Holographic RIS Empowered THz Communications with Hardware Imperfections under Adverse Weather Conditions

Alexandros-Apostolos A. Boulogeorgos, *Senior Member, IEEE,* Stylianos Trevlakis, *Member, IEEE,* and Theodoros A. Tsiftsis, *Senior Member, IEEE*

Abstract—This paper focuses on providing a theoretical framework for the evaluation of the performance of holographic reconfigurable intelligent surface (HRIS) empowered terahertz (THz) wireless systems under fog conditions. In more detail, we present a comprehensive methodology for evaluating the geometric losses of the end-to-end channel. Moreover, the stochastic nature of the end-to-end channel is characterized by novel closedform probability density and cumulative distribution functions. Building upon them, the outage probability and the throughput of the system are extracted in closed form. These formulas account for the impact of transceiver hardware imperfections and are expected to become useful tools for the design of HRIS empowered THz wireless systems due to its remarkable engineering insights.

Index Terms—Fog, hardware imperfections, holographic reconfigurable intelligent surface (HRIS), outage probability, stochastic characterization, throughput.

I. INTRODUCTION

A. State of the Art & Motivation

Bringing the fiber quality of experience into the wireless world through the development of wireless fiber extenders capable of supporting data rates in the Tb/s region is a fundamental promise of terahertz (THz) technologies [\[1\]](#page-11-0). THz wireless fiber extenders aim to establish low-cost medium to long range high-bandwidth links for mid- and back-hauling without demanding the time-consuming processes of optical fiber installation [\[2\]](#page-11-1), [\[3\]](#page-11-2). As a consequence, from a business point of view, flexible almost-instance high-data-rate connectivity is expected to bring important economic benefits, while allowing internet democratization [\[4\]](#page-11-3), [\[5\]](#page-11-4).

Nevertheless, THz wireless communication systems are susceptible to a number of drawbacks. First of all, they suffer from high pathloss due to the high-transmission frequencies as well as molecular resonances that lead to molecular adsorptions [\[6\]](#page-11-5). Motivated by this, a great amount of research effort was put on modeling the deterministic path loss of THz wireless links [\[7\]](#page-11-6)–[\[10\]](#page-11-7). In more detail, in [\[7\]](#page-11-6), the authors employed the radiation theory in order to extract the channel characteristics of nano-scale THz wireless links. In [\[8\]](#page-11-8), an electromagnetic analysis was conducted for the propagation characterization of in-body THz links, whilst in [\[9\]](#page-11-9), the authors presented a path loss model for in-body nano-scale THz wireless systems. A simplified path loss model for THz systems operating in the $275 - 400$ GHz region was presented in [\[10\]](#page-11-7).

Another important drawback of THz wireless systems is the signal fluctuation due to atmospheric conditions. The source of this phenomenon lies in the variation of the reflection index, as a result of inhomogeneities in atmospheric pressure as well as temperature and water molecular density across the propagation path [\[11\]](#page-11-10). Inspired by this, the authors of [\[12\]](#page-11-11) used a weather emulating chamber in order to quantify in laboratory conditions the impact of rain in THz and infrared links. In [\[13\]](#page-11-12), the authors quantified the joint impact of rain and misalignment in THz wireless systems in terms of outage probability. The detrimental impact of turbulence in THz wireless systems was discussed in [\[14\]](#page-11-13). The joint impact of snow and misalignment in THz wireless systems was evaluated in terms of bit error rate and channel capacity in [\[15\]](#page-11-14). The authors of [\[16\]](#page-11-15) quantified the impact of fog in THz wireless systems in terms of bit error rate in laboratory environment. Finally, in [\[17\]](#page-11-16), the authors experimentally demonstrated the distortion to the THz signal that was caused due to fog.

To counterbalance the significant path loss as well as the signal fluctuation due to the atmospheric conditions and establish long-range connections, high-directional antennas, such as Cassegrain antennas, are employed at both the transmitter (TX) and the receiver (RX) ends, establishing high-directional links [\[18\]](#page-11-17). However, these links are sensitive to blockage, due to the high penetration loss of the THz transmission. Therefore, the need to create alternative paths between the TX and RX arises. On another front, with the explosive growth of data and bandwidth requirements in beyond fifth generation (5G) and sixth generation (6G) wireless communication networks, there is a unprecedented demand for improving key performance indicators (KPIs) such as energy efficiency, spectral efficiency, coverage and serviceability at very high levels [\[19\]](#page-11-18), [\[20\]](#page-11-19).

To this end, reconfigurable intelligent surfaces (RIS) are emerging as the revolutionary technology based on programmable metamaterial-based surfaces and seem to be the fundamental component of 6G communication infrastructures in improving the above mentioned KPIs [\[21\]](#page-11-20), [\[22\]](#page-11-21). In particular, conventional RIS plates comprises an array of nearly

passive reflecting meta-elements, which are able to control impinging signals through a field programmable gate array (FPGA) microcontroller. As a result, RIS adapts both the amplitude and phase of incident signals to the specific wireless environment conditions in order to either increase the coverage or cancel interference, and highlight its effectiveness in various applications such as drone-based communications, integrated sensing and communications, full-duplex communications, etc. [\[23\]](#page-11-22)–[\[25\]](#page-11-23).

Above and beyond all other considerations, due to the adaptability of RIS in creating alternative wireless paths in highly penetrated path loss environments i.e., THz communication systems, RIS appears to be a reliable technology to to combat communication blockage [\[26\]](#page-11-24), [\[27\]](#page-12-0). Specifically, the authors in [\[26\]](#page-11-24) presented for the first time key performance results (path loss and error rate) of RIS-enabled wireless communication systems, and conducted theoretical comparisons with wellestablished technologies such as such as relaying, multipleinput multiple-output (MIMO) beamforming, and backscatter communications. In [\[27\]](#page-12-0), the path loss of RIS-assisted wireless systems was analytically investigated based on the vector generalization of Green's theorem. In [\[28\]](#page-12-1), an improved path loss model for RIS-enabled wireless communications at mmWave bands was proposed. In particular, practical electromagnetic phenomena (e.g., gain patterns, received power, phase errors, and specular reflection loss per meta-element), were investigated. A similar approach is followed in [\[29\]](#page-12-2) where an angle-dependent path loss model for RISs was proposed based on the radiation patterns of all involved parts of the communication system. However, the proposed prototype in [\[28\]](#page-12-1), [\[29\]](#page-12-2) are based on PIN diodes, which is impractical for sub-THz bands [\[30\]](#page-12-3). Furthermore, RIS is highly affected by the frequency range of the incident signal to the RIS metaelements. Therefore, RIS's reflection and phase adjustment capability employing either varactors or PIN diodes is limited over RF frequency range and, specifically, between 100 MHz - 10 GHz. Therefore, for much higher frequencies at the sub-THz bands, i.e., 0.1-0.3 THz, micro-electromechanical system (MEMS), mechanical approach, liquid crystal, and microfluidics appear to be the most suitable tuning RIS technologies [\[31\]](#page-12-4). It is worth mentioning that the latter two tuning technologies cover a wide range of THz bandwidths compared to the two first mentioned tuning ones [\[30\]](#page-12-3), [\[32\]](#page-12-5). The operation of RIS at sub-THz is also feasible with tuning technologies involving complementary metal-oxide-semiconductor (CMOS) transistors, Schottky diodes, or high electron mobility transistors (HEMTs) [\[30\]](#page-12-3), [\[33\]](#page-12-6). Very recently, the authors in [\[34\]](#page-12-7), have demonstrated for the first time a THz point-to-point RISaided transmission based on real-time beam tracking. In this experiment, the THz signals near 0.34 THz are controlled via a RIS plate consisted of GaN HEMTs

Despite the fact that RIS is potentially considered as the key enabling technology to drive the evolution of beyond 5G and 6G era, it is true that confronts critical challenges. For example, its nearly passive nature and the absence of any active components makes conventional RIS to perform channel estimation and beam tracking as one of the most challenging issues. Consequently, in real life setups, conventional RISs constraint the bandwidth used for transmission and the achievable data rate. To address the above issues in conventional RIS, the holographic RIS (HRIS) (a.k.a. as reconfigurable holographic surface), has been emerged recently as an alternate technology [\[31\]](#page-12-4), [\[35\]](#page-12-8), [\[36\]](#page-12-9). HRIS is considered as a limited surface area that integrates a virtually infinite number of tiny metamaterial-based radiation elements in order to form a spatially continuous transceiver aperture that can achieve the holographic beamforming. HRIS is able to support channel estimation and act like continuous surface for higher frequencies up to the THz bandwidth compared to conventional RIS [\[31\]](#page-12-4).

