Abstract— This paper presents a prescribed performance-based tracking control strategy for the atmospheric reentry flight of space vehicles subject to rapid maneuvers during flight mission. A time-triggered non-monotonic performance funnel is proposed with the aim of constraints violation avoidance in the case of sudden changes of the reference trajectory. Compared with traditional prescribed performance control methods, the novel funnel boundary is adaptive with respect to the reference path and is capable of achieving stability under disturbances. A recursive control structure is introduced which does not require any knowledge of specific system parameters. By a stability analysis we show that the tracking error evolves within the prescribed error margin under a condition which represents a trade-off between the reference signal and the performance funnel. The effectiveness of the proposed control scheme is verified by simulations.

aerospace industry and have received a large amount of attention during the last decade. Trajectory tracking strategies for reentry vehicles (RVs), characterized by high flight velocity, short response time and large envelope advantages, have long been considered as a hot research area due to its extensive applications in engineering [1]-[4]. Maneuvering flight has stimulated extensive research in the areas of evasion, pursuit and obstacle avoidance for missions achievement [5]-[8]. Commonly, the main objective of maneuvering flight control is stability and robustness of the system and to provide the stabilization capabilities in RV tracking either on-line or for off-line planned reference trajectories. Some widespread control approaches, including PID [9], sliding mode control [10], backstepping control [11], adaptive control [12]-[13] and intelligent algorithms [14]-[15], are the popular choice owing to their simplicity and effectiveness in RV tracking problems. However, apart from the steady state characteristics, also the transient behavior must be taken into account for a successful mission. As RVs travel at very high velocities, the aforementioned control methods, which only focus on the steady state behavior, are not applicable in this context. Although those results demonstrated that the tracking objective can be successfully accomplished, it remains an open issue how to guarantee its high speed convergence, minimum accuracy and small overshoot.

To resolve these drawbacks, control algorithms for constraining the transient performance are flourishing during the past few decades, and two different approaches have been developed. Prescribed performance control (PPC) has been proposed in [16]-[18] and is regarded as a representative nowadays. It relies on an error transformation, which is designed to transform the original output error restrictions into an equivalent interval one. Since its universal control structure, PPC has been thoroughly investigated in combination with unconstrained control methods like backstepping and sliding mode control. Funnel control (FC) is the second control mechanism for guaranteeing a prescribed performance of the tracking error [19]-[23] by introducing a time-varying high-gain feedback in the control law. If the error tends towards the funnel boundary, the gain increases so that the error is kept inside the performance funnel. Both PPC and FC have already been investigated for the control algorithm design for RVs with a focus on the transient performance [24]-[26]. Notice that almost all funnel boundaries selected in works on funnel control are monotonically decreasing functions, although the theory guarantees the stability of the closed-loop system for a vast variety of non-monotonic funnel boundaries. It turns out that for flight maneuvering, non-monotonic funnel boundaries are more suitable. Sudden flight maneuvers may lead to a drastic increase of the control effort or even drive the tracking error across the funnel boundary, resulting in closed-loop system instability.

Considering the various demands of trajectory tracking for RVs during different phases, a control law which adapts itself to the prescribed boundary function is re-

<sup>0018-9251 © 2020</sup> IEEE

quired to guarantee the transient behavior in flight maneuvering. Therefore, a time triggered non-monotonic funnel boundary is proposed in this paper. Using a priori information of the reference trajectory, we design a boundary function which is widened during critical phases, e.g. in the case of sudden course corrections. In this way, peaks in the control input signal are avoided. Additionally, disturbances (such as noises, uncertainties or unmodeled dynamics) are taken into account, as they might have a detrimental effect on the system's performance. A significant challenge in stability analysis is imposed by the dynamics of the RV, where the flight altitude (which is the system output) is influenced by the deflection angle only in a saturated way (via a sin function). Therefore, arbitrary instantaneous changes of the altitude are not possible. Any prescribed trajectory can only be tracked up to a certain accuracy, i.e., there is a trade-off between the derivative of the reference and the funnel boundary function. To the best of our knowledge, this is the first work where such a trade-off is found for RV tracking problems with guaranteed prescribed performance.

Focusing on the issues mentioned above, the main contributions of this paper are summarized as follows.

- A recursive funnel control structure with low complexity is adopted to avoid the requirement of a priori knowledge of system parameters.
- We design a robust funnel control law with time triggered non-monotonic funnel boundary for flight maneuvering with guaranteed transient performance under disturbances.
- We derive a condition representing a trade-off between the reference trajectory and the funnel boundaries, under which the RV is amenable to the proposed funnel control law.

The remainder of this paper is organized as follows. The dynamic model of the RV in yaw channel is presented in Section II, together with the proposed funnel boundary and the control objective. In Section III we state the funnel-based control law design and provide the stability analysis. Simulation results are given in Section IV and Section V finally concludes this article.

