#### Abstract

We study the gonality of curves  $C$  over  $\mathbb C$  whose normalization consist of one or two copies of  $\mathbb{P}^1$ . In the first case, C is a nodal curve with  $g(C)$ nodes, and in the second case  $C$  is a so-called binary curve. In any case we show that the usual bound gon $(C) \leq \left\lfloor \frac{g(C)+3}{2} \right\rfloor$  holds if  $g(C) \geq 2$ , with equality holding generically.

### 1 Introduction

A smooth curve C is said to be k-gonal if it admits a degree-k map to  $\mathbb{P}^1$ . The gonality gon(C), that is, the minimum k such that C is k-gonal, is an important numerical invariant in the study of algebraic curves. When considering smooth curves in families, one feels the need to consider singular curves as well, since smooth curves can degenerate to singular ones.

There are a few possible ways to extend the notion of gonality to singular curves. One way is to simply take the same definition as in the smooth case, as is done in [\[16\]](#page-10-0) and [\[14\]](#page-10-1). The drawback here is that this definition does not work very well in families, since not all curves that are limits of smooth  $k$ -gonal ones have maps of degree k to  $\mathbb{P}^1$ . One solution is to consider limits of maps from smooth curves to  $\mathbb{P}^1$ . This can be done using stable maps, as in [\[1\]](#page-10-2), or using Harris and Mumford's admissible covers [\[12\]](#page-10-3). In this paper we adopt the latter point of view, as was done previously in [\[4\]](#page-10-4), where admissible covers were used to obtain bounds on the gonality of stable curves from the gonality of its components, and [\[5\]](#page-10-5), where two-component nodal curves of gonality 2 or 3 were characterized, with the simplifying hypothesis that the components are not rational.

It is worth mentioning other approaches to the problem. For instance, since a map from a smooth curve to  $\mathbb{P}^1$  is given by a linear series on the curve, one can consider Eisenbud and Harris' limit linear series introduced in [\[7\]](#page-10-6) (see for instance [\[8\]](#page-10-7) and [\[15\]](#page-10-8)). Furthermore, some authors have been working on relating the gonality of stable curves to the gonality of graphs and tropical curves (see [\[3\]](#page-10-9)).

#### 1.1 Main Results

In this paper we always work over the field of complex numbers  $\mathbb{C}$ , and we study the gonality of nodal curves C whose normalizations are one (in Subsection [3.1\)](#page-6-0) or two (in Subsection [3.2\)](#page-7-0) copies of  $\mathbb{P}^1$ . In the first case, C is an irreducible curve with  $g(C)$  nodes, and in the second case, C is a so-called binary curve.

Both types of curves have been extensively used as degeneration targets when proving results that hold generically, since they are combinatorically easier to handle. For instance, in [\[10\]](#page-10-10) the Brill-Noether theory of a general curve was studied by degenerating it to a irreducible curve of genus q with q nodes. In the same way, Prym maps we studied in [\[6\]](#page-10-11) via degeneration to binary curves. Moreover, these curves were also used as test models for results that hold for smooth curves but are yet unknown for singular ones, as in [\[2\]](#page-10-12), [\[9\]](#page-10-13) and [\[13\]](#page-10-14).

In Section [2.1](#page-1-0) we review some background, and we prove some auxiliary results on admissible covers (see Subsection [2.2\)](#page-2-0) and maps between  $\mathbb{P}^1$  (see Subsection [2.3\)](#page-5-0). In Section [3](#page-5-1) we prove the main results of the paper, which are Theorems [6](#page-6-1) and [8.](#page-9-0)

Denote by  $I_q$  (resp.  $B_q$ ) the locus of irreducible curves with g nodes in the moduli of genus-g stable curves  $\overline{M}_g$ .

Theorem. *Let* C *be an irreducible curve with* g *nodes (resp. a binary curve) having genus*  $g \geq 2$ *. Then* 

$$
\text{gon}(C) \le \left\lfloor \frac{g+3}{2} \right\rfloor,
$$

and equality holds if C is general in  $I_g$  (resp.  $B_g$ ).

## <span id="page-1-0"></span>2 Preliminaries

#### 2.1 Technical background

In this paper we always work over the field of complex numbers C.

A *curve* C is a connected, projective and reduced scheme of dimension 1 over  $\mathbb C$ . The *genus* of C is  $g(C) := h^1(C, \mathcal O_C)$ . A *subcurve* Y of C is a reduced subscheme of pure dimension 1, or equivalently, a reduced union of irreducible components of C. If  $Y \subseteq C$  is a subcurve, we say  $Y^c := \overline{C \setminus Y}$  is the *complement* of  $Y$  in  $C$ .

A *nodal curve* C is a curve with at most ordinary double points, called *nodes*. A node is said to be *separating* if there is a subcurve Y of C such that  $Y \cap Y^c = \{n\}.$  A *rational chain* is a nodal curve of genus 0. We remark that a curve is a rational chain if and only if its nodes are all separating and its components are all rational.

