# Multivariate to Bivariate Reduction for Noncommutative Polynomial Factorization 

V. Arvind* Pushkar S Joglekar ${ }^{\dagger}$

#### Abstract

Based on a theorem of Bergman [5] we show that multivariate noncommutative polynomial factorization is deterministic polynomial-time reducible to the factorization of bivariate noncommutative polynomials. More precisely, we show the following: 1. In the white-box setting, given an $n$-variate noncommutative polynomial $f \in \mathbb{F}\langle X\rangle$ over a field $\mathbb{F}$ (either a finite field or the rationals) as an arithmetic circuit (or algebraic branching program), computing a complete factorization of $f$ is deterministic polynomial-time reducible to white-box factorization of a noncommutative bivariate polynomial $g \in \mathbb{F}\langle x, y\rangle$; the reduction transforms $f$ into a circuit for $g$ (resp. ABP for $g$ ), and given a complete factorization of $g$ the reduction recovers a complete factorization of $f$ in polynomial time. We also obtain a similar deterministic polynomial-time reduction in the black-box setting. 2. Additionally, we show over the field of rationals that bivariate linear matrix factorization of $4 \times 4$ matrices is at least as hard as factoring square-free integers. This indicates that reducing noncommutative polynomial factorization to linear matrix factorization (as done in [1]) is unlikely to succeed over the field of rationals even in the bivariate case. In contrast, multivariate linear matrix factorization for $3 \times 3$ matrices over rationals is in polynomial time.

## 1 Introduction

The main aim of this paper is to show that multivariate polynomial factorization in the free noncommutative ring $\mathbb{F}\left\langle x_{1}, x_{2}, \ldots, x_{n}\right\rangle$ is polynomial-time reducible to bivariate noncommutative polynomial factorization in the bivariate ring $\mathbb{F}\langle x, y\rangle$. Such a result for commutative polynomial factorization is well-known due to Kaltofen's seminal work on multivariate polynomial factorization in the commutative polynomial ring $\mathbb{F}\left[y_{1}, y_{2}, \ldots, y_{n}\right]$ [9, 10]. However, this problem was open in the setting of noncommutative polynomials. Recently, [1] a randomized polynomial-time algorithm was obtained for the factorization of noncommutative polynomials over finite fields, where the input polynomial is given by a noncommutative formula ${ }^{1}$ Broadly speaking, the algorithm of [1] works via Higman linearization ([8] [6] [7]) and reduces the problem to linear matrix factorization which turns out to have a randomized polynomial-time algorithm over finite fields.

[^0]Problem 1.1 (Linear Matrix Factorization Problem). The linear matrix factorization problem over a field $\mathbb{F}$ takes as input a linear matrix: $L=A_{0}+\sum_{i=1}^{n} A_{i} x_{i}$, where the $A_{i}$ are $d \times d$ scalar matrices (over $\mathbb{F}$ ), the $x_{i}, 1 \leq i \leq n$ are noncommuting variables, and $A_{0}$ is assumed invertible for technical reasons. The problem is to compute a factorization of $L$ as a product of irreducible linear matrices.

The study of matrix factorization (linear matrix factorization, in particular) is an important part of Cohn's factorization theory over general free ideal rings. [6] [5].

Coming back to the polynomial factorization algorithm described in [1], the algorithm reduces polynomial factorization to linear matrix factorization which is, in turn, reducible to the problem of computing a common invariant subspace for a collection of $n$ matrices. The common invariant subspace problem can be efficiently solved in the case of finite fields using Ronyai's algorithm [12] which is based on the Artin-Wedderburn theorem for decomposition of algebras. This approach, however, runs into serious difficulties when $\mathbb{F}$ is the field of rationals. The main difficulty is that given a simple matrix algebra $2 \mathcal{A}$ over rationals, we do not know an efficient algorithm for finding out if $\mathcal{A}$ is a division algebra or whether it has zero divisors. This is one of our motivations for obtaining a reduction from multivariate polynomial factorization to bivariate factorization. Because Higman Linearization of a bivariate noncommutative polynomial given by a formula will yield a bivariate linear matrix. One could hope that factorization of a bivariate linear matrix is computationally easier than factorization of an $n$-variate linear matrix. Unfortunately, this is not the case. As we will see, even for 4-dimensional bivariate linear matrices the problem of factorization is at least as hard as factoring square-free integers.

Multivariate to Bivariate We start with some formal preliminaries. Let $\mathbb{F}$ be any field and $X=\left\{x_{1}, x_{2}, \ldots, x_{n}\right\}$ be a set of $n$ free noncommuting variables. Let $X^{*}$ denote the set of all free words (which are monomials) over the alphabet $X$ with concatenation of words as the monoid operation and the empty word $\epsilon$ as identity element.

The free noncommutative ring $\mathbb{F}\langle X\rangle$ consists of all finite $\mathbb{F}$-linear combinations of monomials in $X^{*}$, where the ring addition + is coefficient-wise addition and the ring multiplication $*$ is the usual convolution product. More precisely, let $f, g \in \mathbb{F}\langle X\rangle$ and let $f(m) \in \mathbb{F}$ denote the coefficient of monomial $m$ in polynomial $f$. Then we can write $f=\sum_{m} f(m) m$ and $g=\sum_{m} g(m) m$, and in the product polynomial $f g$ for each monomial $m$ we have

$$
f g(m)=\sum_{m_{1} m_{2}=m} f\left(m_{1}\right) g\left(m_{2}\right) .
$$

The degree of a monomial $m \in X^{*}$ is the length of the monomial $m$, and the degree $\operatorname{deg} f$ of a polynomial $f \in \mathbb{F}\langle X\rangle$ is the degree of a largest degree monomial in $f$ with nonzero coefficient. For polynomials $f, g \in \mathbb{F}\langle X\rangle$ we clearly have $\operatorname{deg}(f g)=\operatorname{deg} f+\operatorname{deg} g$.

A nontrivial factorization of a polynomial $f \in \mathbb{F}\langle X\rangle$ is an expression of $f$ as a product $f=g h$ of polynomials $g, h \in \mathbb{F}\langle X\rangle$ such that $\operatorname{deg} g>0$ and $\operatorname{deg} h>0$. A polynomial $f \in \mathbb{F}\langle X\rangle$ is irreducible if it has no nontrivial factorization and is reducible otherwise. For instance, all degree 1 polynomials in $\mathbb{F}\langle X\rangle$ are irreducible. Clearly, by repeated factorization every polynomial in $\mathbb{F}\langle X\rangle$ can be expressed as a product of irreducibles.

The problem of noncommutative polynomial identity testing (PIT) for multivariate polynomials is known to easily reduce to noncommutative PIT for bivariate polynomials: the reduction is given

[^1]by the substitution
$$
x_{i} \rightarrow x y^{i}, 1 \leq i \leq n,
$$
which transforms a given arithmetic circuit (or formula or algebraic branching program) computing a polynomial $f\left(x_{1}, x_{2}, \ldots, x_{n}\right)$ to the bivariate polynomial $g(x, y)=f\left(x y, x y^{2}, \ldots, x y^{n}\right)$. As this substitution map ensures that every monomial of $f$ is mapped to a distinct monomial of $g(x, y)$, it easily follows that $f$ is the zero polynomial if and only if $g(x, y)$ is the zero polynomial.

Indeed, it can be shown [6, Excercise 2.5, Problem 14] that this substitution map give an injective homomorphism from the ring $\mathbb{F}\left\langle x_{1}, x_{2}, \ldots, x_{n}\right\rangle$ to $\mathbb{F}\langle x, y\rangle$. Unfortunately, this map does not preserve factorizations. For example, the polynomial $f=x_{3} x_{1}+x_{4} x_{2}+x_{4} x_{1}+x_{5} x_{2} \in \mathbb{F}\langle X\rangle$ is clearly irreducible but image of $f$ under the above map non trivially factorizes as $\left(x y^{2}+x y^{3}\right)\left(y x y+y^{2} x y^{2}\right)$. Thus, we cannot use this substitution map to obtain a reduction from noncommutative multivariate polynomial factorization to bivariate polynomial factorization.

Bergman's 1-inert embedding However, based on a theorem of Bergman [5, Chapter 4], we can obtain a polynomial-time reduction from factorization of multivariate noncommutative polynomials in $\mathbb{F}\left\langle x_{1}, x_{2}, \ldots, x_{n}\right\rangle$ given by arithmetic circuits (respect. noncommutative algebraic branching programs $(\mathrm{ABP})$ ) to factorization of bivariate noncommutative polynomials in $\mathbb{F}\langle x, y\rangle$, again given by arithmetic circuit (respect. an ABP). This reduction is polynomial-time bounded for both finite fields and rationals. In the case of rationals we need to ensure that the bit complexities of all numbers involved are polynomially bounded. Furthermore, we show that essentially the same reduction works in the black-box setting as well.

More precisely, Bergman's theorem [5, Chapter 4, Theorem 5.2] shows a 1-inert embedding of free algebras of countable rank into free algebras of rank 2. The property of 1-inertness of the embedding map is defined below. We restrict the definition to free noncommutative polynomial rings.

