# On Lie-Bracket Averaging for a Class of Hybrid Dynamical Systems with Applications to Model-Free Control and Optimization

Mahmoud Abdelgalil and Jorge I. Poveda

#### Abstract

Dynamical systems characterized by oscillatory behaviors and well-defined average vector fields have traditionally been subjects of stability analysis through methodologies rooted in averaging theory. Such tools have also found application in the stability analysis of systems that combine continuous-time dynamics and discrete-time dynamics, referred to as hybrid dynamical systems. However, in contrast to the existing results available in the literature for continuous-time systems, averaging results for hybrid systems have mostly been limited to first-order averaging methods. This limitation prevents their direct application for the analysis and design of systems and algorithms requiring high-order averaging techniques. Among other applications, such techniques are necessary to analyze hybrid Lie-bracket-based extremum seeking algorithms and hybrid vibrational controllers. To address this gap, this paper introduces a novel high-order averaging theorem for the stability analysis of hybrid dynamical systems with high-frequency periodic flow maps. The considered systems allow for the incorporation of set-valued flow maps and jump maps, effectively modeling well-posed differential and difference inclusions. By imposing appropriate regularity conditions on the hybrid system's data, results on  $(T, \varepsilon)$ -closeness of solutions and semi-global practical asymptotic stability for sets are established. In this way, our findings yield hybrid Lie-bracket averaging tools that extend those found in the literature on ordinary differential equations. These theoretical results are then applied to the study of three distinct applications in the context of model-free control and optimization.

Hybrid systems, averaging theory, multi-time scale dynamical systems, extremum seeking.

# I. INTRODUCTION

**O** VER the past century, averaging theory has played an important role in analyzing and synthesizing systems with "fast" oscillatory or time-varying terms [1]–[3], including nonlinear controllers [4], estimation methods, and modelfree optimization and stabilization algorithms [5]–[8]. Stability analyses rooted in averaging theory have been extensively explored for dynamical systems modeled as ordinary differential equations (ODEs) [3], [9], [10], and have also been extended to certain hybrid dynamical systems (HDS) that combine continuous-time and discrete-time dynamics [11], see [12]–[14] and references therein.

Stability results based on averaging theory usually rely on having a "well-defined" average system that has suitable regularity and stability properties. In particular, if the trajectories of the average dynamics and those of the original dynamics can be shown to be "close" to each other (on compact time domains and compact subsets of the state space), then the original system might inherit the stability properties of the average system in a semi-global practical sense [10]. The typical approach to establish closeness of solutions relies on a suitable change of variable that can be used to write the original dynamics as a perturbed version of the average dynamics. This construction has been used in oscillating dynamical systems modeled as Lipschitz continuous ODEs [2], [4], [9], [13], as well as in HDS [12], [14]. By leveraging uniform stability properties expressed in terms of  $\mathcal{KL}$  bounds, it can be shown that the convergence properties of the trajectories of original dynamics are similar to those of the average dynamics as the time scale separation increases. These results have recently paved the way for the designing and analyzing hybrid algorithms in the context of extremum-seeking control and vibrational control [6], [15], [16], which harness the power of both hybrid control and averaging-based methods.

Nevertheless, despite the progress made during the last decade, there are still significant gaps between the averaging-based tools available for ODEs and those that are suitable for HDS. In particular, averaging results for HDS have been limited to the setting of "first-order" averaging, where the nominal stabilizing vector field (i.e., the average system) is obtained by neglecting high-order perturbation terms in the dynamics. As shown in [17, Section 2.9], [18], [19], first-order approximations may not always provide accurate characterizations of the stability properties of certain highly oscillatory systems, including those that emerge in vibrational control [8] and Lie-bracket extremum seeking [19], [20]. In such systems, the stabilizing average dynamics are obtained only after considering the effect of second-order (or higher) oscillatory terms in the original dynamics. This setting is known in the literature of ODEs as *high-order averaging*, and the main goal of this paper is to

develop similar high-order averaging tools for a class of well-posed hybrid dynamical systems with highly oscillatory flow maps, and to demonstrate their applications for the solution of control and optimization problems that involve and/or require hybrid tools.

Based on this background, the primary contributions of this work are the following:

(a) First, a novel high-order averaging theorem is introduced to study the "closeness of solutions" property between certain HDS with periodic flow maps and their corresponding average dynamics. In contrast to existing literature, we focus on HDS where stabilizing effects are determined by an average hybrid system obtained through the recursive application of averaging at high orders of the inverse frequency. These higher-order averages become essential when traditional first-order average systems fail to capture stability properties of the system. For compact time domains and compact sets of initial conditions, it is established that each solution of the original HDS is  $(T, \varepsilon)$ -close to some solution of its average hybrid dynamics. This notion of closeness between solutions is needed because, in general, HDS generate solutions with discontinuities, or "jumps", for which the standard (uniform) distance between solutions is not a suitable metric [13], [21]. Moreover, the models studied in this paper enable the incorporation of differential and difference inclusions, and therefore they might admit multiple solutions from a given initial condition of the system. To establish the closeness of solutions property, we introduce a new change of variable that is recursive in nature, and which leverages the structure in which the "high-order" oscillations appear in the flow map.

(b) Next, by leveraging the property of closeness of solutions between the original and the average hybrid dynamics, as well as a uniform asymptotic stability assumption on the average hybrid dynamics, we establish a semi-global practical asymptotic stability result for the original hybrid system. For the purpose of generality, we allow the average hybrid dynamics to have a compact set that is locally asymptotically stable with respect to some basin of attraction, which recovers the entire space whenever the stability properties are actually global. By using proper indicators in the stability analysis, the original hybrid system is shown to render the same compact set semi-global practically asymptotically stable with respect to the same basin of attraction, thus effectively extending [13, Thm. 2] to high-order averaging in HDS.

c) Finally, by exploiting the structure of the HDS, as well as the high-order averaging results, we study three different novel stabilization and optimization problems that involve hybrid dynamics and highly oscillatory control: (a) distance-based synchronization in networks with switching communication topologies and control directions, which extends the setting of [22], [23]; (b) source-seeking problems in non-holonomic vehicles operating under *faulty and spoofed sensors*, which extends the results of [19] to vehicles operating in adversarial environments, and those of [24] to vehicles with non-holonomic models with angular actuation; and (c) the solution of model-free *global* extremum seeking problems on smooth compact manifolds, which extends the recent results from [25] to non-parallelizable manifolds. In this manner, an important gap in the hybrid extremum-seeking control literature is also filled by effectively integrating hybrid dynamics into traditional Lie-bracket-based extremum-seeking algorithms.