In one of the most representative works on HRIS [\[37\]](#page-12-10), the authors proposed the concept of HRIS and studied its application to massive MIMO in THz frequency range. More, in this pioneer work, the authors have addressed the transmission design of nearly-passive HRISs with spatially continuous apertures by designing the beam pattern of a RIS with discrete meta-elements and generalize their beamforming framework to a surface with closely spaced (i.e. continuous) meta-elements yielding the HRIS design. In [\[38\]](#page-12-11), the authors studied the problem of beam pattern design of RISassisted THz communication systems with two-dimensional finite impulse response filter design, and the above method proved to facilitate applications such as wireless positioning and over-the-air computation. In [\[39\]](#page-12-12), the joint phase and delay wideband precoding was investigated to tackle the severe problem of array gain loss of RIS-aided THz communications due to beam split at RIS. Additionally, the authors in [\[40\]](#page-12-13) have investigated the performance of HRIS non-orthogonal multiple access (NOMA) networks, whereas the same authors in [\[41\]](#page-12-14) have very recently evaluated the outage of HRISs-enabled THz NOMA systems in the presence of misalignment errors and for either perfect or imperfect successive interference cancellation.

Motivated by the fact that HRIS supports the same functionalities as conventional RIS, but most importantly due to its holographic pattern is an attractive candidate for RISaided wireless communication systems working at the sub-THz band, in this paper we study the performance of HRISempowered THz wireless systems with hardware imperfections at both ends and under foggy weather conditions.

B. Our Contributions

In contrast that most of the published works study the application of conventional RIS in either sub-6GHz bands or mmwave, in this paper, the communication theoretical framework of HRIS in sub-THz bands over severe weather conditions (fog) is analytically studied under the presence of transceiver hardware imperfections. The contributions of our work can be summarized as follows:

• The end-to-end geometric losses of the proposed system are calculated by considering the following channel coefficients: free-space geometric channel gain, molecular absorption gain, and fog gain. Our analysis shows that the geometric losses are quite affected by the following parameters: the relative position of HRIS in respect to the TX, HRIS size and its orientation, TX/RX antenna gains, the signal frequency, as well as the weather conditions.

- The statistics of the end-to-end channel coefficients of HRIS-enabled THz systems is analytically evaluated in closed form. Based on the latter derivations, new closedform expressions for the outage probability and data throughput are extracted when hardware imperfections take place at both ends of the considered system in foggy weather conditions.
- New engineering insights are extracted such as how the geometric loss is affected by various frequencies in the sub-THZ band, and what is the optimal placement of HRIS between transmitter and receiver. Additionally, our paper provides a comprehensive study on the impact of the placement and orientation of HRIS to both outage and throughput performance metrics under fixed values of frequency range, spectral efficiency, and transceiver hardware imperfection parameters.

C. Organization of the paper

This paper is structured as follows. In the sequel, a few basic mathematical symbols used in this paper are given. The system and signal model studied in this paper are introduced in Section II. In Section III, the geometric losses and the corresponding statistical analysis of the end-to-end channels are analytically presented, while both the outage probability and throughput are obtained in closed form. In Section IV, the analytical expressions are corroborated and cross-compared with Monte Carlo simulation results. In the same Section, some useful engineering insights are revealed and discussed in much detail. Finally, some concluding remarks are given in Section V.

D. Notations

In this paper, \sqrt{x} returns the square root of x. The cosine and exponential functions are denoted by $cos (·)$ and $\exp(\cdot)$, respectively. The natural logarithm is represented as $\ln(\cdot)$, while $\log_a(\cdot)$ is the logarithm to base a. The operator min (a, b) returns the minimum between a and b. The gamma and the upper incomplete gamma functions are respectively represented as $\Gamma(\cdot)$ [\[42,](#page-12-15) eq. (8.310)] and $\Gamma(\cdot, \cdot)$ [42, eq. (8.350/2)]. The Kummer confluent hypergeometric function is denoted by $_1F_1(\cdot, \cdot, \cdot)$ [\[42,](#page-12-15) eq. (9.14/1)]. Moreover, $H_A(a, b; c; x_1, x_2)$ stands for the Lauricella hypergeometric function [\[43\]](#page-12-16). Finally, the Pochhammer operator is denoted by $(n)_m$.

II. SYSTEM AND SIGNAL MODEL

As demonstrated in Fig. [1,](#page-2-0) we consider a long-range THz wireless fiber extender that is established through a HRIS. By assuming that the transmitter (TX)-HRIS and HRIS-receiver (RX) links experience fog, the baseband equivalent received signal can be expressed as

$$
r = h_g h_1 h_2 (s + n_t) + n_r + n,
$$
 (1)

where h_g stands for the end-to-end geometric gain channel coefficient, while h_1 and h_2 are independent random processes that model the impact of fog in the TX-HRIS and HRIS-RX links, respectively. The transmitted signal is denoted by

Fig. 1: Typical model of an HRIS empowered THz communication system.

s, whereas n_t and n_r stands for the distortion noises due to hardware imperfections at the TX and RX, respectively. The additive white Gaussian noise is modeled by the zero-mean complex Gaussian random process *n* of variance σ_n^2 .

The end-to-end geometric gain channel coefficient can be analyzed as

$$
h_g = h_{g,f} h_{g,m} h_f,\tag{2}
$$

where $h_{q,f}$ is the free space geometric gain channel coefficient that can be expressed as $[44, eq. (9)]$

$$
h_{g,f} = \frac{c\sqrt{G_t G_r} l_h l_v}{4\pi f d_1 d_2} \cos(\psi),
$$
 (3)

with c being the speed of light, G_t and G_r standing for the transmission and reception antenna gains, respectively, while l_h and l_v representing the length and width of the HRIS. Also, f is the transmission frequency, whereas d_1 and d_2 are the TX-HRIS and HRIS-RX distances, respectively. Finally, ψ denotes the beam incident angle at the HRIS.

Additionally, $h_{q,m}$ is the molecular absorption gain coefficient that can be obtained as

$$
h_{g,m} = \exp\left(\frac{1}{2} \kappa_m(f, T, \phi, p) (d_1 + d_2)\right), \quad (4)
$$

where κ_m is the molecular absorption coefficient, T is the atmospheric temperature, ϕ stands for the relative humidity, and p represents the atmospheric pressure.

Based on [\[7\]](#page-11-6), the molecular absorption coefficient can be written as

$$
\kappa_m(f, T, \phi, p) = \sum_{k,l} \kappa_{k,l}^g(f, T, \phi, p), \tag{5}
$$

where $\kappa_{k,l}^g$ (f, T, ϕ, p) represents the molecular absorption coefficient for the isotoplogue k of the l −th gas and can be expressed as

$$
\kappa_{k,l}^{g}(f,T,\phi,p) = \frac{p}{p_o} \frac{T_o}{T} Q_{k,l}^{g} \sigma_{k,l}^{g}(f,T,\phi,p) ,
$$
 (6)

with p_o and T_o denoting the standard pressure and temperature respectively, while $Q_{k,l}^g$ and $\sigma_{k,l}^g$ $(f, \overline{T}, \phi, p)$ respectively being the molecular volumetric density and the absorption cross section for the isotopologue k of the l−th gas. The molecular volumetric density can be evaluated as

$$
Q_{k,l}^g = \frac{p}{RT} q_{k,l} N_A,\tag{7}
$$

where R is the gas constant, N_A stands for the Avogadro constant, and $q_{k,l}$ represents the mixing ratio for the isotopologue k of the l−th gas. Note that in the high resolution transmission (HITRAN) database, each isologue contribution is scaled based on its natural abundance in the medium. As a consequence, instead of $q_{k,l}$, the mixing ratio of the specific gas is employed.