Let g and n be non negative integers such that  $2g - 2 + n > 0$ . A n-pointed *stable curve of genus* g is a curve C of genus g together with n distinct *marked points*  $p_1, \ldots, p_n \in C$  such that for every smooth rational component E of C,

the number of points in the intersection  $E \cap E^c$  plus the number of indices i such that  $p_i$  lies on  $E$  is at least three. A *stable curve* is a 0-pointed stable curve. We denote by  $M_q$  the *moduli space of stable curves of genus g*.

Moreover, we denote by  $M_{0,n}$  the *moduli space of n-pointed smoth curves of genus 0*. Such a pointed curve is simply  $\mathbb{P}^1$  with a choice a *n*-uple of distinct points, where two *n*-uples give the same pointed curve in  $M_{0,n}$  if there is an automorphism of  $\mathbb{P}^1$  sending one to the other. More preciselly, if  $\Delta$  is the set of *n*-uples  $(p_1, \ldots, p_n) \in (\mathbb{P}^1)^n$  such that  $n_i \neq n_j$  for all  $i \neq j$ , then there is a surjective map

<span id="page-2-1"></span>
$$
P_n := (\mathbb{P}^1)^n \setminus \Delta \to M_{0,n} \tag{1}
$$

whose fibers have dimension 3. In particular,  $\dim(M_{0,n}) = n-3$ .

#### <span id="page-2-0"></span>2.2 Gonality and admissible covers

A smooth curve is k-gonal if it admits a map of degree k to  $\mathbb{P}^1$ . A stable curve C is k-gonal if it is a limit of smooth k-gonal curves in the moduli space  $\overline{M}_q$ of stable curves. More precisely, a *smoothing* of a curve C is a proper and flat morphism  $f: \mathcal{C} \to \text{Spec}(\mathbb{C}[[t]])$  whose fibers are curves, with special fiber C and such that  $\mathcal C$  is regular. A stable curve  $C$  is then said to be  $k$ -gonal if it admits a smoothing  $f: \mathcal{C} \to S$  whose general fiber is a k-gonal smooth curve and the special fiber is C.

For the sake of completeness, we remark that some authors consider any curve to be k-gonal if it admits a degree-k map to  $\mathbb{P}^1$ . Altough this is a simpler definition, it does not necessarily work well in families.

The *gonality* of a stable curve C, denoted  $\text{gon}(C)$ , is the smallest k such that C is k-gonal. We say that C is *hyperelliptic* if  $\text{gon}(C) = 2$ . It is a well-known fact that all stable curves of genus 2 are hyperelliptic.

Alternatively, k-gonal stable curves can be characterized in terms of admissible covers. A k-sheeted admissible cover consists of a finite morphism  $\pi: C \to B$ of degree  $k$ , such that  $B$  and  $C$  are nodal curves and:

- 1.  $\pi^{-1}(B^{\text{sing}}) = C^{\text{sing}};$
- 2.  $\pi$  is simply branched away from  $C^{\text{sing}}$ , that is, over each smooth point of B there exists at most one point of C where  $\pi$  is ramified and this point has ramification index 2;
- 3. B is a stable pointed curve of genus 0, when considered with its smooth points on the branch locus of  $\pi$ ;
- 4. for every node q of B and every node  $n$  of C lying over it, the two branches of C over n map to the branches of B over q with the same ramification index.

Let  $C$  be a nodal curve. We say that a nodal curve  $C'$  is *stably equivalent* to  $C$  if  $C$  can be obtained from  $C'$  by contracting to a point some of the smooth rational components of  $C'$  meeting the other components of  $C'$  in only one or two points. In that case,  $g(C) = g(C')$  and there is a contraction map  $\tau: C' \to C$ . We say that a point  $p' \in C'$  lies over a point  $p \in C$  if  $\tau(p') = p$ .

We remark that, if C' is stably equivalent to a curve C then, by [\[4,](#page-10-4) Lemma

3.2, we can consider the smooth components of  $C$  as components of  $C'$  as well. The following result is a consequence of [\[12,](#page-10-3) Thm. 4, p. 58] and relates the notion of admissible covers to that of gonality of stable curves.

Theorem 1 (Harris-Mumford). *A stable curve* C *is* k*-gonal if and only if there* exists a k-sheeted admissible cover  $C' \rightarrow B$ , where  $C'$  is stably equivalent to  $C$ .

*Proof.* Cf. [\[11,](#page-10-15) Thm. 3.160, p. 185].