The rest of this paper is organized as follows. Section II introduces the preliminaries. Section IV presents a motivational example. Section IV presents the main results. Section V presents the proofs. Applications are studied in Section VI, and Section VII presents the conclusions.

### **II.** PRELIMINARIES

# A. Notation

Given a closed set  $\mathcal{A} \subset \mathbb{R}^n$  and  $x \in \mathbb{R}^n$ , we use  $|x|_{\mathcal{A}} := \min_{\tilde{x} \in \mathcal{A}} ||x - \tilde{x}||_2$ . We also use  $\overline{co}(\mathcal{A})$  to denote the closure of the convex hull of  $\mathcal{A}$ . A set-valued mapping  $M : \mathbb{R}^p \Rightarrow \mathbb{R}^n$  is outer semicontinuous (OSC) at z if for each sequence  $\{z_i, s_i\} \to (z, s) \in \mathbb{R}^p \times \mathbb{R}^n$  satisfying  $s_i \in M(z_i)$  for all  $i \in \mathbb{Z}_{\geq 0}$ , we have  $s \in M(z)$ . A mapping M is locally bounded (LB) at z if there exists an open neighborhood  $N_z \subset \mathbb{R}^p$  of z such that  $M(N_z)$  is bounded. The mapping M is OSC and LB relative to a set  $K \subset \mathbb{R}^p$  if M is OSC for all  $z \in K$  and  $M(K) := \bigcup_{z \in K} M(x)$  is bounded. A function  $\beta : \mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$  is of class  $K\mathcal{L}$  if it is nondecreasing in its first argument, nonincreasing in its second argument,  $\lim_{r\to 0^+} \beta(r, s) = 0$  for each  $r \in \mathbb{R}_{\geq 0}$ . Throughout the paper, for two (or more) vectors  $u, v \in \mathbb{R}^n$ , we write  $(u, v) = [u^{\top}, v^{\top}]^{\top}$ . Let  $x = (x_1, x_2, \dots, x_n) \in \mathbb{R}^n$ . Given a Lipschitz continuous function f is said to be of class  $\mathcal{C}^k$  if its kth-derivative is locally Lipschitz continuous. For two vectors  $x_1, x_2 \in \mathbb{R}^n$ , the notation  $x_1 \otimes x_2$  denotes the outer product defined as  $x_1 \otimes x_2 = x_1 x_2^{\top}$ . Finally, we use  $\mathbb{S}^1 \subset \mathbb{R}^2$  to denote the unit circle centered at the origin, i.e.,  $\mathbb{S}^1 := \{(x_1, x_2) \in \mathbb{R}^2 : x_1^2 + x_2^2 = 1\}$ .

#### B. Hybrid Dynamical Systems

1) Model: In this paper, we consider hybrid dynamical systems (HDS) aligned with the framework of [11], and characterized by the following inclusions:

$$x \in C, \qquad \dot{x} \in F(x)$$
 (1a)

$$x \in D, \quad x^+ \in G(x), \tag{1b}$$

2

where  $F : \mathbb{R}^n \Rightarrow \mathbb{R}^n$  is called the flow map,  $G : \mathbb{R}^n \Rightarrow \mathbb{R}^n$  is called the jump map,  $C \subset \mathbb{R}^n$  is called the flow set, and  $D \subset \mathbb{R}^n$  is called the jump set. We use  $\mathcal{H} = (C, F, D, G)$  to denote the *data* of the HDS  $\mathcal{H}$ . We note that systems of the form (1) generalize purely continuous-time systems (obtained when  $D = \emptyset$ ) and purely discrete-time systems (obtained when  $C = \emptyset$ ). Of particular interest to us are time-varying systems, which can also be represented as (1) by using an auxiliary state  $\tau \in \mathbb{R}$  with dynamics  $\dot{\tau} = \rho$  and  $\tau^+ = \tau$ , where  $\rho \in \mathbb{R}_{\geq 0}$  indicates the rate of change of  $\tau$ . In this paper, we will always work with well-posed HDS that satisfy the following standing assumption.

Assumption 1: The sets C, D are closed. The set-valued mapping F is OSC, LB, and for each  $x \in C$  the set F(x) is convex and nonempty. The set-valued mapping G is OSC, LB, and for each  $x \in C$  the set G(x) is nonempty.

2) Properties of Solutions: Solutions to (1) are parameterized by a continuous-time index  $t \in \mathbb{R}_{\geq 0}$ , which increases continuously during flows, and a discrete-time index  $j \in \mathbb{Z}_{\geq 0}$ , which increases by one during jumps. Therefore, solutions to (1) are defined on *hybrid time domains* (HTDs). A set  $E \subset \mathbb{R}_{\geq 0} \times \mathbb{Z}_{\geq 0}$  is called a *compact* HTD if  $E = \bigcup_{j=0}^{J-1} ([t_j, t_{j+1}], j)$  for some finite sequence of times  $0 = t_0 \leq t_1 \ldots \leq t_J$ . The set E is a HTD if for all  $(T, J) \in E$ ,  $E \cap ([0, T] \times \{0, \ldots, J\})$  is a compact HTD.

The following definition formalizes the notion of solution to HDS of the form (1).

Definition 1: A hybrid arc x is a function defined on a HTD. In particular,  $x : dom(x) \to \mathbb{R}^n$  is such that  $x(\cdot, j)$  is locally absolutely continuous for each j such that the interval  $I_j := \{t : (t, j) \in dom(x)\}$  has a nonempty interior. A hybrid arc  $x : dom(x) \to \mathbb{R}^n$  is a solution x to the HDS (1) if  $x(0,0) \in C \cup D$ , and:

- 1) For all  $j \in \mathbb{Z}_{\geq 0}$  such that  $I_j$  has nonempty interior:  $x(t, j) \in C$  for all  $t \in I_j$ , and  $\dot{x}(t, j) \in F(x(t, j))$  for almost all  $t \in I_j$ .
- 2) For all  $(t, j) \in \text{dom}(x)$  such that  $(t, j + 1) \in \text{dom}(x)$ :  $x(t, j) \in D$  and  $x(t, j + 1) \in G(x(t, j))$ .

