism group, possibly related to the Klein quartic.

There are similar identities for the hyperkahler manifolds of Kummer and OG6 types, but those lattices are quite small. (In the OG10 type the Picard lattices are of the form  $A_2 \oplus S_X$  and so are not 2-elementary since  $A_2^*/A_2 = \mathbb{Z}_3$ .)

And some of the bigger lattices appear on K3 surfaces and hyperkahler manifolds in positive characteristic, for example the lattice (22, 2, 0) investigated by Dolgachev and Kondō [DK03].

We prove the following (for the converse, see Remark 3.1):

**Theorem 1.5.** The even hyperbolic 2-elementary lattices of Fig. 1 are reflective.

It is interesting to compare the diagrams on the r + a = 22 line with those on the r + a = 20 line, computed in [AE22, Sec. 3]. The latter are smaller but less symmetric: they have the dihedral symmetry of n-gons. Most diagrams for  $r + a \le 18$  do not have any symmetries at all.

The diagrams on the line r + a = 20 turn out to be key to understanding degenerations of K3 surfaces with a nonsymplectic involution via a mirror symmetry

Figure 1. Reflective even hyperbolic 2-elementary lattices

construction. The lattices with  $r+a \geq 22$  do not appear as targets of the mirror symmetry correspondence of the ordinary K3 surfaces. But they may appear on the mirrors of higher-dimensional hyperkahler manifolds. What do the symmetries of the Coxeter diagrams imply about their degenerations?

The organization of the paper is as follows. In Section 2 we recall some standard definitions and fix the notations. In Section 3 we prove the above theorems and give detailed descriptions of the Coxeter diagrams and their maximal parabolic subdiagrams. In Section 4 we give some applications to the infinite automorphism groups of K3 surfaces.

**Acknowledgements.** I am grateful to Boris Alexeev for help at critical points in my computations. I thank Professors Kondō and Mukai for useful discussions. I was partially supported by the NSF grant DMS-2201222.

### 2. Definitions and notations

A lattice is a group  $S \simeq \mathbb{Z}^r$  together with a nondegenerate  $\mathbb{Z}$ -valued symmetric bilinear form. It is even if  $x^2$  is even for all  $x \in S$ . It is 2-elementary if  $A_S := S^*/S \simeq \mathbb{Z}_2^a$  for some  $a \geq 0$ , where  $S^* \subset S \otimes \mathbb{Q}$  is the dual group. Because we are coming from the algebraic geometry direction, for us a hyperbolic lattice of rank r has signature (1, r - 1). A reflection in a vector  $\alpha \in S$  is the linear transformation

$$w_{\alpha}(v) = v \to v - 2 \frac{v \cdot \alpha}{\alpha^2} \alpha.$$

A root is a vector  $\alpha \in S$  such that  $\alpha^2 < 0$  and  $w_{\alpha}(S) = S$ . In an even 2-elementary lattice the roots are the (-2) vectors and the (-4)-vectors of divisibility 2. The divisibility  $\operatorname{div}(\alpha)$  is defined by  $\alpha \cdot S = \operatorname{div}(\alpha)\mathbb{Z}$ .

The reflections in the (-2)-vectors generate the group  $W_2(S)$ , and the reflections in all roots, in our case the (-2)- and (-4)-roots, generate a bigger group  $W_r(S)$ . Both are normal subgroups of the isometry group O(S), and also of its index-2 subgroup  $O^+(S)$  preserving the light cone. The lattice is called 2-reflective, resp. reflective if these subgroups have finite index.

 $A_n, D_n, E_n$  denote the standard root lattices generated by (-2)-roots, and they are negative definite.  $U = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$  denotes the hyperbolic plane. For any lattice H, H(n) denotes the same group with the product  $x \cdot y$  in H(n) equal to  $nx \cdot y$  in H. For the 2-elementary lattices with short (-2) and long (-4)-roots additionally there are root lattices  $B_n(2)$ ,  $C_n$  and  $F_4$ . Considered as the (-2)-root lattices, they are  $A_1^n, D_n$ , and  $D_4$  respectively.

By [Nik79] an indefinite even 2-elementary lattice is uniquely determined by its signature and a triple of integers  $(r, a, \delta)$ , where r is its rank, a is the  $\mathbb{Z}_2$ -rank, and  $\delta \in \{0,1\}$  is an invariant which we call coparity, see [AE22, Def. 2.4, Lem. 2.5]. A 2-elementary lattice S is coeven ( $\delta = 0$ ) if the doubled dual  $S^{\dagger} := S^*(2)$  is even, and it is coodd ( $\delta = 1$ ) if  $S^{\dagger}$  is odd. A direct sum of 2-elementary lattices is coeven iff so is every summand.

Any even hyperbolic 2-elementary lattice is a direct sum of one of the elementary hyperbolic summands  $\langle 2 \rangle$ , U, U(2) with  $(r, a, \delta) = (1, 1, 1)$ , (2, 0, 0), (2, 2, 0) respectively, and a direct sum of the following elliptic root lattices for the full reflection group, which we list with their  $(r, a, \delta)$ .  $B_n(2) : (n, n, 1)$ ,  $C_{4n} : (4n, 2, 0)$  for  $4n \geq 8$ ,  $C_{4n+2} : (4n+2,2,1)$  for  $4n+2 \geq 6$ ,  $F_4 : (4,2,0)$ ,  $E_7 : (7,1,1)$ ,  $E_8 : (8,0,0)$ , and  $E_8(2) : (8,8,0)$ .

We refer to [Vin72] for Vinberg's theory. We use the notations of that paper for elliptic and parabolic Coxeter diagrams. The vertices of  $\Gamma_r$  denote the roots  $\alpha_i$  orthogonal to the facets of the fundamental polyhedron  $P_r$ . The types of edges specify the angle  $\theta$  between  $\alpha_i, \alpha_j$ . A single line means  $\theta = \pi/3$ , double line  $\theta = \pi/4$ , no line  $\theta = \pi/2$ , a bold line means that the hyperplanes defining the two facets meet at an infinite point of the hyperbolic space  $\mathcal{H}$ , and a broken line means that they are skew.

For a 2-elementary lattice, we denote the short, (-2)-roots by white vertices and the long, (-4)-roots by black vertices. Then the types of edges correspond to the following intersection numbers  $\alpha_i \cdot \alpha_i$  between the roots:

$\alpha_i^2$	$\alpha_j^2$	simple	double	bold	broken
-2	-2	1		2	> 2
-4	-4	2		4	>4
-2	-4		2		> 2

The parabolic  $\widetilde{A}_n$ ,  $\widetilde{D}_n$ ,  $\widetilde{E}_n$  diagrams could consist either of all short, or of all long roots. In the latter case we denote them  $\widetilde{A}_n(2)$ ,  $\widetilde{D}_n(2)$ ,  $\widetilde{E}_n(2)$ . If this parabolic subdiagram  $\Gamma \subset \Gamma_r$  corresponds to a vector  $v \in S$  with  $v^2 = 0$  then its image in  $v^{\perp}/v$  spans an elliptic root system. For all white vertices it is  $A_n, D_n, E_n$ , and for all black vertices it is  $A_n(2), D_n(2), E_n(2)$ .

Similarly, for  $\widetilde{B}_n$ ,  $\widetilde{C}_n$  and  $\widetilde{F}_4$  there are two versions, short and long, which are dominated by the short, resp. long roots. We list them in Figure 2, together with the elliptic root lattices  $v^{\perp}/v$ . Here, "dominated" means that they form the majority

of roots "for large n". For example for  $\widetilde{C}_n$  the short roots start to dominate only for  $n \geq 4$ . One should keep in mind that  $D_2 = A_1^2$  and  $D_3 = A_3$ .