□

The next two thechnical results are similar to [\[5,](#page-10-5) Proposition 10] and will be used in Subsections [3.1](#page-6-0) and [3.2.](#page-7-0)

<span id="page-3-0"></span>**Lemma 2.** Let C be an irreducible nodal curve with nodes  $n_1, \ldots, n_\delta$ . Let  $\pi: C' \to B$  *be an admissible cover, where* C' *is stably equivalent to* C. Let  $C^{\nu}$ *be the normalization of* C *and let*  $n_j^{(1)}, n_j^{(2)} \in C^{\nu}$  *be the branches of*  $n_j$ *, for*  $j = 1, \ldots, \delta$ . Then  $C^{\nu}$  is a component of  $C^{\nu}$  and

$$
\deg(\pi) \ge \deg(\pi|_{C^{\nu}}) + \ell,
$$

where  $\ell$  is the cardinality of  $\{1 \leq j \leq \delta \mid \pi(n_j^{(1)}) \neq \pi(n_j^{(2)})\}$ .

*Proof.* By [\[4,](#page-10-4) Lemma 3.2],  $C^{\nu}$  can be considered as a component of  $C'$ . Set  $B' = \pi(C^{\nu})$  and let k' be the degree of  $\pi|_{C^{\nu}} : C^{\nu} \to B'$ .

Now, for each  $1 \leq j \leq \delta$  let  $W_j := \tau^{-1}(n_j)$ , where  $\tau: C' \to C$  is the contraction map. Then  $W_j$  is a rational subcurve of  $C'$  containing both  $n_j^{(1)}$ and  $n_j^{(2)}$  and thus  $\pi(W_j)$  contains both  $\pi(n_j^{(1)})$  and  $\pi(n_j^{(2)})$ .

If  $\pi_1(n_j^{(1)}) \neq \pi_2(n_j^{(2)})$ , since  $\pi(W_j)$  contains two distinct points  $\pi(n_j^{(1)})$  and  $\pi(n_j^{(2)})$  on B', then it must contain the entire line B'. So, for a general point  $q \in B', \pi^{-1}(q)$  contains at least one point on  $W_j$ . Therefore  $\pi^{-1}(q)$  contains  $k'$ points on  $C^{\nu}$ , counted with multiplicity, and at least one point on  $W_j$  for each  $1 \leq j \leq \delta$  such that  $\pi_1(n_j^{(1)}) \neq \pi_2(n_j^{(2)})$ , and the result is proven.  $\Box$ 

<span id="page-3-1"></span>Lemma 3. *Let* C *be a nodal curve with irreducible smooth components* C<sup>1</sup> and  $C_2$  *and nodes*  $n_1, \ldots, n_\delta$ . For  $i = 1, 2$  *let*  $n_j^{(i)}$  *be the branch of*  $n_j$  *at*  $C_i$ *,*  $for \, j = 1, \ldots, \delta.$  Let  $\pi: C' \to B$  be an admissible cover, where  $C'$  is stably *equivalent to* C*.*

- *i. If*  $\pi(C_1) \neq \pi(C_2)$  *then* deg( $\pi$ ) >  $\delta$ *.*
- *ii.* If  $\pi(C_1) = \pi(C_2)$ *, let*  $\ell$  *be the cardinality of the set*

$$
\{1 \le j \le \delta \mid \pi(n_j^{(1)}) \ne \pi(n_j^{(2)})\}.
$$

*Then*  $\deg(\pi) \geq \deg(\pi|_{C_1}) + \deg(\pi|_{C_2}) + \ell$ .

*Proof.* For each  $1 \leq j \leq \delta$  let  $W_j := \tau^{-1}(n_j)$ , where  $\tau: C' \to C$  is the contraction map. Then  $W_j$  is a rational subcurve of C' containing both  $n_j^{(1)}$  and  $n_j^{(2)}$ and thus  $\pi(W_j)$  contains both  $\pi(n_j^{(1)})$  and  $\pi(n_j^{(2)})$ . For each  $i = 1, 2$ , let  $k_i$  be the degree of  $\pi_i := \pi|_{C_i}$  and set  $B_i = \pi(C_i)$ .

First we prove (i), so assume  $B_1 \neq B_2$ . By [\[5,](#page-10-5) Lemma 9], either  $B_1 \cap B_2$  is a point or  $B_0 = B_1^c \cap B_2^c$  is a rational chain and  $B_i \cap B_0$  is a unique point. In any case, we thus determine a unique point  $q_i \in B_i$ .

For each  $1 \leq j \leq \delta$  such that  $n_j^{(i)} \neq q_i$ , the image  $\pi(W_j)$  contains  $B_i$ . Indeed,  $\pi(W_j)$  contains  $\pi(n_j^{(1)}) \in B_1$  and  $\pi(n_j^{(2)}) \in B_2$  and hence it must also contain  $q_i$ . Since  $\pi(W_j)$  contains two distinct points of  $B_i$ , namely  $\pi(n_j^{(i)})$  and  $q_i$ , it must contain the entire line  $B_i$ .

