Finite-temperature ductility-brittleness and electronic structures of Al₃Sc, Al₂Sc and AlSc are studied comparatively by first-principles calculations and *ab-initio* molecular dynamics. Results show that Al₃Sc and Al₂Sc are inherently brittle at both ground state and finite temperatures. By contrast, AlSc possesses a significantly superior ductility evaluated from all Pugh's, Pettifor's and Poisson's ductility-brittleness criteria. At ground state, AlSc meets the criteria of ductile according to Pugh's and Poisson's theories, while it is categorized as the brittle in the frame of Pettifor's picture. With the increasing temperature, the ductility of all the studied compounds exhibits a noticeable improvement. In particular, as the temperature rises, the Cauchy pressure of AlSc undergoes a transition from negative to positive. Thus, at high temperatures (T > 600 K), AlSc is unequivocally classified as the ductile from all criteria considered. In all Al₃Sc, Al₂Sc and AlSc, the Al-Al bond, originated from *s-p* and *p-p* orbital hybridizations, and the Al-Sc bond, dominated by *p-d* covalent hybridization, are the first and second strongest chemical bonds, respectively. To explain the difference in mechanical properties of the studied compounds, the mean bond strength (MBS) is evaluated. The weaker Al-Al bond in AlSc, leading to a smaller MBS, could be the origin for the softer elastic stiffness and superior intrinsic ductility. The longer length of the Al-Al bond in AlSc is responsible for its weaker bond strength. Furthermore, the enhanced metallicity of the Al-Al bond in AlSc would also contribute to its exceptional ductility.

Keywords: AlSc, Target material, Intrinsic ductility, Finite-temperature elastic constant, First-principles calculation

I. INTRODUCTION

Highly Sc-doped Al-Sc alloy target materials (with Sc of as high as 50 at. %) comprised of several Al-Sc binary intermetallics, including Al₃Sc, Al₂Sc and AlSc, are crucial materials to fabricate (Al, Sc)N piezoelectric thin films that are widely utilized in microelectronic systems [1-4], such as radio frequency filters, piezoelectric actuators, and ultrasonic sensors. The microstructure uniformity of the Al-Sc target materials, including chemical composition, grain size, and crystallographic orientation, plays a pivotal role in the piezoelectric performance of the (Al, Sc)N films. Recently, it has been reported that the high-Sc Al-Sc alloys can be thermomechanical processing at elevated temperatures [5-7], which supplies an effective way to improve the microstructure uniformity of Al-Sc target materials. However, for different kinds of Al-Sc intermetallics contained in Al-Sc target materials, the information about the intrinsic brittleness-ductility, at both ground state and finite temperature, and the underlying mechanisms, is greatly limited. This situation severely impedes alloy composition design, thermomechanical process optimization, and ultimately the efficient fabrication of high-quality Al-Sc target materials.

To date, research on the binary Al-Sc intermetallics has primarily focused on Al₃Sc [8–18], due to the fact that the inclusion of Al₃Sc can substantially refine the microstructure and enhance the thermal stability of the conventional Al alloy structural materials. A. H. Reshak et al. [9] revealed that Al₃Sc exhibits a preference for the $L1_2$ structure over the $D0_{22}$ structure in thermodynamics. This preference is attributed to the smaller electronic states at the Fermi energy in the $L1_2$ structure. By Pugh's (B/G) and Pettifor's Cauchy pressure $(C_{12}-C_{44})$ ductility-brittleness criteria, R. Sharma *et al.* [8] suggested that the $L1_2$ -type Al₃Sc is inherently brittle. D. Chen *et al.* [11] observed that the elastic moduli of Al_3Sc increase linearly with the increasing external hydrostatic pressure. In the range of 0 to 50 GPa, the brittle nature of Al₃Sc remains unchanged, while the elastic anisotropy becomes more pronounced. Furthermore, the finite-temperature elastic properties of Al₃Sc were investigated by R.-K. Pan et al. using the quasi-harmonic approximation [18]. With the elevated temperature, the elastic moduli of Al₃Sc exhibit a gentle descent trend but its brittle nature is unchanged. These observations are attributed to the slight weakening of the covalent bonding in Al₃Sc as temperature increases. Different from the situation of Al₃Sc, the studies on the intrinsic mechanical properties of Al₂Sc and AlSc are extremely limited. Only available results were reported by §. Uğur and coworkers [19]. They found that, in contrast to the brittle nature of Al₃Sc, AlSc is inherently ductile in terms of Pugh's criterion. These investigations significantly advance our understanding of the intrinsic ductility-brittleness of the Al-Sc binary intermetallics.

However, the intrinsic mechanical properties and the ductility-brittleness origins of different Al-Sc intermetallics remain elusive. In particular, there is a critical shortage of comparative research on intrinsic mechanical properties of different Al-Sc intermetallics, both at ground state and finite temperatures. Specifically, the following key issues remain unknown. i) Are there additional stable Al-Sc intermetallics

^{*} sunsc@smm.neu.edu.cn

[†] yanghongbo203@grirem.com

[‡] yanhaile@mail.neu.edu.cn

with Sc content less than 50 at. % besides Al₃Sc, Al₂Sc, and AlSc? A recent study [20] has reported that Al_3Sc_2 , which is not depicted in the Al-Sc phase diagram, also exhibits a high thermodynamics stability. Therefore, conducting a systematic search for potential stable structures in the Al-Sc binary systems holds immense significance. *ii*) Which type of Al-Sc intermetallic exhibits the greatest ductility? This information is of utmost importance for the composition design of the Al-Sc target materials. *iii*) What are the temperature effects on the inherent ductility of different Al-Sc intermetallics? This knowledge is essential for the optimization of thermomechanical processes. *iv*) What is the origin behind the varying ductility-brittleness exhibited by different kinds of Al-Sc intermetallics? Clarifying the mechanisms of the difference in ductility-brittleness among different Al-Sc intermetallics is crucial for the design of novel intermetallics with superior ductility.