# II. PROBLEM FORMULATION

# A. RV Dynamics

Considering horizontal lateral maneuvers with constant velocity, the simplified model of a RV in yaw channel is established in [27], [28] and is of the form

$$\dot{z}_{h}(t) = -V\sin\left(\psi_{V}(t)\right) + \Delta_{0}(t) \tag{1}$$

$$\dot{\psi}_V(t) = -\frac{1}{mV}Z(t) + \Delta_1(t) \tag{2}$$

$$\dot{\psi}(t) = \omega_y(t) + \Delta_2(t) \tag{3}$$

$$\dot{\omega}_y(t) = \frac{M_y(t)}{J_y} + \Delta_3(t) \tag{4}$$

$$\beta(t) = \psi(t) - \psi_V(t) \tag{5}$$

where  $z_h$  is the flight altitude, m is the mass, V is the flight speed,  $\psi_V$ ,  $\psi$ ,  $\beta$  represent the deflection angle, yaw angle and sideslip angle,  $\omega_y$  is the yaw rate,  $J_y$  denotes the yaw rotational inertia and  $\Delta_i$  (i = 0, 1, 2, 3) are bounded disturbances. The functions Z and  $M_y$  are the aerodynamic force and moment in yaw channel, expressed by  $Z(t) = \bar{q}S(c_z^{\alpha}\alpha + c_z^{\beta}\beta(t) + c_z^0)$ ,  $M_y(t) = \bar{q}Sl(c_M^{\alpha}\alpha + c_M^{\beta}\beta(t) + c_M^{\delta_y}\delta_y(t) + c_M^0)$ , where  $\alpha$  is the angle of attack,  $\delta_y$  represents the rudder angle,  $\bar{q}$  is the dynamic pressure, S and l are the reference area and aerodynamic chord of the RV, and  $c_z^i$  and  $c_M^j$   $(i = \alpha, \beta, 0, j = \alpha, \beta, \delta_y, 0)$  are the aerodynamic coefficients for force and moment, respectively. The rudder angle  $\delta_y$  can be manipulated and serves as the control input.

We introduce the variables  $y_0(t) = z_h(t)$ ,  $y_1(t) = \psi_V(t)$ ,  $y_2(t) = \beta(t) = \psi(t) - \psi_V(t)$ ,  $y_3(t) = \omega_y(t)$  and the control input  $u(t) = \delta_y(t)$  to rewrite the dynamic model (1)–(5) in the form

$$\dot{y}_0(t) = -V\sin(y_1(t)) + \Delta_0(t)$$
 (6)

$$\dot{y}_1(t) = -c_1 - c_2 y_2(t) + \Delta_1(t) \tag{7}$$

$$\dot{y}_2(t) = y_3(t) + c_1 + c_2 y_2(t) + \Delta_2(t) - \Delta_1(t)$$
 (8)

$$\dot{y}_3(t) = c_3 + c_4 y_2(t) + c_5 u(t) + \Delta_3(t)$$
(9)

with the constants  $c_1 = \frac{1}{mV}\bar{q}S\left(c_z^{\alpha}\alpha + c_z^{0}\right), c_2 = \frac{1}{mV}\bar{q}Sc_z^{\beta}, c_3 = \frac{1}{J_y}\bar{q}Sl\left(c_M^{\alpha}\alpha + c_M^{0}\right), c_4 = \frac{1}{J_y}\bar{q}Sc_M^{\beta}, c_5 = \frac{1}{J_y}\bar{q}Sc_M^{\delta_y}.$ 

It can be seen from the dynamics (1) that the flight altitude  $z_h$  is influenced only by the deflection angle  $\psi_V$ and that this influence is saturated by the sin function. Therefore, it is clear that it is impossible to achieve tracking of arbitrary reference signals with arbitrary prescribed performance. There must be a trade-off between the reference signal  $(\dot{z}_{h_{ref}})$  and the funnel boundary. This trade-off is formulated as condition (15) in Theorem 1.

Fig. 1. Tracking error evolution in the funnel  $\Gamma_{\varphi_i}$  (i = 0, 1, 2, 3).

#### B. Funnel Boundary

We define functions  $\varphi_i$  (i = 0, 1, 2, 3) as the reciprocal of the funnel boundary  $\bar{\rho}_i(t)$ , which describe the performance funnel  $\Gamma_{\varphi_i}$  (cf. [19]) as

$$\Gamma_{\varphi_i} := \{(t, e_i) \in \mathbb{R}_{\geq 0} \times \mathbb{R} \mid \varphi_i(t) \mid e_i \mid < 1\}.$$
(10)

The functions  $\varphi_i$  are continuously differentiable, bounded with bounded derivatives, and satisfy  $\varphi_i(t) > 0$  for all  $t \ge$  0 and  $\liminf_{t\to\infty} \varphi_i(t) > 0$ . Fig. 1 displays the reciprocal  $\bar{\rho}_i(t) = 1/\varphi_i(t)$ .