Note that there are at most  $k_i$  indexes j such that  $\pi(n_j^{(i)}) = q_i$ , that is, there at least  $\delta - k_i$  indexes j such that  $\pi(n_j^{(i)}) \neq q_i$ . Moreover, for a general point  $q \in B_i$ ,  $\pi^{-1}(q)$  contains  $k_i$  points on  $\check{C}_i$ , counted with multiplicity, and at least one pont on  $W_j$  for each  $1 \leq j \leq \delta$  such that  $\pi(n_j^{(i)}) \neq q_i$ . Hence  $deg(\pi) \geq k_i + \delta - k_i = \delta.$ 

Now we show (ii), so assume  $B_1 = B_2$ . Let  $1 \leq j \leq \delta$  be such that  $\pi_1(n_j^{(1)}) \neq \delta$  $\pi_2(n_j^{(2)})$ . Since  $\pi(W_j)$  contains two distinct points  $\pi_1(n_j^{(1)})$  and  $\pi_2(n_j^{(2)})$  on  $B_i$ , then it must contain the entire line  $B_i$ . So, for a general point  $q \in B_i$ ,  $\pi^{-1}(q)$ contains at least one point on  $W_j$ . Therefore  $\pi^{-1}(q)$  contains  $k_1$  points on  $C_1$ and  $k_2$  points on  $C_2$ , counted with multiplicity, and at least one point on  $W_j$ for each  $1 \leq j \leq \delta$  such that  $\pi_1(n_j^{(1)}) \neq \pi_2(n_j^{(2)})$ , and the result is proven.  $\Box$ 

The following result is a slight improvement upon [\[4,](#page-10-4) Proposition 3.11], and will be used in Subsection [3.2.](#page-7-0)

<span id="page-4-0"></span>Proposition 4. *Let* C *be a stable curve with* p *smooth irreducible components*  $C_1, \ldots, C_p$ . For each node  $n_j$  of C, let  $C_{j(1)}$  and  $C_{j(2)}$  be the irreducible com*ponents of* C *containing*  $n_j$  *and denote by*  $n_j^{(1)}$  *and*  $n_j^{(2)}$  *the branches of*  $n_j$  *on*  $C_{j(1)}$  and  $C_{j(2)}$ , respectively. Assume that there is a degree- $k_s$  map  $\pi_s: C_s \to \mathbb{P}^1$  $for~ each~ component~ C_s$  *of*  $C$  *such that*  $\pi_{j(1)}(n_j^{(1)}) = \pi_{j(2)}(n_j^{(2)})$  *for every node*  $n_j$ *. Then C* is  $(k_1 + \ldots + k_p)$ -gonal.

*Proof.* Let  $n_1, \ldots, n_\delta$  be the nodes of C and let

$$
Q = \{\pi_{j(1)}(n_j^{(1)}) \mid j = 1, \ldots, \delta\}.
$$

For each  $q \in Q$ , fix one  $1 \leq j(q) \leq \delta$  such that  $\pi_{j(q)(1)}(n_{j(q)}^{(1)})$  $j(q)$  = q.

Let  $J = \{1, ..., \delta\} \setminus \{j(q) | q \in Q\}$  and let  $C_J$  be the curve obtained by normalizing C at the nodes  $n_j$  such that  $j \in J$ . Note that  $C_J$  may be disconnected. However, applying [\[4,](#page-10-4) Proposition 3.11] to  $C_1, \ldots, C_p$  and the nodes  $n_{j(q)}$  for  $q \in Q$ , we obtain a finite map  $\pi'_J: C'_J \to B$  of degree  $k_1 + \ldots + k_p$ , where  $C'_J$ is stably equivalent to  $C_J$ , satisfying conditions 1 to 4 of the definition of an admissible covering. By construction,  $\pi'_J|_{C_s} = \pi_s$  for every component  $C_s$  of  $C$ .

Furthermore, it is easy to see that [\[4,](#page-10-4) Proposition 3.4] can be applied to a map such as  $\pi_J$ , even if  $C'_J$  is not connected. We thus proceed in the following manner. Write  $J = \{j_1, \ldots, j_r\}$  and for each  $\ell = 1, \ldots, r$  let  $C(\ell)$  be the curve obtained by normalizing C at the nodes  $n_{j_{\ell}}, \ldots, n_{j_r}$ , and let  $C(r+1) = C$ . We will show by induction that for every  $1 \leq \ell \leq r+1$  there is a finite map  $\pi'_{\ell}$  $\mathcal{L}'_e: C'(\ell) \to B_\ell$  of degree  $k_1 + \ldots + k_p$  satisfying conditions 1 to 4 of the definition of an admissible covering, and such that  $C'(\ell)$  is stably equivalent to  $C(\ell)$  and  $\pi'_{\ell}$  $C_s$  =  $\pi_s$  for every component  $C_s$  of C. Note that  $\pi'_J$  satisfies the statement for  $\ell = 1$ .