The absorption cross section for the isotopologue k of the l−th gas can be calculated as

$$
\sigma_{k,l}^{g}(f, T, \phi, p) = S_{k,l} G_{k,l} (f, T, \phi, p), \qquad (8)
$$

where $S_{k,l}$ is the absorption strength of a specific type of molecule and can be directly extracted from the HITRAN database, while $G_{k,l}$ (f, T, ϕ, p) is the spectral line shape for the isotopologue k of the l −th gas that can be evaluated as in [\[45\]](#page-12-18)

$$
G_{k,l}(f,T,\phi,p) = \frac{f}{f_{k,l}} \frac{\tanh\left(\frac{h\,c\,f}{2\,k_b\,T}\right)}{\tanh\left(\frac{h\,c\,f_{k,l}}{2\,k_b\,T}\right)} F_{k,l}(f), \quad (9)
$$

with h and k_b respectively being the Plank and Bolzmann constants, $f_{k,l}$ representing the resonant frequency for the isotopologue k of the l−th gas, and $F_{k,l}(f)$ denoting the Van Vleck-Weisskopf asymmetric line shape that can be calculated as in [\[46\]](#page-12-19)

$$
F_{k,l}(f) = 100 \, c \frac{\alpha_{k,l}}{\pi} \frac{f}{f_{k,l}} \times \left(\frac{1}{\left(f - f_{k,l}\right)^2 + \alpha_{k,l}^2} + \frac{1}{\left(f + f_{k,l}\right)^2 + \alpha_{k,l}^2} \right), \qquad (10)
$$

where $\alpha_{k,l}$ is the Lorentz half-width that can be expressed as

$$
\alpha_{k,l} = ((1 - q_{k,l}) \alpha_o^a + q_{k,l} a_{k,l}^o) \frac{p}{p_o} \left(\frac{T_o}{T}\right)^t, \quad (11)
$$

with t being the temperature broadening coefficient, while α_o^a and $a_{k,l}^o$ respectively denoting Lorentz half-width of air and the reference value of the Lorentz half-width for the isotopologue k of the l−th gas. Note that t, α_o^a , and $\alpha_{k,l}^o$ can be directly extracted from HITRAN.

Note that except from the aforementioned model for the molecular absorption coefficient, a number of approximations including [\[10\]](#page-11-7), [\[47\]](#page-12-20), [\[48\]](#page-12-21) have been published. Although these approximations are very accurate and have been widely used, since their application is in the area of $100-500$ GHz, in this paper, we decided to use a more general model that can cover all the THz band.

Finally, h_f denotes the fog gain, which based on [\[49\]](#page-12-22), can be analyzed as

$$
h_f = 10^{-\frac{1}{2}\kappa_f M \frac{d_1 + d_2}{1000}},\tag{12}
$$

where M is the liquid water density in the fog and κ_f is the fog attenuation coefficient, which can be obtained as

$$
\kappa_f = \frac{0.819 f}{\epsilon_i (1 + \eta^2)},\tag{13}
$$

with

$$
\eta = \frac{2 + \epsilon_i}{\epsilon_r}.\tag{14}
$$

In [\(14\)](#page-3-0), ϵ_r and ϵ_i are the real and imaginary part of the dielectric permittivity of water, which can be expressed as

$$
\epsilon_r = \frac{\epsilon_0 - \epsilon_1}{1 + \left(\frac{f}{f_p}\right)^2} + \frac{\epsilon_1 - \epsilon_2}{1 + \left(\frac{f}{f_s}\right)^2} + \epsilon_2 \tag{15}
$$

and

$$
\epsilon_i = \frac{f}{f_p} \frac{\epsilon_0 - \epsilon_1}{1 + \left(\frac{f}{f_p}\right)^2} + \frac{f}{f_s} \frac{\epsilon_1 - \epsilon_2}{1 + \left(\frac{f}{f_s}\right)^2},\tag{16}
$$

respectively. The parameters f_p and f_s denote the principal and secondary relaxation frequencies, which can be evaluated as

$$
f_p = 20.2 \times 10^{-9} - 146 \times 10^{-9} (\theta - 1)
$$

+ 316 \times 10^{-9} (\theta - 1)² (17)

and

$$
f_s = 39.9 f_p,\tag{18}
$$

while

$$
\epsilon_0 = 77.66 + 103.3 \; (\theta - 1)\,,\tag{19}
$$

$$
\epsilon_1 = 0.0671 \,\epsilon_0,\tag{20}
$$

$$
\epsilon_2 = 3.52 \tag{21}
$$

and

$$
\theta = \frac{300}{T}.\tag{22}
$$

As discussed in [\[50\]](#page-12-23), h_i with $i = 1, 2$, follows a logarithmic distribution with probability density function (PDF) and cumulative distribution function (CDF) that can be, respectively, obtained as

$$
f_{h_i}(x) = \frac{\zeta_i^{k_i}}{\Gamma(k_i)} x^{k_i - 1} \left(\ln \left(\frac{1}{x} \right) \right)^{k_i - 1}, \text{ with } 0 < x \le 1 \tag{23}
$$

and

$$
F_{h_i}(x) = \frac{\Gamma\left(k_i, \zeta_i \ln\left(\frac{1}{x}\right)\right)}{\Gamma(k_i)}, \qquad \text{with } 0 < x \le 1, \tag{24}
$$

where

$$
\zeta_i = \frac{4.343}{\beta_i d_i}.\tag{25}
$$

In [\(23\)](#page-3-1)–[\(25\)](#page-3-2), k_1 and β_1 stands for the foggy conditions of the TX-HRIS link, while k_2 and β_2 stands for the foggy conditions of the HRIS-RX link. For instance, (k_i, β_i) , with $i \in \{1, 2\}$, refers to light fog, if $(2.32, 13.12)$, to moderate fog, if $(5.49, 12.06)$, to thick fog, if $(6, 23)$, and to dense fog, if (36.06, 11.91).

According to [\[51\]](#page-12-24), the distortion noise due to the TX hardware imperfections can be modeled as a zero-mean complex Gaussian random process with variance that can be obtained as

$$
\sigma_{n_t}^2 = \kappa_t^2 P_s,\tag{26}
$$

where κ_t is the TX error vector magnitude (EVM) and P_s is the transmission power. Similarly, for a given channel realization, the distortion noise due to the RX hardware imperfections can be modeled as a zero-mean complex Gaussian random process with variance that can be expressed as

$$
\sigma_{n_r}^2 = \kappa_r^2 \, h_g^2 \, h_1^2 \, h_2^2 \, P_s,\tag{27}
$$

where κ_r is the RX EVM. Of note, the EVM in THz wireless systems is in the range of [0.07, 0.4] [\[18\]](#page-11-17), [\[52\]](#page-12-25)–[\[56\]](#page-12-26).

III. PERFORMANCE ANALYSIS

This section is devoted to analyze the performance of HRIS-empowered THz wireless systems. In this direction, Section [III-A](#page-4-0) provides a closed-form expression for the HRIS-empowered THz wireless system geometric losses. Section [III-B](#page-4-1) presents the statistical characterization of the end-toend channel in terms of PDF and CDF. The outage probability of the system is presented in Section [III-C,](#page-4-2) while the throughput is given in Section [III-D.](#page-5-0)

A. Geometric Losses

From [\(2\)](#page-2-1), it becomes evident that the geometric losses can be obtained as

$$
P_L = \frac{1}{h_g^2},\tag{28}
$$

or equivalently

$$
P_L = \frac{1}{h_{g,f}^2} \frac{1}{h_{g,m}^2} \frac{1}{h_f^2}.
$$
 (29)

Thus, from [\(3\)](#page-2-2), [\(4\)](#page-2-3), and [\(12\)](#page-3-3), we observe that the end-to-end geometric loss depends on the relative position of the HRIS in respect to the TX, the HRIS size, the TX and RX antenna gains, the transmission frequency, as well as the atmospheric conditions, i.e. temperature and liquid water density.