In order to avoid peaks in the control input signal due to a strongly varying reference trajectory, we employ a non-monotonic funnel boundary defined as

$$1/\varphi_{i}(t) = \bar{\rho}_{i}(t) = \frac{\bar{\rho}_{i,0}(t)}{a_{i,0}(t-t_{1})^{3} + b_{i,0}(t-t_{1})^{2}} & 0 \le t < t_{1}$$

$$a_{i,0}(t-t_{1})^{3} + b_{i,0}(t-t_{1})^{2} & t_{1} \le t < \bar{t}_{1}$$

$$+c_{i,0}(t-t_{1}) + d_{i,0} & \bar{t}_{1} \le t < t_{2}$$

$$\vdots & \vdots$$

$$a_{i,j-1}(t-t_{j})^{3} + b_{i,j-1}(t-t_{j})^{2} & t_{j} \le t < \bar{t}_{j}$$

$$+c_{i,j-1}(t-t_{j}) + d_{i,j-1} & \bar{t}_{j} \le t < t_{j+1}$$

$$\vdots$$

$$a_{i,p-1}(t-t_{p})^{3} + b_{i,p-1}(t-t_{p})^{2} & t_{p} \le t < \bar{t}_{p}$$

$$+c_{i,p-1}(t-t_{p}) + d_{i,p-1} & \bar{t}_{p} \le t$$

$$(11)$$

where  $t_j$  and  $\bar{t}_j$  (j = 1, ..., p) are the triggered time and initial time points of every phase after maneuvering,  $\bar{t}_j - t_j$  is the time range for maneuvering and p represents the number of triggered times. The polynomials in each interval of the form  $[t_j, \bar{t}_j]$  are chosen based on the current maneuver encoded in the reference trajectory, and they ensure a widening of the funnel boundary. The functions  $\bar{\rho}_{i,j}(t)$  (i = 0, 1, 2, 3, j = 1, 2, ..., p) are of the form

$$\bar{\rho}_{i,j}(t) = \left(\rho_{i,j}^0 - \rho_{i,j}^\infty\right) e^{-l_{i,j}t} + \rho_{i,j}^\infty$$
(12)

with initial funnel width  $\rho_{i,j}^0 > 0$ , required minimum exponential convergence rate  $l_{i,j} > 0$  and the maximum steady state error  $\rho_{i,j}^\infty > 0$ , respectively. In order to guarantee that  $\bar{\rho}_i$  is continuously differentiable, the parameters  $a_{i,j}, b_{i,j}, c_{i,j}, d_{i,j}$  are chosen such that  $\lim_{t \to t_j^-} \bar{\rho}_i(t) = \lim_{t \to t_j^+} \bar{\rho}_i(t), \lim_{t \to \bar{t}_j^-} \bar{\rho}_i(t) = \lim_{t \to \bar{t}_j^+} \bar{\rho}_i(t),$  $\lim_{t \to t_j^-} \dot{\rho}_i(t) = \lim_{t \to t_j^+} \dot{\rho}_i(t), \lim_{t \to \bar{t}_j^-} \dot{\rho}_i(t) = \lim_{t \to \bar{t}_j^+} \dot{\rho}_i(t)$  for  $j = 1, \dots, p$ .

The proposed funnel boundary is displayed in Fig. 1 and we stress that it is different from the monotonically decreasing boundary functions of the form (12) widely used in [18], [20], [23]. Instead, it is a time triggered mechanism with trigger time points  $t_j$ , chosen in accordance with the reference trajectory, so that the proposed funnel (11) adapts itself and is suitable for the timevarying maneuvering command of RVs. For  $t > t_p$  the novel funnel boundary converges to a neighbourhood of the origin, satisfying  $\lim_{t\to\infty} \bar{\rho}_i(t) = \rho_{i,p}^{\infty} > 0$ .

## C. Control Objective

The control objective is to design an output derivative feedback such that for any sufficiently smooth reference trajectory  $z_{h_{ref}}$ , any initial values and under the influence of disturbances, the tracking error  $z_h - z_{h_{ref}}$  evolves

Fig. 2. Funnel control structure for RV tracking issue.

within a prescribed performance funnel  $\Gamma_{\varphi_0}$  as in (10) and hence exhibits the desired transient and steady behavior. Furthermore, all signals u,  $z_h$ ,  $\psi_V$ ,  $\psi$ ,  $\beta$  and  $\omega_y$  in the closed-loop system should remain bounded.

## **III. FUNNEL CONTROLLER DESIGN**

#### A. Funnel-based control law design

Before we define the control law we introduce the following assumptions.

ASSUMPTION 1 The reference trajectory  $z_{h_{ref}}$  is known, it is four times continuously differentiable and its first four derivatives are bounded.

ASSUMPTION 2 The disturbances  $\Delta_i$  are measurable and essentially bounded with  $\|\Delta_i\|_{\infty} \leq D_i$  for known constants  $D_i \geq 0$  (i = 0, 1, 2, 3).

Assumptions 1 and 2 are reasonable and frequently used in the literature. The disturbances  $\Delta_i$  (i = 0, 1, 2, 3)involved in (1)-(5) account for uncertainties in the aerodynamic coefficients, noises and external disturbances, which are usually bounded throughout the flight process.

We define the tracking error as

$$e_0(t) = y_0(t) - z_{h_{ref}}(t) = z_h(t) - z_{h_{ref}}(t)$$

and introduce the following recursive structure

$$e_{i}(t) = y_{i}(t) - z_{h_{ref}}^{(i)}(t) + k_{i-1}(t) \,\varpi_{i-1}(t) \,, \ i = 1, 2, 3$$
(13)

where  $k_i(t) = \frac{1}{1 - \varpi_i^2(t)}$  and  $\varpi_i(t) = \varphi_i(t) e_i(t)$  for  $\varphi_i$  as in (11).