Assume that the statement holds for  $\ell - 1$ . Choose points  $n'^{(1)}_{j_\ell}$  and  $n'^{(2)}_{j_\ell}$ on  $C'(\ell-1)$  lying over  $n_{j_{\ell}}^{(1)}$  and  $n_{j_{\ell}}^{(2)}$ , respectively, such that  $\pi'_{\ell-1}(n'_{j_{\ell}}^{(1)}) =$  $\pi'_{\ell-1}(n'^{(2)}_{j_{\ell}})$ . Then [\[4,](#page-10-4) Theorem 3.4 (b)] gives the required admissible cover  $\pi'_{\ell}$  $_{\ell}^{\prime}$  as stated.

 $\Box$ 

The case  $\ell = r + 1$  shows that C is  $(k_1 + \ldots + k_n)$ -gonal.

# <span id="page-5-0"></span>2.3 Maps between  $\mathbb{P}^1$

In the following section we will study the gonality of nodal curves whose nornalizations are one or two copies of  $\mathbb{P}^1$ . For that end, we will first examine endomorphisms of  $\mathbb{P}^1$ .

Recall that set of non-constant morphisms  $\varphi: \mathbb{P}^1 \to \mathbb{P}^1$  of degree at most k can be identified with the Grassmanian  $\mathcal{G}_k := Gr(2, H^0(\mathbb{P}^1, \mathcal{O}_{\mathbb{P}^1}(k)))$  of 2dimensional subspaces of  $H^0(\mathbb{P}^1, \mathcal{O}_{\mathbb{P}^1}(k))$ . Indeed, such a morphism corresponds to a linear system of degree  $k$  and (projective) dimension 1, which, up to change of projective coordinates, corresponds to a linear subspaces of  $H^0(\mathbb{P}^1, \mathcal{O}_{\mathbb{P}^1}(k))$ of dimension 2. Since  $H^0(\mathbb{P}^1, \mathcal{O}_{\mathbb{P}^1}(k))$  is a vector space of dimension  $k+1$ , we get in particular that  $\dim(\mathcal{G}_k) = 2k - 2$ .

<span id="page-5-2"></span>**Lemma 5.** Let  $k, \ell \geq 1$  be integers such that  $\ell \leq 2k - 2$  and let  $n_1^{(i)}, \ldots, n_\ell^{(i)} \in$  $\mathbb{P}^1$ *, for*  $i = 1, 2$ *.* 

- *i.* There exists  $\varphi \in \mathcal{G}_k$  such that  $\varphi(n_j^{(1)}) = n_j^{(2)}$  for every  $j = 1, \ldots, \ell$ .
- *ii.* There exists  $\varphi \in \mathcal{G}_k$  such that  $\varphi(n_j^{(1)}) = \varphi(n_j^{(2)})$  for every  $j = 1, \ldots, \ell$ .

*Proof.* For  $j = 1, ..., \ell$  we let  $V_j$  (resp.  $W_j$ ) be the set of  $\varphi \in \mathcal{G}_k$  such that  $\varphi(n_j^{(1)}) = n_j^{(2)}$  (resp.  $\varphi(n_j^{(1)}) = \varphi(n_j^{(2)})$ ). Then  $V_j$  (resp.  $W_j$ ) is a hyperplane (resp. quadric hypersurface) in  $\mathcal{G}_k$ . Since  $\ell \leq \dim(\mathcal{G}_k)$ , the intersection  $V_1 \cap$  $\cdots \cap V_{\ell}$  (resp.  $W_1 \cap \cdots \cap W_{\ell}$ ) is non-empty and any point on this intersection gives the desired  $\varphi$ , thus showing (i) (resp. (ii)).  $\Box$ 

# <span id="page-5-1"></span>3 Results on gonality

In [\[5\]](#page-10-5), the gonality of two-component nodal curves is studied, focusing on the case where both components are non-rational. In this work we study the case of nodal curves whose normalization are one (Subsection [3.1\)](#page-6-0) or two (Subsection [3.2\)](#page-7-0) copies of  $\mathbb{P}^1$ .

#### <span id="page-6-0"></span>3.1 Irreducible curves of genus q with q nodes

In this subsection we study the gonality of irreducible curves C having  $q(C)$ nodes. We note that the normalization of such a curve is  $\mathbb{P}^1$ . Indeed, the curve C is obtained from  $\mathbb{P}^1$  by identifying  $g(C)$  pairs of distinct points on  $\mathbb{P}^1$ .

An irreducible curve of genus 3 with 3 nodes.

<span id="page-6-1"></span>Denote by  $I_g$  the locus in  $\overline{M}_g$  of irreducible curves of genus g with g nodes. **Theorem 6.** Let C be an irreducible curve with  $g(C)$  nodes. Then

$$
\text{gon}(C) \le \left\lceil \frac{g(C) + 3}{2} \right\rceil
$$

and equality holds if  $C$  is general in  $I_q$ .