To bridge these knowledge gaps, the stable phase searching, the ground-state and finite-temperature intrinsic mechanical properties, and the electronic structures of various Al-Sc intermetallics are studied systematically by first-principles calculations and *ab-initio* molecular dynamics. First, the potential stable phases in the Al-Sc binary system are searched systematically using the variable-composition evolutionary structure search algorithm [21-23] (Section III A). Second, the ground-state elastic moduli, the ductility-brittleness behaviors in terms of Pugh's ratio B/G, Pettifor's Cauchy pressure C_{12} - C_{44} and Poisson's ratio v, are investigated (Section III B 1). Third, the temperature dependences of elastic moduli and ductility-brittleness of different Al-Sc intermetallics are studied comparatively (Section III B 2). Lastly, the electronic structures, including band structure, density of states, charge density difference, electron localization function and crystal orbital Hamilton population, are analyzed (Section III C). The underlying mechanisms of various ductility-brittleness exhibited by different Al-Sc intermetallics are finally discussed (Section IV).

II. METHODOLOGY

First-principles calculations were performed using density functional theory (DFT) implemented in the Vienna ab initio Simulation Package (VASP 6.3) [24, 25]. The Perdew-Burke-Ernzerhof (PBE) parametrization of the generalized gradient approximation (GGA) was employed to describe the exchange-correlation function [26, 27]. The electron-ion interactions were described by the projector augmented wave (PAW) pseudopotential approach. The valence electron configurations of Al $(3s^23p^1)$ and Sc $(3d^14s^2)$ were adopted. A kinetic energy cutoff of 500 eV was adopted for wave-function expansion. The k-point meshes with an interval of $0.03 \times 2\pi$ $Å^{-1}$ for the Brillouin zone to ensure that all enthalpy calculations converged within 10^{-5} eV. During structural relaxation, the force on each atom was relaxed to be less than 10^{-2} eV/Å . During the calculation of the electronic structure, the tetrahedron method with the Blöchl correction [28] was used to integrate the Brillouin zone, and a denser k-point mesh with

an interval of $0.01 \times 2\pi$ Å⁻¹ was adopted. Crystalline orbital Hamiltonian population (COHP) [29, 30] was calculated by using the Local Orbital Basis Suite Towards Electronic-Structure Reconstruction (LOBSTER) program [31, 32]. The charge analysis was performed using the Bader decomposition technique [33]. The states of 3*s* and 3*p* for Al and 3*d* and 4*s* for Sc were taken as basis function sets. The phonon dispersion curves were calculated under the harmonic approximation by using the PHONOPY code [34].

The stable phase searching in the Al-Sc system was carried out using the generic evolutionary algorithm as implemented in the USPEX code [21-23]. The variable composition mode was used to realize a high-efficient determination of different compositions. In the first generation, 200 structures were randomly created. Starting from the second generation, 120 structures were generated at each generation using six different operators: heredity (45%), symmetric random generator (15%), permutation (10%), softmutation (10%), transmutation (10%), and lattice mutation (10%). The maximum number of atoms in the unit cell was set to be 18. For each structure, to compromise speed and accuracy, five-step DFT calculations with increasing precision were adopted. To increase the efficiency of structure prediction, the known structures of Al₃Sc, Al₂Sc and AlSc were taken as the seeds. The search process continued until the 60th generation was reached. After the calculation, the stabilities of the predicted phases close to the convex hull were re-evaluated with higher precision.

The ground-state elastic constants were determined by computing the second-order derivatives of the total energy with respect to the position of the ions using a finite differences approach [35]. The finite-temperature elastic constants were calculated by using *ab-initio* molecular dynamics (AIMD) simulation. For Al₃Sc, Al₂Sc and AlSc, a 108-atom supercell with 3×3×3 L1₂-type unit cells, a 192-atom supercell with 2×2×2 C15-type unit cells, and a 128-atom supercell with 4×4×4 B2-type unit cells were adopted, respectively. During the calculations, the canonical ensemble (NVT) was employed, and the Nosé-Hoover thermostat [36, 37] was adopted to control the system temperature. The Verlet algorithm [38] with a time step of 2 fs was used to solve Newton's equations of motion. The finite-temperature elastic constants were determined with two consecutive steps. First, the equilibrium lattice constant at a certain temperature was determined. At a specific temperature, four independent 10-ps AIMD simulations were conducted. Each simulation started from an isotropically expanded ground state structure at a guessed expansion. At 300 K, the initial applied expansion for the four AIMD simulations were 0.3%, 0.33%, 0.4%, and 0.43%, respectively. After each simulation, the average internal pressure at each expansion can be obtained. With this information, the equilibrium lattice parameter at a certain temperature, *i.e.*, the one with the average pressure near zero, can be determined. Second, at each temperature, five anisotropic strains (Eq. 1) with ε ranging from -0.04 to 0.04 at a interval of 0.02 [39]

were separately applied.

$$\begin{pmatrix}
\varepsilon & 0 & 0 \\
0 & 0 & \frac{\varepsilon}{2} \\
0 & \frac{\varepsilon}{2} & 0
\end{pmatrix}$$
(1)

For each strained structure, a 10-ps AIMD simulation was performed to determine the stress tensor. By linear fitting between stress and strain with the following relations, the elastic constants at a specific temperature can be obtained.

$$\sigma_1 = C_{11}\varepsilon, \ \sigma_2 = \sigma_3 = C_{12}\varepsilon, \ and \ \sigma_4 = C_{44}\varepsilon \tag{2}$$