Definition 1.2 (1-inert embedding). [5] Let $X=\left\{x_{1}, x_{2}, \ldots\right\}$ be a countably infinite set of free noncommuting variables and $Y=\{x, y\}$ be two free noncommuting variables. A 1-inert embedding of $\mathbb{F}\langle X\rangle$ into $\mathbb{F}\langle Y\rangle$ is an injective homomorphism $\varphi: \mathbb{F}\langle X\rangle \rightarrow \mathbb{F}\langle Y\rangle$ such that for each polynomial $f \in \mathbb{F}\langle X\rangle$, if its image $\varphi(f)$ factorizes nontrivially in $\mathbb{F}\langle Y\rangle$ as

$$
\varphi(f)=g_{1} \cdot g_{2}
$$

then their preimages $\varphi^{-1}\left(g_{1}\right)$ and $\varphi^{-1}\left(g_{2}\right)$ exist and, since $\varphi$ is a homomorphism, it gives a nontrivial factorization $f=\varphi^{-1}\left(g_{1}\right) \varphi^{-1}\left(g_{2}\right)$ of $f$ in the ring $\mathbb{F}\langle X\rangle$.

Remark 1.3. The above definition implies that for all factorizations $\varphi(f)=g_{1} g_{2}$, the polynomials $g_{1}$ and $g_{2}$ are in the range of $\varphi$. We note that Cohn's work [6. 5] treats 1-inert embeddings $\varphi: R_{1} \rightarrow R_{2}$ for general noncommutative integral domains $R_{1}$ and $R_{2}$. In the general case, the definition only requires that there is some unit $u \in R_{2}$ such that $g_{1} u$ and $u^{-1} g_{2}$ are in the range of the map $\varphi$ which means that the factorization $\varphi(f)=\left(g_{1} u\right)\left(u^{-1} g_{2}\right)$ holds in the range of $\varphi$. As the only units in $\mathbb{F}\langle X\rangle$ are elements of $\mathbb{F}$, for a polynomial $f \in \mathbb{F}\langle X\rangle$, the factors of its image $\varphi(f)$ are all in the range $\varphi(\mathbb{F}\langle X\rangle)$ of the 1-inert embedding $\varphi$.

Definition 1.4. A complete factorization of noncommutative polynomial $f \in \mathbb{F}\langle X\rangle$ is a factorization $f=f_{1} \cdot f_{2} \cdots f_{r}$ into a product of irreducible polynomials $f_{i} \in \mathbb{F}\langle X\rangle$.

Given an algebraic branching program (respec. Arithmetic Circuit) for $f$, we can efficiently obtain an algebraic branching program (respec. Arithmetic Circuit) for $\varphi(f)$ and then we use idea
of running a substitution automata on ABPs or circuits (see e.g. [4], [2], [3]) to construct a complete factorization of $f$ given a complete factorization of $\varphi(f)$. In the next section we will elaborate and expand upon Bergman's embedding theorem [5] and show how to get its effective algorithmic version which is useful for our purpose of reconstruction of factors of $f$ from factors of $\varphi(f)$.

## 2 Bergman's embedding

We define a total ordering $<$ on monomials in $\{x, y\}^{*}$ as follows.
Definition 2.1. For $m_{1}, m_{2} \in\{x, y\}^{*}, m_{1} \neq m_{2}$, we say $m_{1}<m_{2}$ if one of the following holds:

- $m_{1}=m_{2}$.
- $\operatorname{deg}\left(m_{1}\right)<\operatorname{deg}\left(m_{2}\right)$.
- $\operatorname{deg}\left(m_{1}\right)=\operatorname{deg}\left(m_{2}\right)$ and if $m_{1} \neq m_{2}$ then the leftmost position $i$ where they differ we have $m_{1}[i]=y$ and $m_{2}[i]=x$.

The above ordering is just the usual lexicographic ordering on binary strings treating $y$ as 0 and $x$ as 1 . For any polynomial $g$, let $\operatorname{Mon}(g)$ denotes set of all monomials of $g$ with non-zero coefficient.

When $m_{1}<m_{2}$ we say that monomial $m_{1}$ is smaller than monomial $m_{2}$. Equivalently, $m_{2}$ is larger than $m_{1}$. The leading monomial of a polynomial $g \in \mathbb{F}\langle x, y\rangle$ is the monomial $m \in \operatorname{Mon}(g)$ (denoted by $\operatorname{lm}(g)$ ) such that $w<m$ for all $w \in \operatorname{Mon}(g)$. That is, the leading monomial of $g$ is the largest monomial in $\operatorname{Mon}(g)$.

Definition 2.2. For a monomial $m \in\{x, y\}^{*}$ let $d_{x}(m)$ (respectively, $d_{y}(m)$ ) denote the number of occurrences of $x$ (respectively, $y$ ) in $m$. The imbalance $i(m)$ of the monomial $m$ is defined as

$$
i(m)=d_{x}(m)-d_{y}(m)
$$

Let $B$ be the algebra of all polynomials such that every monomial of the polynomials has imbalance 0 .

Let $T$ be set of all monomials $m$ such that either $m=\epsilon$ or $i(m)=0$ and for any prefix $m^{\prime}$ of $m$ with $m^{\prime} \neq \epsilon, m^{\prime} \neq m, i\left(m^{\prime}\right)>0$. We call these monomials as minimally balanced monomials. Clearly in all the non-empty monomials in $T$ the leftmost symbol is $x$. We arrange the non-empty monomials in $T$ in lexicographic ordering $<$ and the $i^{t h}$ monomial in the sequence is denoted by $u_{i}$. Let $\overline{u_{i}}$ is a monomial obtained by replacing every occurrence of $x$ by $y$ and $y$ by $x$ in $u_{i}$. Let $\bar{T}=\left\{\overline{u_{i}} \mid i \geq 1\right\}$. It is clear that the monomials in $T$ and $\bar{T}$ together generate the algebra $B$.

Let $C$ be an algebra generated by $\left\{u_{i}+\overline{u_{i}} \mid i \geq 1\right\}$. Clearly $C$ is a subalgebra of $B$.
As each $u_{i}$ and $\overline{u_{i}}$ is balanced, clearly the imbalance of any monomial of a polynomial in $C$ is 0 . Let $X=\left\{x_{1}, x_{2}, \ldots, x_{n}\right\}$ and $X_{\infty}=\left\{x_{1}, x_{2}, \ldots\right\}$ be a countably infinite set of indeterminates.

We observe a crucial property of polynomials in $B \backslash C$.

## Lemma 2.3.

- The leading monomial $m$ of any polynomial in $C$ has the form $m=u_{i_{1}} u_{i_{2}} \cdots u_{i_{\ell}}$, where each $u_{i_{j}} \in T$. That is, $m$ does not have as subword any $\bar{u} \in \bar{T}$.
- Every polynomial $f \in B \backslash C$ can be expressed as $f=g+h$ for $g \in C$ and $h \in B$. Moreover, if $h \neq 0$ then the leading monomial of $h$ has some $\bar{u} \in \bar{T}$ as subword.
Proof. By definition of algebra $B$ (and hence $C$ ), for $g \in B$ and any monomial $m \in \operatorname{supp}(g)$ we have $m \in(T \cup \bar{T})^{*}$. Moreover, each $g \in C$ is an linear combination of products of the form $\prod_{k=1}^{\ell}\left(u_{i_{k}}+\overline{u_{i k}}\right)$. Hence, if $\operatorname{deg}(g)=d$ and $\operatorname{supp}(g)$ contains a degree- $d$ monomial $g_{j_{1}} g_{j_{2}} \ldots g_{j_{\ell}}$, where $g_{j_{k}} \in\left\{u_{j_{k}}, \overline{u_{j_{k}}}\right\}$ for $k \in[\ell]$, then $\operatorname{supp}(g)$ also contains the degree- $d$ monomial $u_{j_{1}} u_{j_{2}} \ldots u_{j_{\ell}}$. By the definition $<$, the monomial $u_{j_{1}} u_{j_{2}} \ldots u_{j_{\ell}}$ is larger than (with respect to ordering $<$ ) all the monomials with some $\bar{u} \in \bar{T}$ as a subword. Therefore, the leading monomial of any polynomial $g \in C$ has the form claimed.

Next, let $f \in B \backslash C$. If the leading monomial of $f$ has a subword $\bar{u} \in \bar{T}$ then the claim follows as $f=0+f$ and $0 \in C$. Suppose the leading monomial of $f$ is $m=u_{j_{1}} u_{j_{2}} \cdots u_{j_{\ell}}, u_{j_{k}} \in T$ for all $k$. If coefficient of $m$ in $f$ is $\alpha$, Let

$$
\begin{equation*}
f_{1}=f-\alpha\left(u_{j_{1}}+\overline{u_{j_{1}}}\right)\left(u_{j_{2}}+\overline{u_{j_{2}}}\right) \ldots\left(u_{j_{\ell}}+\overline{u_{j_{\ell}}}\right) . \tag{1}
\end{equation*}
$$

If $m_{1}$ is the leading monomial of $f_{1}$ then clearly $m_{1}<m$. Furthermore, $f_{1} \in B \backslash C$ as $f-f_{1} \in C$. Hence, it suffices to show $f_{1}=g_{1}+h_{1}$ for some $g_{1} \in C$ and $h_{1} \in B$ with the claimed property. We can apply the subtraction step of Equation 1 to $f_{1}$ to obtain $f_{2}$ and so on, where in the $i^{\text {th }}$ step we obtain a new polynomial $f_{i}$ whose leading monomial is smaller than the leading monomials of $f$ and each $f_{j}, j<i$. Since the <-ordering is a well-ordering on monomials, this process will terminate giving us the desired expression of $f$ as $f=g+h$ where $g \in C$ and the leading term of $h$ has a subword $\bar{u}$ for some $u \in T$. This proves the second part.