FIGURE 2. Extended Dynkin diagrams dominated by short or long vectors

By [AE22, Prop. 5.5] the primitive isotropic vectors  $v \in S$ ,  $v^2 = 0$  are of three types. Denoting  $\overline{S} = v^{\perp}/v$  and with v a vector in the first summand, the types are:

- $\begin{array}{l} \text{(1) (odd) } S=U\oplus \overline{S},\, a_{\overline{S}}=a_S,\, \delta_{\overline{S}}=\delta_S.\\ \text{(2) (even ordinary) } S=U(2)\oplus \overline{S},\, a_{\overline{S}}=a_S-2,\, \delta_{\overline{S}}=\delta_S.\\ \text{(3) (even characteristic) } S=I_{1,1}(2)\oplus \overline{S},\, a_{\overline{S}}=a_S-2,\, \delta_S=1 \text{ and } \delta_{\overline{S}}=0. \end{array}$

Thus, classifying isotropic vectors in an even hyperbolic 2-elementary lattice with the invariants  $(r, a, \delta)$  is equivalent to classifying the even negative definite lattices  $\overline{S}$  with the invariants  $(r-2, a, \delta)$ ,  $(r-2, a-2, \delta)$  and (r-2, a-2, 0).

#### 3. Coxeter diagrams and maximal parabolic subdiagrams

*Proof of Thm.* 1.5. For some of these lattices the Coxeter diagrams are well known: for those on the a=0 line (they are unimodular) and for those on the r=a line (they are twice the unimodular). The two hardest cases were done by Vinberg and Kaplinskaja [VK78].

For others we performed the computation following Vinberg's algorithm. Each of these lattices can be written as  $U \oplus \Lambda$  or  $U(2) \oplus \Lambda$  for some root lattice  $\Lambda$ , where U is the hyperbolic plane. We chose the control vector to be a vector  $v_0$  in the first summand, with  $v_0^2 = 2$  for U, resp.  $v_0^2 = 4$  for U(2), and ran the algorithm using a custom Sage [Sag22] script written for this purpose.

We checked the completeness of the diagrams directly, by confirming that the cones in the Minkowski spaces  $\mathbb{R}^{1,r-1}$  defined by the roots of  $\Gamma_r$  lie entirely in  $\overline{\mathcal{C}}$ .

For the diagrams without broken edges the easy sufficient condition of [Vin75] also works to verify the completeness by hands: the diagrams do not contain Lannér subgraphs, and every connected parabolic subdiagram is contained in a maximal parabolic subdiagram of maximal rank. For the diagrams with broken edges, the criterion of [Vin72, Prop. 2] works.

Proof of Thm. 1.4. This follows by observation, analyzing the Coxeter diagrams produced by the above method. 

*Proof of Thm.* 1.1. For the nonreflective lattices the proof is as follows. One has  $(19,3,1) = \langle -2 \rangle \oplus (18,2,1)$  and  $(18,4,1) = \langle -2 \rangle \oplus (17,3,1)$ .

The fundamental polyhedron  $P_r(18,2,1)$  is a face of  $P_r(19,3,1)$  and  $\Gamma_r(18,2,1)$ is smaller than  $\Gamma_r(19,3,1)$ , see [AE22, Lem. 4.14]. Similarly for (18,4,1). The diagrams  $\Gamma_r(18,2,1)$ ,  $\Gamma_r(17,3,1)$  are infinite by [AE22, Thm. 3.6], and so are  $\Gamma_r(19,3,1)$  and  $\Gamma_r(18,4,1)$ .

Finally, one has  $(17,5,1) \simeq U(2) \oplus \Lambda$  for any even 2-elementary negative definite lattice  $\Lambda$  with  $(r,a,\delta)=(15,3,1)$ , where U is a hyperbolic plane. If the lattice (17,5,1) were reflective then  $\Lambda$  would correspond to a maximal parabolic subdiagram of  $\Gamma_r$  and the root sublattice  $R(\Lambda)$  would have rank equal to  $r(\Lambda)=15$ . But by [AE22, Table 2] there exists  $\Lambda$  with  $R(\Lambda)=A_{13}A_1(2)$  of rank 14.

**Remark 3.1.** From the experimental data, it appears that the list of reflective 2-elementary lattices given in Fig. 1 may be complete. For many, but not all of the missing nodes the non-reflectivity can be checked by using the duality  $L \to L^{\dagger}$  and the arguments as in the proof of Theorem 1.1.

Next, we list the Coxeter diagrams of Fig. 1 with  $r + a \ge 22$  and the maximal parabolic diagrams in them. The diagrams for the lattices (11, 11, 1), (12, 10, 1), (13, 9, 1), (14, 8, 0) and (14, 8, 1) are shown in Figure 3.

FIGURE 3. Coxeter diagrams  $\Gamma_r$  for ranks  $r \leq 14$ 

(11, 11, 1).  $\Gamma_r$  has 12 roots. There are two isotropic vectors v modulo  $O^+(S)$ . They correspond to the following subdiagrams of the Coxeter diagram, both even ordinary:  $\widetilde{E}_8(2)\widetilde{A}_1$  and  $\widetilde{B}_9(2)$ . The automorphism group of  $\Gamma_r$  is trivial.

- (12, 10, 1).  $\Gamma_r$  has 14 roots. Note that for the parabolic subdiagram  $\tilde{C}_3$  the corresponding root lattice  $v^{\perp}/v$  is  $C_3 = D_3 = A_3$ . There are 5 maximal parabolic subdiagrams listed below. The automorphism group of  $\Gamma_r$  is trivial.
  - (1) odd:  $\widetilde{E}_8(2)\widetilde{C}_2(2)$ ,  $\widetilde{C}_{10}(2)$ .
  - (2) even ordinary:  $\widetilde{E}_7(2)\widetilde{C}_3$ ,  $\widetilde{B}_6(2)\widetilde{F}_4(2)$ ,  $\widetilde{B}_8(2)\widetilde{C}_2$ .
- (13, 9, 1).  $\Gamma_r$  has 19 roots. There are 22 maximal parabolic subdiagrams, and 7 modulo Aut  $\Gamma_r = S_3$ :

  - (1) odd:  $\widetilde{C}_8(2)\widetilde{C}_3(2)$ ,  $\widetilde{E}_7(2)\widetilde{B}_3\widetilde{A}_1$ ,  $\widetilde{C}_7(2)\widetilde{F}_4$ . (2) even ordinary:  $\widetilde{F}_4^2(2)\widetilde{B}_3(2)$ ,  $\widetilde{C}_6\widetilde{B}_5(2)$ ,  $\widetilde{B}_6(2)\widetilde{C}_4\widetilde{A}_1$   $\widetilde{E}_6(2)\widetilde{A}_5$ .

It is clear that this diagram is built on top of the graph  $K_3^{(2)}$ . The main roots are the 6 roots on the outside hexagon, and the additional roots come in four layers culminating with the central vertex. The roots generate the lattice, so the  $S_3$ -action on  $\Gamma_r$  extends to the action on the lattice H itself.

- (14, 8, 0).  $\Gamma_r$  has 17 roots. There are 11 maximal parabolic subdiagrams, and 5 modulo Aut  $\Gamma_r = S_3$ :
  - (1) odd:  $\widetilde{E}_7(2)\widetilde{B}_5$ ,  $\widetilde{C}_8(2)\widetilde{F}_4$ .
  - (2) even ordinary:  $\widetilde{F}_4^3(2)$ ,  $\widetilde{C}_6\widetilde{B}_6(2)$ ,  $\widetilde{E}_6\widetilde{E}_6(2)$ .