A solution x is *maximal* if it cannot be further extended. A solution x is said to be *complete* if length dom(x) =  $\infty$ . In this paper, we also work with an "inflated" version of (1), which is instrumental for robustness analysis [11, Def. 6.27].

Definition 2: For  $\delta > 0$ , the  $\delta$ -inflation  $\mathcal{H}_{\delta}$  of the HDS  $\mathcal{H}$  with data (1) is given by  $\mathcal{H}_{\delta} := (C_{\delta}, D_{\delta}, F_{\delta}, G_{\delta})$ , where the sets  $C_{\delta}, D_{\delta}$  are defined as:

$$C_{\delta} := \{ x \in \mathbb{R}^n : (\{x\} + \delta \mathbb{B}) \cap C \neq \emptyset \}$$
(2a)

$$D_{\delta} := \left\{ x \in \mathbb{R}^n : \left( \left\{ x \right\} + \delta \mathbb{B} \right) \cap D \neq \emptyset \right\},\tag{2b}$$

and the set-valued mappings  $F_{\delta}, G_{\delta}$  are defined as:

$$F_{\delta}(x) := \overline{\operatorname{con}} \ F((x + \delta \mathbb{B}) \cap C) + \delta \mathbb{B}, \tag{2c}$$

$$G_{\delta}(x) := \{ v \in \mathbb{R}^n : v \in g + \delta \mathbb{B}, g \in G((x + \delta \mathbb{B}) \cap D) \},$$
(2d)

for all  $x \in \mathbb{R}^n$ .

The following definition ([11, Def. 5.23]) will also be used to study the "closeness" between two hybrid arcs.

- Definition 3: Given  $T, \rho > 0$ , two hybrid arcs  $x_1 : \operatorname{dom}(x_1) \to \mathbb{R}^n$  and  $x_2 : \operatorname{dom}(x_2) \to \mathbb{R}^n$  are said to be  $(T, \rho)$ -close if: • for each  $(t, j) \in \operatorname{dom}(x_1)$  with  $t + j \leq T$  there exists s such that  $(s, j) \in \operatorname{dom}(x_2)$ , with  $|t - s| \leq \rho$  and  $|x_1(t, j) - \rho| \leq \rho$ .
- for each  $(t,j) \in \text{dom}(x_1)$  with  $t+j \leq T$  there exists s such that  $(s,j) \in \text{dom}(x_2)$ , with  $|t-s| \leq \rho$  and  $|x_2(t,j) \sigma(t)| \leq 1$ .
- For each  $(t, j) \in \text{dom}(x_2)$  with  $t + j \le 1$  there exists s such that  $(s, j) \in \text{dom}(x_1)$ , with  $|t s| \le \rho$  and  $|x_2(t, j) x_1(s, j)| \le \rho$ .

3) Stability Notions: To study the stability properties of the HDS (1) we make use of the following notion, which is instrumental for the study of "local" stability properties.

Definition 4: Let  $\mathcal{A}$  be a compact set contained in an open set  $\mathcal{B}_{\mathcal{A}}$ . A function  $\omega : \mathcal{B}_{\mathcal{A}} \to \mathbb{R}_{\geq 0}$  is said to be a proper indicator function for  $\mathcal{A}$  on  $\mathcal{B}_{\mathcal{A}}$  if  $\omega$  is continuous and,  $\omega(x) = 0$  if and only if  $x \in \mathcal{A}$ , and if the sequence  $\{x_i\}_{i=1}^{\infty}, x_i \in \mathcal{B}_{\mathcal{A}}$ , approaches the boundary of  $\mathcal{B}_{\mathcal{A}}$  or is unbounded then the sequence  $\{\omega(x_i)\}_{i=1}^{\infty}$  is also unbounded.

The use of proper indicators is common when studying (uniform) local stability properties, see also [27].

The following definition is borrowed from [11, Def. 7.10 and Thm. 7.12].

Definition 5: A compact set  $\mathcal{A} \subset \mathbb{R}^n$  contained in an open set  $\mathcal{B}_{\mathcal{A}}$  is said to be *uniformly asymptotically stable (UAS)* with a basin of attraction  $\mathcal{B}_{\mathcal{A}}$  for the HDS (1) if for every proper indicator  $\omega$  on  $\mathcal{B}_{\mathcal{A}}$  there exists  $\beta \in \mathcal{KL}$  such that for each solution x to (1) starting in  $\mathcal{B}_{\mathcal{A}}$ , we have

$$\omega(x(t,j)) \le \beta(\omega(x(0,0)), t+j), \tag{3}$$

for all  $(t, j) \in \text{dom}(x)$ . If  $\mathcal{B}_{\mathcal{A}}$  is the whole space, then  $\omega(x) = |x|_{\mathcal{A}}$ , and in this case the set  $\mathcal{A}$  is said to be *uniformly globally* asymptotically stable (UGAS) for the HDS (1).

#### **III. MOTIVATIONAL EXAMPLE**

The problem of target seeking in mobile robotic systems is ubiquitous across various engineering applications, including rescue missions [28], gas leak detection, and general autonomous vehicles performing exploration missions in hazardous environments that could be too dangerous for humans [24], [29]. Different algorithms with stability and convergence guarantees have been considered for resolving source-seeking problems in mobile robots [29], [30]. Naturally, these algorithms rely on real-time exploration and exploitation mechanisms that have shown resilience and robustness with respect to different types of disturbances, including *small* measurement noise and implementation errors [24], as well as certain structured and bounded additive perturbations [31]. Nevertheless, in many realistic applications, the seeking robots operate in environments where their sensors rarely have continuous and perfect access to measurements of the environment. Common reasons for faulty measurements include intermittent communication networks, interference due to obstacles or external environmental conditions, and imperfect hardware implementation, to name just a few [32], [33]. In addition to encountering faulty and intermittent measurements, autonomous robots operating in adversarial environments might also be subject to malicious *spoofing* attacks that deliberately modify some of the signals used by the control systems of the robots. In such adversarial situations, it is natural to inquire whether the mobile robots are still capable of successfully completing their missions, and under what conditions (if any) such success can be guaranteed