*Proof.* Let C be an irreducible curve of genus  $g = g(C)$  and nodes  $n_1, \ldots, n_g$ . Then the branches of the nodes give two g-uples of points  $\underline{n}^{(i)} = (n_1^{(i)}, \ldots, n_g^{(i)}) \in$  $(\mathbb{P}^1)^g$ , such that

<span id="page-6-2"></span>
$$
n_j^{(i)} \neq n_{j'}^{(i')}
$$
 unless  $(i, j) = (i', j')$  (2)

for  $i = 1, 2$  and  $j = 1, ..., g$ .

By Lemma [5](#page-5-2) (ii), there exists a non-constant morphism  $\varphi \colon \mathbb{P}^1 \to \mathbb{P}^1$  of degree at most  $k = \lfloor \frac{g+2}{2} \rfloor$  such that  $\varphi(n_j^{(1)}) = \varphi(n_j^{(2)})$  for every  $j = 1, \ldots, g$ . Hence, by [\[4,](#page-10-4) Corollary 3.5], C is k-gonal and  $\text{gon}(C) \le k = \lfloor \frac{g+2}{2} \rfloor = \lceil \frac{g+3}{2} \rceil$ , showing the first statement.

To show the second statement, we note that  $P := P_{2g}$  is the set of  $(\underline{n}^{(1)}, \underline{n}^{(2)}) \in$  $(\mathbb{P}^1)^g \times (\mathbb{P}^1)^g$  satisfying [\(2\)](#page-6-2) (see Subsection [2.1\)](#page-1-0). Since any  $(\underline{n}^{(1)}, \underline{n}^{(2)}) \in P$  gives

an irreducible curve of genus g with g nodes by identifying  $n_j^{(1)}$  and  $n_j^{(2)}$  for every  $j = 1, \ldots, g$ , then there is a surjective map  $\Phi \colon P \to I_g$ .

For each  $k, r \in \mathbb{N}$ , denote by  $P(k,r)$  the set of the pairs  $(\underline{n}^{(1)}, \underline{n}^{(2)})$  in P such that there exists  $I \subset \{1, \ldots, g\}$  of cardinality r and a non-constant map  $\varphi \colon \mathbb{P}^1 \to \mathbb{P}^1$  of degree at most k satisfying  $\varphi(n_j^{(1)}) = \varphi(n_j^{(2)})$  for all  $j \in I$ . Then  $P(k,r) \subset P(k+1,r)$ ,  $P(k,r)$  is closed in P and, by Lemma [5](#page-5-2) (ii), we have  $P(\lceil \frac{r+3}{2} \rceil, r) = P$  for every  $1 \le r \le g$ . Set

$$
U := P \setminus \bigcup_{r=1}^{g} P\left(\left\lceil \frac{r+3}{2} \right\rceil - 1, r\right).
$$

Since U is open and dense in P, its image  $\Phi(U)$  contains an open an dense subscheme of  $I_g$ . Let C be an irreducible curve with  $g(C) = g$  nodes corresponding to a point  $(\underline{n}^{(1)}, \underline{n}^{(2)}) \in U$ . We will show that  $\text{gon}(C) = \lceil \frac{g+3}{2} \rceil$ .

Let  $\pi: C' \to B$  be an admissible cover of degree  $k := \text{gon}(C)$ , where C' is stably equivalent to C. Restricting  $\pi$  to the normalization  $C^{\nu} = \mathbb{P}^{1}$  of C, we obtain a non-constant map  $\varphi := \pi|_{C^{\nu}}: \mathbb{P}^1 \to \mathbb{P}^1$  of degree  $k' := \deg(\varphi)$ . Let *J* be the set of  $j \in \{1, ..., g\}$  such that  $\varphi(n_j^{(1)}) \neq \varphi(n_j^{(2)})$  and let  $\ell = |J|$ . By Lemma [2,](#page-3-0) we have  $k \geq k' + \ell$ .

On the other hand, let  $\gamma$  be the cardinality of  $I := \{1, \ldots, g\} \setminus J$ , then  $\ell + \gamma = g$ . Since  $(\underline{n}^{(1)}, \underline{n}^{(2)}) \in U$ , from the existence of the degree-k' map  $\varphi$ such that  $\varphi(n_j^{(1)}) = \varphi(n_j^{(2)})$  for every  $j \in I$ , we get that  $k' \geq \lceil \frac{\gamma+3}{2} \rceil = \lceil \frac{g-\ell+3}{2} \rceil$ . Since  $k \leq \lceil \frac{g+3}{2} \rceil$ , then

$$
\left\lceil \frac{g-\ell+3}{2}\right\rceil + \ell \leq k'+\ell \leq k \leq \left\lceil \frac{g+3}{2}\right\rceil,
$$

which implies that  $\ell = 0$  and we must have  $k = \lceil \frac{g+3}{2} \rceil$ .

#### <span id="page-7-0"></span>3.2 Binary curves

A binary curve C is a nodal curve made of two smooth rational components meeting at  $g + 1$  points. Note that the genus of C is  $g(C) = g$  and its normalization is two disjoint copies of  $\mathbb{P}^1$ .