III. RESULTS

A. Stable phase, crystal structure and phase stability

The stable phases in the binary Al-Sc system are systematically explored by the variable-composition evolutionary structure search algorithm [21–23]. The formation energies E_f of the predicted Al-Sc phases at ambient pressure are shown in Fig. 1b. The structures with the lowest E_f forming the convex hull are thought to be the ground-state stable phases. Clearly, the convex hull of the binary Al-Sc system is constituted by Al₃Sc with the Ni₃Al-type L1₂ structure (space group: $Pm\overline{3}m$, 221), Al₂Sc with the Cu₂Mg-type C15 structure (space group: $Fd\overline{3}m$, 227), AlSc with the CsCl-type B2 structure (space group: Pm3m, 221) and AlSc₂ with the InNi₂type B8₂ structure (space group: P6₃/mmc, 194). This result is in excellent agreement with the reported binary Al-Sc phase diagram [4] (Fig. 1a). Note that E_f of Al₃Sc₂ with space group Cmmm is slightly above the convex hull, indicated by the blue cross in the inset of Fig. 1b. This observation indicates that Al₃Sc₂ is not a thermodynamically stable phase, which is in good concordance with the investigation conducted by A. Bilić et al. [20]. Thus, in subsequent studies, we focus on Al₃Sc, Al₂Sc, and AlSc because these three intermetallics exist in the Al-Sc target materials with the Sc content not exceeding 50 at. % [40].

Phonon dispersion relation examinations show that the Al₃Sc with the L1₂ structure, the Al₂Sc with the C15 structure and the AlSc with the B2 structure are stable dynamically (see Supplementary Materials Fig. S1). Table I lists the equilibrium lattice parameters a₀ of Al₃Sc, Al₂Sc and AlSc, along with the data extracted from the literature [10, 11, 19, 41–48]. The determined a_0 of Al₃Sc, Al₂Sc and AlSc are 4.103 Å, 7.572 Å and 3.378 Å, respectively, which are consistent with the experimental [19, 41, 44] (with differences less than 1 %) and theoretical reports [10, 11, 42, 43, 45–48]. Fig. 2a, b and c display the crystal structure of Al₃Sc, Al₂Sc and AlSc, respectively. In the L1₂-type Al₃Sc, Al and Sc atoms occupy the 3c (0.5, 0, 0.5) and the 1a (0, 0, 0) sites, respectively. Each Al has 12 first-nearest neighboring atoms, comprising 8 Al and 4 Sc atoms. Similarly, each Sc also has 12 first-nearest neighboring atoms, which are all Al atoms. In the C15-type Al₂Sc, Sc and Al occupy the 8a (0, 0, 0) and the 16d (0.625, 0.625, 0.625) sites, respectively. Each Al atom has 6 firstnearest neighboring Al atoms. Four adjacent Al atoms form

Figure 1. Phase diagram and convex hull of the Al-Sc binary system. (a) Al-Sc equilibrium phase diagram. The red, green, blue and black vertical lines indicate Al_3Sc , Al_2Sc , AlSc and $AlSc_2$ stable phase, respectively. (b) The calculated convex hull of the Al-Sc binary system. The blue circles indicate the formation energies and compositions of the predicted structures after each generation of the evolutionary algorithm search. The red line indicates the formation energies and compositions of the final thermodynamically stable Al-Sc phases, forming the convex hull. The inset is the enlarged region around Al_3Sc_2 .

a tetrahedral structure. Each Sc atom, on the other hand, has no first-nearest neighboring atom. For the B2-type AlSc, Al and Sc atoms occupy the Ia (0, 0, 0) and Ic (0.5, 0.5, 0.5) sites, respectively. Each Al has 8 first-nearest neighboring Sc atoms, and each Sc has 8 first-nearest neighboring Al atoms. For phase stability, among Al₃Sc, Al₂Sc and AlSc, Al₂Sc exhibits the highest thermodynamic stability, evidenced by the smallest E_f (Fig. 1b), which corresponds well to the highest melting point (1392°C) of Al₂Sc. E_f of AlSc is comparable to that of Al₃Sc, with a slight difference of 7 meV/atom higher than Al₃Sc, which aligns with the slightly lower melting point of AlSc (1240°C) than Al₃Sc (1280°C).

B. Intrinsic mechanical properties

1. Ground-state mechanical properties

To evaluate the ground-state mechanical properties, the elastic moduli of Al₃Sc, Al₂Sc and AlSc are calculated. Table II lists the independent elastic constants C_{ij} and the tetragonal shear modulus *C*' (defined by $(C_{11}-C_{12})/2$) of Al₃Sc, Al₂Sc and AlSc. For Al₃Sc, C_{11} , C_{12} and C_{44} are determined to be 188.8, 40.8 and 72.4 GPa, respectively, in good agreement with the report by R.-K. Pan and colleagues (*i.e.*, 179.2, 40.6 and 71.0 GPa) [18]. For all Al₃Sc, Al₂Sc and AlSc, their elastic constants satisfy the Born-Huang elastic stability criteria for cubic crystals [49], *i.e.*, C_{11} >0, C_{44} >0, C'>0 and $(C_{11}+2C_{12})$ >0, indicating that these intermetallics are elastically stable.