To answer the above question, we consider a typical model of a mobile robot: a planar kinematic model of a nonholonomic vehicle, with equations

$$\dot{x}_1 = u \, x_3, \qquad \qquad \dot{x}_2 = u \, x_4, \qquad \qquad \dot{x}_3 = \Omega x_4, \qquad \qquad \dot{x}_4 = -\Omega x_3,$$

where the vector  $x_p := (x_1, x_2) \in \mathbb{R}^2$  models the position of the vehicle in the plane, the vector  $x_{3,4} := (x_3, x_4) \in \mathbb{S}^1$  captures the orientation of the vehicle, u is the forward velocity, and  $\Omega$  is the angular velocity. The main objective of the vehicle is to stabilize its position at a particular target  $x_p^* \in \mathbb{R}^2$  using only real-time measurements of distance-like signal  $J(x_p)$ , which is assumed to be  $C^1$ , strongly convex with a unique minimizer at the point  $x_p^*$ , and which has a globally Lipschitz gradient (these assumptions will be relaxed later in Section VI-A.2). Since nonholonomic vehicles cannot be simultaneously stabilized in position and orientation using smooth feedback, we let the vehicles oscillate using a predefined constant angular velocity  $\Omega > 0$ . This model also captures vehicles that have no *directional* control over  $\Omega$ , such as in quad-copters that have lost one propeller, leading to a constant yaw rate during hover that can be effected, though not eliminated or reversed, by modulating the remaining propellers.

Under "nominal" operating conditions, and to stabilize (a neighborhood of) the target  $x_p^*$ , we can consider the following feedback controller that only uses real-time measurements of the potential field J evaluated at the current position

$$u(x_p, \tau_2) = \varepsilon^{-1} \cos\left(\tau_2 + J(x_p)\right), \ \dot{\tau}_2 = \frac{1}{\varepsilon^2}, \ \Omega = \frac{1}{\varepsilon}$$

where  $\varepsilon > 0$  is a tunable parameter. To capture the effect of having intermittent measurements and malicious spoofing attacks in the algorithm, we re-write the nominal closed-loop system as the following mode-dependent dynamical system:

$$\dot{x}_1 = \varepsilon^{-1} x_3 u_{z_1}(x, \tau_2), \qquad \dot{x}_3 = \varepsilon^{-1} x_4, \qquad (4a)$$

$$\varepsilon^{-1}x_4u_{z_1}(x,\tau_2), \qquad \dot{x}_4 = -\varepsilon^{-1}x_3, \qquad (4b)$$

$$\dot{\tau}_2 = \varepsilon^{-2}, \qquad \qquad \dot{z}_1 = 0, \tag{4c}$$

where  $z_1 \in \mathcal{Q} := \{1, 2, 3\}$  is a logic mode that is kept constant during the evolution of (4). In this case, the map  $u_{z_1}$  is

 $\dot{x}_{2} =$ 

$$u_{z_1}(x_p, \tau_2) = \cos\left(\tau_2 + (z_1 - 2)J(x_p)\right),\tag{4d}$$

where  $z_1 = 3$  describes the nominal operation mode,  $z_1 = 2$  describes the mode in which no measurement is available to the vehicle, and  $z_1 = 1$  corresponds to the mode in which the control algorithm is under spoofing. In this way, the dynamics of the vehicle switch between the three operating modes as the robot simultaneously seeks the target  $x_p^*$ . Note that, at every switching instant, the states  $x = (x_1, x_2, x_3, x_4)$  remain constant, and  $z_1$  jumps according to  $z_1^+ \in Q \setminus \{z_1\}$ , i.e., the system is allowed to switch from its current mode to any of the other two modes. Figure 1 illustrates this switching behavior. To study the stability properties of the system, we consider the coordinate transformation:

$$\begin{pmatrix} x_3 \\ x_4 \end{pmatrix} = \begin{pmatrix} \cos\left(\varepsilon^{-1}t\right) & \sin\left(\varepsilon^{-1}t\right) \\ -\sin\left(\varepsilon^{-1}t\right) & \cos\left(\varepsilon^{-1}t\right) \end{pmatrix} \begin{pmatrix} \tilde{x}_3 \\ \tilde{x}_4 \end{pmatrix},$$

which is defined via a rotation matrix and therefore is invertible for all  $t \ge 0$ . The transformation leads to the system

$$\dot{x}_{p} = \varepsilon^{-1} \begin{pmatrix} \cos(\tau_{1}) & \sin(\tau_{1}) \\ -\sin(\tau_{1}) & \cos(\tau_{1}) \end{pmatrix} \begin{pmatrix} \tilde{x}_{3} \\ \tilde{x}_{4} \end{pmatrix} u_{z_{1}}(x_{p}, \tau_{2}),$$
(5a)  
$$\dot{\tilde{x}}_{3,4} = 0, \quad \dot{\tau}_{1} = \varepsilon^{-1}, \quad \dot{\tau}_{2} = \varepsilon^{-2}, \quad \dot{z}_{1} = 0.$$
(5b)

Fig. 1: Automaton-like representation of switching seeking dynamics in nonholonomic vehicles with multiple operating modes: under spoofing  $(z_1 = 1)$ , under no measurement  $(z_1 = 2)$ , and under nominal operation  $(z_1 = 3)$ .

with jumps  $x^+ = x$  and  $z_1^+ \in Q \setminus \{z_1\}$ . In (5), the vector  $\tilde{x}_{3,4}$  is now constant, but still restricted to the compact set  $\mathbb{S}^1$ . For this system, we can investigate the stability properties of the state x with respect to the set  $\{x_p^\star\} \times \mathbb{S}^1$ . To do this, we model the closed-loop system as a HDS of the form (1), with switching signal  $z_1$  being generated by an extended hybrid automaton with states  $z := (z_1, z_2, z_3) \in \mathbb{R}^3_+$  and dynamics

$$z \in C_z, \quad \dot{z} \in \mathcal{T}_F(z) := \begin{pmatrix} \{0\} \\ [0,\eta_1] \\ [0,\eta_2] - \mathbb{I}_{\mathcal{Q}_u}(z_1), \end{pmatrix}$$
(6a)

$$z \in D_z, \quad z^+ \in \mathcal{T}_G(z) := \begin{pmatrix} \mathcal{Q} \setminus \{z_1\} \\ z_2 - 1 \\ z_3 \end{pmatrix}$$
(6b)

where  $\eta_1, \eta_2 > 0$ ,  $\mathbb{I}_{Q_u}(\cdot)$  is the classic indicator function, the set of logic modes has been partitioned as  $Q = Q_s \cup Q_u$ , with  $Q_s = \{3\}$  and  $Q_u = \{1, 2\}$ , and the sets  $C_z, D_z$  are given by

$$C_z = \mathcal{Q} \times [0, N_\circ] \times [0, T_\circ], \quad D_z = \mathcal{Q} \times [1, N_\circ] \times [0, T_\circ]. \tag{7}$$