It is clear that this diagram is built on top of the graph  $D_4^{(2)}$ , where  $D_4$  is a tree with four vertices, the central vertex of degree 3 and three ends.

- (14, 8, 1).  $\Gamma_r$  has 24 roots. There are 127 maximal parabolic subdiagrams, and 15 modulo Aut  $\Gamma_r = S_4$ :
  - (1) odd:  $\widetilde{F}_{4}^{2}\widetilde{C}_{4}(2)$ ,  $\widetilde{B}_{6}\widetilde{C}_{6}(2)$ ,  $\widetilde{C}_{6}(2)\widetilde{B}_{4}\widetilde{C}_{2}(2)$ ,  $\widetilde{E}_{6}(2)\widetilde{A}_{5}\widetilde{A}_{1}$ ,  $\widetilde{D}_{6}(2)\widetilde{B}_{3}^{2}$ ,  $\widetilde{C}_{4}^{3}(2)$ .
  - (2) even ord:  $\widetilde{C}_6\widetilde{F}_4(2)\widetilde{C}_2$ ,  $\widetilde{C}_4^2\widetilde{B}_4(2)$ ,  $\widetilde{D}_6\widetilde{B}_5(2)\widetilde{A}_1$ ,  $\widetilde{E}_7\widetilde{B}_5(2)$ ,  $\widetilde{C}_8\widetilde{B}_4(2)$ ,  $\widetilde{A}_7\widetilde{D}_5(2)$ .
  - (3) even char:  $\widetilde{F}_{4}^{3}(2)$ ,  $\widetilde{C}_{6}\widetilde{B}_{6}(2)$ ,  $\widetilde{E}_{6}\widetilde{E}_{6}(2)$ .

It is clear that this diagram is built on top of the graph  $K_4^{(2)}$ . Denote the main roots  $\alpha_i^m$  with i=1,2,3,4 for the 4 vertices and  $\alpha_{ij}^m$  with  $1 \leq i < j \leq 4$  for the 6 edges of  $K_4$ . For each edge there is an additional (-2)-root  $\alpha_{ij}$  attached to it, and a (-4)-root  $\alpha_{ij}^+$  attached to  $\alpha_{ij}$ . One has  $\alpha_{ij}^m \cdot \alpha_{ij} = \alpha_{ij} \cdot \alpha_{ij}^+ = 2$ ,  $\alpha_{ij}^m \cdot \alpha_{ij}^+ = 0$ . Let  $\bar{\alpha}_{ij} = \alpha_{ij} + \alpha_{ij}^+.$ 

Then the 12 roots  $\alpha_{ij}$ ,  $\bar{\alpha}_{ij}$  are mutually orthogonal, and are also orthogonal to the central (-4)-root  $\alpha_{cen}$ . The orthogonal complement of these 13 vectors in H is  $\mathbb{Z}h$  with  $h = \frac{1}{2}(\sum \alpha_i^m + \sum \alpha_{ij} + \sum \bar{\alpha}_{ij})$ . One has  $h^2 = 4$ . Set  $e = \frac{1}{2}(h + \alpha_{cen})$  and  $f = \frac{1}{2}(h - \alpha_{cen})$ . Then the 14 vectors  $\alpha_{ij}$ ,  $\bar{\alpha}_{ij}$ , e, f form the standard basis of a sublattice of H isomorphic to  $(I_{0,12} \oplus U)(2)$ . Thus, H can be identified with an  $S_4$ -invariant lattice lying between it and its dual  $(I_{0,12} \oplus U)(\frac{1}{2})$ .

Picking  $v_0 = h$  to be the control vector, Vinberg's algorithm ends in two steps.

(15, 7, 1).  $\Gamma_r$  contains 60 roots. As in Definition 1.3, it is build on top of the graph  $K_5^{(2)}$ . The subdiagram of the main roots is  $K_5^{(2)}$ , as shown on the left in Fig. 4. The 15 main roots form a basis of the lattice.

Recall Definition 1.2 of the graph  $G^{(2)}$ . The vertices of  $G^{(2)}$  are naturally in a bijection with the set of vertices + edges of G. Using this bijection, we identify the additional roots  $\alpha_C$  (see Definition 1.3) with certain collections C of vertices and edges of G. We use this notation for the other graphs below as well.

FIGURE 4. Additional roots for (15, 7, 1)

For  $G = K_5$  these collections C of vertices and edges are pictured in Fig. 4:

- (1) 10 (-4)-roots with C an edge, e.g.  $C = \{12\}$ .
- (2) 15 (-2)-roots with C a vertex and two edges, all disjoint from each other, e.g.  $C = \{1, 23, 45\}$ .
- (3) 20 (-2)-roots with  $C = \{1, 12, 34, 35, 45\}$  etc, with C consisting of three edges in a triangle, an edge disjoint from it, plus a vertex on the latter edge.

The edges between the main and additional roots are specified in Definition 1.3. We now list the typical edges between the additional roots  $\alpha_C$ ,  $\alpha_{C'}$ . The others follow by  $S_5$ -symmetry.

- (1)  $\alpha_{12}$  is connected by a single line to  $\alpha_{34}$ ; by a double line to  $\alpha_{3,14,25}$ ; and by a broken line to  $\alpha_{3,13,24,25,45}$ .
- (2)  $\alpha_{1,23,45}$  is connected by a double line to  $\alpha_{24}$ ; a bold line to  $\alpha_{1,24,35}$ ,  $\alpha_{2,13,45}$ ,  $\alpha_{1,12,34,35,45}$  and  $\alpha_{2,14,15,23,45}$ ; and a broken line to  $\alpha_{2,14,35}$ ,  $\alpha_{2,12,34,35,45}$  and  $\alpha_{2,13,14,25,34}$ .
- (3)  $\alpha_{1,12,34,35,45}$  a bold line to  $\alpha_{1,23,45}$  and  $\alpha_{3,12,45}$ ; and a broken line to  $\alpha_{23}$ ,  $\alpha_{2,13,45}$ ,  $\alpha_{3,14,25}$ ,  $\alpha_{1,13,24,25,45}$ ,  $\alpha_{2,12,34,35,45}$ ,  $\alpha_{3,12,15,25,34}$ ,  $\alpha_{3,14,15,23,45}$ ,  $\alpha_{2,14,15,23,45}$ , and  $\alpha_{3,13,24,25,45}$ .

The entire intersection matrix can be easily described as follows. The main roots  $\alpha_1^m$ ,  $\alpha_{12}^m$  etc. form a basis of the lattice S. Let  $\omega_1$  and  $\omega_{12}$  etc. denote the vectors such that  $\alpha_I^m \cdot \omega_J = 2\delta_{IJ}$ , i.e. forming twice the dual basis. Then  $\alpha_C = \sum_{I \in C} \omega_I$ , where I is one of the sets  $1, \ldots, 5, 12, \ldots, 45$ . Thus, it suffices to specify the typical intersection numbers between  $\omega_I$ . They are:

$$\omega_1^2 = -6, \ \omega_1 \cdot \omega_2 = 2, \ \omega_1 \cdot \omega_{12} = -2, \ \omega_1 \cdot \omega_{23} = 2, \ \omega_{12}^2 = -4, \ \omega_{12} \cdot \omega_{23} = 0, \ \omega_{12} \cdot \omega_{34} = 2.$$

The (-4)-vectors of  $\Gamma_r$  form the Petersen graph on 10 vertices, with simple edges. There are 1027 maximal parabolic subdiagrams, and 20 modulo Aut  $\Gamma_r = S_5$ :