More preciselly, if  $n_1^{(i)}, \ldots, n_{g+1}^{(i)} \in \mathbb{P}^1$  are distinct points, we set  $\underline{n}^{(i)} =$  $(n_1^{(i)}, \ldots, n_{g+1}^{(i)})$ , for  $i = 1, 2$ , and we denote by  $C(\underline{n}^{(1)}, \underline{n}^{(2)})$  the binary curve obtained by gluing two copies of  $\mathbb{P}^1$  at  $n_j^{(1)}$  and  $n_j^{(2)}$  for every j.

A binary curve of genus 2.

Two binary curves  $C(\underline{n}^{(1)}, \underline{n}^{(2)})$  and  $C(\underline{m}^{(1)}, \underline{m}^{(2)})$  are isomorphic if there are isomorphisms  $\psi_i$  of  $\mathbb{P}^1$  such that  $\psi_i(n_j^{(i)}) = m_j^{(i)}$  for every  $j = 1, \ldots, n$  and  $i = 1, 2$ . Hence, if  $B_g \subset \overline{M}_g$  is the locus of binary curves of genus  $g \geq 2$ , there exists a surjective morphism with finite fibers

<span id="page-8-0"></span>
$$
M_{0,g+1} \times M_{0,g+1} \to B_g. \tag{3}
$$

**Proposition 7.** Let  $C = C(\underline{n}^{(1)}, \underline{n}^{(2)})$  be a binary curve of genus  $g \geq 2$ . Then C is hyperelliptic if and only if there exists an automorphism  $\psi \colon \mathbb{P}^1 \to \mathbb{P}^1$  such *that*  $\psi(n_j^{(1)}) = n_j^{(2)}$  *for every*  $j = 1, ..., \delta$ *.* 

*Proof.* First assume there is such an automorphism. Set  $C_1 := \mathbb{P}^1 =: C_2$  and  $\pi_1 := \psi$  and let  $\pi_2$  be the identity on  $\mathbb{P}^1$ . Then, for  $i = 1, 2, \pi_i : C_i \to \mathbb{P}^1$  are maps of degree 1 that satisfy the conditions of Proposition [4,](#page-4-0) which implies that C is 2-gonal. Since C is not rational, we have  $\text{gon}(C) = 2$ .

Now assume that C is hyperelliptic and let  $\pi: C' \to B$  be an admissible cover of degree 2 where C' is stably equivalent to C. For  $i = 1, 2$  let  $k_i$  be the degree of  $\pi_i := \pi|_{C_i}$ , then  $k_i \leq \deg(\pi) = 2$ .

Let  $B_i := \pi_i(C_i)$  for  $i = 1, 2$ . If  $B_1 \neq B_2$ , by Lemma [3,](#page-3-1) we have  $3 \leq g + 1 =$  $\delta \leq \deg(\pi) = 2$ , a contradiction. Then  $B_1 = B_2$  and, in the notation of Lemma [3,](#page-3-1) we have  $2 = \deg(\pi) \ge k_1 + k_2 + \ell$ . Hence  $k_1 = k_2 = 1$ ,  $\ell = 0$  and  $\psi := \pi_2^{-1} \circ \pi_1$ is the required automorphism of  $\mathbb{P}^1$ .  $\Box$ 

In particular, since there is always an automorphism of  $\mathbb{P}^1$  taking any set of three distinct points to another one, we see that the previous result recovers, in the case of binary curves, the already know fact that all stable curves of genus 2 are hyperelliptic.

The first part of the following result was already proved in [\[9,](#page-10-13) Lemma 5.3], with the same argument. We include a proof here, for the sake of completeness. <span id="page-9-0"></span>**Theorem 8.** Let C be a binary curve of genus  $g(C) \geq 2$ . Then

$$
\text{gon}(C) \le \left\lfloor \frac{g(C) + 3}{2} \right\rfloor
$$

and equality holds if  $C$  is general in  $B_q$ .

*Proof.* Set  $C = C(\underline{n}^{(1)}, \underline{n}^{(2)})$  and set  $g = g(C)$ . By Lemma [5](#page-5-2) (i) with  $\ell = g - 2$ , there exists a morphism  $\varphi: \mathbb{P}^1 \to \mathbb{P}^1$  of degree  $k = \lceil \frac{g}{2} \rceil$  $\frac{g}{2}$  such that  $\varphi(n_j^{(1)}) = n_j^{(2)}$ for every  $j = 1, \ldots, q - 2$ .