Then the funnel-based control law is given by

$$u(t) = -k_3(t) e_3(t) = -\frac{e_3(t)}{1 - \varphi_3^2(t) e_3^2(t)}$$
(14)

and the block diagram of the proposed control scheme is shown in Fig. 2. In the sequel we investigate existence of solutions of the initial value problem resulting from the application of the funnel controller (14) to the RV with dynamics (1)-(5). By a solution of (1)-(5), (14) we mean a function  $(z_h, \psi_V, \psi, \omega_y) : [0, t_f) \to \mathbb{R}^4$ ,  $t_f \in (0, \infty]$ , which is locally absolutely continuous and satisfies the initial conditions as well as the differential equations (1)-(5) for almost all  $t \in [0, t_f)$ . A solution is called maximal, if it has no right extension that is also a solution.

# B. Stability Analysis

In this part, we present the stability analysis of the proposed control law.

THEOREM 1 Consider a RV with dynamics (1)-(5), satisfying Assumptions 1-2, under the funnel control law (14). Choose funnel boundaries  $\varphi_i$  (i = 0, 1, 2, 3) as in (11) such that the initial values satisfy

$$\varphi_i(0)|e_i(0)| < 1 \quad (i = 0, 1, 2, 3).$$

Additionally, assume that the functions  $\varphi_0, \varphi_1$  and  $z_{h_{ref}}$  satisfy the following condition:

$$\exists \mu \in (0,1) \ \forall t \ge 0: \frac{|\dot{\varphi}_0(t)|}{V\varphi_0^2(t)} + \frac{1}{\varphi_1(t)} + \frac{D_0}{V} + \frac{(1+V)}{V} |\dot{z}_{h_{ref}}(t)| \le \mu.$$
(15)

Then the funnel controller (14) applied to (1)-(5) yields an initial-value problem which has a solution, every solution can be maximally extended and every maximal solution  $(z_h, \psi_V, \psi, \omega_y) : [0, t_f) \to \mathbb{R}^4$ ,  $t_f \in (0, \infty]$  has the following properties:

- global existence:  $t_f = \infty$ ;
- all errors evolve uniformly in the respective prescribed performance funnels, that is for all i = 0, 1, 2, 3 there exists  $\varepsilon_i \in (0, 1)$  such that for all  $t \ge 0$ we have  $|\varpi_i(t)| \le \varepsilon_i$ .
- all signals  $z_h$ ,  $\psi_V$ ,  $\psi$ ,  $\omega_y$ ,  $\delta_y$  and  $k_i$  (i = 0, 1, 2, 3) in the closed-loop system are bounded.

### Proof:

Before the analysis, we record that it follows from (6)-(9) that the derivatives of  $e_i(t)$  (i = 0, 1, 2, 3) can be expressed as

$$\dot{e}_0(t) = -V\sin(y_1(t)) - \dot{z}_{h_{ref}}(t) + \Delta_0(t)$$
 (16)

$$\dot{e}_{1}(t) = e_{2}(t) - k_{1}(t) \,\varpi_{1}(t) + \frac{d}{dt} \left(k_{0}(t) \,\varpi_{0}(t)\right) - (1 + c_{2})y_{2}(t) - c_{1} + \Delta_{1}(t)$$
(17)

$$\dot{e}_{2}(t) = e_{3}(t) - k_{2}(t) \,\varpi_{2}(t) + \frac{a}{dt} \left(k_{1}(t) \,\varpi_{1}(t)\right) + c_{1} + c_{2}y_{2}(t) + \Delta_{2}(t) - \Delta_{1}(t)$$
(18)

$$\dot{e}_{3}(t) = c_{5}u(t) - z_{h_{ref}}^{(4)}(t) + \frac{d}{dt}(k_{2}(t)\,\varpi_{2}(t)) + c_{3} + c_{4}y_{2}(t) + \Delta_{3}(t)$$
(19)

In the following, we will first show that a local solution exists on  $[0, t_f)$  and the tracking error evolves uniformly within the prescribed performance funnel, and we show  $t_f = \infty$  in the last step.

Step 1: To show existence of a solution of the closed-loop system, consider the functions

$$\tilde{e}_0: D_0 \to \mathbb{R}, \ (t, y_0) \mapsto y_0 - z_{h_{ref}}(t)$$
 (20)

with the set  $D_0 := \mathbb{R}_{\geq 0} \times \mathbb{R}$  and

$$\tilde{e}_{i}: D_{i} \to \mathbb{R}, \ (t, y_{0}, \dots, y_{i}) \mapsto y_{i} - z_{h_{ref}}^{(i)}(t) \\ + \frac{\varphi_{i-1}(t)\tilde{e}_{i-1}(t, y_{0}, \dots, y_{i-1})}{1 - \varphi_{i-1}^{2}(t)\tilde{e}_{i-1}^{2}(t, y_{0}, \dots, y_{i-1})}$$
(21)

with the sets

$$D_{i} := \{(t, y_{0}, \dots, y_{i}) \in D_{i-1} \times \mathbb{R} \mid \varphi_{i-1}(t) | \tilde{e}_{i-1}(t, y_{0}, \dots, y_{i}) | < 1\}, (i = 1, 2, 3), \\D_{4} := \{(t, y_{0}, \dots, y_{3}) \in D_{3} \mid \varphi_{3}(t) | \tilde{e}_{3}(t, y_{0}, \dots, y_{3}) | < 1\}.$$