Lemma 2.4. There is an injective homomorphism (i.e. a homomorphic embedding) from the ring $\mathbb{F}\left\langle X_{\infty}\right\rangle$ to $\mathbb{F}\langle x, y\rangle$.
Proof. Consider the function $\varphi: \mathbb{F}\left\langle X_{\infty}\right\rangle \mapsto \mathbb{F}\langle x, y\rangle$ defined as follows:

- Let $\varphi\left(x_{i}\right)=u_{i}+\overline{u_{i}}$ for all $x_{i} \in X_{\infty}$.
- Extend $\varphi$ to all monomials by multiplication. That is, $\varphi\left(x_{i_{1}} x_{i_{2}} \ldots x_{i_{k}}\right)=\prod_{j=1}^{k} \varphi\left(x_{i_{j}}\right)$.
- Further, extend $\varphi$ to the ring $\mathbb{F}\left\langle X_{\infty}\right\rangle$ by linearity: $\varphi\left(\sum_{i=1}^{t} \alpha_{i} m_{i}\right)=\sum_{i=1}^{t} \alpha_{i} \varphi\left(m_{i}\right)$, for monomials $m_{i} \in X_{\infty}^{*}$ and scalars $\alpha_{i} \in \mathbb{F}$ for $i=1$ to $t$.

To see that $\varphi$ is a homomorphism, we first note that, by linearity, we have $\varphi(f+g)=\varphi(f)+\varphi(g)$ for $f, g \in \mathbb{F}\left\langle X_{\infty}\right\rangle$. To verify that $\varphi(f g)=\varphi(f) \varphi(g)$, let $f=\sum_{m} f_{m} m$ and $g=\sum_{m} g_{m} m$ where $f_{m}, g_{m} \in \mathbb{F}$ are the coefficients of monomial $m$ in $f$ and $g$, respectively. Then

$$
\begin{aligned}
\varphi(f g) & =\varphi\left(\left(\sum_{m} f_{m} m\right)\left(\sum_{w} g_{w} w\right)\right) \\
& =\varphi\left(\sum_{m, w} f_{m} g_{w} m w\right) \\
& =\sum_{m, w} f_{m} g_{w} \varphi(m w) \quad \text { (by linearity of } \varphi \text { ) } \\
& =\left(\sum_{m} f_{m} \varphi(m)\right)\left(\sum_{w} f_{w} \varphi(w)\right) \\
& =\varphi(f) \varphi(g) .
\end{aligned}
$$

In order to show $\varphi$ is injective, it suffices to show $\varphi(f) \neq 0$ for $f \neq 0$. Suppose $m \in \operatorname{supp}(f)$. Then we note that $\varphi(m) \neq 0$ by the definition of $\varphi$. Hence, if $m$ is the only monomial in $\operatorname{supp}(f)$ it follows that $\varphi(f) \neq 0$.

Otherwise, let $m^{\prime} \in \operatorname{supp}(f)$ and $m^{\prime} \neq m$. Let $u$ be largest common prefix of $m$ and $m^{\prime}$. Then

$$
m=u x_{i} v \text { and } m^{\prime}=u x_{j} w,
$$

for monomials $u, v, w \in X_{\infty}^{*}$ and $x_{i} \neq x_{j}$. Noting that $\varphi\left(x_{i}\right)=u_{i}+\bar{u}_{i}$ and $\varphi\left(x_{j}\right)=u_{j}+\bar{u}_{j}$ we have

$$
\varphi(m)=\varphi(u)\left(u_{i}+\bar{u}_{i}\right) \varphi(v) \text { and } \varphi\left(m^{\prime}\right)=\varphi(u)\left(u_{j}+\bar{u}_{j}\right) \varphi(w) .
$$

From the definition of $\varphi$, clearly $\varphi(u)$ is a homogeneous polynomial in $\mathbb{F}\langle x, y\rangle$. Let $\operatorname{deg}(\varphi(u))=D$. Suppose $\ell=\left|u_{i}\right|=\left|\bar{u}_{i}\right|$ and $\ell^{\prime}=\left|u_{j}\right|=\left|\bar{u}_{j}\right|$. We can assume without loss of generality that $u_{i}<u_{j}$. Hence $\ell \leq \ell^{\prime}$. As $u_{i}$ and $u_{j}$ are minimally balanced, $u_{i}$ cannot be a prefix of $u_{j}$. Therefore, for any monomials $w_{1}, w_{2}$ in $\operatorname{supp}\left(\varphi\left(m_{1}\right)\right)$ and $\operatorname{supp}\left(\varphi\left(m_{2}\right)\right)$, respectively, $w_{1}$ and $w_{2}$ will differ in the length $\ell$ subword starting at location $D+1$. It follows that $\operatorname{supp}(\varphi(m)) \cap\left(\varphi\left(m^{\prime}\right)\right)=\emptyset$. Hence, $\varphi(f) \neq 0$ implying that $\varphi$ is injective.

We next have an important property about factorization of polynomials in the algebra $C$. In order to keep our presentation self-contained we give a complete proof with more details than in Cohn's book [5].

Theorem 2.5 (Bergman). [5. Chapter 4, Theorem 5.2] Let $f \in C$. For any factorization $f=g \cdot h$ the polynomials $g$ and $h$ are in $C$.

Proof. First we show that all monomials of $g$ have the same imbalance. Likewise, all monomials of $h$ have the same imbalance. Suppose $a_{\min }$ and $a_{\max }$ are the minimum and the maximum imbalances of monomials of $g$. Let $b_{\min }$ and $b_{\max }$ be the minimum and the maximum imbalance of monomials of $h$. Let $m_{\text {min }}$ be a smallest monomial (with respect to $<$ ) among all monomials of $g$ with imbalance $a_{\min }$, and $m_{\max }$ be a largest monomial (with respect to $<$ ) among all the monomials of $g$ with imbalance $a_{\max }$. Let $w_{\min }, w_{\max }$ be monomials similarly defined for polynomial $h$ corresponding to $b_{\min }$ and $b_{\max }$. Now consider the monomial $u=m_{\max } w_{\max }$. It is non-zero in $f=g . h$ and has imbalance $a_{\max }+b_{\max }$. Similarly, monomial $v=m_{\min } w_{\min }$ is non-zero in $f$ and has imbalance $a_{\text {min }}+b_{\text {min }}$. As $f \in C \subset B$, each monomial of $f$ has imbalance 0 . Hence, $a_{\max }+b_{\max }=0$ and $a_{\min }+b_{\min }=0$. So $a_{\max }=-b_{\max } \leq-b_{\min }=a_{\min }$, implying $a_{\min }=a_{\max }=a$ and $b_{\min }=b_{\max }=-a$. Thus, all monomials of $g$ have imbalance $a$ and all monomials of $h$ have imbalance $-a$.

Let $m$ be the leading monomial of $f$. Clearly, $m$ is a maximum degree monomial of $f$. Moreover, $m$ is largest among the max-degree monomials of $f$. Let $m=m_{1} m_{2}$ with $m_{1} \in \operatorname{supp}(g)$ and $m_{2} \in \operatorname{supp}(h)$. We have $i\left(m_{1}\right)=a, i\left(m_{2}\right)=-a$. As $f \in C$, the monomial $\bar{m}$ obtained by replacing every occurrence of $x$ by $y$, and $y$ by $x$ in $m$ is also in $\operatorname{supp}(f)$. Moreover, $\bar{m}$ is the smallest monomial among the max-degree monomials of $f$. This forces that the monomial $\bar{m}_{1}$ (obtained by interchanging $x, y$ in $m_{1}$ ) is in $\operatorname{supp}(g)$. Similarly, monomial $\bar{m}_{2}$ (obtained by swapping $x, y$ in $m_{2}$ ) is in $\operatorname{supp}(h)$. We have $i\left(\bar{m}_{1}\right)=-a$ and $i\left(\bar{m}_{2}\right)=a$. Now, all the monomials of $g$ have the same imbalance, and $m_{1}, \bar{m}_{1} \in \operatorname{supp}(g)$. This forces $a=-a=0$. Consequently, all monomials in $\operatorname{supp}(g) \cup \operatorname{supp}(h)$ have imbalance zero which implies $g, h \in B$.

By Lemma 2.3 applied to $g$ and $h$ we have

1. $g=g_{1}+g_{2}, h=h_{1}+h_{2}, g_{1}, h_{1} \in C, \operatorname{lm}\left(g_{2}\right)$ contains $\bar{u} \in \bar{T}$, and $\operatorname{lm}\left(h_{2}\right)$ contains $\bar{v} \in \bar{T}$,
2. Consequently, the $\operatorname{deg}\left(g_{2}\right)$ prefix of $\operatorname{lm}\left(g_{2} h_{1}\right)$ contains the subword $\bar{u}$ and the $\operatorname{deg}\left(h_{2}\right)$ suffix of $\operatorname{lm}\left(g_{1} h_{2}\right)$ contains the subword $\bar{v}$.
3. Finally, the $\operatorname{deg}\left(g_{2}\right)$ prefix and the $\operatorname{deg}\left(h_{2}\right)$ suffix of $\operatorname{lm}\left(g_{2} \cdot h_{2}\right)$ contains both subwords $\bar{u}$ and $\bar{v}$.