Every hybrid arc generated by the hybrid automaton (6) satisfies the following two conditions for any two times  $t_2 > t_1$  that are in its domain:

$$N_{\sharp}(t_1, t_2) \le \eta_1(t_2 - t_1) + N_{\circ}, \tag{8a}$$

$$T_{\sharp}(t_1, t_2) \le \eta_2(t_2 - t_1) + T_{\circ},$$
(8b)

where  $N_{\sharp}(t_1, t_2)$  is the total number of jumps during the time interval  $(t_1, t_2)$ , and  $T_{\sharp}(t_1, t_2) = \int_{t_1}^{t_2} \mathcal{I}_{Q_u}(z(t)) dt$  is the total activation time, during flows of the system, of the modes in the set  $Q_u$ , and during the same time interval  $[t_1, t_2]$ . Indeed, condition (8a) induces an average dwell-time constraint on the number of switches of  $z_1$ , while condition (8b) imposes an average activation time constraint on the amount of time that the system spends on the modes 1 and 2. The conditions are parameterized by the constants  $\eta_1$  and  $\eta_2$ , respectively. Note that (8a) immediately rules out Zeno behavior.

While the HDS given by (5)-(7) has a periodic flow map with high-frequency oscillations, existing averaging tools in the literature [13], [34] do not capture the stabilizing effect of the control law (4d). This can be observed by introducing a new time scale  $s = \frac{t}{s}$ , which leads to the following continuous-time dynamics (in the s-time scale):

$$\dot{x}_p = A(\tau_1)\tilde{x}_{3,4}u_{z_1}(x_p,\tau_2), \quad \dot{\tau}_1 = 1, \quad \dot{\tau}_2 = \frac{1}{\varepsilon}.$$
(9)

Using (4d) and the property  $\cos(\alpha + \beta) = \cos(\alpha)\cos(\beta) - \sin(\alpha)\sin(\beta)$ , it is easy to see that for any constant vector  $\tilde{x}_{3,4} \in \mathbb{S}^1$  the average of the vector field (9) along the fast varying state  $\tau_2$  is equal to zero. Therefore, no stability conclusions can be obtained from a direct application of first-order averaging theory. Similar obstacles emerge when using first-order averaging theory in the analysis of Lie-bracket-based extremum seeking controllers [19] and in certain vibrational controllers [8]. On the other hand, as we will show in the next section, by using *second-order* averaging theory for HDS we can obtain the following average hybrid dynamics:

$$(\bar{x}, \bar{z}) \in \left(\mathbb{R}^2 \times \mathbb{S}^1\right) \times C_z, \begin{cases} \dot{\bar{x}}_p = \frac{(2 - \bar{z}_1)}{2} \nabla J(\bar{x}_p) \\ \dot{\bar{x}}_{3,4} = 0 \\ \dot{\bar{z}} \in \mathcal{T}_F(\bar{z}) \end{cases}$$
(10a)

$$(\bar{x}, \bar{z}) \in (\mathbb{R}^2 \times \mathbb{S}^1) \times D_z, \begin{cases} \bar{x}^+ = \bar{x} \\ \bar{z}^+ \in \mathcal{T}_G(\bar{z}) \end{cases}$$
 (10b)

In turn, under the smoothness and strong convexity assumption on J, this HDS renders UGAS the compact set  $\mathcal{A} := \{x_p^*\} \times \mathbb{S}^1 \times \mathcal{Q} \times [0, N_\circ] \times [0, T_\circ]$  for  $\eta_1 > 0$  and  $\eta_2$  sufficiently small (see Section VI-A-2). By using Theorem 2 in Section IV, we

Fig. 2: A sample trajectory of the target seeking vehicle, starting from two initial conditions  $(x_1(0), x_2(0)) = (-4, 4)$  (blue) and  $(x_1(0), x_2(0)) = (-4, -4)$  (red), for  $\varepsilon = 1/\sqrt{10\pi}$ ,  $J(x) = 0.5x_1^2 + 0.5x_2^2$ , and for two different switching signals. The bottom right graph shows the switching signal  $z_1(t)$ .

will be able to conclude that for any compact set  $K_0 \subset \mathbb{R}^2$  and any  $\nu > 0$  there exists  $\varepsilon^* > 0$  such that for all  $\varepsilon \in (0, \varepsilon^*)$  every trajectory of (5) that starts in  $K_0$  satisfies

$$|x_p(t,j) - x^*| \le \beta \left( |x_p(0,0) - x^*|, t+j \right) + \nu,$$

for all (t, j) in the domain of the solution. A more general result will be stated later in Section VI-A for a class of hybrid Lie-bracket averaging-based systems. In the meantime, we illustrate in Figure 2 (in blue color) the convergence properties of the vehicle under the controller (4d). The inset also shows the evolution in time of the switching signal  $z_1$ , indicating which mode is active at each time. As observed, the vehicle operating under spoofing and intermittent sensing is able to successfully complete the source-seeking mission. We also show in red color an unstable trajectory of the vehicle under the same controller and a more aggressive (i.e., frequent) spoofing attack, also shown in the inset.

The motivational problem studied in this section is modeled using a high-amplitude, high-frequency oscillatory switching system. However, our averaging results will be applicable to a broader class of oscillatory hybrid systems, which encompasses switching systems as a particular case.

#### IV. SECOND-ORDER AVERAGING FOR A CLASS OF HYBRID DYNAMICAL SYSTEMS

We consider a subclass of HDS (1), given by

$$((x,z),\tau) \in C \times \mathbb{R}^{2}_{+}, \qquad \begin{cases} \begin{pmatrix} \dot{x} \\ \dot{z} \end{pmatrix} \in F_{\varepsilon}(x,z,\tau_{1},\tau_{2}) \\ \dot{\tau}_{1} &= \varepsilon^{-1} \\ \dot{\tau}_{2} &= \varepsilon^{-2} \\ \begin{cases} \begin{pmatrix} x^{+} \\ z^{+} \end{pmatrix} \in G(x,z) \\ &+ \end{pmatrix} \end{cases}$$
(11a)

$$(z, z), \tau) \in D \times \mathbb{R}^2_+,$$

$$\begin{cases} \begin{pmatrix} z^+ \\ \tau_1^+ \\ \tau_2^+ \\ \tau_2^+ \\ \tau_2 \end{cases} = \tau_2 \end{cases}$$
(11b)