- (1) odd:  $\widetilde{E}_7\widetilde{C}_6(2)$ ,  $\widetilde{B}_6\widetilde{F}_4\widetilde{C}_3(2)$ ,  $\widetilde{B}_6\widetilde{C}_6(2)\widetilde{A}_1$ ,  $\widetilde{D}_6\widetilde{C}_5(2)\widetilde{C}_2(2)$ ,  $\widetilde{B}_8\widetilde{C}_5(2)$ ,  $\widetilde{A}_5\widetilde{A}_5(2)\widetilde{B}_3$ ,  $\widetilde{F}_4^3\widetilde{A}_1$ ,  $\widetilde{C}_4(2)\widetilde{B}_4^2\widetilde{A}_1$ ,  $\widetilde{E}_6\widetilde{E}_6(2)\widetilde{A}_1$ ,  $\widetilde{A}_7\widetilde{D}_5(2)\widetilde{A}_1$ ,  $\widetilde{D}_4\widetilde{C}_3^3(2)$ .
- (2) even ordinary:  $\widetilde{E}_7\widetilde{B}_5(2)\widetilde{A}_1$ ,  $\widetilde{D}_8\widetilde{B}_4(2)\widetilde{A}_1$ ,  $\widetilde{E}_8\widetilde{B}_5(2)$ ,  $\widetilde{C}_8\widetilde{F}_4(2)\widetilde{A}_1$ ,  $\widetilde{E}_7\widetilde{F}_4(2)\widetilde{C}_2$ ,  $\widetilde{D}_6\widetilde{C}_4\widetilde{B}_3(2)$ ,  $\widetilde{A}_9\widetilde{A}_4(2)$ ,  $\widetilde{C}_6^2\widetilde{A}_1$ ,  $\widetilde{C}_{10}\widetilde{B}_3(2)$ .

(16, 6, 1).  $\Gamma_r$  contains 118 roots. The starting graph G is  $K_6$ , a complete graph on 6 vertices. As in Definition 1.3, the subdiagram of the main roots is  $K_6^{(2)}$ . It has 6 (-2)-roots corresponding to vertices of  $K_6$ —call them 1, 2, 3, 4, 5, 6—and 15 (-2)-roots corresponding to the edges of  $K_6$ —call them 12, 13 etc, for a total of 21 main roots. Let us denote the main roots  $\alpha_1^m$ ,  $\alpha_{12}^m$  etc.

FIGURE 5. Additional roots for (16, 6, 1)

The additional roots  $\alpha_C$  correspond to the following collections of vertices and edges of the starting graph G, pictured in Fig. 5, modulo  $S_6$ :

- (1) 15 (-4)-roots  $\alpha_{12,34,56}$  for C equal to a triple of disjoint edges.
- (2) 10 (-4)-roots  $\alpha_{12,23,31,45,56,64}$  for C equal to the 6 edges in two disjoint triangles.
- (3) 72 (-2)-roots  $\alpha_{12,23,34,45,51,6}$  for a cycle of 5 edges and a vertex.

The 15 main roots  $\alpha_{12}$  for the edges, together with  $\alpha^m = \alpha_1^m + \alpha_2^m + \cdots + \alpha_6^m$  span the lattice over  $\mathbb{Q}$ . Let  $\omega_{12}, \ldots, \omega_{56}, \omega$  be twice the dual basis. Then the additional roots are  $\alpha_C = \sum_{I \in C} \omega_I$ , where we formally set  $\omega_1 = \omega$  etc for the vertices. The multiplication table for this dual basis is very easy:  $\omega_{12}^2 = -\frac{16}{9}$  for the edges, and all the other products and squares are  $\frac{2}{9}$ . Thus,

$$\omega_C \cdot \omega_{C'} = \frac{2}{9}|C| \cdot |C'| - 2|C \cap C' \cap \text{Edges}(G)|.$$

Explicitly, the edges between the additional roots are:

- (1) Two roots of type (1) are joined by a bold line if they don't share an edge.
- (2) Two roots of type (2) are joined by a bold line.
- (3) Two roots of type (3) are joined by a bold line if they share 3 edges, and by a broken line otherwise.
- (4) Roots of types (1) and (2) are joined by a bold line if they don't share an edge, by a single line if they share one edge.
- (5) Roots of types (1) and (3) are joined by a broken line if they don't share edges, and by a double line if they share one edge.
- (6) Roots of types (2) and (3) are joined by a double line if they share three edges, and by a broken line if they share fewer edges.

The 15 additional roots  $\alpha_{12}$  etc. for the edges are mutually orthogonal (-2)-roots. Denote by  $v = \alpha_1^m + \cdots + \alpha_6^m$  the sum of the main roots for the vertices of  $K_6$  and by  $e = \alpha_{12}^m + \cdots + \alpha_{56}^m$  the sum of the main roots for the edges of  $K_6$ . Then  $h = \frac{1}{3}(v+e)$  is a vector in H satisfying  $h^2 = 2$  and orthogonal to the above 15 roots. Then  $h, \alpha_{12}, \ldots, \alpha_{56}$  form a sublattice of H isomorphic to  $I_{1,15}(2)$ . Thus, H can be identified with an  $S_6$ -symmetric lattice lying between it and its dual  $I_{1,15}(\frac{1}{2})$ .

With the control vector  $v_0 = h$ , Vinberg's algorithm terminates in four steps.

There are 8917 maximal parabolic subdiagrams, 28 modulo Aut  $\Gamma_r = S_6$ :

 $(1) \text{ odd: } \widetilde{B}_{6}\widetilde{C}_{4}(2)\widetilde{B}_{4}, \ \widetilde{B}_{10}\widetilde{C}_{4}(2), \ \widetilde{B}_{6}^{2}\widetilde{C}_{2}(2), \ \widetilde{E}_{8}\widetilde{C}_{6}(2), \ \widetilde{D}_{6}\widetilde{B}_{4}\widetilde{C}_{3}(2)\widetilde{A}_{1}, \ \widetilde{D}_{8}\widetilde{C}_{4}(2)\widetilde{C}_{2}(2), \\ \widetilde{E}_{6}\widetilde{A}_{5}(2)\widetilde{B}_{3}, \ \ \widetilde{B}_{8}\widetilde{F}_{4}\widetilde{C}_{2}(2), \ \ \widetilde{B}_{8}\widetilde{C}_{6}(2), \ \ \widetilde{B}_{6}\widetilde{F}_{4}^{2}, \ \ \widetilde{E}_{7}\widetilde{F}_{4}\widetilde{C}_{3}(2), \ \ \widetilde{E}_{7}\widetilde{C}_{5}(2)\widetilde{C}_{2}(2), \\ \widetilde{D}_{6}\widetilde{C}_{3}^{2}(2)\widetilde{C}_{2}(2), \ \widetilde{D}_{4}^{2}\widetilde{C}_{2}^{3}(2), \ \widetilde{A}_{5}^{2}\widetilde{A}_{2}^{2}(2), \ \widetilde{A}_{7}\widetilde{A}_{3}(2)\widetilde{B}_{3}\widetilde{A}_{1}(2), \ \widetilde{B}_{4}^{3}\widetilde{C}_{2}(2), \ \widetilde{A}_{9}\widetilde{A}_{4}(2)\widetilde{A}_{1}.$ 

(2) even ordinary:  $\widetilde{E}_8\widetilde{F}_4(2)\widetilde{C}_2$ ,  $\widetilde{D}_{10}\widetilde{B}_3(2)\widetilde{A}_1$ ,  $\widetilde{C}_{10}\widetilde{F}_4(2)$ ,  $\widetilde{E}_7\widetilde{C}_4\widetilde{B}_3(2)$ ,  $\widetilde{C}_{12}\widetilde{C}_2$ ,  $\widetilde{D}_8\widetilde{C}_4\widetilde{C}_2$ ,  $\widetilde{A}_{11}\widetilde{A}_2(2)\widetilde{A}_1(2)$ ,  $\widetilde{E}_7\widetilde{C}_6\widetilde{A}_1$ ,  $\widetilde{C}_8\widetilde{C}_6$ ,  $\widetilde{D}_6^2\widetilde{C}_2$ .