Hence the leading monomials $\operatorname{lm}\left(g_{2} \cdot h_{1}\right), \operatorname{lm}\left(g_{1} \cdot h_{2}\right)$, and $\operatorname{lm}\left(g_{2} \cdot h_{2}\right)$ cannot cancel with each other. As a consequence, the leading monomial of $g_{2} \cdot h_{1}+g_{1} \cdot h_{2}+g_{2} \cdot h_{2}$ contains a sub-word from $\bar{T}$ unless both $g_{2}=0$ and $h_{2}=0$. Hence,

$$
\begin{aligned}
g_{2} \cdot h_{1}+g_{1} \cdot h_{2}+g_{2} \cdot h_{2} & =g h-g_{1} \cdot h_{1} \in C \text { and } \\
f & =g \cdot h, g_{1}, h_{1} \in C .
\end{aligned}
$$

By Lemma 2.3, for any polynomial $\mathfrak{f} \in C$ its leading monomial $\operatorname{lm}(\mathfrak{f})$ cannot have a subword from $\bar{T}$. It forces $g_{2}=0$ and $h_{2}=0$ which implies $g, h \in C$.

The following theorem, which is a consequence of Theorem 2.5shows that the embedding $\varphi$ is a 1-inert embedding (see Definition 1.2). That is, it preserves factorizations.

Theorem 2.6. Let $f \in \mathbb{F}\langle X\rangle$, where $X=\left\{x_{1}, \ldots, x_{n}\right\}$. Suppose $f^{\prime}=\varphi(f)=g^{\prime} \cdot h^{\prime}$ is a non-trivial factorization of $\varphi(f)$ in the ring $\mathbb{F}\langle x, y\rangle$. Then there exist polynomials $g, h \in \mathbb{F}\langle X\rangle, g, h \notin \mathbb{F}$ such that $g^{\prime}=\varphi(g), h^{\prime}=\varphi(h)$ and $f=g \cdot h$.

Proof. By construction, the homomorphism $\varphi$ injectively maps $\mathbb{F}\left\langle X_{\infty}\right\rangle$ into $\mathbb{F}\langle x, y\rangle$. As $\mathbb{F}\langle X\rangle \subset$ $\mathbb{F}\left\langle X_{\infty}\right\rangle, \varphi$ maps $f \in \mathbb{F}\langle X\rangle$ to some $f^{\prime}=\varphi(f) \in C$. Suppose $f^{\prime}=g^{\prime} \cdot h^{\prime}$ is a nontrivial factorization of $f^{\prime}$ in $\mathbb{F}\langle x, y\rangle$. By Theorem [2.5, as $f^{\prime} \in C$ both the factors $g^{\prime}, h^{\prime} \in C$. Since $g^{\prime} \in C$, it is an $\mathbb{F}$-linear combination of products of the form $\left(u_{t_{1}}+\overline{u_{t_{1}}}\right)\left(u_{t_{2}}+\overline{u_{t_{2}}}\right) \ldots\left(u_{t_{\ell}}+\overline{u_{t_{\ell}}}\right)$. By definition of $\varphi$,

$$
\left(u_{t_{1}}+\overline{u_{t_{1}}}\right)\left(u_{t_{2}}+\overline{u_{t_{2}}}\right) \ldots\left(u_{t_{\ell}}+\overline{u_{t_{\ell}}}\right)=\varphi\left(x_{t_{1}} x_{t_{2}} \ldots x_{t_{\ell}}\right) .
$$

Hence, by linearity, it follows that $g^{\prime}=\varphi(g)$ for some nontrivial polynomial $g \in \mathbb{F}\left\langle X_{\infty}\right\rangle$, similarly there is a nontrivial polynomial $h \in \mathbb{F}\left\langle X_{\infty}\right\rangle$ such that $h^{\prime}=\varphi(h)$. Since $\varphi$ is a homomorphism, we have

$$
\varphi(f)=f^{\prime}=g^{\prime} \cdot h^{\prime}=\varphi(g) \cdot \varphi(h)=\varphi(g \cdot h)
$$

As $\varphi$ is injective, we have $f=g \cdot h$. To complete the proof we need to argue that $g, h \in \mathbb{F}\langle X\rangle$. Let $\operatorname{Var}(g)$ denotes set of variables $x_{i}$ which appears in some non-zero monomial of $g$. We want to show that $\operatorname{Var}(g) \subseteq X$. Suppose $\operatorname{Var}(g)$ contains some $x_{i} \notin X$. Among all monomials of $g$ containing $x_{i}$, let $m$ be the largest monomial (under <-ordering). Then the monomial $m \cdot \operatorname{lm}(h)$ contains the variable $x_{i}$ and has a non-zero coefficient in $f=g h$. This is a contradiction as $f \in \mathbb{F}\langle X\rangle$ and $X$ does not contain $x_{i}$. Hence $\operatorname{Var}(g) \subseteq X$. Similarly, $\operatorname{Var}(h) \subseteq X$.

## 3 Multivariate to Bivariate reduction

In this section we will apply Bergman's theorem to show that multivariate noncommutative polynomial factorization is reducible to bivariate noncommutative polynomial factorization in both white-box and black-box.

We first describe some simple tools using which we can obtain an efficient reduction from Bergman's theorem (Theorem 2.5).

Let $X=\left\{x_{1}, x_{2}, \ldots, x_{n}\right\}$, and $v_{1}, v_{2}, \ldots, v_{n}$ be any $n$ distinct and minimally balanced monomials in $\{x, y\}^{*}$. We define function $\varphi: \mathbb{F}\langle X\rangle \rightarrow \mathbb{F}\langle x, y\rangle$ :

- $\varphi\left(x_{i}\right)=v_{i}+\overline{v_{i}}$ for all $i$.
- $\varphi$ is extended to monomials by multiplication, i.e. $\varphi\left(x_{i_{1}} x_{i_{2}} \ldots x_{i_{k}}\right)=\prod_{j=1}^{k} \varphi\left(x_{i_{j}}\right)$.
- $\varphi$ is extended to $\mathbb{F}\langle X\rangle$ by linearity.

Remark 3.1. The above definition is essentially like in the proof of Bergman's theorem, except that here $X$ is a finite set of variables and the $v_{i}, 1 \leq i \leq n$ are any $n$ distinct minimally balanced monomials.

We can show the following along the same lines as Theorem[2.5]and Theorem 2.6. The straightforward proof is by a suitable renaming of the variables $x_{1}, \ldots, x_{n}$ before and after application of Theorem [2.5 in the proof of the Theorem 2.6 .

Lemma 3.2. Let $X=\left\{x_{1}, \ldots, x_{n}\right\}, f \in \mathbb{F}\langle X\rangle$. Suppose $v_{1}, v_{2}, \ldots, v_{n}$ are any distinct minimally balanced monomials in $\{x, y\}^{*}$. If $f^{\prime}=\varphi(f)=g^{\prime} \cdot h^{\prime}$ is a non-trivial factorization of $f^{\prime}$ in $\mathbb{F}\langle x, y\rangle$ then there are polynomials $g, h \in \mathbb{F}\langle X\rangle$ such that $g^{\prime}=\varphi(g), h^{\prime}=\varphi(h)$ and $f=g \cdot h$.

In order to obtain polynomial-time computable reduction it is convenient to choose $v_{1}, v_{2}, \ldots, v_{n}$ such that each $v_{i}$ has the same length. The next lemma ensures that $\ell=O(\log n)$ suffices.

Lemma 3.3. There are at least $n$ minimally balanced monomials oflength $2 \ell$ in $\{x, y\}^{*}$ for $\ell \geq \max ([\log 4 n\rceil, 7)$. Furthermore, the lexicographically first $n$ minimally balanced monomials of length $2 \ell$ can be computed in time polynomial in $n$.

Proof. First we consider the number of minimally balanced monomials of length $2 \ell$ for $\ell \geq 2$. The first symbol of any minimally balanced monomial is $x$. If it is more than 2 , the second symbol is also $x$ (if it was $y$, then the balanced monomial $x y$ would be a strict prefix of the minimally balanced monomial, which is a contradiction.) We consider monomials of the form

$$
v=x x \cdot w \cdot y y
$$

where $w$ is a Dyck monomial 3 . That is, $w$ is a balanced monomial such that every prefix of $w$ has at most as many $y^{\prime}$ s as $x^{\prime}$ s. Notice that $w \in\{x, y\}^{2 \ell-4}$. It follows that any nontrivial prefix of $v$ has strictly more $x$ than $y$. So any such monomial is minimally balanced of length $2 \ell$. The number of Dyck monomials of length $2 \ell-4$ is $C_{\ell-2}$ (the $(\ell-2)^{t h}$ Catalan number). A standard estimate yields

$$
C_{k} \sim \frac{4^{k}}{k^{3 / 2} \sqrt{\pi}}
$$

which implies that $C_{k}$ is $2^{\Omega(k)}$. Specifically, $C_{k}>2^{k}$ for $k \geq 5$. If $n<2^{\ell-2}$ and $\ell \geq 7$ then there are at least $n$ minimally balanced monomials of length $2 \ell$, for $\ell=\max (\lceil\log 4 n\rceil, 7)$.

Clearly, we can compute the $v_{i}, 1 \leq i \leq n$ by enumeration in poly $(n)$ time.