$$(22)$$

Introducing  $Y(t) = (y_0(t), \dots, y_3(t))^{\top}$  and the function

$$F: D_4 \to \mathbb{R}^4, \ (t, y_0, \dots, y_3) \\ \mapsto \begin{pmatrix} -V \sin(y_1) + \Delta_0(t) \\ -c_1 - c_2 y_2 + \Delta_1(t) \\ y_3 + c_1 + c_2 y_2 + \Delta_2(t) - \Delta_1(t) \\ c_3 + c_4 y_2 + \Delta_3(t) - c_5 \frac{\varphi_3(t)\tilde{e}_3(t, y_0, \dots, y_3)}{1 - \varphi_3^2(t)\tilde{e}_3^2(t, y_0, \dots, y_3)} \end{pmatrix}$$
(23)

the closed-loop system takes the form

$$\dot{Y}(t) = F(t, Y(t)), \quad Y(0) = (y_0^0, \dots, y_3^0)^\top.$$
 (24)

Since  $(0, Y(0)) \in D_4$  and F is measurable in t, continuous in  $(y_0, \ldots, y_3)$  and locally essentially bounded, an application of Theorem B.1 from [29] yields the existence of a solution and every solution can be extended to a maximal solution  $Y : [0, t_f) \to \mathbb{R}^4$  with  $t_f \in (0, \infty]$ . Furthermore, the graph of Y is not a compact subset of  $D_4$ .

**Step 2:** We show that  $k_0$  is bounded on  $[0, t_f)$ . According to the definition of  $\varpi_0(t)$  and (16) we have

$$\dot{\varpi}_{0}(t) = \frac{\dot{\varphi}_{0}(t)}{\varphi_{0}(t)} \varpi_{0}(t) - \varphi_{0}(t) V \sin(y_{1}(t)) + \varphi_{0}(t) \left(\Delta_{0}(t) - \dot{z}_{h_{ref}}(t)\right).$$
(25)

By the mean value theorem, for each  $t \in [0, t_f)$ , there exists  $\xi(t)$  between  $-k_0(t) \varpi_0(t)$  and  $-k_0(t) \varpi_0(t) + e_1(t) + \dot{z}_{h_{ref}}(t)$  such that

$$\sin (y_1(t)) = \sin (-k_0(t) \varpi_0(t) + e_1(t) + \dot{z}_{h_{ref}}(t))$$
  
= sin (-k\_0(t) \overline{\alpha\_0}(t))  
+ (e\_1(t) + \overline{z}\_{h\_{ref}}(t)) cos(\xi(t)). (26)

Now define  $U_0(t) = \frac{1}{2}\varpi_0^2(t)$ , then from (15), (25) and (26), and invoking  $|\varpi_0(t)| < 1$  and  $|e_1(t)| < 1/\varphi_1(t)$ , we find that

$$\begin{aligned} \dot{U}_{0}(t) &= \varpi_{0}\left(t\right) \dot{\varpi}_{0}\left(t\right) \\ &= \frac{\dot{\varphi}_{0}(t)}{\varphi_{0}(t)} \varpi_{0}^{2}(t) + \varphi_{0}\left(t\right) \varpi_{0}\left(t\right) \left(-V \sin(-k_{0}(t) \varpi_{0}\left(t\right))\right) \\ &- V(e_{1}(t) + \dot{z}_{h_{ref}}(t)) \cos(\xi(t)) + \Delta_{0}(t) - \dot{z}_{h_{ref}}(t)) \\ &\leq -V\varphi_{0}(t) \sin\left(-k_{0}(t) \varpi_{0}\left(t\right)\right) \varpi_{0}\left(t\right) + \frac{|\dot{\varphi}_{0}(t)|}{\varphi_{0}(t)} \\ &+ V\varphi_{0}(t) \left(\frac{1}{\varphi_{1}(t)} + \frac{D_{0}}{V} + \frac{(1+V)}{V} |\dot{z}_{h_{ref}}(t)|\right) \\ &\leq V\varphi_{0}(t) \left(-N(-\varpi_{0}\left(t\right)) + \mu\right) \end{aligned}$$

$$(27)$$

where  $N : (-1,1) \to (-1,1)$ ,  $s \mapsto \sin\left(\frac{s}{1-s^2}\right)s$ . The function N is symmetric and satisfies N(-s) = N(s).