Prof. Shigeru Mukai has informed me that this Coxeter diagram can also be obtained as a face of the fundamental polyhedron for the lattice  $(A_3 \oplus A_1^6)^{\perp}$  in  $II_{1,25}$  which was computed by Kondō [Kon98] using the Borcherds method [Bor87].

(18, 4, 0). The diagram  $\Gamma_r$  was described by Keum and Kondō [KK01] using the method of [Bor87] and the Leech lattice. Our description is quite different. The Borcherds method does not always produce the Coxeter diagram of a reflexive lattice (e.g. it does not in the (16,6,1) case). So the equivalence between our diagram and Keum-Kondō's is not immediate. But it can be checked directly.

FIGURE 6. Additional roots for (18, 4, 0)

The Coxeter diagram  $\Gamma_r$  contains 48 roots. The starting graph is  $G = K_{4,4}$ , the complete bipartite graph on 8 vertices, shown in Figure 6. As in Definition 1.3, the subdiagram of the main roots is  $K_{4,4}^{(2)}$ . It has 8 (-2)-roots corresponding to the vertices of  $K_{4,4}$  and 16 (-2)-roots corresponding to the edges of  $K_{4,4}$ , for a total of 24 main roots.

The additional 24 (-4)-roots  $\alpha_C$  are in bijection with the sets of four disjoint edges in G, i.e. with the perfect matchings on the set of vertices of G. The intersection numbers are  $\alpha_C \cdot \alpha_{C'} = 4 - 2|C \cap C'|$ . Thus,  $\alpha_C$  and  $\alpha_{C'}$  are connected by a bold line if they don't share any edges, and by a single line if they share exactly one edge. Via a natural bijection between the perfect matchings in  $K_{4,4}$  and elements of the group  $S_4$ ,  $C \cap C'$  is the set of fixed points of  $C^{-1} \circ C' \in S_4$ .

The graph  $K_{4,4}$  is bipartite, its vertices are split into two groups of four. Denote by  $v^{(1)}$ , resp.  $v^{(2)}$ , the sum of the main roots in the first, resp. the second group. Denote by e the sum of the main roots for the 16 edges. Then  $a=\frac{1}{4}(2v^{(1)}+e)$  and  $b=\frac{1}{4}(2v^{(2)}+e)$  are two vectors in H satisfying  $a^2=b^2=0,\ a\cdot b=4$ . They are also orthogonal to the 16 main (-2)-roots  $\alpha^m_{ij}$  for the edges, which are mutually orthogonal as well. Together they form a standard basis of the sublattice  $(I_{0,16}\oplus U)(2)$  in H. Thus, H can be identified with an  $(\operatorname{Aut} K_{4,4})$ -invariant lattice lying between it and its dual  $(I_{0,16}\oplus U)(\frac{1}{2})$ .

With the control vector  $v_0 = a + b$ , Vinberg's algorithm terminates in two steps.

The automorphism group of the diagram is Aut  $\Gamma_r = \operatorname{Aut} K_{4,4} = S_2 \ltimes (S_4 \times S_4)$ . There are 5244 maximal parabolic subgraphs, 17 modulo Aut  $\Gamma_r$ :

- (1) odd:  $\widetilde{D}_8\widetilde{B}_4^2$ ,  $\widetilde{E}_8\widetilde{F}_4^2$ ,  $\widetilde{E}_7\widetilde{B}_6\widetilde{C}_3(2)$ ,  $\widetilde{A}_{11}\widetilde{B}_3\widetilde{A}_2(2)$ ,  $\widetilde{E}_6^2\widetilde{A}_2^2(2)$ ,  $\widetilde{B}_{12}\widetilde{F}_4$ ,  $\widetilde{D}_6^2\widetilde{C}_2^2(2)$ ,  $\widetilde{D}_{10}\widetilde{C}_3^2(2)$ ,  $\widetilde{B}_8^2$ ,  $\widetilde{A}_7^2\widetilde{A}_1^2(2)$ ,  $\widetilde{D}_4^4$ .
- (2) even ordinary:  $\widetilde{A}_{15}$   $\widetilde{\widetilde{A}}_{1}$  (2),  $\widetilde{\widetilde{E}}_{7}^{2}$   $\widetilde{C}_{2}$ ,  $\widetilde{D}_{12}$   $\widetilde{C}_{4}$ ,  $\widetilde{C}_{8}$   $\widetilde{E}_{8}$ ,  $\widetilde{C}_{16}$ ,  $\widetilde{D}_{8}^{2}$ .

(20, 2, 1). The Coxeter diagram was computed by Vinberg and Kaplinskaja in [VK78], see also Vin83. For easier comparison with the above diagrams we list the roots in Figure 7. There are 25 main roots for the vertices and edges of the Petersen's graph and 25 additional roots: 20 (-2)-roots of the first kind and 5 (-4)-roots of the second kind.

FIGURE 7. Additional roots for (20, 2, 1)

There are 581 maximal parabolic subdiagrams, 13 modulo Aut  $\Gamma_r = S_5$ , all odd:  $\widetilde{B}_{18},\ \widetilde{B}_{10}\widetilde{E}_{8},\ \widetilde{D}_{16}\widetilde{C}_{2}(2),\ \widetilde{D}_{10}^{*}\widetilde{E}_{7}\widetilde{A}_{1},\ \widetilde{E}_{8}^{2}\widetilde{C}_{2}(2),\ \widetilde{E}_{7}^{2}\widetilde{B}_{4},\ \widetilde{D}_{12}\widetilde{B}_{6},\ \widetilde{D}_{8}^{2}\widetilde{C}_{2}(2),\ \widetilde{A}_{9}^{2},\ \widetilde{A}_{15}\widetilde{B}_{3},$  $A_{11}E_6A_1(2)$ ,  $A_{17}A_1$ ,  $D_6^3$ . On the unique K3 surface with this Picard lattice they define 13 types of elliptic pencils with a section. The rules of Fig. 2 lead to a description of the Kodaira types of the singular fibers in these pencils.

(13,11,1).  $\Gamma_r$  has 16 roots. There are 9 maximal parabolic subdiagrams, 5 modulo Aut  $\Gamma_r = S_2$ :

- (1) odd:  $\widetilde{C}_{11}(2)$ ,  $\widetilde{E}_{8}(2)\widetilde{C}_{3}(2)$ ,
- (2) even ord:  $\widetilde{B}_8(2)\widetilde{B}_3(2)$ ,  $\widetilde{B}_7(2)\widetilde{F}_4(2)$ ,  $\widetilde{E}_7(2)\widetilde{C}_3\widetilde{A}_1$ .