[^2]
### 3.1 White-box reduction

We first describe the reduction in the white-box case for input polynomial $f \in \mathbb{F}\langle X\rangle$ given by a noncommutative arithmetic circuit.

Lemma 3.4. Let $X=\left\{x_{1}, \ldots, x_{n}\right\}$ and $f \in \mathbb{F}\langle X\rangle$ be a noncommutative polynomial given by arithmetic circuit $C$ of size $s$. Then there is a deterministic polynomial time algorithm that outputs an arithmetic circuit computing the polynomial $\varphi(f) \in \mathbb{F}\langle x, y\rangle$, where the minimally balanced monomials $v_{i}, 1 \leq i \leq n$ defining the map $\varphi$ are as described by Lemma 3.3

Proof. For $1 \leq i \leq n$, we note that the sum of two monomials $v_{i}+\overline{v_{i}}$ can be computed by a noncommutative arithmetic formula $F_{i}$ of size $O(\log n)$. Let $C^{\prime}$ be the arithmetic circuit obtained from circuit $C$ by replacing input variable $x_{i}$ with the formula $F_{i}$. Clearly, $C^{\prime}$ computes $\varphi(f)$ and its size is polynomially bounded.

Lemma 3.5. For $f \in \mathbb{F}\langle X\rangle$ suppose $\varphi(f)=f_{1}^{\prime} \cdot f_{2}^{\prime} \cdots f_{r}^{\prime}$ is a complete factorization of $\varphi(f)$ in $\mathbb{F}\langle x, y\rangle$ into irreducible factors $f_{i}^{\prime} \in \mathbb{F}\langle x, y\rangle$. Then there are irreducible polynomials $f_{1}, f_{2}, \ldots, f_{r} \in \mathbb{F}\langle X\rangle$ such that $f=f_{1} f_{2} \ldots f_{r}$ and $\varphi\left(f_{i}\right)=f_{i}^{\prime}$ for each $i$.

Proof. It follows by repeated application of Lemma 3.2 that if

$$
\varphi(f)=f_{1}^{\prime} \cdot f_{2}^{\prime} \cdots f_{r}^{\prime}
$$

is a factorization into irreducible factors $f_{i}^{\prime} \in \mathbb{F}\langle x, y\rangle$, then there are polynomials $f_{1}, f_{2}, \ldots, f_{r} \in$ $\mathbb{F}\langle X\rangle$ such that $f=f_{1} f_{2} \ldots f_{r}$ and $\varphi\left(f_{i}\right)=f_{i}^{\prime}$ for each $i$. We claim each $f_{i}$ is irreducible. For, if $f_{i}=g \cdot h$ is a nontrivial factorization of $f_{i}$ in $\mathbb{F}\langle X\rangle$ then clearly $f_{i}^{\prime}=\varphi\left(f_{i}\right)=\varphi(g) \varphi(h)$ is a nontrivial factorization of $f_{i}^{\prime}$, which contradicts its irreducibility.

Suppose $C_{i}^{\prime}$ is an arithmetic circuit of size $s_{i}^{\prime}$ for $f_{i}^{\prime}$ for $i \in[r]$. We will construct a circuit of size poly $\left(s_{i}^{\prime}, n\right)$ for $f_{i}$ efficiently for each $i \in[r]$, which is the crucial part of our multivariate to bivariate reduction.

The next lemma describes the algorithm crucial to the white-box reduction.
Lemma 3.6. Given as input a noncommutative arithmetic circuit $C$ for the polynomial $\varphi(g) \in \mathbb{F}\langle x, y\rangle$, where $g \in \mathbb{F}\langle X\rangle$ is a degree d polynomial, $X=\left\{x_{1}, x_{2}, \ldots, x_{n}\right\}$, there is a deterministic polynomial-time algorithm, running in time $\operatorname{poly}(d, \operatorname{size}(C), n)$ that computes a noncommutative arithmetic circuit $C^{\prime}$ for the polynomial $g$. Furthermore, if $\varphi(g)$ is given by an algebraic branching program then the algorithm computes an algebraic branching program for $g$.

Proof. The proof is based on the idea of evaluating a noncommutative arithmetic circuit on an automaton (specifically, a substitution automaton) described in [4] (see e.g., for related applications [2], [3]).

Let $g^{\prime}=\varphi(g)$. Let $g=\sum_{m} \alpha_{m} m$ where $m \in X^{*}$ and $\alpha_{m}$ is the coefficient of $m$ in $g$. As noted before, the map $\varphi$ has the property that $\operatorname{Mon}(\varphi(m)) \cap \operatorname{Mon}\left(\varphi\left(m^{\prime}\right)=\right.$ for monomials $m \neq m^{\prime}$ in $X^{*}$. Moreover if $m=x_{i_{1}} x_{i_{2}} \ldots x_{i_{\ell}}$ has nonzero coefficient $\alpha_{m}$ in $g$ then $g^{\prime}$ has a monomial $m^{\prime}=v_{i_{1}} v_{i_{2}} \ldots v_{i_{\ell}}$ with coefficient $\alpha_{m}$. Hence, to retrieve an arithmetic circuit for $g$ from the given circuit $C^{\prime}$ for $g^{\prime}$ our aim is to carry out the following transformation of the polynomial $g^{\prime}$ given by the circuit $C^{\prime}$ :

- Get rid of the monomials of $g^{\prime}$ containing of all $\overline{v_{j}} \in \bar{T}$ for $j \in[n]$.
- For each remaining monomial $m^{\prime}$ of $g^{\prime}$ substitute $x_{i}$ wherever the monomial $v_{i}$ occurs as substring in $m^{\prime}$ for $i \in[n]$.

We will accomplish this transformation by evaluating the circuit $C^{\prime}$ at suitably chosen matrix substitutions $x \leftarrow M_{x}$ and $y \leftarrow M_{y}$, where $M_{x}$ and $M_{y}$ will be $N \times N$ matrices for polynomially bounded $N$. The resulting evaluation $C^{\prime}\left(M_{x}, M_{y}\right)$ will be be an $N \times N$ matrix. A designated entry of this matrix will contain the polynomial $g$. Clearly, if we can efficiently compute the claimed matrices $M_{x}$ and $M_{y}$ it will yield an arithmetic circuit $C$ for the polynomial $g$. These matrices $M_{x}$ and $M_{y}$ will be obtained as transition matrices of a substitution automaton that will carry out the above transformation steps on the polynomial $g^{\prime}$.

We recall substitution automata in the current context. A finite substitution automaton $\mathcal{A}$ is a deterministic finite automata $\mathcal{A}$ along with a substitution map

$$
\delta: Q \times\{x, y\} \rightarrow Q \times(X \cup \mathbb{F})
$$

where $Q$ is a set of states and $X=\left\{x_{1}, x_{2}, \ldots, x_{n}\right\}$ are noncommuting variables. For $i, j \in Q$, $a \in\{x, y\}, u \in X \cup \mathbb{F}$, if $\delta(i, a)=(j, u)$, it means that when automata $\mathcal{A}$ in state $i$ reads $a$, it replaces $a$ by $u$ and transitions to state $j$. For each $a \in\{x, y\}$ we can define $|Q| \times|Q|$ transition matrix $M_{a}$ such that $M_{a}(i, j)=u$ if $\delta(i, a)=(j, u)$ and 0 otherwise.

With $\delta$ we associate projections $\delta_{1}: Q \times\{x, y\} \rightarrow Q$ and $\delta_{2}: Q \times\{x, y\} \rightarrow X \cup \mathbb{F}$ defined as $\delta_{1}(i, a)=j$ and $\delta_{2}(i, a)=u$ if $\delta(i, a)=(j, u)$. The functions $\delta_{1}$ and $\delta_{2}$ extend naturally to monomials: For $w \in\{x, y\}^{*}, \delta_{1}(i, w)=j$ means the automaton $\mathcal{A}$ goes from state $i$ to $j$ on reading $w$. Let $\tilde{w}_{\ell}$ denotes length $\ell$ prefix of $w$ and $w_{\ell}$ denotes $\ell^{t h}$ symbol of $w$ from left. $\delta_{2}(i, w)=p$ means

$$
p=\prod_{\ell=0}^{|w|-1} \delta_{2}\left(\delta_{1}\left(i, \tilde{w}_{\ell}\right), w_{\ell+1}\right)
$$

Note that $\delta_{2}(i, w)$ has the form $\beta \cdot w^{\prime}$ where $\beta \in \mathbb{F}, w^{\prime} \in X^{*}$. For $\alpha \in \mathbb{F}$ define $\delta_{2}(i, \alpha \cdot w)$ as $\alpha \cdot \delta_{2}(i, w)$.
Let $g^{\prime}(x, y)=\sum_{m} \alpha_{m} m \in \mathbb{F}\langle x, y\rangle$. Then, the $(s, t)^{t h}$ entry of the $|Q| \times|Q|$ matrix $g^{\prime}\left(M_{x}, M_{y}\right)$ is a polynomial $g \in \mathbb{F}\langle X\rangle$ such that

$$
g=\sum_{m \in W_{t}} \alpha_{m} \delta_{2}(s, m)
$$

where $W_{t}$ is the set of all monomials that take the automaton $\mathcal{A}$ from state $s$ to state $t$.
Clearly, if $g^{\prime}$ has an arithmetic circuit of size $s$ then we can construct an arithmetic circuit of size poly( $s, n,|Q|)$ for $g$ in deterministic time $\operatorname{poly}(s, n,|Q|)$.