Fig. $3a_1$, a_2 and a_3 display isotropic bulk modulus *B*, shear modulus G and Young's modulus E, respectively. Herein, the Voigt-Ruess-Hill polycrystalline averaging algorithm[50] is adopted (see details in Appendix A). It is evident that for all B, G and E, the values of Al_3Sc are comparable to Al_2Sc , but both of them are obviously larger than that of AlSc. These results tell us that the elastic stiffnesses of Al₃Sc and Al₂Sc are higher than that of AlSc. Apart from elastic stiffness, the intrinsic ductility of Al₃Sc, Al₂Sc and AlSc are evaluated by using the three widely used ductility-brittleness criteria, *i.e.*, Pugh's ratio B/G, Pettifor's Cauchy pressure $C_{12}-C_{44}$ and Poisson's ratio v. In Fig. $3b_1$, b_2 and b_3 , we display, respectively, B/G, $C_{12}-C_{44}$ and ν for Al₃Sc, Al₂Sc and AlSc. For clarity, the critical minimum values for ductility, *i.e.*, B/G =1.75 in Pugh's theory, $C_{12}-C_{44} = 0$ in Pettifor's theory, and v = 0.26 in Poisson's theory [51, 52], are plotted as dashed lines. In Al₃Sc, B/G, $C_{12}-C_{44}$ and ν are determined to be 1.2, -31.7 GPa and 0.18, respectively. Based on all Pugh's, Pettifor's and Poisson's criteria, Al₃Sc is classified as the intrinsically brittle, in line with the investigations of R. Sharma et al. [8] and D. Chen et al. [11]. In analogy to Al_3Sc , the C15-type Al₂Sc is also inherently brittle since all the values of B/G (1.3), $C_{12}-C_{44}$ (-27.5 GPa) and ν (0.19) are smaller than the critical minimum values of ductility.

As for the B2-type AlSc, the values of B/G (1.9) and ν (0.28) are higher than 1.75 and 0.26, respectively. Thus, AlSc is inherently ductile according to Pugh's and Poisson's criteria. Note that in terms of all Pugh's, Pettifor's and Poisson's criteria, the values of Al₃Sc are comparable to Al₂Sc, while both of them are obviously smaller than those of AlSc. Therefore, it can be concluded that at ground state, the ductility of the B2-type AlSc is significantly superior to the L1₂-type Al₃Sc and the C15-type Al₂Sc. However, as seen in Fig. 3b₂, the Cauchy pressure $C_{12}-C_{44}$ of AlSc is negative (-18.3 GPa). Thus, in the frame of Pettifor's theory, AlSc should be considered to be brittle. This inconsistency of ductility-

brittleness concluded by different criteria indicates that the inherent ductility of AlSc is not excellent enough. It may explain the challenges encountered when attempting severe plastic deformation in the high-Sc Al-Sc alloys at room temperature.

2. Finite-temperature mechanical properties

To clarify the intrinsic mechanical properties at high temperatures, the finite-temperature crystal structures and elastic constants are calculated by the AIMD technique. Investigations show that for all Al₃Sc, Al₂Sc and AlSc, no structural transitions occur at the investigated temperatures (<1200 K), in good agreement with the Al-Sc phase diagram [4] (Fig. 1a). In Table III, we list the determined finite-temperature lattice parameters. Phonon dispersion relation examinations evidence that Al₃Sc with the L1₂ structure, Al₂Sc with the C15 structure and AISc with B2 structure are still stable dynamically at the temperature up to 1200 K (see Supplementary Materials Fig. S2). Fig. $4a_1$, a_2 and a_3 show the temperature dependences of independent elastic constants C_{ii} for Al₃Sc, Al₂Sc and AlSc, respectively. As a reference, the finitetemperature C_{ij} of Al₃Sc, calculated by the quasi-harmonic approximation [18], is also included in Fig. $4a_1$ (open symbols). We see that the determined temperature dependences of C_{12} , C_{11} and C_{44} in Al₃Sc by AIMD are in reasonable agreement with those calculated by the quasi-harmonic approximation [18].

For all Al₃Sc, Al₂Sc and AlSc, there is a noticeable decrease in C_{11} and C_{44} as the temperature increases. The temperature-induced variation in elastic constants is majorly attributed to the expansion of lattice volume with the increasing temperature (Table III), which typically weakens the bonding strength between the constituent elements and further results in a decrease in elastic constants. For Al₃Sc and Al₂Sc, the decrease rate of C_{11} is significantly larger than that of C_{44} . For instance, in Al₃Sc, the temperature sensitivity coefficient of C_{11} (*i.e.*, dC_{11}/dT) is -0.049 GPa/K, which is around three times larger than that of C_{44} (d C_{44} /dT = -0.018 GPa/K). Nevertheless, in the case of AlSc, C_{44} exhibits a larger decrease rate (-0.030 GPa/K) compared to C_{11} (-0.022 GPa/K) (Fig. 4a₃). Different from C_{11} and C_{44} , C_{12} shows a much weaker sensitivity on temperature, particularly for Al₃Sc ($dC_{12}/dT =$ -0.003 GPa/K) and Al₂Sc (dC₁₂/dT = -0.004 GPa/K). It is worth noting that in the cases of Al_3Sc and Al_2Sc , C_{44} consistently remains larger than C_{12} even for the temperature up to 1200 K, whereas for AlSc there is a reversal in the relative sizes of C_{12} and C_{44} (Fig. 4a₃). As is known, the difference between C_{12} and C_{44} , *i.e.*, Cauchy pressure, is a crucial parameter that characterizes intrinsic ductility in Pettifor's theory. The reversal in the relative magnitudes of C_{12} and C_{44} suggests a great improvement of ductility under the assistance of temperature, which is detailedly discussed later.

Fig. $4b_1$, b_2 and b_3 display the temperature dependences for isotropic bulk modulus *B*, shear modulus *G* and Young's modulus *E*, respectively. With the increasing temperature, all values of *B*, *G*, and *E* exhibit a linearly decreasing tendency.