(14, 10, 1).  $\Gamma_r$  has 21 roots, There are 69 maximal parabolic subdiagrams, 12 modulo Aut  $\Gamma_r = D_6$ :

- $\begin{array}{lll} \text{(1) odd: } \widetilde{C}_8(2)\widetilde{F}_4,\ \widetilde{E}_7(2)\widetilde{B}_3\widetilde{C}_2(2),\ \widetilde{C}_8(2)\widetilde{C}_4(2),\ \widetilde{D}_8(2)\widetilde{C}_4(2),\\ \text{(2) even ord: } \widetilde{B}_4(2)\widetilde{B}_4(2)\widetilde{B}_4(2),\ \widetilde{C}_6\widetilde{B}_6(2),\ \widetilde{B}_6(2)\widetilde{C}_4\widetilde{C}_2,\ \widetilde{B}_4(2)\widetilde{F}_4(2)\widetilde{F}_4(2),\\ \end{array}$  $\widetilde{D}_6(2)\widetilde{C}_3\widetilde{C}_3, \ \widetilde{E}_6(2)\widetilde{A}_5\widetilde{A}_1,$ (3) even char:  $\widetilde{E}_7(2)\widetilde{C}_5, \ \widetilde{B}_8(2)\widetilde{F}_4(2).$

(15, 9, 1).  $\Gamma_r$  has 98 roots which modulo Aut  $\Gamma_r = PGL(2,7)$  of order 336 split into four orbits of sizes 14, 14, 14, 56. The first group of 14 forms the subdiagram G of the main roots. Here, G is a 4-regular bipartite graph on 14 vertices. It has a natural embedding into the complete bipartite graph  $K_{7,7}$ . G is the co-Heawood graph; its edges in  $K_{7,7}$  are complementary to the edges of the well known Heawood graph, a 3-regular graph on 14 vertices. One way to describe G is to say that its vertices correspond to the points and lines in the Fano plane  $\mathbb{P}^2$  over  $\mathbb{F}_2$ , and that a line and a point are joined by an edge iff they are not incident.

The remaining roots are additional. They are connected to the main roots by 1, 4 and 6 edges. The first of these groups is formed by the (-4)-roots. This subdiagram is isomorphic to the Heawood graph. Each of these roots is connected to exactly one main root and  $\alpha_i^m \alpha_i = 4$ . The remaining two orbits are formed by the (-2)-roots of divisibility 2. By [AE22, Lem. 4.14] removing one of these roots

and its (-2)-neighbors gives the Coxeter diagrams for the lattices (14, 8, 0) and (14, 8, 1).

There are 2114 maximal parabolic subdiagrams, and 20 modulo Aut  $\Gamma_r = \text{Aut } G$ :

- $\begin{array}{ll} \text{(1)} & \text{odd:} & \widetilde{D}_6(2)\widetilde{B}_3^2\widetilde{A}_1, \ \widetilde{A}_7(2)\widetilde{A}_3\widetilde{C}_3(2), \ \widetilde{E}_6(2)\widetilde{A}_5\widetilde{C}_2(2), \ \widetilde{C}_6(2)\widetilde{B}_4\widetilde{C}_3(2), \ \widetilde{C}_4^3(2)\widetilde{A}_1, \\ & \widetilde{E}_7(2)\widetilde{B}_5\widetilde{A}_1, \ \widetilde{C}_8(2)\widetilde{F}_4\widetilde{A}_1, \ \widetilde{C}_7(2)\widetilde{B}_6, \ \widetilde{C}_5(2)\widetilde{F}_4^2. \end{array}$
- (2) even ord:  $\widetilde{A}_7\widetilde{D}_5(2)\widetilde{A}_1$ ,  $\widetilde{E}_6\widetilde{E}_6(2)\widetilde{A}_1$ ,  $\widetilde{C}_4^2\widetilde{B}_4(2)\widetilde{A}_1$ ,  $\widetilde{D}_4\widetilde{B}_3^3(2)$ ,  $\widetilde{F}_4^3(2)\widetilde{A}_1$ ,  $\widetilde{C}_8\widetilde{B}_5(2)$ ,  $\widetilde{A}_5\widetilde{A}_5(2)\widetilde{C}_3$ ,  $\widetilde{E}_7\widetilde{B}_6(2)$ ,  $\widetilde{C}_6\widetilde{F}_4(2)\widetilde{B}_3(2)$ ,  $\widetilde{D}_6\widetilde{B}_5(2)\widetilde{C}_2$ ,  $\widetilde{C}_6\widetilde{B}_6(2)\widetilde{A}_1$ .

Note that  $(15,9,1) \simeq \langle -2 \rangle \oplus (14,8,1) \simeq \langle -2 \rangle \oplus (14,8,0)$ . Among these two,  $(14,8,1) = S_X$  for some K3 surface with a nonsymplectic involution, and (15,9,1) is the Picard lattice of the hyperkahler manifold  $\operatorname{Hilb}^2(X)$ . The symmetry group of the Coxeter diagram  $\Gamma_r(14,8,1)$  is only  $S_4$ , so in this case  $\operatorname{Hilb}^2(X)$  is much more symmetric than the K3 surface X.

- (18, 6, 0). The Coxeter diagram  $\Gamma_r$  was described by Borcherds [Bor00] and it consists of 64+896 roots. I computed the maximal parabolic subdiagrams of  $\Gamma_r$ . There are 90897634 of them, 28 modulo the group Aut  $\Gamma_r$  of order  $2^{16} \cdot 3^2 \cdot 5 \cdot 7$ :
  - $\begin{array}{llll} (1) & \mathrm{odd:} & \widetilde{B}_{8}\widetilde{F}_{4}^{2}, & \widetilde{E}_{7}\widetilde{C}_{5}(2)\widetilde{F}_{4}, & \widetilde{C}_{8}(2)\widetilde{E}_{8}, & \widetilde{D}_{8}\widetilde{C}_{4}(2)^{2}, & \widetilde{B}_{6}^{2}\widetilde{C}_{4}(2), & \widetilde{E}_{6}\widetilde{A}_{5}(2)\widetilde{B}_{5}, & \widetilde{B}_{4}^{4}, \\ & \widetilde{B}_{10}\widetilde{C}_{6}(2), & \widetilde{D}_{6}\widetilde{B}_{4}\widetilde{C}_{3}(2)^{2}, & \widetilde{D}_{9}\widetilde{A}_{7}(2), & \widetilde{A}_{9}\widetilde{A}_{4}(2)\widetilde{C}_{3}(2), & \widetilde{A}_{5}^{2}\widetilde{C}_{2}(2)\widetilde{A}_{2}(2)^{2}, & \widetilde{D}_{5}^{2}\widetilde{A}_{3}(2)^{2}, \\ & \widetilde{A}_{7}\widetilde{A}_{3}(2)\widetilde{B}_{3}^{2}, & \widetilde{D}_{4}^{2}\widetilde{C}_{2}(2)^{4}, & \widetilde{A}_{3}^{4}\widetilde{A}_{1}(2)^{4}, & \widetilde{A}_{1}^{16}. \end{array}$
  - (2) even ord:  $\widetilde{E}_{7}\widetilde{C}_{6}\widetilde{B}_{3}(2)$ ,  $\widetilde{D}_{10}\widetilde{B}_{3}(2)^{2}$ ,  $\widetilde{C}_{12}\widetilde{F}_{4}(2)$ ,  $\widetilde{E}_{8}\widetilde{F}_{4}(2)^{2}$ ,  $\widetilde{D}_{8}\widetilde{C}_{4}^{2}$ ,  $\widetilde{D}_{6}^{2}\widetilde{C}_{2}^{2}$ ,  $\widetilde{C}_{8}^{2}$ ,  $\widetilde{A}_{11}\widetilde{C}_{3}\widetilde{A}_{2}(2)$ ,  $\widetilde{E}_{6}^{2}\widetilde{A}_{2}(2)^{2}$ ,  $\widetilde{A}_{7}^{2}\widetilde{A}_{1}(2)^{2}$ ,  $\widetilde{D}_{4}^{4}$ .
- (22, 2, 0). The Coxeter diagram  $\Gamma_r$  was described by Borcherds [Bor87] and by Dolgachev-Kondō [DK03]. It consists of 42 main (-2)-roots corresponding to the 21 points and 21 lines of  $\mathbb{P}^2(\mathbb{F}_4)$ , and 168 additional (-4)-roots. Aut  $\Gamma_r = \text{PSL}(3, \mathbb{F}_4).D_6$  has order 241920. By Esselmann [Ess96] this lattice has the maximal possible rank for a reflective hyperbolic lattice.