Turning back to the reduction, consider the input circuit $C$ for $g^{\prime}=\varphi(g) \in \mathbb{F}\langle x, y\rangle$. We will construct a substitution automaton $\mathcal{A}$ such that the polynomial $g$ is the $(s, t)^{t h}$ entry of the matrix $g^{\prime}\left(M_{x}, M_{y}\right)$.

Description of the Substitution Automata As already observed each $v_{i}$ is of the form $x x w_{i} y y$, where $w_{i}$ is a Dyck monomial. Let $v_{i}^{\prime}=x w_{i} y$ for $i \in[n]$. We can easily design a deterministic finite automaton $A^{\prime}$ with $O(m n)$ states such that the language accepted by $A^{\prime}$ is precisely the finite set $\left\{v_{1}^{\prime}, v_{2}^{\prime}, \ldots, v_{n}^{\prime}\right\}$, where $m$ is the length of $v_{i}$ for $i \in[n]$. Let $\delta^{\prime}$ denote the transition function and $Q^{\prime}$ be the set of states of $A^{\prime}$, where $q_{1}$ is the initial state and $q_{f_{i}}$ is the final state associated with
acceptance of string $v_{i}^{\prime}$ for $i \in[n]$. $A^{\prime}$ has a tree structure with root $q_{1}$ and leaves $q_{f_{i}}$ for $i \in[n]$, and any root to leaf path has length exactly $2 \ell-2$. We now define the substitution automaton $\mathcal{A}$. Its state set is $Q=Q^{\prime} \cup\left\{q_{0}, q_{f}, q_{r}\right\}$. The transition function $\delta: Q \times\{x, y\} \rightarrow Q \times(X \cup \mathbb{F})$ is defined as follows:

1. $\delta\left(q_{0}, x\right)=\left(q_{1}, 1\right) ; \delta\left(q_{0}, y\right)=\left(q_{r}, 0\right)$.
2. for $q \in Q^{\prime} \backslash\left\{q_{f_{i}} \mid 1 \leq i \leq n\right\}$. and $a \in\{x, y\}$, let $\delta(q, a)=\left(\delta^{\prime}(q, a), 1\right)$.
3. $\delta\left(q_{f_{i}}, x\right)=\left(q_{r}, 0\right) ; \delta\left(q_{f_{i}}, y\right)=\left(q_{f}, x_{i}\right)$ for each $i \in[n]$.
4. $\delta\left(q_{f}, x\right)=\left(q_{1}, 1\right)$ and $\delta\left(q_{f}, y\right)=\left(q_{r}, 0\right)$.
5. $\delta\left(q_{r}, a\right)=\left(q_{r}, 0\right)$ for $a \in\{x, y\}$.

The final state of $\mathcal{A}$ is $q_{f}$. For a monomial $w \in\{x, y\}^{*}$, starting at state $q_{0}$ the automaton $\mathcal{A}$ substitutes all the variables with 1 as long as it matches with a prefix of $v_{i}$ for $i \in[n]$ (given by transitions in 1,2 above). When the monomial matches with $v_{i}$ for some $i$ (which will happen while reading symbol $y$ as each string $v_{i}$ ends with $y$ ), $\mathcal{A}$ substitutes $y$ by $x_{i}$ and moves to state $q_{f}$. If it reads $x$ instead of $y$ then $\mathcal{A}$ enters a rejecting state $q_{r}$ (given by transition in 3 above). Hence, if $\mathcal{A}$ finds substring $v_{i}$ in $w$ it replaces it with $x_{i}$. Whenever $\mathcal{A}$ is in state $q_{f}$, it means the monomial read so far is of the form $v_{i_{1}} v_{i_{2}} \ldots v_{i_{t}}$, and it has replaced it with $x_{i_{1}} x_{i_{2}} \ldots x_{i_{t}}$. If in the state $q_{f}$ symbol $y$ is encountered, it means the next substring cannot match with a minimally balanced monomial (as these start with $x$ ) and the automaton goes to the rejecting state $q_{r}$. If in state $q_{f}$ variable $x$ is read the automaton goes to state $q_{1}$ and restarts the search for a new substring that matches with some $v_{i}$ (transition in 4 above).

In conclusion $\mathcal{A}$ replaces all the monomials of the form $v_{i_{1}} v_{i_{2}} \ldots v_{i_{t}}$ by $x_{i_{1}} x_{i_{2}} \ldots x_{i_{t}}$. If the monomial contains an occurrence of $\overline{v_{i}}$, or it is not of the form $v_{i_{1}} v_{i_{2}} \ldots v_{i_{t}}$, then $\mathcal{A}$ zeros out that monomial by suitably setting an occurrence of $y$ to zero or enters the reject state $q_{r} \mathbb{U}^{4}$

It follows that the $\left(q_{0}, q_{f}\right)^{t h}$ entry of the $|Q| \times|Q|$ matrix $g^{\prime}\left(M_{x}, M_{y}\right)$ is the polynomial $g$, where $g^{\prime}=\varphi(g)$, and $M_{x}, M_{y}$ are the transition matrices for the substitution automaton $\mathcal{A}$. This completes the proof.

Finally, if $\varphi(g)$ is given by an algebraic branching program $P$ then it is easy to see that the above construction with the substitution automaton $\mathcal{A}$ yields $P\left(M_{x}, M_{y}\right)$ which is an algebraic branching program.

The main theorem of this section, stated below, summarizes the discussion in this section.
Theorem 3.7. In the white-box setting, factorization of multivariate noncommutative polynomials into irreducible factors is deterministic polynomial-time reducible to factorization of bivariate noncommutative polynomials into irreducible factors. More precisely, given as input $f \in \mathbb{F}\langle X\rangle$ by an arithmetic circuit (respectively, algebraic branching program), the problem of computing a complete factorization $f=f_{1}$. $f_{2} \cdots f_{r}$ where each $f_{i}$ is output as an arithmetic circuit (resp. algebraic branching program) is deterministic polynomial-time reducible to the same problem for bivariate polynomials in $\mathbb{F}\langle x, y\rangle$.

Proof. We describe the reduction:

[^3]1. Input $f \in \mathbb{F}\langle X\rangle$ (as a circuit or ABP ).
2. Transform $f$ to $f^{\prime}=\varphi(f) \in \mathbb{F}\langle x, y\rangle$ as a circuit (resp. ABP) by the algorithm of Lemma 3.3.
3. Compute a complete factorization of $f^{\prime}=f_{1}^{\prime} \cdot f_{2}^{\prime} \cdots f_{r}^{\prime}$, where each $f_{i}^{\prime} \in \mathbb{F}\langle x, y\rangle$ is irreducible and is computed as a circuit (resp. ABP).
4. Apply the algorithm of Lemma 3.6 to obtain a complete factorization of $f=f_{1} \cdot f_{2} \cdots f_{r}$, where each $f_{i}$ is irreducible and is output as circuit (resp. ABP).

The correctness of the reduction and its polynomial time bound follow from Lemmas $3.2,3.3$ and 3.6

Remark 3.8. We note that in the case $\mathbb{F}$ is the field $\mathbb{Q}$ (of rationals), we need to take into account the bit complexity of the rational numbers involved and argue that the reduction is still polynomial time computable. The main point to note here is that the reduction guarantees the size of the factor $f_{i}$ is polynomially bounded in the size of $g_{i}, 1 \leq i \leq r$, where the size of $g_{i}$ includes the sizes of any rational numbers that might be involved in the description of the arithmetic circuit (or ABP) for $g_{i}$.

Remark 3.9. We note here that the ring $\mathbb{F}\langle X\rangle$ is not a unique factorization domain. That is, a polynomial $f \in \mathbb{F}\langle X\rangle$ may have, in general, multiple factorizations into irreducibles [6]. A standard example is the polynomial $x+x y x$ which factorizes as $x(1+y x)$ as well as $(1+x y) x$, where $x, y, 1+y x, 1+x y$ are irreducible. As the map $\varphi$ is an injective homomorphism, there is a 1-1 correspondence between factorizations of $\varphi(f)$ and factorizations of $f$. More specifically, our reduction takes as input any complete factorization $\varphi(f)=f_{1}^{\prime} f_{2}^{\prime} \ldots f_{r}^{\prime}$ and computes the corresponding complete factorization $f=f_{1} f_{2} \ldots f_{r}$ of $f$.

Remark 3.10. We note that the embedding $\varphi$ does not preserve sparsity 5 of the polynomial $f$. More precisely, if the sparsity of the n-variate degree $d$ polynomial $f$ is s then the sparsity of the bivariate polynomial $\varphi(f)$ is $O\left(2^{d}\right.$ s). Thus, using this embedding map we do not get a reduction from sparse $n$-variate degree $d$ polynomial factorization to sparse bivariate polynomial factorization, where s, $d$ are allowed to be part of the running time. This problem remains unanswered.

### 3.2 Black-box reduction

The reduction in the black-box case is essentially identical. The only point to note, which is easy to see, is the that analogue of Lemma 3.6 holds in the black-box setting. We state that below. We recall what a black-box means in the noncommutative setting.

Definition 3.11. A noncommutative polynomial $f \in \mathbb{F}\langle X\rangle$ given by black-box essentially means we can evaluate $f$ at any matrix substitution $x_{i} \leftarrow M_{i}, M_{i} \in \mathbb{F}^{N \times N}$, where the cost of each evaluation is the matrix dimension $N$.