B. Statistical Characterization of the End-to-End Channel

Let

$$
A = h_1 h_2,\tag{30}
$$

the following theorem returns the PDF of A.

Theorem 1. *The PDF and CDF of* A *can be, respectively, expressed as*

$$
f_A(x) = \frac{\zeta_1^{k_1} \zeta_2^{k_2}}{\Gamma(k_1 + k_2)} x^{\zeta_2 - 1} \left(-\ln(x) \right)^{k_1 + k_2 - 1}
$$

$$
\times {}_1F_1(k_1; k_1 + k_2; (\zeta_1 - \zeta_2) \ln(x)) \tag{31}
$$

and

$$
F_A(x) = (-1)^{k_1 + k_2 = 1} \frac{\zeta_1^{k_1} \zeta_2^{k_2}}{k_1 + k_2} \frac{\left(\ln(x)\right)^{k_1 + k_2}}{\Gamma(k_1) \Gamma(k_2)}
$$

× H_A (k₁ + k₂, k₁; k₁ + k₂ + 1; (ζ₁ - ζ₂) ln(x), ζ₂ ln(x)), (32)

with $x \in (0, 1]$ *.*

Proof: For brevity, the proof of Theorem 1 is given in Appendix A.

The PDF of the end-to-end channel coefficient

$$
A_t = h_g A,\tag{33}
$$

can be evaluated as

$$
f_{A_t}(x) = \frac{1}{h_g} f_A\left(\frac{x}{h_g}\right). \tag{34}
$$

By applying [\(31\)](#page-4-3) to [\(34\)](#page-4-4), we obtain

$$
f_{A_t}(x) = \frac{\zeta_1^{k_1} \zeta_2^{k_2}}{h_g \Gamma(k_1 + k_2)} \left(\frac{x}{h_g}\right)^{\zeta_2 - 1} \left(-\ln\left(\frac{x}{h_g}\right)\right)^{k_1 + k_2 - 1} \times {}_{1}F_1\left(k_1; k_1 + k_2; (\zeta_1 - \zeta_2)\ln(\frac{x}{h_g})\right). \tag{35}
$$

Additionally, the CDF of A_t can be expressed as

$$
F_{A_t}(x) = F_A\left(\frac{x}{h_g}\right),\tag{36}
$$

which, by applying [\(32\)](#page-4-5), yields

$$
F_{A_t}(x) = (-1)^{k_1 + k_2 = 1} \frac{\zeta_1^{k_1} \zeta_2^{k_2}}{k_1 + k_2} \frac{\left(\ln\left(\frac{x}{h_g}\right)\right)^{k_1 + k_2}}{\Gamma(k_1)\Gamma(k_2)} \times \text{H}_A\left(k_1 + k_2, k_1; k_1 + k_2 + 1; (\zeta_1 - \zeta_2)\ln\left(\frac{x}{h_g}\right),\right) \zeta_2 \ln\left(\frac{x}{h_g}\right)\right).
$$
\n(37)

C. Outage Probability

From [\(1\)](#page-2-4), the signal-to-distortion-plus-noise-ratio (SDNR) can be obtained as

$$
\gamma = \frac{h_g^2 A^2 P_s}{h_g^2 A^2 \left(\kappa_t^2 + \kappa_r^2\right) P_s + \sigma_n^2},\tag{38}
$$

or equivalently

$$
\gamma = \frac{A^2}{A^2(\kappa_t^2 + \kappa_r^2) + \frac{1}{\rho}},\tag{39}
$$

where

$$
\rho = \frac{h_g^2 P_s}{\sigma_n^2}.\tag{40}
$$

The outage probability is defined as

$$
P_o(\gamma_{\rm th}) = \Pr\left(\gamma \le \gamma_{\rm th}\right),\tag{41}
$$

where γ_{th} stands for the SNR threshold. The following proposition returns a closed-form expression for the outage probability.

Proposition 1. *The outage probability can be evaluated as in* [\(42\)](#page-5-1)*, given at the top of the next page. In* [\(42\)](#page-5-1)*, the following condition should hold:*

$$
\gamma_{\text{th}} \le \min\left(\frac{1}{\kappa_t^2 + \kappa_r^2}, \frac{\rho}{(\kappa_t^2 + \kappa_r^2)\,\rho + 1}\right). \tag{43}
$$

Otherwise, $P_o(\gamma_{\text{th}}) = 1$.

Proof: For brevity, the proof of Theorem 1 is given in Appendix B.

$$
P_o(\gamma_{th}) = (-1)^{k_1 + k_2 = 1} \frac{\zeta_1^{k_1} \zeta_2^{k_2}}{k_1 + k_2} \frac{\left(\ln\left(\sqrt{\frac{\gamma_{th}}{\rho}} \frac{1}{\sqrt{1 - \gamma_{th}(\kappa_t^2 + \kappa_r^2)}}\right)\right)^{k_1 + k_2}}{\Gamma(k_1) \Gamma(k_2)}\right)}{\sqrt{(k_1 + k_2)^2 k_1^2}} \times \text{H}_A\left(k_1 + k_2, k_1; k_1 + k_2 + 1; (\zeta_1 - \zeta_2) \ln\left(\sqrt{\frac{\gamma_{th}}{\rho}} \frac{1}{\sqrt{1 - \gamma_{th}(\kappa_t^2 + \kappa_r^2)}}\right), \zeta_2 \ln\left(\sqrt{\frac{\gamma_{th}}{\rho}} \frac{1}{\sqrt{1 - \gamma_{th}(\kappa_t^2 + \kappa_r^2)}}\right)\right)}
$$
(42)

D. Throughput

The throughput is defined as

$$
D = W r_t \left(1 - P_o \left(\gamma_{\text{th}}\right)\right),\tag{44}
$$

where W and r_t are respectively the bandwidth and the spectral efficiency of the modulation and coding scheme that is used. Note that r_t and γ_{th} are connected through

$$
r_t = \log_2\left(1 + \gamma_{\text{th}}\right). \tag{45}
$$

As a result, [\(44\)](#page-5-2) can be rewritten as

$$
D = W r_t (1 - P_o (2^{r_t} - 1)). \tag{46}
$$

By applying [\(42\)](#page-5-1) to [\(46\)](#page-5-3), we obtain [\(47\)](#page-6-0), given at the top of the next page.

Notice that [\(47\)](#page-6-0) is valid, if and only if [\(43\)](#page-4-6) is satisfied. Or equivalently, if

$$
r_{\rm th} \le \min\left(\log_2\left(\frac{1}{\kappa_t^2 + \kappa_r^2} + 1\right),\right)
$$

$$
\log_2\left(1 + \frac{\rho}{(\kappa_t^2 + \kappa_r^2)\,\rho + 1}\right)\right). \tag{48}
$$

Otherwise, the throughput is equal to 0.

IV. RESULTS & DISCUSSION

This section focuses on verifying the theoretical framework by means of Monte Carlo simulations and extracting engineering insights. In what follows, lines stand for analytical results, while markers are used for simulations. Unless otherwise stated, black, red, orange, and blue colors are used for light, moderate, thick, and dense fog, respectively.