Now note that  $C(\underline{n}^{(1)}, \underline{n}^{(2)})$  is isomorphic to the binary curve  $C(\underline{n}^{(1)}, \underline{m}^{(2)})$ where  $m_j^{(2)} = n_j^{(2)}$  for  $j = 1, ..., g-2$  and  $m_j^{(2)} = \varphi(n_j^{(1)})$  for  $j = g-1, g, g+1$ . Hence we may assume that  $\varphi(n_j^{(1)}) = n_j^{(2)}$  for every  $j = 1, \ldots, g+1$ . Therefore, by Proposition [4](#page-4-0) applied to  $\varphi$  and the identity of  $\mathbb{P}^1$ , C is  $(k+1)$ -gonal and

$$
\text{gon}(C) \le k + 1 = \left\lceil \frac{g+2}{2} \right\rceil = \left\lfloor \frac{g+3}{2} \right\rfloor.
$$

Now we prove the second statement. As in the proof of Theorem [6,](#page-6-1) for each  $k, \gamma \in \mathbb{N}$ , we denote by  $P(k, \gamma)$  the set of the pairs  $(\underline{n}^{(1)}, \underline{n}^{(2)})$  in  $P_{g+1} \times P_{g+1}$ (see Subsection [2.1\)](#page-1-0) such that there exists  $I \subset \{1, \ldots, g+1\}$  of cardinality  $\gamma$ and, for  $i = 1, 2$ , a map  $\psi_i : \mathbb{P}^1 \to \mathbb{P}^1$  satisfying  $\psi_1(n_j^{(1)}) = \psi_2(n_j^{(2)})$  for all  $j \in I$ and such that  $\deg(\psi_1) + \deg(\psi_2)$  is at most k. Then  $P(k,\gamma) \subset P(k+1,\gamma)$ ,  $P(k,\gamma)$  is closed in  $P_{g+1} \times P_{g+1}$  and, by Lemma [5](#page-5-2) (i), we have  $P(\lfloor \frac{\gamma+2}{2} \rfloor, \gamma) = P$ for every  $\gamma \geq 4$ .

Set

$$
U:=P\setminus\bigcup_{\gamma=1}^{g+1}P\left(\left\lfloor\frac{\gamma+2}{2}\right\rfloor-1,\gamma\right)
$$

and note that U is open and dense in  $P_{g+1} \times P_{g+1}$ . If  $\Phi: P_{g+1} \times P_{g+1} \to M_{0,g+1} \times$  $M_{0,q+1} \to B_q$  is the composition of the maps [\(1\)](#page-2-1) and [\(3\)](#page-8-0), then the image  $\Phi(U)$ contains an open dense subscheme of  $B<sub>q</sub>$ . Let C be a binary curve of genus g corresponding to a point  $(\underline{n}^{(1)}, \underline{n}^{(2)}) \in U$ . We will show that  $\text{gon}(C) = \lfloor \frac{g+3}{2} \rfloor$ .

Let  $\pi: C' \to B$  be an admissible cover of degree  $k := \text{gon}(C)$ , where  $C'$  is stably equivalent to C. By the first part of the result, we have  $k \leq \lfloor \frac{g+3}{2} \rfloor < g+1$ . Restricting  $\pi$  to the components  $C_i = \mathbb{P}^1$  of C, we obtain maps  $\psi_i := \pi|_{C_i}: \mathbb{P}^1 \to$  $\mathbb{P}^1$  of degree  $k_i := \deg(\psi_i)$ . Let J be the set of  $j \in \{1, ..., g+1\}$  such that  $\psi_1(n_j^{(1)}) \neq \psi_2(n_j^{(2)})$  and let  $\ell = |J|$ . By Lemma [3,](#page-3-1) we have  $\pi(C_1) = \pi(C_2)$  and thus  $k \geq k_1 + k_2 + \ell$ .

On the other hand, let  $\gamma$  be the cardinality of  $I := \{1, \ldots, g+1\} \setminus J$ , then  $\gamma = g + 1 - \ell$ . Since  $(\underline{n}^{(1)}, \underline{n}^{(2)}) \in U$ , from the existence of  $\psi_1$  and  $\psi_2$  such that  $\psi_1(n_j^{(1)}) = \psi_2(n_j^{(2)})$  for every  $j \in I$ , we get that  $k_1 + k_2 \geq \lfloor \frac{\gamma+2}{2} \rfloor = \lfloor \frac{g+3-\ell}{2} \rfloor$ . Since by Proposition ?? we have  $k \leq \lfloor \frac{g+3}{2} \rfloor$ , then

$$
\left\lfloor \frac{g+3+\ell}{2} \right\rfloor = \left\lfloor \frac{g+3-\ell}{2} \right\rfloor + \ell \le k_1 + k_2 + \ell \le k \le \left\lfloor \frac{g+3}{2} \right\rfloor
$$
\nimplies that  $\ell = 0$ . Thus  $\alpha = a + 1$  and  $k = \lfloor \frac{g+3}{2} \rfloor$ .

which implies that  $\ell = 0$ . Thus  $\gamma = g + 1$  and  $k = \lfloor \frac{g+3}{2} \rfloor$ .

 $\Box$