At the examined temperatures, Al_3Sc and Al_2Sc possess similar values for *B*, *G*, and *E*, which are significantly larger compared to those of AlSc. For *B*, the temperature sensitivity coefficients of Al_3Sc , Al_2Sc , and AlSc are nearly identical, with values around -0.014 GPa/K (Fig. 4b₁). Nevertheless, noticeable differences are observed for the temperature sensitivities of *G* and *E*. For *G*, the temperature sensitivity coefficients of Al₃Sc, Al₂Sc and AlSc are -0.019, -0.016 and -0.012 GPa/K,

respectively, while these three values for *E* are -0.043, -0.037 and -0.030 GPa/K, respectively. Clearly, for both *G* and *E*, the temperature sensitivities in Al₃Sc are the highest, while those in AlSc are the lowest. Moreover, it is worth noting that for different elastic moduli, the temperature sensitivities exhibit significant differences. Among *B*, *E* and *G*, *E* exhibits the highest temperature sensitivity. For all the studied compounds, the temperature sensitivity coefficients of *E* are around -0.035 GPa/K, which is approximately twice larger than those of *B* and *G* (about -0.015 GPa/K).

Fig. 5a, b and c display the temperature dependences of B/G, C_{12} – C_{44} and ν , respectively. For Al₃Sc, Al₂Sc, and AlSc, all B/G, $C_{12}-C_{44}$ and v exhibit a monotonically increasing tendency with the elevated temperature. This result suggests that the intrinsic ductility of all compounds can be effectively improved under the assistance of temperature, which aligns well with the experimental observations of the improved plasticity deformation ability of Al-Sc alloys at high temperatures [5–7]. At the investigated temperatures, B/G, $C_{12}-C_{44}$ and ν of AlSc are always larger than those of Al₃Sc and Al₂Sc, indicating that AISc still exhibits a noticeably superior intrinsic ductility compared to Al₃Sc and Al₂Sc at high temperatures. As described earlier, at ground state, AlSc is classified as the ductile based on Pugh's and Poisson's theories but as the brittle according to Pettifor's criterion. However, with the increasing temperature, the Cauchy pressure of AlSc evolves from negative to positive (Fig. 5b). Consequently, at high temperatures (T > around 600 K), according to all Pugh's, Pettifor's, and Poisson's theories, the B2-type AlSc should be

treated as the inherently ductile. This may be the reason for the high plasticity deformation ability of high-Sc Al-Sc target materials at high temperatures [5–7]. These findings could serve as a crucial foundation for the composition design and the thermomechanical processing optimization of Al-Sc target materials.

Furthermore, we note that as the temperature increases, the relative ductility of Al₃Sc and Al₂Sc changes. At ground state, the values of B/G, $C_{12}-C_{44}$ and ν for Al₃Sc are slightly smaller than those of Al₂Sc. It indicates that Al₃Sc exhibits an inferior ductility compared to Al₂Sc, although the differences are not significant. However, the relative magnitudes of B/G, $C_{12}-C_{44}$ and ν for Al₃Sc and Al₂Sc undergo a shift when the temperature exceeds around 600 K (Fig. 5). This result implies that Al₃Sc possesses superior high-temperature ductility compared to Al₂Sc. This change is ascribed to the higher temperature sensitivities of B/G, $C_{12}-C_{44}$ and ν of Al₃Sc. For Al₃Sc, the temperature sensitivity coefficients of B/G, $C_{12}-C_{44}$ and vare fitting to be 2.19×10^{-4} , 0.019 GPa/K and 3.81×10^{-5} , respectively, which are significantly larger than those of Al₂Sc, *i.e.*, 1.28×10^{-4} , 0.013 GPa/K and 2.24×10^{-5} . Analysis shows that the higher temperature sensitivity of Al₃Sc could be attributed to the higher thermal expansion coefficient of this compound. With the finite-temperature equilibrium lattice parameters determined by AIMD simulation (Table III), the linear thermal expansion coefficient of Al₃Sc is found to be 1.34×10^{-5} K⁻¹, which is larger than that of Al₂Sc (1.23 $\times 10^{-5}$ K⁻¹) as well as AlSc (1.20×10^{-5} K⁻¹). However, it is important to note that despite a great improvement in the ductilities of Al₃Sc and Al₂Sc with increasing temperature, both these two compounds retain their brittle nature even at temperatures up to 1200 K.

C. Electronic structures

1. Band structure and DOS

To understand the origin of different intrinsic mechanical properties of Al₃Sc, Al₂Sc, and AlSc, a thorough investigation of their electron structures is conducted, including band structure, density of states (DOS), electron localization function (ELF), charge density difference (CDD), Bader charge and crystalline orbital Hamiltonian population (COHP). Fig. 6a, b and c display the electronic band structures and the total and partial DOSs for Al₃Sc, Al₂Sc and AlSc, respectively. Analyses reveal that despite the significant differences in composition and structure, the electronic band and DOS structures of

Figure 4. Finite-temperature elastic moduli. (a_1-a_3) Elastic constants of Al₃Sc, Al₂Sc and AlSc. The data represented by open symbols in (a) are calculated by quasi-harmonic approximation extracted from Ref. [18]. (b_1-b_3) Isotropic bulk modulus *B*, shear modulus *G* and Young's modulus *E*.

Al₃Sc, Al₂Sc and AlSc exhibit some common features, as depicted in Fig. 7 and detailed below. In all Al₃Sc, Al₂Sc, and AlSc, the 3*s* electrons of Al are primarily distributed within the energy range of -9 to -3 eV; by contrast, the 3*p* electrons of Al appear at a broad region with energies above -9 eV (Fig. 6a₃-c₃). As for the Sc atom, its 3*d* electron predominantly occupies the energies above -3 eV, while below the Fermi level the 4s electrons are limited (Fig. 6a₄-c₄). For all the examined compounds, in the low-energy region, a strong *s*-*p* hybridization between Al and Al is observed (Fig. 6a₂-c₂). When the energy approaches the Fermi level, the *p*-*p* hybridization between Al and the *p*-*d* orbital interaction between Al and Sc becomes dominant.