Fig. [2](#page-6-1) depicts the geometric loss as a function of f for different values of $l_h = l_v$, assuming $G_t = G_r = 50$ dBi, $\psi = \pi/4$, $T = 20^{\circ}\text{C}$, $P = 101300.0 \text{ Pa}$, $d_1 = d_2 = 50 \text{ m}$ and water vapour density equals to 7.5 g/m^3 . Notice that a water vapour density that is equal to 7.5 g/m^2 corresponds to moderate fog. From this figure, we observe that in the range of 100 to 1000 GHz, 10 transmission windows exist. In more detail, the first transmission windows is from 100 to 180 GHz; there, the available bandwidth is equal to 80 GHz. The second transmission window is from 192 to 322 GHz. The available bandwidth of the second transmission window is 130 GHz. Notice that although the available bandwidth of the second transmission window is greater than the one of the first transmission window, the average geometric loss in the second transmission window is also higher than the one of the first transmission window. The range of the third transmission window is $335 - 373$ GHz. As a consequence, the available bandwidth of the third transmission window

is 38 GHz. The forth transmission window is from 390 to approximately 443 GHz. Thus, the available bandwidth of the forth transmission window is 53 GHz. The fifth transmission window is from 456 to 472 GHz, while the sixth transmission window is from 477 to 487 GHz. The seventh transmission window is from 587 to 616 GHz. The range of the eighth transmission window is from 630 to 715 GHz. The ninth transmission window is from 790 to 890 GHz, while the tenth is from 950 to 970 GHz. Finally, from a given f, as $l_h = l_v$ increases, i.e., as the size of the HRIS increases, the geometric loss decreases.

Fig. [3](#page-6-2) demonstrates the geometric loss as a function of d_1 for different values of f, assuming $d_1 + d_2 = 100 \,\text{m}$, $G_t = G_r = 50$ dBi, $l_h = l_v = 1$ m, $\psi = \pi/4$, $T =$ 20° C, $P = 101300.0$ Pa, and water vapour density equals to 7.5 g/m^3 . Note that the selected frequencies are within the transmission windows. From this figure, we observe that for fixed frequency and $d_1 < \frac{d_1+d_2}{2}$, as d_1 increases, the geometric loss also increases, while for $d_1 > \frac{d_1 + d_2}{2}$, as d_1 increases, the geometric loss decreases. Likewise, for a given f, the maximum geometric loss is at $d_1 = \frac{d_1 + d_2}{2}$. For example, for $f = 100$ GHz, as d_1 increases from 1 to 10 m, the geometric loss increases from 21.72 to 40.89 dB, while, for the same f, as d_1 increases from 90 to 99 m, the geometric loss increases from 40.89 to 21.72 dB. From this example, it becomes evident that for a given frequency, the same geometric loss is achieved for d_1 and $d_t - d_1$, where d_t is the total distance. Moreover, we observe that based on the geometric loss, the optimal position of the HRIS is as near to the TX or the RX as possible. Finally, for a given d_1 , as f increases, the geometric loss increases.

In Fig. [4,](#page-6-3) the outage probability is plotted as a function of f, for different values of $\frac{P_s}{\sigma_n^2}$, assuming $G_t = G_r = 50$ dBi, $\psi = \pi/4, T = 20^{\circ}\text{C}, P = 101300.0 \text{ Pa}, d_1 = d_2 = 50 \text{ m},$ $l_h = l_v = 1$ m, and ideal RF front-end at both the TX and the RX. Moreover, the water vapour density is set to 7.5 g/m^3 . Notice that these conditions corresponds to moderate fog; thus, $k_1 = k_2 = 5.49$ and $\beta_1 = \beta + 2 = 12.06$. As expected, for a given f, as $\frac{P_s}{\sigma_n^2}$ increases, the outage performance improves. For example, for $f = 200$ GHz, the outage probability decreases from 1 to 0.36, as $\frac{P_s}{\sigma_n^2}$ increases from 60 to 80 dB. Additionally, for a fixed $\frac{P_s}{\sigma_p^2}$, a local maximum in the outage probability is observed, at the water resonating frequencies. Likewise, from this figure, we observe that based on the application reliability requirement, i.e., the maximum allowed outage probability, as well as the required energy consumption, which is translated to $\frac{P_s}{\sigma_p^2}$, a different range of frequencies can be employed. For instance, if the maximum

$$
D = W r_t \left(1 - (-1)^{k_1 + k_2 = 1} \frac{\zeta_1^{k_1} \zeta_2^{k_2}}{k_1 + k_2} \frac{\left(\ln \left(\sqrt{\frac{2^{r_t} - 1}{\rho}} \frac{1}{\sqrt{1 - (2^{r_t} - 1)(\kappa_t^2 + \kappa_r^2)}} \right) \right)^{k_1 + k_2}}{\Gamma(k_1) \Gamma(k_2)} \right)
$$

$$
\times H_A \left(k_1 + k_2, k_1; k_1 + k_2 + 1; (\zeta_1 - \zeta_2) \ln(\sqrt{\frac{(2^{r_t} - 1)}{\rho}} \frac{1}{\sqrt{1 - (2^{r_t} - 1)(\kappa_t^2 + \kappa_r^2)}}),
$$

$$
\zeta_2 \ln(\sqrt{\frac{(2^{r_t} - 1)}{\rho}} \frac{1}{\sqrt{1 - (2^{r_t} - 1)(\kappa_t^2 + \kappa_r^2)}}) \right)
$$
(47)

Fig. 2: Geometric loss as a function of f for different values of $l_h = l_v$.

Fig. 3: Geometric loss vs d_1 for different values of f.

Fig. 4: Outage probability vs of f for different values of $\frac{P_s}{\sigma_n^2}$.

allowed outage probability is set to 10^{-6} , which is a realistic value for backhauling scenarios, and the transmission SNR is set to 100 dB, the transmission frequency should be in the range of $[100, 151.5 \text{ GHz}]$. Note that this frequency range is a subset of the first transmission frequency window, which is defined in Fig. [2.](#page-6-1) For the same reliability requirement, and for a transmission SNR equal to 120 dB, we observe that the range of the transmission frequency increases to [100, 309.5 GHz]. In other words, as the transmission SNR increases, the range of the transmission frequencies that can be used to support the system increases. As discussed in [\[1\]](#page-11-0), this highlights the importance of adopting new type of transceivers in THz wireless systems that minimizes their noise figure.

Fig. [5](#page-7-0) illustrates the outage probability as a function of $\frac{\rho}{\gamma_{\text{th}}}$ for different values of $d_1 = d_2 = d$ and fog conditions. Moreover, we assume that the transceivers are equipped with ideal RF front-end, i.e. $\kappa_t = \kappa_r = 0$. As expected for given fog conditions and d, as $\frac{\rho}{\gamma_{\text{th}}}$ increases, the outage performance improves. For example for light fog and $d = 30$ m, as $\frac{\rho}{\gamma_{\text{th}}}$ increases from 5 to 10 dB, the outage probability decreases for about 2 orders of magnitude. Moreover, for fixed fog conditions and $\frac{\rho}{\gamma_{\text{th}}}$, as d increases, the outage probability also increases. For instance, for light fog and $\frac{\rho}{\gamma_{\text{th}}} = 15 \text{ dB}$, the outage probability increases from 2.08×10^{-5} to 7.63×10^{-3} ,

Fig. 5: Outage probability vs $\frac{\rho}{\gamma_{\text{th}}}$ for different values of $d_1 =$ $d_2 = d$, assuming light (black), moderate (red), thick (orange), and dense (blue) fog.

Fig. 6: Outage probability vs d_1 for different values of $\frac{\rho}{\gamma_{\text{th}}}$, assuming light (black), moderate (red), thick (orange) fog and $d_1 + d_2 = 100$ m.

as d increases from 30 to 50 m. Finally, for given $\frac{\rho}{\gamma_{\text{th}}}$ and d, as the fog becomes more severe, the outage performance degrades. For example, for $\frac{\rho}{\gamma_{\text{th}}} = 15 \text{ dB}$ and $d = 30 \text{ m}$, as the fog conditions changes from light to moderate, the outage probability increases from 2.08×10^{-5} to 7.15×10^{-3} . For the same $\frac{\rho}{\gamma_{\text{th}}}$ and d, the system under thick fog, achieves an outage probability that is equal to 5.9×10^{-1} , while, under dense fog, it is equal to 1. These examples indicate the importance of accounting for the fog impact on the performance of HRISempowered THz wireless systems.