I computed the maximal parabolic subdiagrams of  $\Gamma_r$ . There are 1095990 of them, 18 modulo Aut  $\Gamma_r$ , all odd:  $\widetilde{E}_7^2\widetilde{B}_6$ ,  $\widetilde{E}_8^2\widetilde{F}_4$ ,  $\widetilde{A}_7^2\widetilde{D}_5\widetilde{A}_1(2)$ ,  $\widetilde{D}_{12}\widetilde{B}_8$ ,  $\widetilde{B}_{20}$ ,  $\widetilde{B}_{12}\widetilde{E}_8$ ,  $\widetilde{D}_6^3\widetilde{C}_2(2)$ ,  $\widetilde{D}_{16}\widetilde{F}_4$ ,  $\widetilde{D}_{10}\widetilde{E}_7\widetilde{C}_3(2)$ ,  $\widetilde{D}_8^2\widetilde{B}_4$ ,  $\widetilde{A}_{15}\widetilde{B}_5$ ,  $\widetilde{A}_9^2\widetilde{C}_2(2)$ ,  $\widetilde{A}_{11}\widetilde{E}_6\widetilde{B}_3$ ,  $\widetilde{A}_{11}\widetilde{D}_7\widetilde{A}_2(2)$ ,  $\widetilde{A}_{17}\widetilde{C}_3(2)$ ,  $\widetilde{E}_6^3\widetilde{A}_2(2)$ ,  $\widetilde{A}_5^4$ ,  $\widetilde{D}_5^4$ .

- (14, 12, 1).  $\Gamma_r$  has 17 roots. There are 16 maximal parabolic subdiagrams, 9 modulo Aut  $\Gamma_r = S_2$ :
  - (1) odd:  $\widetilde{E}_8(2)\widetilde{C}_4(2)$ ,  $\widetilde{C}_{12}(2)$ ,  $\widetilde{D}_{12}(2)$ ,
  - (2) even ord:  $\widetilde{D}_8(2)\widetilde{B}_4(2)$ ,  $\widetilde{B}_8(2)\widetilde{B}_4(2)$ ,  $\widetilde{B}_8(2)\widetilde{F}_4(2)$ ,  $\widetilde{E}_7(2)\widetilde{C}_3\widetilde{C}_2$ ,
  - (3) even char:  $E_8(2)F_4(2)$ ,  $B_{12}(2)$ .
- (15, 11, 1). There are 66 roots which modulo  $\operatorname{Aut}\Gamma_r = S_2 \ltimes (S_3 \times S_3)$  split into five orbits. The subdiagram of the main roots is the graph  $L(K_{3,3})$ , the line graph of  $K_{3,3}$ , a 4-regular on 9 vertices. The other roots are additional.

The (-4)-roots are split into two groups of sizes 6, and 9, connected to the main roots by 0, resp. 2 edges. Together, they form the graph  $K_{3,3}^{(2)}$ . There are also two orbits of sizes 6 and 36 connected to the main roots by 3, resp. 5 edges, latter with multiplicities 2, 2, 2, 4, 4. These are (-2)-roots of divisibility 2. By [AE22, Lem. 4.14] removing one of these roots and its (-2)-neighbors gives the Coxeter diagrams for the lattices (14, 10, 0) and (14, 10, 1).

There are 522 maximal parabolic subdiagrams, 16 modulo Aut  $\Gamma_r$  = Aut G:

- $(1) \text{ odd: } \widetilde{A}_{11}(2)\widetilde{A}_2, \widetilde{E}_7(2)\widetilde{C}_3(2)\widetilde{B}_3, \widetilde{C}_{12}(2)\widetilde{A}_1, \widetilde{E}_8(2)\widetilde{F}_4\widetilde{A}_1, \widetilde{C}_8(2)\widetilde{C}_5(2), \widetilde{C}_9(2)\widetilde{F}_4,$  $\widetilde{D}_8(2)\widetilde{C}_4(2)\widetilde{A}_1$ .
- (2) even ord:  $\widetilde{E}_{6}(2)\widetilde{A}_{5}\widetilde{C}_{2}$ ,  $\widetilde{B}_{6}(2)\widetilde{C}_{4}\widetilde{B}_{3}(2)$ ,  $\widetilde{A}_{7}(2)\widetilde{B}_{3}(2)\widetilde{A}_{3}$ ,  $\widetilde{B}_{7}(2)\widetilde{C}_{6}$ ,  $\widetilde{B}_{4}^{3}(2)\widetilde{A}_{1}$ ,  $\widetilde{D}_6(2)\widetilde{C}_3^2\widetilde{A}_1$ ,  $\widetilde{B}_8(2)\widetilde{F}_4(2)\widetilde{A}_1$ ,  $\widetilde{E}_7(2)\widetilde{C}_5\widetilde{A}_1$ ,  $\widetilde{B}_5(2)\widetilde{F}_4^2(2)$ .

(15, 13, 1).  $\Gamma_r$  has 27 roots. There are 46 maximal parabolic subdiagrams, 10 modulo Aut  $\Gamma_r = S_3$ :

- $\begin{array}{lll} \text{(1) odd: } \widetilde{E}_{8}(2)\widetilde{C}_{5}(2), \ \widetilde{D}_{12}(2)\widetilde{A}_{1}, \ \widetilde{C}_{13}(2), \\ \text{(2) even ord: } \widetilde{E}_{7}(2)\widetilde{C}_{3}\widetilde{B}_{3}(2), \ \widetilde{B}_{8}(2)\widetilde{B}_{5}(2), \ \widetilde{A}_{11}(2)\widetilde{A}_{2}, \ \widetilde{B}_{12}(2)\widetilde{A}_{1}, \ \widetilde{B}_{9}(2)\widetilde{F}_{4}(2), \end{array}$  $\widetilde{D}_8(2)\widetilde{B}_4(2)\widetilde{A}_1$ ,  $\widetilde{E}_8(2)\widetilde{F}_4(2)\widetilde{A}_1$ .
- (16, 12, 1). There are 118 roots which modulo Aut  $\Gamma_r = S_6$  split into five orbits of sizes 15, 15, 6, 10, 72 of vectors with square -2, -4, -4, -2, -4. There are 15 main roots forming  $L(K_6)$ , the line graph of the complete graph  $K_6$ . If L=(16,6,1) then (16, 12, 1) is the even sublattice of  $L^*(2)$ . This implies that the maximal parabolic diagrams of the (16, 12, 1) lattice are in a bijection with those of the (16, 6, 1) lattice, with the (-2) and (-4)-roots interchanged, and odd and even ordinary diagrams interchanged.
- (16, 14, 1). There are 29 roots. This diagram is dual to that of (16, 4, 1), with the (-2) and (-4) roots switched. There are 115 maximal parabolic subdiagrams, 14 modulo Aut  $\Gamma_r = D_6$ :
  - (1) odd:  $\widetilde{E}_8(2)\widetilde{C}_6(2)$ ,  $\widetilde{C}_{14}(2)$ ,  $\widetilde{D}_{12}(2)\widetilde{C}_2(2)$ ,  $\widetilde{E}_7(2)\widetilde{E}_7(2)$ ,
  - (2) even ord:  $\widetilde{E}_8(2)\widetilde{F}_4(2)\widetilde{C}_2$ ,  $\widetilde{D}_8(2)\widetilde{B}_4(2)\widetilde{C}_2$ ,  $\widetilde{B}_{12}(2)\widetilde{C}_2$ ,  $\widetilde{D}_{10}(2)\widetilde{C}_3\widetilde{A}_1(2)$ ,  $\widetilde{E}_{7}(2)\widetilde{B}_{4}(2)\widetilde{C}_{3},\ \widetilde{E}_{7}(2)\widetilde{B}_{6}(2)\widetilde{A}_{1}(2),\ \widetilde{B}_{8}(2)\widetilde{B}_{6}(2),\ \widetilde{B}_{10}(2)\widetilde{F}_{4}(2),\ \widetilde{A}_{11}(2)\widetilde{A}_{2}\widetilde{A}_{1},$  $\widetilde{D}_6(2)\widetilde{D}_6(2)\widetilde{C}_2$ .