2. ELF, CDD and Bader charge

We shift our focus on electron structure from the reciprocal space to the real space. In Fig. 8a, b and c, we display the three-dimensional (3D) isosurfaces of ELF and CDD for Al₃Sc, Al₂Sc and AlSc, respectively. The isosurface values of ELF and CDD are carefully selected to signify the maxima. It is observed that in all Al₃Sc, Al₂Sc, and AlSc, there are prominent highly localized electrons and electron accumulation between the neighboring Al and Al atoms, indicating a strong chemical interaction of the Al-Al pairs. The strong interaction between Al-Al pairs majorly arises from the hybridizations of 3s-3p and 3p-3p orbital electrons, as revealed in the DOS analyses (Fig. 6). For AlSc, the maximum of ELF appears roughly at the center of the Al-Al pair (Fig. $8c_1$). Nevertheless, in the cases of both Al₃Sc (Fig. $8a_1$) and Al₂Sc (Fig. $8b_1$), an obvious deviation of the ELF maximum from the center of the Al-Al pair is observed.

Although visualizing the ELF maximum in the 3D representation helps identify the strongest interaction between the constituent atoms, it may lose the information of relatively weaker interactions. To address this limitation, the line profile analyses of ELF between neighboring atoms are conducted. In Fig. 9a and b, we display the ELF distributions along the adjacent Al-Al and Al-Sc pair, respectively. Herein, to realize a direct comparison, the lengths of Al-Al and Al-Sc pairs in dif-

Figure 5. Temperature dependence of intrinsic ductilitybrittleness of Al₃Sc, Al₂Sc and AlSc. (a) Pugh's ratio B/G; (b) Cauchy pressure $C_{12}-C_{44}$; (c) Poisson's ratio v.

ferent compounds are normalized. Besides, to better illustrate the electron localization around the Al-Al pair, the maximum of ELF in Al₃Sc and Al₂Sc that slightly deviates from the Al-Al connection line are also displayed in Fig. 9a. We see that in terms of the maximum values of ELF around the Al-Al pair, Al₃Sc, Al₂Sc and AlSc are very close to each other. However, the ELF profile of the Al-Al pair in AlSc is much wider than those of Al₃Sc and Al₂Sc. The full width at half maximum (FWHM) of the ELF profiles of AlSc is measured to be 0.65, which is significantly longer than those of Al₃Sc (0.56) and Al₂Sc (0.51). In fact, the width of the ELF profile of the Al-Al pair in AlSc is compared to that of pure Al with excellent ductility, as indicated by the dashed line in Fig. 9a. Thus, in terms of the metallicity of the Al-Al bond, AlSc should be superior to Al₃Sc and Al₂Sc.

From Fig. 9b, it is observed that there exists pronounced localized electrons between Al and Sc, which indicates a nonnegligible covalent interaction between the adjacent Al and Sc. From the DOS result (Fig. 6), it is clear that this interaction is primarily attributed to the *p-d* orbital interaction between the 3p electrons of Al and the 3d orbitals of Sc. Remarkably, despite the significant differences between the examined compounds, the ELF profiles along Al and Sc exhibit a remarkable overlap, implying a similarity in the bonding characteristics along Al-Sc. Furthermore, we note that the position of the ELF maximum deviates from the center of Al-Sc pair and shifts towards the Al atom (Fig. 9). This is attributed to the larger electronegativity of Al (1.61) compared to Sc (1.36), indicating the polarity nature of the Al-Sc bond.

In Table IV, we list the transferred charge between Al and Sc during bonding following Bader's idea of the partition on space charge [33]. Compared to neutral atoms, the charge amount of Al increases while that of Sc decreases, which is consistent with the polarity of the Al-Sc bond. In Al₃Sc, Al₂Sc, and AlSc, the transferred electrons from a Sc atom are approximately the same (around 1 electron), which are evenly distributed among the surrounding Al atoms. In AlSc, a single Al atom gets the most electrons (1.03) while receiving the least electrons (0.34) in Al₃Sc. This difference is attributed to the different Al content in the studied three compounds, with AlSc having the lowest (50 at. %) and Al₃Sc having the highest (75 at. %) one.

Table IV. Charge transfer during bonding of Al_3Sc , Al_2Sc and AlSc.

Compounds	Bader charge in neutra atoms		Bader charge in compounds		Transferred charge during bonding		
	Al	Sc	Al	Sc	Al	Sc	
Al ₃ Sc	3	3	3.34	1.97	0.34	-1.03	
Al_2Sc	3	3	3.56	1.89	0.56	-1.11	
AlSc	3	3	4.03	1.97	1.03	-1.03	

3. Chemical bonding

To gain a comprehensive understanding of chemical bonding of Al₃Sc, Al₂Sc and AlSc, the crystalline orbital Hamiltonian population (COHP) method [29, 30] is adopted. Herein, we focus on the chemical bonds with lengths less than 3.5 Å because the strengths of bonds with longer lengths are very weak. Fig. 10a, b and c display the total and orbital-resolved COHP curves of chemical bonds in Al₃Sc, Al₂Sc and AlSc, respectively. In Table V and Table VI, we provide a summary of chemical bond type, bond length, bond number in a unit cell, and the absolute values of the integration of COHP (|ICOHP|) and the orbital-resolved |ICOHP|. For the L1₂-type

Figure 6. Electronic band structures and density of states (DOSs) of $(a_1-a_4)Al_3Sc$, $(b_1-b_4)Al_2Sc$ and $(c_1-c_4)AlSc$. a_1-c_1 , a_2-c_2 , a_3-c_3 and a_4-c_4 are electronic band structure, total DOS, partial DOS of Al, and partial DOS of Sc, respectively. The horizontal dashed line represents the Fermi energy E_F .