Fig. [6](#page-7-1) depicts the outage probability as a function of d_1 for different values of $\frac{\rho}{\gamma_{\text{th}}}$ and fog conditions, assuming $d_1 + d_2 =$ 100 m and ideal RF front-end. From this figure, we observe that for given $\frac{\rho}{\gamma_{\text{th}}}$ and fog conditions, for $d_1 < \frac{d_1+d_2}{2}$, as d increases the outage probability decreases. For example, for $\frac{\rho}{\gamma_{\text{th}}}$ = 40 dB and light fog, as d_1 increases from 10 to 20 m, the outage probability decreases from 2.17×10^{-6} to 4.35×10^{-7} . On the other hand, for fixed $\frac{\rho}{\gamma_{\text{th}}}$ and fog conditions, for $d_1 > \frac{d_1 + d_2}{2}$, as d_1 increases, the outage probability also increases. For instance, $\frac{\rho}{\gamma_{\text{th}}}$ = 40 dB and light fog, as d_1 increases from 80 to 90 m, the outage probability increases from 4.35×10^{-7} to 2.17×10^{-6} . For given fog conditions and $\frac{\rho}{\gamma_{\text{th}}}$, the outage probability achieves the minimum value for $d_1 = \frac{d_1 + d_2}{2}$. In other words, the optimal place for the HRIS is at $\frac{d_1+d_2}{2}$. Moreover, we observe that the same outage performance are achieved for d_1 and $d_t - d_1$, where $d_t = d_1 + d_2$. For example, for $\frac{\rho}{\gamma_{\text{th}}} = 40 \,\text{dB}$ and light fog, for both $d_1 = 10 \,\mathrm{m}$ and $d_1 = 90 \,\mathrm{m}$, the outage probability is equal to 2.17×10^{-6} . Additionally, for given d and fog conditions, as $\frac{\rho}{\gamma_{\text{th}}}$ increases, the outage probability decreases. For instance, for $d = 10 \text{ m}$ and light fog, as $\frac{\rho}{\gamma_{\text{th}}}$ changes from 20 to 40 dB, the outage probability decreases for approximately 5 orders of magnitude. Finally, for fixed d and $\frac{\rho}{\gamma_{\text{th}}}$, as the fog density increases, the outage performance of the system degrades.

Fig. [7](#page-8-0) demonstrates the impact of transceiver hardware imperfections on the outage performance of HRIS-empowered THz wireless systems. In more detail, the outage probability is plotted as a function of $\kappa = \sqrt{\kappa_t^2 + \kappa_r^2}$ for different values of γ_{th} , ρ , as well as fog conditions, assuming $d_1 = d_2 = 50 \,\text{m}$. As expected, for given γ_{th} , ρ and fog conditions, as κ increases, the impact of transceivers hardware imperfections increases; thus, the outage probability increases. For example, for γ_{th} = 10 dB, ρ = 30 dB, and light fog, the outage probability increases for more than 2 orders of magnitude, as κ increases from 0.1 to 0.3. This indicates the importance of taking into account the impact of transceiver hardware imperfections, when designing modulation and coding schemes. From this figure, it become evident that, for given κ , ρ , and fog conditions, as γ_{th} increases, the impact of hardware imperfections becomes more severe; as a consequence, an outage performance degradation is observed. For instance, for $\kappa = 0.2$, $\rho = 30$ dB, and light fog, the outage probability increases for more than 1 order of magnitude, as γ_{th} increases from 5 to 10 dB. Moreover, or given κ , ρ , and γ_{th} , as the density of fog increases, the outage probability also increases. For example, for $\kappa = 0.2$, $\rho = 30$ dB, and $\gamma_{\text{th}} = 5$ dB, as the fog conditions change from light to moderate, the outage probability increases for more than 2 orders of magnitude. Finally, for given κ , γ_{th} , and fog conditions, as ρ increases, the outage probability decreases.

Fig. [8](#page-8-1) presents the throughput to bandwidth ratio as a function of r_t for different values of ρ and fog conditions, assuming ideal RF front-end and $d_1 = d_2 = 50$ m. From this figure, we observe that for given ρ and fog condition, an optimal spectral efficiency of the modulation and coding transmission scheme, r_t^o , exists that maximizes the throughput to bandwidth ratio. For $r_t < r_t^o$, as r_t increases, $\frac{D}{W}$ also increases. On the other hand, for $r_t > r_t^o$, as r_t increases, $\frac{D}{W}$ decreases. Moreover, for fixed ρ_t and fog conditions, as ρ increases, $\frac{D}{W}$ also increases. For example, under light fog, for $r_t = 8 \text{ bits/s/Hz}$, the D/W increases from 4.32 to

Fig. 7: Outage probability vs κ for different values of γ_{th} , assuming light (black), moderate (red), thick (orange) fog and $\rho = 30$ dB (a) and $\rho = 40$ dB (b).

7.96 bits/s/Hz, as ρ increases from 30 to 40 dB. Finally, for given r_t and ρ , as the fog density increases, D/W decreases.

Fig. [9](#page-8-2) presents the throughput to bandwidth ratio as a function of the transmission scheme spectral efficiency for different values of κ and under different fog conditions. As a benchmark, the case of ideal RF front-end is plotted. As expected, an optimal transmission spectral efficiency, r_t^o , exists, for which the throughput to bandwidth ratio is maximized. For given κ , fog density, and $r_t < r_t^o$, as r_t increases, D/W also increases. For example, thick fog and $\kappa = 0.07$, the optimal transmission spectral efficiency is equal to 5.5 bits/s/Hz, where the achievable throughput to bandwidth ratio is 4.125 bits/s/Hz. Moreover, as the transmission spectral efficiency increases from 4 to 5 bits/s/Hz , the throughput to bandwidth ratio increases from 3.58 to 4.058 bits/s/Hz. On the other hand, for $r_t > r_t^o$, as the transmission spectral efficiency increases, the throughput to bandwidth ratio decreases. For instance,

Fig. 8: D/W vs r_t for different values of ρ , assuming light (black), moderate (red), thick (orange) fog and $d_1 = d_2$ = 50 m.

Fig. 9: D/W vs r_t for different values of κ , assuming light (black), moderate (red), thick (orange) fog, $d_1 = d_2 = 50 \,\text{m}$ and $\rho = 50$ dB.

for thick fog and $\kappa = 0.07$, as the transmission spectral efficiency increases from 6 to 7 bits/s/Hz, the throughput to bandwidth ratio decreases from 4.01 to 2.74 bits/s/Hz . Likewise, for given fog density and transmission spectral efficiency, as κ increases, the throughput to bandwidth ratio decreases. For example, for thick fog and transmission spectral efficiency equal to 6 bits/s/Hz , the throughput to bandwidth ratio decreases from 4.01 to 3.26 bits/s/Hz, as κ increases from 0.07 to 0.1. Additionally, for fixed transmission spectral efficiency and κ , as the fog density increases, the throughput to bandwidth ratio decreases. For instance, for $r_t = 6$ bits/s/Hz and $\kappa = 0.07$, if the fog condition changes from light to thick, the throughput to bandwidth ratio will decrease from 6.0 to 3.26 bits/s/Hz. This indicates the importance of

Fig. 10: D/W vs ψ for different values of $\kappa_t = \kappa_r$, assuming $f = 100$ GHz (black) and $f = 370$ GHz (red).

accurately modeling the fog conditions, when estimating the throughput performance of HRIS-empowered wireless THz systems. Finally, from this figure, it becomes apparent that a maximum transmission spectral efficiency exists beyond which the throughput to bandwidth ratio becomes equal to 0. The maximum transmission spectral efficiency depends on the level of transceiver hardware imperfections. For example, for $\kappa = 0.07$, it is equal to 7.68 bits/s/Hz, while, for $\kappa = 0.1$, it is equal to 6.66 bits/s/Hz. Note that the maximum transmission spectral efficiency is independent of the fog conditions. Also, we observe that the maximum transmission spectral efficiency is lower than the optimal transmission spectral efficiency for the case of ideal RF front-end. This highlights the importance of accounting for the impact of hardware imperfections, when selecting the transmission scheme.