Other coeven lattices. If S = (r, a, 0) is an even coeven lattice then so is  $S^{\dagger} =$  $S^*(2) = (r, r - a, 0)$ . Their Coxeter diagrams are dual, with (-2) and (-4)-roots interchanged, and there is a bijection between the maximal parabolic subdiagrams. The remaining lattices in Fig. 1 are obtained from the ones already listed here or in [AE22]. This applies to the following lattices:

$$(14, 10, 0), (14, 12, 0), (18, 12, 0), (18, 14, 0), (18, 16, 0), (22, 20, 0).$$

### 4. Applications to infinite automorphism groups of K3 surfaces

The main application of the Coxeter diagrams in [Vin83] was the description, for the very first time, of two infinite automorphism groups of K3 surfaces. In the same way our computations imply such a description in several more cases.

A K3 surface X whose Picard lattice  $S_X$  is 2-elementary comes with a canonical nonsymplectic involution  $\iota$  on X, acting as +1 on S and as -1 on the lattice of transcendental cycles  $T = S^{\perp}$  in  $L_{K3}$ . Any automorphism of X commutes with  $\iota$ . Let  $Y = X/\iota$  be the quotient surface. It is a rational surface unless S = (10, 0, 0)in which case Y is an Enriques surface. Let B be the branch divisor of  $\pi: X \to Y$ and denote by  $\operatorname{Aut}'(Y, B)$  the subgroup of  $\operatorname{Aut}(Y, B)$  acting trivially on Pic Y.

**Lemma 4.1.** Let S be a 2-elementary K3 lattice  $S \neq (10, 10, 0)$ ,  $\Gamma_r$  the Coxeter diagram of S, and let X be a K3 surface with Picard lattice  $S_X = S$ . Then there exists an exact sequence

$$0 \to \langle \iota \rangle \times \operatorname{Aut}'(Y, B) \to \operatorname{Aut} X \to \operatorname{Sym} \Gamma_r \ltimes W(\Gamma_4) \to 0$$

Lattice	$\operatorname{Aut}\Gamma_r$	$\Gamma_4$
(11, 11, 1)	1	$T_{2,3,7}$
(12, 10, 1)	1	$T_{2,4,6} \sqcup A_1$
(13, 9, 1)	$S_3$	$T_{4,4,4}$
(14, 8, 1)	$S_4$	a 10-vertex trivalent tree with 6 ends
(15, 7, 1)	$S_5$	the Petersen graph
(16, 6, 1)	$S_6$	a diagram with $10 + 15$ vertices
(18, 4, 0)	$S_2 \ltimes (S_4 \times S_4)$	a diagram with 24 vertices
(20, 2, 1)	$S_5$	$K_5$ with bold edges

Table 1. Coxeter diagrams  $\Gamma_4$  defining Aut X

where  $\Gamma_4 \subset \Gamma_r$  is the subdiagram formed by the (-4)-roots, and  $W(\Gamma_4)$  is the corresponding Coxeter group.

*Proof.* A well-known application of Torelli theorem [PSS71] says that for a projective K3 surface with an ample cone A(X) the natural homomorphism

$$\rho : \operatorname{Aut} X \to \operatorname{Aut} A(X) = O^{+}(S)/W_{2}(S) = O(S)/\pm W_{2}(S),$$

has finite kernel and cokernel. The kernel of  $\rho$  consists of automorphisms that act trivially on  $S_X$ . They descend to automorphisms of the pair (Y, B), and  $\iota$  is the only one descending to the identity. Vice versa, an automorphism of (Y, B) lifts to an automorphism of X since  $X = \operatorname{Spec} \mathcal{O} \oplus L^{-1}$  with  $L^2 \simeq \mathcal{O}(B)$  and  $\operatorname{Pic} Y$  has no 2torsion. (Pic Y)  $\otimes \mathbb{Q}$  is identified with (Pic X) $^{\iota} \otimes \mathbb{Q} = S \otimes \mathbb{Q}$ . So, the automorphisms of X acting trivially on S descend to  $\operatorname{Aut}'(Y, D)$ . Thus,  $\ker \rho = \mathbb{Z}_2 \times \operatorname{Aut}(Y, B)$ .

The homomorphism  $\rho$  is surjective. Indeed, an isometry of  $L_{\rm K3}$  is equivalent to a pair of isometries of S and T which have the same image in the finite isometry group of the discriminant group under  $O(S) \to O(A_S, q_S) = O(A_T, q_T) \leftarrow O(T)$ . By [Nik79] for an indefinite 2-elementary lattice H, such as S and T, the homomorphism  $O(H) \to O(A_H, q_H)$  is surjective. So any element of O(S) can be lifted to  $a \in O(L_{K3})$ . Then a composition  $w \circ a$  with some  $w \in W_2(S)$  sends the fundamental domain A(X) to itself and therefore is induced by some  $g \in \operatorname{Aut} X$ .

By [Vin83, Prop., p.2] or [AN06, Prop. 2.4] the quotient group  $W(\Gamma_r)/W_2(S)$  is isomorphic to  $W(\Gamma_4)$ . Together with the equality  $O^+(S) = \operatorname{Sym} \Gamma_r \ltimes W(\Gamma_r)$  this gives  $O^+(S)/W_2(S) = \operatorname{Sym} \Gamma_r \ltimes W(\Gamma_4)$ .

By [AE22, Sec. 3], for the 2-elementary K3 lattices on the r + a = 20 line the groups Sym  $\Gamma_r \ltimes W(\Gamma_4)$  are extensions of affine groups  $W(\tilde{E}_n)$  by dihedral groups. The diagrams of this paper provide even more interesting examples. The (-4)subdiagrams for the K3 lattices with r + a = 22 were given in the previous section. We list them in Table 1.  $T_{p,q,r}$  denotes a tree with legs of lengths p, q, r.

The diagrams  $\Gamma_4$  for (16,6,1) and (18,4,0) are quite complicated, and have both simple and bold edges. It is a little easier to describe the subdiagram  $\Gamma'_4$  of  $\Gamma_4$  with the bold edges removed. The Coxeter group  $W(\Gamma'_4)$  is the quotient of  $W(\Gamma_4)$  by the additional commuting relations for the bold edges.

For (16,6,1) the graph  $\Gamma'_4$  is a union of 10 disjoint vertices and  $L(K_6)$ . For (18,4,0) the graph  $\Gamma'_4$  is a union of two disjoint subgraphs  $G_1 \sqcup G_2$ , and each  $G_i$  can be defined as the complement of  $K_4 \sqcup K_4 \sqcup K_4$  in the complete graph  $K_{12}$ : an edge of  $K_{12}$  is in  $G_i$  iff it is not in  $K_4 \sqcup K_4 \sqcup K_4$ . The two 12-element sets can be identified with the cosets of  $A_4$  in  $S_4$  and the three 4-element sets with the cosets of the Klein four-group  $V_4$  in  $A_4$ .