Al₃Sc, only the first neighboring Al-Al (Fig. 10a₁) and Al-Sc (Fig. 10a₂) bonds with a length of 2.90 Å are included. In the case of C15-type Al₂Sc, the first neighboring Al-Al (Fig. 10b₁) with a length of 2.68 Å, the second neighboring Al-Sc (Fig. 10b₂) with a length of 3.14 Å, and the third neighboring Sc-Sc (Fig. 10b₃) with a length of 3.28 Å bonds are satisfied. For the B2-type AlSc, the first neighboring Al-Sc (Fig. 10c₂) with a length of 2.92 Å and the second neighboring Al-Sc (Fig. 10c₂) with a length of 2.92 Å and the second neighboring Al-Sc (Fig. 10c₂) with a length of 2.92 Å and the second neighboring Al-Sc (Fig. 10c₂) with a length of 2.92 Å and the second neighboring Al-Sc (Fig. 10c₂) with a length of 2.92 Å and the second neighboring Al-Sc (Fig. 10c₂) with a length of 2.92 Å and the second neighboring Al-Sc (Fig. 10c₂) with a length of 2.92 Å and the second neighboring Al-Sc (Fig. 10c₂) with a length of 2.92 Å and the second neighboring Al-Sc (Fig. 10c₂) with a length of 2.92 Å and the second neighboring Al-Sc (Fig. 10c₂) with a length of 2.92 Å and the second neighboring Al-Sc (Fig. 10c₂) with a length of 2.92 Å and the second neighboring Al-Sc (Fig. 10c₂) with a length of 2.92 Å and the second neighboring Al-Sc (Fig. 10c₂) with a length of 2.92 Å and the second neighboring Al-Sc (Fig. 10c₂) with a length of 2.92 Å and the second neighboring Al-Sc (Fig. 10c₂) with a length of 2.92 Å and the second neighboring Al-Sc (Fig. 10c₂) with a length of 2.92 Å and the second neighboring Al-Sc (Fig. 10c₂) with a length of 2.92 Å and the second neighboring Al-Sc (Fig. 10c₂) with a length of 2.92 Å and the second neighboring Al-Sc (Fig. 10c₂) with a length of 2.92 Å and the second neighboring Al-Sc (Fig. 10c₂) with a length of 2.92 Å and the second neighboring Al-Sc (Fig. 10c₂) with a length of 2.92 Å and the second neighboring Al-Sc (Fig. 10c₂) with a length of 2.92 Å and the second neighboring Al-Sc (Fig. 10c₂) with a length of 2.92 Å and the seco

Al (Fig. $10c_1$) and Sc-Sc (Fig. $10c_3$) bonds with a length of 3.37 Å are covered.

For all Al₃Sc, Al₂Sc, and AlSc, |ICOHP| of the Al-Al bond possesses the largest value among all chemical bonds in each compound. This result suggests that in all examined compounds, the Al-Al bond is the strongest chemical bond, in good accordance with the observations of ELF and CDD (Fig. 8). From the orbital-resolved COHP curves and |ICOHP| (Fig.

Figure 7. Illustration of the DOS structure of the studied binary Al-Sc compounds.

 $10a_1$ -c₁ and Table VI), it is clear that the strength of Al-Al bond majorly arises from *s*-*p* hybridization at the low-energy region and the p-p hybridization near the Fermi level, in agreement with the DOS analyses (Fig. 7). Among Al₃Sc, Al₂Sc, and AlSc, the Al-Al bonds in Al₃Sc and AlSc possess the highest (|ICOHP| = 2.20 eV) and the lowest (|ICOHP| = 1.05eV) strength, respectively. This variation in bond strength is ascribed to the differences in bond lengths, with Al₃Sc having the shortest (2.68 Å) and AlSc having the longest bond length (3.37 Å), respectively. The second strongest bonds in Al₃Sc, Al₂Sc, and AlSc are all the Al-Sc bonds. The p-d covalent hybridization between Al and Sc contributes mostly to the strength of the Al-Sc bond (Fig. $10a_2-c_2$). In terms of the Al-Sc bond, the highest strength appears in AlSc (ICOHP) = 1.04 eV), while the lowest one appears in Al_2Sc (|ICOHP| = 0.62 eV), which is exactly opposite to the sequence sorted by the Al-Al bond strength. The bond length is also a crucial factor in deciding the Al-Sc bond strength. Specifically, AlSc and Al₂Sc with the strongest and the weakest Al-Sc bond possess the shortest (2.92 Å) and the longest (3.14 Å) length, respectively. Apart from Al-Al and Al-Sc bonds, even though the lengths of Sc-Sc bond are also less than 3.5 Å in Al_2Sc $(3.28 \text{ Å}, \text{Fig. } 10c_2)$ and AlSc $(3.37 \text{ Å}, \text{Fig. } 10c_3)$, their bonding strength is already very weak. The |ICOHP| values of the Sc-Sc bond in Al₂Sc and AlSc are calculated to be 0.32 eV and 0.28 eV, respectively, which are significantly smaller than those of their corresponding Al-Al bond.