where  $\varepsilon > 0$  is a small parameter,  $x \in \mathbb{R}^{n_1}$ ,  $z \in \mathbb{R}^{n_2}$ ,  $n_1 + n_2 = n$ ,  $C, D \subset \mathbb{R}^n$   $\tau_i \in \mathbb{R}_+$ , for  $i \in \{1, 2\}$ , and  $\tau = (\tau_1, \tau_2) \in \mathbb{R}^2_+$ . The set-valued mapping  $F_{\varepsilon}$  is given by

$$F_{\varepsilon}(x, z, \tau_1, \tau_2) := \left\{ f_{\varepsilon}(x, z, \tau_1, \tau_2) \right\} \times \Phi(z),$$
(12)

where  $f_{\varepsilon}$  is a continuous function of the form

$$f_{\varepsilon}(x, z, \tau_1, \tau_2) = \sum_{k=1}^{2} \varepsilon^{k-2} \phi_k(x, z, \tau_1, \tau_2).$$
(13)

and  $\{\phi_k\}_{k=1}^2$  is a collection of functions to be characterized.

In order to have a well-posed HDS, we first make the following regularity assumption on the data of system (11):

Assumption 2: C and D are closed.  $\Phi$  is OSC, LB, and convex-valued relative to C; G is OSC and LB relative to D; for all  $z \in C$  the set  $\Phi(z)$  is nonempty; and for all  $(x, z) \in D$  the set G(x, z) is non empty.

For the function  $f_{\varepsilon}$  defined in (13) we will ask for stronger regularity conditions in terms of smoothness and periodicity of the mappings  $\phi_k$  in a small inflation of C (c.f. Eq. (2a)).

Assumption 3: There exists  $\delta^* > 0$  and  $T_k > 0$ , for  $k \in \{1, 2\}$ , such that for all  $\delta \in [0, \delta^*]$  the following holds:

- (a) Smoothness: For  $k \in \{1, 2\}$ , the functions  $\phi_k : C_\delta \times \mathbb{R}^2_+ \to \mathbb{R}^{n_1}$  satisfy that:  $\phi_k \in \mathcal{C}^{2-k}$  with respect to  $(x, \tau_1), \phi_k \in \mathcal{C}^0$  with respect to z, and  $\phi_k$  is continuous in  $\tau_2$ .
- (b) *Periodicity*: For  $k \in \{1, 2\}$ , we have

$$\phi_k(x, z, \tau_1 + T_1, \tau_2) = \phi_k(x, z, \tau_1, \tau_2),$$
  
$$\phi_k(x, z, \tau_1, \tau_2 + T_2) = \phi_k(x, z, \tau_1, \tau_2),$$

for all  $((x, z), \tau) \in C_{\delta} \times \mathbb{R}^2_+$ . (c) Zero-Average of  $\phi_1$  in  $\tau_2$ :

$$\int_0^{T_2} \phi_1(x, z, \tau_1, s_2) \, ds_2 = 0, \tag{14}$$

for all  $((x, z), \tau) \in C_{\delta} \times \mathbb{R}^2_+$ .

*Remark 1:* The periodicity and smoothness assumptions are standard in the literature of high-order averaging theory [17, Ch.2] where C is usually taken to be an open subset of  $\mathbb{R}^n$ . Moreover, periodicity plays an important role in high-order averaging to facilitate computations that otherwise would be intractable, and it is satisfied in the applications of interest in this paper.

To study the stability properties of the HDS (11), we first characterize its corresponding 2nd-order average hybrid dynamical system  $\mathcal{H}_2^{\text{ave}}$ . To define this system, we first define the following auxiliary function for each  $((x, z), \tau) \in C_{\delta} \times \mathbb{R}^2_+$ :

$$u_1(x,z,\tau) := \int_0^{\tau_2} \phi_1(x,z,\tau_1,s_2) \, ds_2, \tag{15a}$$

as well as the following *Lie bracket* between (15a) and its derivative with respect to  $\tau_2$ :

$$\left[u_{1},\phi_{1}\right]_{x}\left(\cdot\right) = \left(\partial_{x}\phi_{1}\cdot u_{1} - \partial_{x}u_{1}\cdot\phi_{1}\right)\left(\cdot\right),\tag{15b}$$

where we omitted the function arguments to simplify notation. Using (15a)-(15b), we introduce the 2nd-order average mapping of  $f_{\varepsilon}$ , denoted  $\bar{f}: C_{\delta} \to \mathbb{R}^{n_1}$ , and given by:

$$\bar{f}(\theta) := \frac{1}{T_1 T_2} \int_0^{T_1} \int_0^{T_2} \left( \phi_2(\theta, \tau) + \frac{1}{2} \left[ u_1, \phi_1 \right]_x(\theta, \tau) \right) d\tau_2 \, d\tau_1, \tag{16}$$

where  $\theta := (x, z)$ . The following definition formalizes  $\mathcal{H}_2^{ave}$ .

Definition 6: The 2nd-order average HDS  $\mathcal{H}_2^{ave}$  of (11) is given by the HDS

$$\mathcal{H}_{2}^{\text{ave}}: \quad \begin{cases} \bar{\theta} \in C, & \dot{\bar{\theta}} \in F(\bar{\theta}) \\ \bar{\theta} \in D, & \bar{\theta}^{+} \in G(\bar{\theta}) \end{cases},$$
(17)

where  $\bar{\theta} := (\bar{x}, \bar{z}) \in \mathbb{R}^{n_1} \times \mathbb{R}^{n_2}$ , G is the same mapping of (11b), and F is defined as

$$F(\bar{\theta}) := \left\{ \bar{f}\left(\bar{\theta}\right) \right\} \times \Phi(z),$$

for all  $\bar{\theta} \in C$ .