In Fig. [10,](#page-9-0) D/W is illustrated as a function of ψ for different levels of transceiver hardware imperfections and frequencies, assuming $\frac{P_s}{\sigma_n^2}$ = 120 dB, r_t = 5 bits/s/Hz, $G_t = G_r = 50$ dBi, $\psi = \pi/4$, $T = 20^{\circ}\text{C}$, $P = 101300.0$ Pa, $d_1 = d_2 = 50 \,\text{m}$, $l_h = l_v = 1 \,\text{m}$, and water vapor equal to 7.5 g/m^3 , which corresponds to moderate fog conditions. As a benchmark, the ideal RF front-end scenario is also plotted. From this figure, we observe that for given $\kappa_t = \kappa_r$ and f, as ψ increases, D/W decreases. For example, for $\kappa_t = \kappa_r = 0$ and $f = 370$ GHz, as ψ increases from 10^o to 45^o, D/W decreases from 4.55 to 3.84 bits/s/Hz. This indicates that not only the relative distance from the TX and the RX, but also the orientation of the HRIS plays a pivotal role on the throughput performance of HRIS-empowered wireless THz systems. Additionally, it is become apparent that, for fixed ψ and $\kappa_t = \kappa_r$, as the geometric loss increases through a frequency increase, D/W decreases. For instance, for $\psi = 45^{\circ}$ and $\kappa_t = \kappa_r = 0$, D/W decreases from 5.0 to 3.84 bits/s/Hz, as f increases from 100 to 370 GHz. This example reveals the importance of appropriately allocating the frequencies in order to make the most out of the available bandwidth. Finally, for given f and ψ , as the level of transceiver hardware imperfections increase, D/W decreases.

Fig. [11](#page-9-1) depicts D/W as a function of d_1 for different values of ψ and levels of hardware imperfections, assuming moderate fog conditions, $d_1 + d_2 = 100 \text{ m}, \frac{P_s}{\sigma_n^2} = 80 \text{ dB}, f = 100 \text{ GHz},$ $r_t = 5 \text{ bits/s/Hz}, G_t = G_r = 50 \text{ dBi}, \psi = \pi/4, T = 20^{\circ} \text{C},$ $P = 101300.0$ Pa, and $l_h = l_v = 1$ m. The water vapor

Fig. 11: D/W vs d_1 for different values of ψ assuming $\kappa_t =$ $\kappa_r = 0$ (black), $\kappa_t = \kappa_r = 0.1$ (red) and $d_1 + d_2 = 100$ m.

is set to 7.5 g/m^3 . From this figure, we observe that for given ψ , $\kappa_t = \kappa_r$ and $d_1 < \frac{d_1 + d_2}{2}$, as d_1 increases, the outage probability also increases; thus, D/W decreases. On the other hand, for fixed ψ , $\kappa_t = \kappa_r$ and $d_1 > \frac{d_1 + d_2}{2}$, as d_1 increases, the outage probability decreases; hence, D/W increases. For $d_1 = \frac{d_1 + d_2}{2}$, D/W is minimized. Notice that this observation contradicts Fig. [6.](#page-7-1) This is because in Fig. [6,](#page-7-1) the impact of geometric losses was neglected. This indicates the importance of taking into account both the deterministic and stochastic phenomena that affect the performance of the HRIS-empowered wireless THz system. Moreover, it becomes evident that the maximum D/W is achieved for $d_1 \rightarrow 0$ and $d_1 \rightarrow d_1 + d_2$. In other words, the optimal placement of the HRIS is as near either the TX or the RX as possible. Of note, this observation is in line with the results of [\[57\]](#page-12-27). Likewise, we observe that for fixed d_1 and $\kappa_t = \kappa_r$, as ψ increases, D/W decreases. For example, for $d_1 = 50 \,\text{m}$ and $\kappa_t = \kappa_r = 0.1$, as ψ increases from 45^o to 75^o, D/W decreases about two orders of magnitude. Finally, the deterministic impact of hardware imperfections is revealed by this figure. In more detail, for given d_1 and ψ , as the level of transceiver hardware imperfections increases, D/W decreases.

V. CONCLUSION

In this paper, we have investigated the outage and throughput performance of HRIS-empowered THz wireless systems that suffer from the joint impact of transceiver hardware imperfections and fog. In more detail, after providing the methodology to evaluate the end-to-end geometric losses and characterizing the stochastic nature of the channel in terms of PDF and CDF, we have extracted novel closed-form expressions for the system's outage probability and throughput. These expressions have revealed a number of engineering insights, such as the existence of transmission windows, the optimum placement of the HRIS, the need to design transceivers with low noise figure, as well as the severe impact of transceiver hardware imperfections and fog. Therefore, they are expected to play a key role in the design of such systems.

APPENDICES

APPENDIX A

PROOF OF THEOREM 1

Since h_1 and h_2 are independent random variables (RVs), the PDF of A can be expressed as

$$
f_A(x) = \int_x^1 \frac{1}{y} f_{h_1}(y) f_{h_2}\left(\frac{x}{y}\right) dy.
$$
 (49)

By applying [\(23\)](#page-3-1) into [\(49\)](#page-10-0), we obtain

$$
f_A(x) = \frac{\zeta_1^{k_1} \zeta_2^{k_2}}{\Gamma(k_1)\,\Gamma(k_2)} x^{\zeta_2 - 1} \int_x^1 y^{\zeta_1 - \zeta_2 - 1} \left(\ln\left(\frac{1}{y}\right)\right)^{k_1 - 1} \times \left(\ln\left(\frac{y}{x}\right)\right)^{k_2 - 1} dy, \quad (50)
$$

or equivalently

$$
f_A(x) = \frac{\zeta_1^{k_1} \zeta_2^{k_2}}{\Gamma(k_1) \Gamma(k_2)} x^{\zeta_2 - 1} \int_x^1 y^{\zeta_1 - \zeta_2 - 1} (-\ln(y))^{k_1 - 1}
$$

$$
\times (\ln(y) - \ln(x))^{k_2 - 1} dy. \tag{51}
$$

By setting $ln(y) = t$, [\(51\)](#page-10-1) can be rewritten as

$$
f_A(x) = \frac{\zeta_1^{k_1} \zeta_2^{k_2}}{\Gamma(k_1) \Gamma(k_2)} x^{\zeta_2 - 1} \int_{\ln(x)}^0 (-t)^{k_1 - 1} (\exp(t))^{\zeta_1 - \zeta_2} \times (t - \ln(x))^{k_2 - 1} dt,
$$
 (52)

which, by applying [\[42,](#page-12-15) eq. (3.383/1)], yields [\(31\)](#page-4-3).