In the black-box setting, suppose we have an efficient algorithm for bivariate noncommutative polynomial factorization of degree $D$ polynomials $g \in \mathbb{F}\langle x, y\rangle$, where the algorithm takes a blackbox for $g$ and outputs black-boxes for the irreducible factors of some factorization of $g$ in time $\operatorname{poly}(D)$. Then, given a black-box for a degree $D n$-variate polynomial $f \in \mathbb{F}\langle X\rangle$ as input, we require that the reduction transforms it into a black-box of a bivariate polynomial $g \in \mathbb{F}\langle x, y\rangle$, and from the output black-boxes of $g$ 's irreducible factors, the reduction has to efficiently recover black-boxes for the corresponding irreducible factors of $f$.

[^4]Lemma 3.12. Given as input a black-box for the polynomial $\varphi(g) \in \mathbb{F}\{x, y\}$, where $g \in \mathbb{F}\langle X\rangle$ is a degree d polynomial, $X=\left\{x_{1}, x_{2}, \ldots, x_{n}\right\}$, with matrix substitutions for $x$ and $y$ computed in deterministic polynomial-time time we can obtain a black-box for the polynomial $g \in \mathbb{F}\langle X\rangle$.

Proof. The proof of Lemma 3.6 already implies this because the matrices $M_{x}$ and $M_{y}$ described there do not require $\varphi(g)$ to be given in white-box as circuit or ABP. Thus, the black-box for $\varphi(g)$ yields a black-box for $g$ by accessing the $\left(q_{0}, q_{f}\right)^{t h}$ entry of the matrix output $\varphi(g)\left(M_{x}, M_{y}\right)$.

As a consequence we obtain the claimed reduction from multivariate factorization to bivariate factorization in the black-box setting as well.

Theorem 3.13. The problem of computing a complete factorization of $f \in \mathbb{F}\langle X\rangle$ given by black-box is deterministic polynomial-time reducible to the problem of black-box computation of a complete factorization of polynomials in $\mathbb{F}\langle x, y\rangle$.

Proof. Given a black-box for $f$ we obtain a black-box for $\varphi(f)$ applying Lemma 3.3. Then, given a complete factorization

$$
\varphi(f)=f_{1}^{\prime} \cdot f_{2}^{\prime} \cdots f_{r}^{\prime}
$$

where each factor $f_{i}^{\prime}$ is output by a black-box for it, by Lemma 3.12 we can obtain black-boxes for each $f_{i}$. This yields a complete factorization $f=f_{1} \cdot f_{2} \cdots f_{r}$ of $f$ where the factors are given by black-box.

## 4 Factorizing $4 \times 4$ linear matrices over $\mathbb{Q}$

We have shown in Section 3 that multivariate noncommutative polynomial factorization is efficiently reducible to the bivariate case. Suppose $f \in \mathbb{F}\langle x, y\rangle$ is a bivariate polynomial given by a formula of size $s$. Applying Higman linearization [6], as done in [1], we can transform the problem to factorization of bivariate linear matrices $A_{0}+A_{1} x+A_{2} y$, where the matrices have size bounded by $2 s$. In [1] the problem of factorizing an $n$-variate polynomial $f \in \mathbb{F}\langle X\rangle$ given by a formula was solved in two steps when $\mathbb{F}$ is a finite field: (i) Transform $f$ to a linear matrix $L$ and factorize $L$ into irreducible factors by reducing it to the common invariant subspace problem, and (ii) extract the factors of $f$ from the factors of $L$. This approach does not work for $\mathbb{F}=\mathbb{Q}$ because the common invariant subspace problem for matrices over $\mathbb{Q}$ is shown by Ronyai [12] to be at least as hard as factoring square-free integers.

In this section we show that even for $4 \times 4$ bivariate linear matrices factorization remains at least as hard as factoring square-free integers. Thus, efficient polynomial factorization over $\mathbb{Q}$ remains elusive even for bivariate polynomials. The proof is based on Ronyai's aforementioned result.

Definition 4.1 (generalized quaternion algebra). Let $\alpha, \beta \in Q$ be nonzero rationals. The generalized quaternion algebra $H(\alpha, \beta)$ is the 4-dimensional algebra over $\mathbb{Q}$ generated by elements $1, u, v, u v$ where the rules for multiplication in $H(\alpha, \beta)$ are given by $u^{2}=\alpha, v^{2}=\beta$, and $u v=-v u$.

A simple algebra $\mathcal{A}$ over a field $\mathbb{F}$ is an algebra that has no nontrivial two-sided ideal. The center $C$ of algebra $\mathcal{A}$ is the subalgebra consisting of all elements of $\mathcal{A}$ that commute with every element of $\mathcal{A}$.

Fact 4.2. For any nonzero $\alpha, \beta \in \mathbb{Q}$, the algebra $H(\alpha, \beta)$ is a simple algebra with center $\mathbb{Q}$.

Furthermore, it follows from general theory [11, Chapter 1.6] that
Fact 4.3. The algebra $H(\alpha, \beta)$ is either a division algebra (which means no zero divisors in it) or is isomorphic to the algebra of $2 \times 2$ matrices over $\mathbb{Q}$ (which means it has zero divisors).

The 4-dimensional algebra $H(\alpha, \beta)$ can be represented as an algebra of $4 \times 4$ matrices over $\mathbb{Q}$, which is the regular representation. It is easy to see that the matrix corresponding to 1 is $I_{4}$, and the matrices $M_{u}$ and $M_{v}$ corresponding to $u$ and $v$ are

$$
\begin{align*}
M_{u} & =\left[\begin{array}{cccc}
0 & 1 & 0 & 0 \\
\alpha & 0 & 0 & 0 \\
0 & 0 & 0 & 1 \\
0 & 0 & \alpha & 0
\end{array}\right]  \tag{2}\\
M_{v} & =\left[\begin{array}{cccc}
0 & 0 & 1 & 0 \\
0 & 0 & 0 & -1 \\
\beta & 0 & 0 & 0 \\
0 & -\beta & 0 & 0
\end{array}\right] \tag{3}
\end{align*}
$$

We next observe that factorizing $4 \times 4$ bivariate linear matrices is at least as hard as finding zero divisors in generalized quaternion algebras.

Theorem 4.4. Finding zero divisors in an input quaternion algebra $H(\alpha, \beta)$ is polynomial-time reducible to factorizing $4 \times 4$ bivariate linear matrices $A_{0}+A_{1} x+A_{2} y$, where each scalar matrix $A_{i}$ is in $\mathcal{M}_{4}(\mathbb{Q})$.

Proof. Let $H(\alpha, \beta)$ be the given generalized quaternion algebra. Then

$$
H(\alpha, \beta)=\left\{a_{0}+a_{1} u+a_{2} v+a_{3} u v \mid a_{i} \in \mathbb{Q}\right\},
$$

where $u^{2}=\alpha, v^{2}=\beta$, and $u v=-v u$ defines the algebra multiplication.
It is well-known (see e.g. Pierce's book [11, Chapter 1.6]) that the algebra $H(\alpha, \beta)$ is simple (that is, it has no nontrivial 2-sided ideals) with center $\mathbb{Q}$. Furthermore, it is either a division algebra (which means there are no zero divisors in it) or it is isomorphic to the algebra $\mathcal{M}_{2}(\mathbb{Q})$ of $2 \times 2$ matrices over $\mathbb{Q}$ (which has zero divisors).

We now consider factorizations of the $4 \times 4$ linear matrix $I_{4}+M_{u} x+M_{v} y$, where matrices $M_{u}$ and $M_{v}$ are defined in Equations 2] and 3.

Claim. The linear matrix $I_{4}+M_{u} x+M_{v} y$ is irreducible if and only if the quaternion algebra is a division algebra.
Proof of Claim. Suppose the linear matrix $L=I_{4}+M_{u} x+M_{v} y$ has a nontrivial factorization

$$
L=I_{4}+M_{u} x+M_{v} y=F G .
$$

That means neither $F$ nor $G$ is a scalar matrix. By a theorem of Cohn [6, Theorem 5.8.8], there are invertible scalar matrices $P$ and $Q$ in $\mathcal{M}_{4}(\mathbb{Q})$ such that

$$
P L Q=\left[\begin{array}{cc}
A & 0  \tag{4}\\
D & B
\end{array}\right]
$$

Remark 4.5. To apply Cohn's theorem we need to have matrix $L$ to be monic (that is the matrix $\left[M_{u} \mid M_{v}\right]$ has full row rank and the matrix $\left[M_{u}^{T} \mid M_{v}^{T}\right]^{T}$ has full column rank). The monicity is ensured for $L$ as matrices $M_{u}$ and $M_{v}$ are full rank matrices.