IV. DISCUSSION

We now discuss the underlying mechanisms behind different elastic stiffness and ductility-brittleness of Al₃Sc, Al₂Sc, and AlSc from electronic structure. In this work, the mean bonding strengths (MBS) of the different compounds are calculated. This evaluation involves two steps. Firstly, the total |ICOHP| per unit cell is computed by multiplying the |ICOHP| values of different bonds by their respective bond numbers in the unit cell and summing them up. Secondly, the averaged |ICOHP| per atom, which can be used to characterize the MBS, is calculated by dividing the total |ICOHP| by the number of atoms in the unit cell. The results are presented in Table V. We find that the averaged |ICOHP| of AlSc is 6.18 eV/atom, which is significantly lower than those of

Al₃Sc (7.74 eV/atom) and Al₂Sc (7.11 eV/atom). This indicates that AISc has the smallest MBS, even though the |ICOHP| value of the second strongest Al-Sc bond in this compound is the largest. The weakest MBS of AlSc accounts well for its lowest elastic stiffness, including B, G and E, as displayed in Fig. 3. Analyses show that the smallest MBS of AlSc arises from its weakest Al-Al bond. The |ICOHP| value of the Al-Al bond in AISc is 1.05 eV, which is much smaller than those in Al₃Sc (1.63 eV) and Al₂Sc (2.20 eV). Moreover, we find that the longer bond length of the Al-Al bond in AlSc should be responsible for the weaker bond strength. Different from the first neighboring Al-Al bonds in the L1₂-type Al₃Sc and the C15-type Al₂Sc, the Al-Al bond in the B2-type AlSc is the second neighboring, leading to a much longer bond length in AlSc (3.37 Å) compared to Al₃Sc (2.90 Å) and Al₂Sc (2.68 Å) (Table V).

It is well-known that there exists an inevitable trade-off between intrinsic strength/stiffness and ductility in materials. Materials with high strength/stiffness often exhibit poor toughness and vice versa. For example, pure metals (e.g., Al and Cu) are ductile but relatively soft, whereas ceramics are hard but brittle. In this study, AISc with the lowest stiffness possesses superior ductility, aligning well with the stiffnessductility trade-off principle. Thus, the weakest Al-Al bond of AlSc would also contribute significantly to its exceptional intrinsic ductility. In addition, from the analyses of ELF distribution along the Al-Al bond (Fig. 9a), it is evident that the metallicity of the Al-Al bond in AlSc is more pronounced compared to those in Al₃Sc and Al₂Sc. This enhanced metallicity would also play a non-negligible role in the superior ductility of AlSc relative to Al₂Sc and Al₃Sc. The notable metallicity of the Al-Al bond in AlSc could be attributed to the higher valence electron concentration around Al atoms. As shown in Table IV, the Bader charge of Al in AlSc is 4.03, which is significantly higher than that of Al_2Sc (3.56) and Al₃Sc (3.34). Increasing valence electron concentration generally tends to improve the intrinsic ductility of materials [53]. Before closing the discussion, we would like to stress that apart from the emphasized intrinsic ductility-brittleness, the plasticity of metallic materials is also influenced by defects [54], such as dislocation. The AlSc compound, with its simple B2 structure, may facilitate dislocation movement. Details of dislocation structures of Al₃Sc, Al₂Sc and AlSc, out of the scope of this work, need to be further investigated specifically.

V. CONCLUSIONS

In this work, the stable phases, the ground-state and finitetemperature inherent ductility-brittleness and the electronic structures of the Al-Sc binary systems with Sc content of less than 50 at. % are studied systematically. Using the variablecomposition evolutionary structure search algorithm, it is confirmed that apart from the L1₂-type Al₃Sc, the C15-type Al₂Sc and the B2-type AlSc, there are no other stable Al-Sc binary intermetallics. From all Pugh's, Pettifor's, and Poisson's ductility-brittleness criteria, Al₃Sc and Al₂Sc are inherently

brittle at ground state. AlSc possesses a prominently superior intrinsic ductility compared to Al₃Sc and Al₂Sc evaluated from all Pugh's, Pettifor's and Poisson's criteria. Through AIMD simulation, the finite-temperature elastic moduli are determined. By rising temperature, for all Al₃Sc, Al₂Sc, and AlSc, their intrinsic ductilities can be notably improved. As the temperature increases, accompanied by the transition of the Cauchy pressure from negative to positive, AISc is unequivocally classified as the inherently ductile based on all the criteria considered. However, Al₃Sc and Al₂Sc retain their brittle nature even at temperatures up to 1200 K. In all Al₃Sc, Al₂Sc and AlSc, the Al-Al bond, resulting from s-p and p-porbital hybridizations, and the Al-Sc bond, dominated by p-dcovalent hybridization, are the first and the second strongest chemical bonds, respectively. The mean bond strength (MBS) is introduced in this work to explain the differences in intrinsic mechanical properties of Al₃Sc, Al₂Sc, and AlSc. The weaker Al-Al bond in AlSc, leading to a smaller MBS, could be the origin of the softer elastic stiffness and superior intrinsic ductility. The longer length of the Al-Al bond in AlSc is responsible for its weaker bond strength. Moreover, an enhanced metallicity of the Al-Al bond in AlSc would also play a non-negligible role in its superior ductility. The findings of this work are expected to provide a crucial foundation for the design of alloy compositions and optimization of thermomechanical processing for Al-Sc target materials.

Appendix A: Appendix

The isotropic elastic moduli of bulk modulus B, shear modulus G, Young's modulus E and Poisson's ratio v are calculated by Voigt-Reuss-Hill (V-R-H) approximation [50] as follows:

$$B = \frac{1}{2}(B_{\rm V} + B_{\rm R}) \tag{A1}$$

$$G = \frac{1}{2} \left(G_{\rm V} + G_{\rm R} \right) \tag{A2}$$

$$V = \frac{3B - 2G}{2(3B + G)} \tag{A3}$$

$$E = \frac{9GB}{G+3B} \tag{A4}$$

where B_V and G_V are Voigt bulk modulus and Voigt shear modulus, respectively, and B_R and G_R are Reuss bulk modulus and Reuss shear modulus, respectively. For cubic crystals, B_V , G_V , B_R and G_R can be calculated by the relations:

$$G_{\rm V} = \frac{1}{5} \left[(C_{11} - C_{12}) + 3C_{44} \right] \tag{A5}$$

$$B_{\rm V} = \frac{1}{3} \left(C_{11} + 2C_{12} \right) \tag{A6}$$