*Remark 2:* It is worth mentioning that if  $\phi_1$  satisfies

$$\phi_1(\theta,\tau) = \sum_{\ell=1}^r b_\ell(\theta,\tau_1) \, v_\ell(\tau),$$
$$\int_0^{\tau_2} \phi_1(\theta,\tau_1,s_2) ds_2 = \sum_{\ell=1}^r b_\ell(\theta,\tau_1) \, \int_0^{\tau_2} v_\ell(\tau_1,s_2) \, ds_2,$$

for some functions  $b_{\ell}, v_{\ell}$  and some  $r \in \mathbb{Z}_{\geq 1}$ , then the Lie bracket in (15b) reduces to:

$$[u_1, \phi_1]_x (\cdot) = \sum_{\ell_1, \ell_2 = 1}^r [b_{\ell_1}, b_{\ell_2}]_x (\theta, \tau_1) \int_0^{s_2} v_{\ell_1}(\tau_1, s_2) v_{\ell_2}(\tau) \, ds_2$$
  
= 
$$\sum_{\ell_1 > \ell_2}^r [b_{\ell_1}, b_{\ell_2}] (\theta, \tau_1) v_{\ell}(\tau),$$

where  $v_{\ell}$  is the time-varying function:

$$v_{\ell}(\tau) = \int_{0}^{\tau_2} v_{\ell_1}(\tau_1, s_2) v_{\ell_2}(\tau) \, ds_2 - \int_{0}^{\tau_2} v_{\ell_2}(\tau_1, s_2) v_{\ell_1}(\tau) \, ds_2,$$

and, consequently, the average of  $[u_1, \phi_1]_x(\cdot)$  reduces to:

$$\frac{1}{T_2} \int_0^{T_2} \left[ u_1, \phi_1 \right]_x (\theta, \tau_1, s_2) ds_2 = \sum_{\ell_1 > \ell_2}^r \left[ b_{\ell_1}, b_{\ell_2} \right]_x (\theta, s_1) \Lambda(\tau_1),$$

where  $\Lambda(\tau_1) = \frac{1}{T_2} \int_0^{T_2} v_\ell(\tau_1, s_2) ds_2$ . However, in contrast to the standard Lie-bracket averaging framework [19], here we do not necessarily assume that the function  $\phi_1$  admits such a decomposition, which enables the study of more general vector fields  $f_{\varepsilon}$ .

The next lemma follows directly by Assumption 2 and the continuity properties  $\phi_k$ ,  $k \in \{1, 2\}$ , c.f., Assumption 3.

*Lemma 1:* Suppose that Assumptions 2-3 hold. Then, the HDS (11) and the HDS  $\mathcal{H}_2^{\text{ave}}$  in (17) satisfy Assumption 1. The following is the first main result of this paper. It uses the notion of  $(T, \rho)$ -closeness, introduced in Definition 3.

Theorem 1: Suppose that Assumptions 2-3 hold. Let  $K_0 \subset \mathbb{R}^n$  be a compact set such that every solution of the HDS (17) with initial conditions in  $K_0$  has no finite escape times. Then, for each  $\rho > 0$  and each T > 0, there exists  $\varepsilon^* > 0$  such that for each  $\varepsilon \in (0, \varepsilon^*)$  every solution of (11) starting in  $K_0 + \rho \mathbb{B}$  is  $(T, \rho)$ -close to some solution of (17) starting in  $K_0$ .

*Remark 3:* The result of Theorem 1 establishes a closeness-of-trajectories property (in the sense of Definition 3) between the high-frequency high-amplitude periodic-in-the-flows HDS (11) and the second-order average HDS  $\mathcal{H}_2^{\text{ave}}$  defined in (17). Unlike Lie-bracking averaging results for Lipschitz ODEs [19, Thm. 1], the result does not assert closeness between all solutions of (11) and  $\mathcal{H}_2^{\text{ave}}$ , but rather that for every solution of the original HDS (11) we can find a solution of the 2nd-order average dynamics  $\mathcal{H}_2^{\text{ave}}$  that is  $(T, \rho)$ -close. In this way, Theorem 1 effectively extends to the second-order case existing averaging results for HDS, such as [13, Thm. 1].

As a consequence of Theorem 1, if all the trajectories  $\bar{\theta}$  of the average system  $\mathcal{H}_2^{\text{ave}}$  satisfy suitable convergence bounds, then the trajectories  $\theta$  of the original HDS (11) would approximately inherit the same bounds, on compact sets and compact time domains. To extend these bounds to potentially unbounded hybrid time domains, we will work with the following stability definition, which is common in averaging [13, Def. 6], and leverages the proper indicators  $\omega$  introduced in Definition 4.

Definition 7: For the HDS (11), a compact set  $\mathcal{A} \subset \mathbb{R}^n$  is said to be Semi-Globally Practically Asymptotically Stable (SGPAS) with respect to the basin of attraction  $\mathcal{B}_{\mathcal{A}}$  as  $\varepsilon \to 0^+$  if, for each proper indicator function  $\omega$  on  $\mathcal{B}_{\mathcal{A}}$  there exists  $\beta \in \mathcal{KL}$  such that for each compact set  $K \subset \mathcal{B}_{\mathcal{A}}$  and for each  $\nu > 0$ , there exists  $\varepsilon^* > 0$  such that for all  $\varepsilon \in (0, \varepsilon^*]$  and for all solutions of (11) with  $\theta(0, 0) \in K$ , the following holds:

$$\omega(\theta(t,j)) \le \beta(\omega(\theta(0,0)), t+j) + \nu, \tag{18}$$

for all  $(t, j) \in \operatorname{dom}(\theta, \tau)$ .

As discussed in Definition 5, if  $\mathcal{B}_{\mathcal{A}}$  covers the whole space, then we can also take  $\omega(x) = |x|_{\mathcal{A}}$  in (18). If, additionally,  $C \cup D$  is compact, then (18) describes a Global Practical Asymptotic Stability (GPAS) property.

With Definition 7 at hand, we can now state the second main result of this paper.

Theorem 2: Suppose that Assumptions 2 and 3 hold, and let  $\mathcal{A} \subset \mathbb{R}^n$  be a compact set. If the set  $\mathcal{A}$  is UAS with basin of attraction  $\mathcal{B}_{\mathcal{A}}$  for the average HDS  $\mathcal{H}_2^{\text{ave}}$ , then  $\mathcal{A}$  is also SGPAS as  $\varepsilon \to 0^+$  with respect to the basin of attraction  $\mathcal{B}_{\mathcal{A}}$  for the original HDS (11).

*Remark 4:* In Theorem 2, it is assumed that the average HDS  $\mathcal{H}_2^{\text{ave}}$  renders UAS the set  $\mathcal{A}$ . However, in certain cases the average HDS might be parameterized by an additional tunable positive number (or vector)  $\eta > 0$ , and  $\mathcal{A}$  might only be SGPAS as  $\eta \to 0^+$ , see [6], [14], [16]. In the context of this paper, the SGPAS result of Theorem 2 still applies as  $(\varepsilon, \eta) \to 0^+$ , where the tunable parameters are now sequentially tuned, starting with  $\eta$ . This observation follows directly by the proof of Theorem 2 which can be directly extended as in [14, Thm. 7]. An example will be presented in Section VI in the context of slow switching systems.