Putting $x=y=0$ we observe that

$$
P Q=\left[\begin{array}{cc}
A_{0} & 0 \\
D_{0} & B_{0}
\end{array}\right]
$$

where $A_{0}, B_{0}$ and $D_{0}$ are scalar matrices. As $P$ and $Q$ are invertible, it following that both $A_{0}$ and $B_{0}$ are invertible matrices. Hence we have

$$
P L P^{-1}=\left[\begin{array}{cc}
A & 0 \\
D & B
\end{array}\right] \cdot\left[\begin{array}{cc}
A_{0} & 0 \\
D_{0} & B_{0}
\end{array}\right]^{-1}=\left[\begin{array}{cc}
A^{\prime} & 0 \\
D^{\prime} & B^{\prime}
\end{array}\right]
$$

where $A^{\prime}, B^{\prime}$ and $D^{\prime}$ are also linear matrices. We now recall that the matrices $I_{4}, M_{u}$ and $M_{v}$ are the matrix representation of the elements $1, u, v \in H(\alpha, \beta)$ w.r.t. the basis $\{1, u, v, u v\}$ is the basis of $H(\alpha, \beta)$. Treating $P$ as a basis change matrix, the above equation yields a new basis $\left\{w_{1}, w_{2}, w_{3}, w_{4}\right\}$ of $H(\alpha, \beta)$. Let $\operatorname{dim}\left(A^{\prime}\right)=k$. Then $1 \leq \operatorname{dim}\left(A^{\prime}\right) \leq 3$ and the vectors $w_{1}, \ldots, w_{k}$ spans a $k$-dimensional subspace $W \subset H(\alpha, \beta)$ that is a common invariant subspace for the matrices $I_{4}, M_{u}, M_{v}$ and $M_{u v}$. In other words, the subspace $W$ is preserved under left multiplication by $u$ and $v$. We can assume, without loss of generality, that $w_{1} \neq 1$ : if $k>1$ then clearly we can assume this. If $k=1$ notice that $w_{1}=1$ is impossible because the subspace $W$ is not preserved under left multiplication by $u$ or $v$. Then the four elements $w_{1}, u w_{1}, v w_{1}, u v w_{1}$ are all in $W$ and hence linearly dependent. Thus for some nontrivial linear combination

$$
\gamma_{0} w_{1}+\gamma_{1} u w_{1}+\gamma_{2} v w_{1}+\gamma_{3} u v w_{1}=0 .
$$

which means $\left(\gamma_{0}+\gamma_{1} u+\gamma_{2} v+\gamma_{3} u v\right) \times w_{1}=0$. Hence $w_{1}$ is a zero divisor in $H(\alpha, \beta)$.
Conversely, if $z \in H(\alpha, \beta)$ is a zero divisor then the we can see that the left ideal

$$
J=\{x z \mid x \in H(\alpha, \beta)\}
$$

is a proper subspace of $H(\alpha, \beta)$ that is invariant under $M_{u}$ and $M_{v}$. Then, applying Cohn's theorem [6. Theorem 5.8.8], we can obtain invertible scalar matrices $P$ and $Q$ such that Equation 4 holds which yields the factorization

$$
P L Q=\left[\begin{array}{cc}
A & 0 \\
D & B
\end{array}\right]=\left[\begin{array}{cc}
A & 0 \\
0 & I
\end{array}\right] \cdot\left[\begin{array}{cc}
I & 0 \\
D & I
\end{array}\right] \cdot\left[\begin{array}{cc}
I & 0 \\
0 & B
\end{array}\right] .
$$

To complete the reduction, notice that if $I_{4}+M_{u} x+M_{v} y$ is irreducible then $H(\alpha, \beta)$ is a division algebra. On the other hand, if we are given a nontrivial factorization $I_{4}+M_{u} x+M_{v} y=F G$ then, analyzing the proof of Cohn's theorem [6, Theorem 5.8.8] (also see [1] for details), by suitable row and column operations we can compute in polynomial time the invertible scalar matrices $P$ and $Q$ from the factors $F$ and $G$. Hence, by the proof of the above claim, we can efficiently compute a zero divisor $w_{1}$ in $H(\alpha, \beta)$.

As finding zero-divisors in the quaternion algebra $H(\alpha, \beta)$ is known to be at least as hard as square-free integer factorization [12] we have the following.
Corollary 4.6. Factorizing $4 \times 4$ bivariate linear matrices over $\mathbb{Q}$ is at least as hard as factorizing square-free integers.

## 5 Factorizing $3 \times 3$ linear matrices over $\mathbb{Q}$

In this section we present a deterministic polynomial-time algorithm for factorization of $3 \times 3$ multivariate linear matrices over $\mathbb{Q}$. We start with a simple observation about linear matrix factorization in general.

Lemma 5.1. Suppose $L=I_{d}+\sum_{i=1}^{n} A_{i} x_{i}$ is a linear matrix where each $A_{i}, 0 \leq i \leq d$ is a $d \times d$ matrix over $\mathbb{Q}$. Then $L$ is irreducible if the characteristic polynomial of $A_{i}$ is irreducible over $\mathbb{Q}$ for any $i$.

Proof. For if $L$ is reducible then there is an invertible scalar matrix $P$ such that

$$
P L P^{-1}=\left[\begin{array}{cc}
A & 0 \\
D & B
\end{array}\right]
$$

which implies that

$$
P A_{i} P^{-1}=\left[\begin{array}{cc}
A_{i}^{\prime} & 0 \\
D_{i}^{\prime} & B_{i}^{\prime}
\end{array}\right],
$$

for scalar matrices $A_{i}^{\prime}, B_{i}^{\prime}$, and $D_{i}^{\prime}$. Thus, the characteristic polynomial of $A_{i}$ is the product of the characteristic polynomials of $A_{i}^{\prime}$ and $B_{i}^{\prime}$ which is a nontrivial factorization.

Theorem 5.2. There is a deterministic polynomial-time algorithm for factorization of $3 \times 3$ multivariate linear matrices over $\mathbb{Q}$.

Proof. We will first consider linear matrices of the form $L=I_{3}+\sum_{i=1}^{n} A_{i} x_{i}$, where each $A_{i} \in \mathcal{M}_{3}(\mathbb{Q})$ and the $x_{i}$ are noncommuting variables. The algorithm computes a complete factorization of $L$ into (at most three) irreducible linear matrix factors. By Cohn's theorem [6, Theorem 5.8.8], either $L$ is irreducible or there is an invertible scalar matrix $P$ such that

$$
P L P^{-1}=\left[\begin{array}{ll}
A & 0 \\
D & B
\end{array}\right] .
$$

Either $A$ or $B$ is a $1 \times 1$ matrix. If $A$ is a $1 \times 1$ matrix then corresponding to it there is a 1 dimensional common invariant subspace spanned by a vector, say $v$, for the matrices $A_{i}, 1 \leq i \leq n$. More precisely, the row vector $v^{T}$ is an eigenvector for each matrix $A_{i}$, and $v^{T} A_{i}=\lambda_{i} v^{T}$ where $\lambda_{i} \in \mathbb{Q}$ is the corresponding eigenvalue of matrix $A_{i}$ for each $i$. Likewise, if $B$ is a $1 \times 1$ matrix then there is a corresponding 1-dimensional common invariant subspace spanned by a (column) vector $u$ such that $A_{i} u=\mu_{i} u$ for eigenvalues $\mu_{i}$ of $A_{i}$. In either case, the common eigenspace is easy to compute from the characteristic polynomial of say $A_{1}$ and then verifying that it is an eigenspace for the remaining $A_{i}$ as well. This will yield the factorization

$$
P L P^{-1}=\left[\begin{array}{cc}
A & 0 \\
0 & I
\end{array}\right] \cdot\left[\begin{array}{cc}
I & 0 \\
D & I
\end{array}\right] \cdot\left[\begin{array}{cc}
I & 0 \\
0 & B
\end{array}\right]
$$

where $B$ is a $2 \times 2$ linear matrix. The problem now reduces to factorizing the linear matrix $B=I_{2}+\sum_{i=1}^{n} B_{i} x_{i}$, where $B_{i} \in \mathcal{M}_{2}(\mathbb{Q})$. A simple case analysis discussed below yields a polynomialtime algorithm for factorization of $B$.

1. If the characteristic polynomial of any $B_{i}$ is irreducible over $\mathbb{Q}$ then the linear matrix $B$ is clearly irreducible.
2. Some $B_{i}$ has two distinct eigenvalues $\lambda \neq \lambda^{\prime} \in \mathbb{Q}$ then the corresponding eigenspaces are 1-dimensional, spanned by their eigenvectors $u \neq u^{\prime}$. Then either $u$ or $u^{\prime}$ has to be an eigenvector for every $B_{j}$ (otherwise $B$ is irreducible), in which case we have a factorization of B.
3. Suppose each $B_{i}$ has only one eigenvalue $\lambda_{i}$. Then, by linear algebra, after a basis change $B_{i}$ is either of the form

$$
\left[\begin{array}{cc}
\lambda_{i} & 1 \\
0 & \lambda_{i}
\end{array}\right]
$$

in which case the eigenspace is 1-dimensional with eigenvector (10) ${ }^{T}$. We can check if this eigenspace is invariant for each $B_{j}$ or not as before. Otherwise, after basis change each

$$
B_{i}=\left[\begin{array}{cc}
\lambda_{i} & \\
0 & \lambda_{i}
\end{array}\right]
$$

which means $B_{i}=\lambda_{i} I_{2}$ for each $i$ and the factorization of $B$ is given by

$$
B=\left[\begin{array}{cc}
1+\sum_{i=1}^{n} \lambda_{i} x_{i} & 0 \\
0 & 1
\end{array}\right] \cdot\left[\begin{array}{cc}
1 & 0 \\
0 & 1+\sum_{i=1}^{n} \lambda_{i} x_{i}
\end{array}\right]
$$