The CDF of A can be evaluated as

$$
F_A(x) = \int_0^x f_A(x) \, \mathrm{d}x,\tag{53}
$$

which, by applying (31) , can be rewritten as

$$
F_A(x) = (-1)^{k_1 + k_2 = 1} \frac{\zeta_1^{k_1} \zeta_2^{k_2}}{\Gamma(k_1) \Gamma(k_2)} \mathcal{J},\tag{54}
$$

where

$$
\mathcal{J} = \int_0^x y^{\zeta_2 - 1} (\ln(y))^{k_1 + k_2 - 1}
$$

 $\times {}_1F_1(k_1; k_1 + k_2; (\zeta_1 - \zeta_2) \ln(y)) \, dy.$ (55)

By setting $ln(y) = t$, [\(55\)](#page-10-2) can be rewritten as

$$
\mathcal{J} = -\int_{\ln(y)}^{\infty} t^{k_1 + k_2 - 1} \exp(\zeta_2 t)
$$

 $\times {}_{1}F_1(k_1; k_1 + k_2; (\zeta_1 - \zeta_2) t) dt.$ (56)

With the aid of [\[42,](#page-12-15) eq. (9.14/1)], [\(56\)](#page-10-3) can be equivalently expressed as

$$
\mathcal{J} = -\sum_{n=0}^{\infty} \frac{(k_1)_n (\zeta_1 - \zeta_2)^n}{(k_1 + k_2)_n n!} \mathcal{K},\tag{57}
$$

where

$$
\mathcal{K} = \int_{\ln(x)}^{\infty} t^{k_1 + k_2 + n - 1} \exp\left(\zeta_2 t\right) dt.
$$
 (58)

Next, by employing [\[42,](#page-12-15) eq. (1.211/1)], [\(58\)](#page-10-4) can be written as

$$
\mathcal{K} = \sum_{m=0}^{\infty} \frac{\zeta_2^m}{m!} \int_{\ln(y)}^{\infty} t^{k_1 + k_2 + n + m - 1} \, \mathrm{d}t,\tag{59}
$$

which, by applying [\[42,](#page-12-15) eq. (3.191/1], can be rewritten as

$$
\mathcal{K} = -\sum_{m=0}^{\infty} \frac{\zeta_2^m}{m!} \frac{1}{k_1 + k_2 + m + n} \left(\ln(x) \right)^{k_1 + k_2 + m + n} . \tag{60}
$$

By applying [\(60\)](#page-10-5) into [\(57\)](#page-10-6), we obtain

$$
\mathcal{J} = \left(\ln\left(x\right)\right)^{k_1 + k_2} \mathcal{L},\tag{61}
$$

where

$$
\mathcal{L} = \sum_{n=0}^{\infty} \sum_{m=0}^{\infty} \frac{1}{k_1 + k_2 + m + n} \frac{(k_1)_n}{(k_1 + k_2)_n} \frac{1}{n!} \frac{1}{m!}
$$

$$
\times \left((\zeta_1 - \zeta_2) \ln(x) \right)^n (\zeta_2 \ln(x))^m. \tag{62}
$$

However,

$$
\frac{1}{k_1 + k_2 + m + n} = \frac{(k_1 + k_2 + m + n - 1)!}{(k_1 + k_2 + m + n)!},
$$
 (63)

or equivalently

$$
\frac{1}{k_1 + k_2 + m + n} = \frac{\Gamma(k_1 + k_2 + m + n - 1)}{\Gamma(k_1 + k_2 + m + n)},
$$
 (64)

or

$$
\frac{1}{k_1 + k_2 + m + n} = \frac{(k_1 + k_2)_{m+n} \Gamma(m+n)}{(k_1 + k_2 + 1)_{m+n} \Gamma(m+n+1)},
$$
(65)

which can be rewritten as

$$
\frac{1}{k_1 + k_2 + m + n} = \frac{(k_1 + k_2)_{m+n}}{(k_1 + k_2 + 1)_{m+n}(k_1 + k_2)_1}.
$$
 (66)

Moreover, by accounting for the fact that $(k_1 + k_2)_1 = k_1 + k_2$ k_2 , [\(66\)](#page-10-7) can be written as

$$
\frac{1}{k_1 + k_2 + m + n} = \frac{1}{k_1 + k_2} \frac{(k_1 + k_2)_{m+n}}{(k_1 + k_2 + 1)_{m+n}}.
$$
 (67)

By applying [\(67\)](#page-10-8) to [\(62\)](#page-10-9), we get

$$
\mathcal{L} = \frac{1}{k_1 + k_2} \sum_{n=0}^{\infty} \sum_{m=0}^{\infty} \frac{(k_1 + k_2)_{m+n}}{(k_1 + k_2 + 1)_{m+n}} \frac{(k_1)_n}{(k_1 + k_2)_n} \frac{1}{n!} \frac{1}{m!}
$$

$$
\times \left((\zeta_1 - \zeta_2) \ln(x) \right)^n \left(\zeta_2 \ln(x) \right)^m. \tag{68}
$$

or equivalently

$$
\mathcal{L} = \frac{H_A (k_1 + k_2, k_1; k_1 + k_2 + 1; (\zeta_1 - \zeta_2) \ln(x), \zeta_2 \ln(x))}{k_1 + k_2}.
$$
\n(69)

By applying (69) to (61) , we obtain

$$
\mathcal{J} = \frac{(\ln(x))^{k_1 + k_2}}{k_1 + k_2} \times \text{H}_{\text{A}}\left(k_1 + k_2, k_1; k_1 + k_2 + 1; (\zeta_1 - \zeta_2) \ln(x), \zeta_2 \ln(x)\right),\tag{70}
$$

Finally, by employing [\(70\)](#page-10-12) to [\(54\)](#page-10-13), we obtain [\(32\)](#page-4-5). This concludes the proof.

APPENDIX B

PROOF OF PROPOSITION 1

By applying [\(39\)](#page-4-7) to [\(41\)](#page-4-8), we obtain

$$
P_o(\gamma_{\text{th}}) = \Pr\left(\frac{A^2}{A^2(\kappa_t^2 + \kappa_r^2) + \frac{1}{\rho}} \le \gamma_{\text{th}}\right),\qquad(71)
$$

or equivalently

$$
P_o\left(\gamma_{\text{th}}\right) = \Pr\left(A^2\left(1 - \gamma_{\text{th}}\left(\kappa_t^2 + \kappa_r^2\right)\right) \le \frac{\gamma_{\text{th}}}{\rho}\right). \tag{72}
$$

By assuming that $1 - \gamma_{\text{th}} \left(\kappa_t^2 + \kappa_r^2 \right) > 0$ or equivalently

$$
\gamma_{\text{th}} < \frac{1}{\kappa_t^2 + \kappa_r^2},\tag{73}
$$

[\(72\)](#page-11-25) can be rewritten as

$$
P_o(\gamma_{\text{th}}) = \Pr\left(A \le \sqrt{\frac{\gamma_{\text{th}}}{\rho}} \frac{1}{\sqrt{1 - \gamma_{\text{th}}\left(\kappa_t^2 + \kappa_r^2\right)}}\right), \quad (74)
$$

or

$$
P_o\left(\gamma_{\rm th}\right) = F_A \left(\sqrt{\frac{\gamma_{\rm th}}{\rho}} \frac{1}{\sqrt{1 - \gamma_{\rm th}\left(\kappa_t^2 + \kappa_r^2\right)}}\right),\qquad(75)
$$

which, by applying [\(32\)](#page-4-5), returns [\(42\)](#page-5-1).

From [\(32\)](#page-4-5), the following inequality should hold:

$$
0 < \sqrt{\frac{\gamma_{\text{th}}}{\rho}} \frac{1}{\sqrt{1 - \gamma_{\text{th}}\left(\kappa_t^2 + \kappa_r^2\right)}} \le 1 \tag{76}
$$

or equivalently

$$
0 < \frac{\gamma_{\text{th}}}{\rho} \frac{1}{1 - \gamma_{\text{th}} \left(\kappa_t^2 + \kappa_r^2 \right)} \le 1 \tag{77}
$$

From [\(73\)](#page-11-26), $\frac{\gamma_{\text{th}}}{\rho} \frac{1}{1 - \gamma_{\text{th}}(\kappa_t^2 + \kappa_r^2)} > 0$ is always true. Likewise, in order for $\frac{\gamma_{\text{th}}}{\rho} \frac{1}{1-\gamma_{\text{th}}(\kappa_t^2+\kappa_t^2)} \leq 1$ to be true, the following condition should be satisfied:

$$
\gamma_{\text{th}} \le \frac{\rho}{\left(\kappa_t^2 + \kappa_r^2\right)\rho + 1}.\tag{78}
$$

By combining [\(73\)](#page-11-26) and [\(78\)](#page-11-27), we obtain [\(43\)](#page-4-6). This concludes the proof.