Choose  $\varepsilon_0 \in (0,1)$  such that  $|\varpi_0(0)| < \varepsilon_0$  and  $N(\varepsilon_0) < -\mu$ . In the following, we show that  $|\varpi_0(t)| \le \varepsilon_0$ 

for all  $t \in [0, t_f)$ . Assume there exists some  $t \in [0, t_f)$ with  $|\varpi_0(t)| > \varepsilon_0$  and define

$$\bar{t}_0 := \inf \{ t \in [0, t_f) \mid |\varpi_0(t)| > \varepsilon_0 \} > 0.$$

Since N is continuous there exists  $\eta > 0$  such that  $N(s) \leq$  $-\mu$  for all  $s \in \mathbb{R}$  with  $|s - \varepsilon_0| \leq \eta$ . By symmetry of N we also have  $N(s) \leq -\mu$  for all  $s \in \mathbb{R}$  with  $|s + \varepsilon_0| \leq \eta$ . Since  $\varpi_0$  is continuous with  $|\varpi_0(\bar{t}_0)| = \varepsilon_0$ , there exists  $\overline{t}_1 \in (\overline{t}_0, t_f)$  such that  $|\varpi_0(t)| > \varepsilon_0$  and  $|\varpi_0(\overline{t}_0) - \varpi_0(t)| < \varepsilon_0$  $\eta$  for all  $t \in (\overline{t}_0, \overline{t}_1]$ .

Let  $\sigma = \operatorname{sgn} \varpi_0(\overline{t}_0)$ , then  $\varpi_0(\overline{t}_0) = \sigma |\varpi_0(\overline{t}_0)| = \sigma \varepsilon_0$ and hence  $|\varpi_0(t) - \varpi_0(\bar{t}_0)| = |\varpi_0(t) - \sigma \varepsilon_0| \le \eta$  for all  $t \in$  $[\bar{t}_0, \bar{t}_1]$ . It follows that  $N(\varpi_0(t)) \leq -\mu$  for all  $t \in [\bar{t}_0, \bar{t}_1]$ , and hence  $U_0(t) \leq V\varphi_0(t) (N(\varpi_0(t)) + \mu) \leq 0$ , which upon integration gives  $\varepsilon_0^2 = \varpi_0(\bar{t}_0)^2 \ge \varpi_0(\bar{t}_1)^2 > \varepsilon_0^2$ , a contradiction. Hence,  $|\varpi_0(t)| \leq \varepsilon_0$  for all  $t \in [0, t_f)$  and thus  $k_0$  is bounded on  $[0, t_f)$ .

Step 3: We show that  $k_1$  is bounded on  $[0, t_f)$ . A standard procedure in funnel control is used by seeking a contradiction. For some  $\varepsilon_1 \in (0,1)$ , which we will determine later, suppose that there exists  $t_1^* \in [0, t_f)$  such that  $\varpi_1(t_1^*) > \varepsilon_1$  and define

$$t_0^* := \max\{t \in [0, t_1^*) \mid \varpi_1(t) = \varepsilon_1\}.$$

Then we find that

$$\forall t \in [t_0^*, t_1^*]: \ \varpi_1(t) \ge \varepsilon_1 \tag{28}$$

and hence

$$\forall t \in [t_0^*, t_1^*]: \ k_1(t) = \frac{1}{1 - \varpi_1^2(t)} \ge \frac{1}{1 - \varepsilon_1^2}.$$
 (29)

Define  $U_1(t) = \frac{1}{2}\varpi_1^2(t)$ , then according to (17) we have Define  $U_3(t) = \frac{1}{2}\varpi_3^2(t)$  and calculate

$$\begin{split} \dot{U}_{1}(t) &= \varpi_{1}\left(t\right)\dot{\varpi}_{1}\left(t\right) \\ &= \varpi_{1}\left(t\right)\left(\dot{\varphi}_{1}\left(t\right)e_{1}\left(t\right)+\varphi_{1}\left(t\right)\dot{e}_{1}\left(t\right)\right) \\ &= \frac{\dot{\varphi}_{1}(t)}{\varphi_{1}(t)}\varpi_{1}^{2}(t)-\varphi_{1}(t)k_{1}(t)\varpi_{1}^{2}(t)-c_{1}\varphi_{1}(t)\varpi_{1}(t) \\ &+\varphi_{1}(t)\varpi_{1}(t)\left(-c_{2}y_{2}(t)+\Delta_{1}(t)+e_{2}(t)-y_{2}(t)\right) \\ &+\varphi_{1}(t)\varpi_{1}(t)\left(1+2\varpi_{0}^{2}(t)k_{0}\left(t\right)\right)k_{0}(t)\dot{\varpi}_{0}(t). \end{split}$$

From Step 2 we have that  $k_0$  is bounded on  $t \in [0, t_f)$ . Furthermore,  $\dot{\varpi}_0$  is bounded by (25),  $|e_2(t)| < 1/\varphi_2(t)$ and  $y_2, \Delta_1, \varphi_1, \dot{\varphi}_1$  are clearly bounded as well, hence there exists an upper bound  $C_1 > 0$  such that for all  $t \in [0, t_f)$  we have

$$\frac{|\dot{\varphi}_1(t)|}{\varphi_1^2(t)} + c_1 + (1+c_2)|y_2(t)| + |\Delta_1(t)| + |e_2(t)| + (1+2\varpi_0^2(t)k_0(t))k_0(t)\dot{\varpi}_0(t) \le C_1.$$
(31)

Invoking  $|\varpi_1(t)| < 1$  we thus obtain

$$\dot{U}_1(t) \le \varphi_1(t) |\varpi_1(t)| (-k_1(t) |\varpi_1(t)| + C_1) \le 0$$
(32)

when we choose  $\varepsilon_1 \in (0,1)$  large enough so that  $\frac{\varepsilon_1}{1-\varepsilon_1^2} \geq$  $C_1$ . Upon integration over  $[t_0^*, t_1^*]$  we find that

$$\varepsilon_1^2 = \omega_1(t_0^*)^2 \ge \omega_1(t_1^*)^2 > \varepsilon_1^2,$$
 (33)

a contradiction. Hence  $|\varpi_1(t)| \leq \varepsilon_1$  for all  $t \in [0, t_f)$ , and thus  $k_1$  is bounded on  $[0, t_f]$ .

Step 4: We prove that  $k_2$  is bounded on  $[0, t_f)$ . With  $U_2(t) = \frac{1}{2}\varpi_2^2(t)$  it follows from (18) that

$$\begin{aligned} U_{2}(t) &= \varpi_{2}(t) \dot{\varpi}_{2}(t) \\ &= \varpi_{2}(t) \left( \dot{\varphi}_{2}(t) e_{2}(t) + \varphi_{2}(t) \dot{e}_{2}(t) \right) \\ &= \frac{\dot{\varphi}_{2}(t)}{\varphi_{2}(t)} \varpi_{2}^{2}(t) - \varphi_{2}(t) k_{2}(t) \varpi_{2}^{2}(t) \\ &+ \varphi_{2}(t) \varpi_{2}(t) \left( c_{1} + c_{2}y_{2}(t) + \Delta_{2}(t) - \Delta_{1}(t) + e_{3}(t) \right) \\ &+ \varphi_{2}(t) \varpi_{2}(t) \left( 1 + 2 \varpi_{1}^{2}(t) k_{1}(t) \right) k_{1}(t) \dot{\varpi}_{1}(t). \end{aligned}$$

$$(34)$$

By Step 3 it follows that  $k_1$  is bounded on  $t \in$  $[0, t_f)$ . Furthermore,  $|e_3(t)| < 1/\varphi_3(t)$  and  $\varpi_1, \dot{\varpi}_1,$  $y_2, \Delta_1, \Delta_2, \varphi_2, \dot{\varphi}_2$  are bounded on  $[0, t_f)$ , hence there exists a constant  $C_2 > 0$  satisfying

$$\frac{|\dot{\varphi}_{2}(t)|}{\varphi_{2}^{2}(t)} + c_{1} + c_{2}|y_{2}(t)| + |\Delta_{2}(t)| + |\Delta_{1}(t)| + |e_{3}(t)| + (1 + 2\omega_{1}^{2}(t)k_{1}(t))k_{1}(t)|\dot{\omega}_{1}(t)| \leq C_{2}.$$
(35)

Invoking  $|\varpi_2(t)| < 1$  we thus obtain

$$\dot{U}_2(t) \le \varphi_2(t) |\varpi_2(t)| (-k_2(t) |\varpi_2(t)| + C_2)$$
 (36)

and with a similar argument as in Step 3 it can be shown that  $k_2$  is bounded on  $[0, t_f)$ .

Step 5: We show that  $k_3$  is bounded on  $[0, t_f)$ . To this end, we substitute (14) into (19), yielding

$$\dot{e}_{3}(t) = -c_{5}k_{3}(t)\frac{\varpi_{3}(t)}{\varphi_{3}(t)} - z_{h_{ref}}^{(4)}(t) + \frac{d}{dt}(k_{2}(t)\varpi_{2}(t)) + c_{3} + c_{4}y_{2}(t) + \Delta_{3}(t)$$
(37)

$$\begin{split} \dot{U}_{3}(t) &= \varpi_{3}(t) \dot{\varpi}_{3}(t) \\ &= \varpi_{3}(t) (\dot{\varphi}_{3}(t) e_{3}(t) + \varphi_{3}(t) \dot{e}_{3}(t)) \\ &= -c_{5}k_{3}(t) \varpi_{3}^{2}(t) + \frac{\dot{\varphi}_{3}(t)}{\varphi_{3}(t)} \varpi_{3}^{2}(t) \\ &+ \varpi_{3}(t) \varphi_{3}(t) \left( -z_{h_{ref}}^{(4)}(t) + c_{3} + c_{4}y_{2}(t) + \Delta_{3}(t) \right) \\ &+ \varpi_{3}(t) \varphi_{3}(t) \left( 1 + 2\varpi_{2}^{2}(t)k_{2}(t) \right) k_{2}(t) \dot{\varpi}_{2}(t). \end{split}$$
(38)

From Step 4 we find that  $k_2$  is bounded on  $[0, t_f)$ . Because of  $|e_3(t)| < 1/\varphi_3(t)$  and boundedness of  $\varpi_2$ ,  $\dot{\varpi}_2, y_2, \Delta_3, \varphi_3, \dot{\varphi}_3, z_{h_{ref}}^{(4)}$  on  $[0, t_f)$  it follows that there exists  $C_3 > 0$  such that

$$\varphi_{3}(t) \left( \frac{|\dot{\varphi}_{3}(t)|}{\varphi_{3}^{2}(t)} + \left| z_{h_{ref}}^{(4)}(t) \right| + c_{3} + c_{4} |y_{2}(t)| + |\Delta_{3}| + \left( 1 + 2\overline{\omega}_{2}^{2}(t)k_{2}(t) \right) k_{2}(t) |\dot{\omega}_{2}(t)| \right) \leq C_{3}.$$
(39)

Invoking  $|\varpi_3(t)| < 1$  we thus obtain

 $\dot{U}_3(t) \le |\varpi_3(t)| (-c_5 k_3(t) |\varpi_3(t)| + C_3)$ (40)

and with a similar argument as in Step 3 it can be shown that  $k_3$  is bounded on  $[0, t_f)$ .

Step 6: We show that  $t_f = \infty$ . Assuming  $t_f < \infty$  it follows from Steps 2-5 that the closure of the graph of  $(y_0,\ldots,y_3)$  is a compact subset of  $D_4$ , which contradicts the findings of Step 1. Therefore,  $t_f = \infty$ . 

Fig. 3. Planning trajectory for RV

Note that the work [24] also employs funnel control techniques to solve the tracking problem with prescribed transient behavior for RVs. However, the controller there requires additional design parameters which need to be sufficiently large, but it is not known a priori how large they must be chosen. In the present paper, we avoid this problem by introducing a novel error variable form as in (13). This seems advantageous for practical engineering.

## IV. SIMULATION

In this section, we illustrate the performance of the funnel controller (14) by considering the lateral action of a RV with constant speed V = 5Ma at a height of 20 km. The initial states of the RV and the values of the geometric system parameters are shown in Table I. As disturbances we choose  $\Delta_0(t) = \frac{1}{57.3} 5 \sin(\frac{\pi}{4}t)$ ,  $\Delta_1(t) = \frac{1}{57.3} 0.2 \sin(\frac{\pi}{4}t)$ ,  $\Delta_2(t) = \frac{1}{57.3} 2 \sin(\frac{\pi}{4}t)$ ,  $\Delta_3(t) = \frac{1}{57.3} 10 \sin(\frac{\pi}{4}t)$ . The simulation was performed in MATLAB (solver: ODE45, default tolerances).

In practical engineering applications, input constraints are always present. Therefore, although such constraints are not considered in the theoretical treatment in Theorem 1, we incorporated them in the simulation such that the actual control input is sat(u(t)), where sat(v) = v for  $|v| \le 40$  and sat(v) = sgn(v)40 for |v| > 40.

As for the maneuvering reference trajectory, an extensively used Dubins trajectory is selected as the planning path, shown in Fig. 3, where  $\theta_j$  (j BC, DE, FG) and  $R_i$  are the turning radius and central angles, respectively. The coordinates of the starting point, turning points and end point are A(0, 450), B(12000, 50), C(15000, 0), D(24000, 0), E(27000, 50),F(30000, 150), G(35000, 260) and H(48530, -200). The time consumed per period is calculated by  $t_i = \frac{l_i}{V}$ (i = AB, CD, EF, GH) through straight regions and  $t_j =$  $\frac{\widehat{l}_j}{V} = \frac{\theta_j R_j}{V}$  (j = BC, DE, FG) in turning areas. Since the proposed performance funnel is time-triggered based on the planning path, the triggered times are set in accordance with the time points of the reference trajectory, resulting in p = 3. Thus the parameters of the funnel boundary function of the form (11) are chosen as in Table II.

The simulation is depicted in Figs. 4–10. The tracking error  $e_0$  and the auxiliary errors  $e_1, e_2, e_3$  are shown

Fig. 4. Response of tracking error  $e_0(t)$ .

Fig. 5. Response of error  $e_1(t)$ .

in Figs. 4–7. It is found that  $e_3$  is more sensitive to maneuvering than  $e_0$ , where a slight jump appears near each trigger time. Every error  $e_i$  (i = 0, 1, 2, 3) is kept within its respective funnel through the whole process and under the influence of disturbances. The control input, namely the rudder angle, is shown in Fig. 8. It can be seen that the control input reaches saturation due to the input constraints. Although the saturation is not covered by Theorem 1, the controller obviously exhibits an exceptional performance under input constraints. Further research is necessary to find theoretical guarantees for this performance.

Fig. 9 shows the deflection angle, sideslip angle, yaw angle and yaw rate to illustrate that all variables in the closed-loop system are bounded. The tracking maneuver reference trajectory is shown in Fig. 10 together with the output signal generated under control. Although the performance of the vehicle in the continuous large maneuver segment is not as good as that in the single maneuver segment, we observe a decent tracking performance overall.

However, we like to note that in this example the theoretical condition (15) from Theorem 1 is not satisfied, yet the controller still works. This shows that the assumptions of Theorem 1 are quite conservative and further research is necessary to relax them. A thorough inspection of the proof of Theorem 1 reveals that the conservativeness of condition (15) is due to the utilization of the mean value theorem and avoiding it could lead to a weaker condition.

# V. CONCLUSION

In this paper, we proposed a novel funnel-based tracking control algorithm for guaranteeing prescribed performance of the tracking error in reentry vehicle maneuvering flight. A time triggered non-monotonic funnel boundary is designed to successfully improve the controller performance, which is verified by simulations. The results show that the proposed control method has the ability to stabilize the closed-loop system under arbitrary bounded disturbances. Future research will focus on the relaxation of the conditions of Theorem 1 as well as their extension to the presence of input constraints. To this end, the recent results in [30] might be a starting point.