The discussion preceding Theorem 2 directly implies the following Corollary, which we will leverage in Section VI for the study of *globally* practically stable Lie-bracket hybrid ES systems on smooth compact manifolds.

Corollary 1: Suppose that Assumptions 2 and 3 hold, and let  $\mathcal{A} \subset \mathbb{R}^n$  be a compact set. If  $C \cup D$  is compact, and the set  $\mathcal{A}$  is UGAS for the average HDS  $\mathcal{H}_2^{\text{ave}}$ , then  $\mathcal{A}$  is GPAS as  $\varepsilon \to 0^+$  for the original HDS (11) and the trajectories satisfy

$$|\theta(t,j)|_{\mathcal{A}} \le \beta(|\theta(0,0)|_{\mathcal{A}}, t+j) + \nu, \tag{19}$$

for all  $(t, j) \in \text{dom}(\theta, \tau)$ .

The proofs of Theorems 1-2 are presented in the next section. Specific applications are deferred to Section VI.

#### V. ANALYSIS AND PROOFS

## A. Proof of Theorem 1

The proof uses similar ideas as in standard averaging theorems [4, Thm. 10.4], [13, Thm.1], but using a recursive variable transformation applied to the analysis of the HDS.

Fix  $K_0 \subset \mathbb{R}^n$ , T > 0 and  $\rho > 0$ , and let Assumption 3 generate  $\delta^* > 0$ . For any  $\delta \in (0, \delta^*]$ , consider the  $\delta$ -inflation of  $\mathcal{H}_2^{\text{ave}}$ , given by

$$\mathcal{H}_{2,\delta}^{\text{ave}}: \quad \begin{cases} \bar{\theta} \in C_{\delta}, & \bar{\theta} \in F_{\delta}\left(\bar{\theta}\right) \\ \bar{\theta} \in D_{\delta}, & \bar{\theta}^{+} \in G_{\delta}\left(\bar{\theta}\right) \end{cases}, \tag{20}$$

where the data  $(C_{\delta}, F_{\delta}, D_{\delta}, G_{\delta})$  is constructed as in Definition 2 from the data of  $\mathcal{H}_2^{\text{ave}}$  in (6). Fix  $\delta \in (0, \delta^*]$  such that for any solution  $\tilde{\theta} = (\tilde{x}, \tilde{z})$  to the system (20) starting in  $K_0 + \delta \mathbb{B}$  there exists a solution  $\bar{\theta} = (\bar{x}, \bar{z})$  to system (17) starting in  $K_0$ such that the two solutions are  $(T, \frac{\rho}{2})$ -close. Such  $\delta$  exists due to [11, Proposition 6.34]. Without loss of generality, we may take  $\delta < 1$  and  $\rho < 1$ .

Let  $\mathcal{S}_{\mathcal{H}^{spe}_{0}}(K_{0})$  be the set of maximal solutions to (17) starting in  $K_{0}$ , and define the following sets:

$$\mathcal{R}_{T}(K_{0}) := \left\{ \xi = \bar{\theta}(t, j) : \bar{\theta} \in \mathcal{S}_{\mathcal{H}_{2}^{\text{ave}}}(K_{0}), \\ (t, j) \in \text{dom}(\bar{\theta}), \ t + j \leq T \right\}$$
$$K_{1} := \mathcal{R}_{T}(K_{0}) + \mathbb{B}$$
$$K := K_{1} \cup G\left(K_{1} \cap D\right),$$
(21a)

where K is compact by [13, Proposition 2]. Consider the functions  $\psi_m, \psi_p : C_\delta \times \mathbb{R}^2_{>0} \to \mathbb{R}^{n_1}$  defined as follows:

$$\psi_m(\theta,\tau) := \frac{1}{2} \left( \partial_x \phi_1 \cdot u_1 - \partial_x u_1 \cdot \phi_1 \right) \tag{22a}$$

$$\psi_p(\theta,\tau) := \frac{1}{2} \left( \partial_x \phi_1 \cdot u_1 + \partial_x u_1 \cdot \phi_1 \right), \tag{22b}$$

where for simplicity we omitted the arguments in the right-hand side of (22). Using integration by parts and (14):

$$\int_0^{T_2} \psi_p(\theta, \tau) \, d\tau_2 = 0, \quad \forall \ (\theta, \tau_1) \in C_\delta \times \mathbb{R}_+.$$

Let  $\bar{h}: C_{\delta} \times \mathbb{R}_{>0} \to \mathbb{R}^{n_1}$  be defined as:

$$\bar{h}(\theta,\tau_1) := \frac{1}{T_2} \int_0^{T_2} \left( \phi_2(\theta,\tau) + \psi_m(\theta,\tau) \right) d\tau_2, \tag{23}$$

which satisfies  $\bar{f}(\theta) = \frac{1}{T_1} \int_0^{T_1} \bar{h}(\theta, \tau_1) d\tau_1$ . We state some regularity properties of  $\bar{f}$  and  $\bar{h}$ . Lemma 2: Let  $K \subset \mathbb{R}^n$  be a compact set. Then, there exist  $L_{\bar{h}}, L_{\bar{f}}, M_{\bar{h}} > 0$  such that

$$|\bar{h}(\theta,\tau_1) - \bar{h}(\theta',\tau_1)| \le L_{\bar{h}}|\theta - \theta'|$$
(24a)

$$|\bar{f}(\theta) - \bar{f}(\theta')| \le L_{\bar{f}}|\theta - \theta'| \tag{24b}$$

$$|\bar{h}(\theta,\tau_1)| \le M_{\bar{h}},\tag{24c}$$

for all  $\theta, \theta' \in K \cap C_{\delta}$  and all  $\tau_1 \in \mathbb{R}_{>0}$ .

*Proof:* We recall that, due to Assumption 3, the vector field  $\phi_1$  is  $C^1$  in x and  $\tau_1$  and  $C^0$  in z, and therefore so is  $u_1$  since it is the integral of  $\phi_1$  with respect to  $\tau_2$ . In addition, the vector field  $\phi_2$  is  $\mathcal{C}^0$  in x,  $\tau_1$ , and z. It follows that  $\psi_m$  is  $\mathcal{C}^0$  in x,  $\tau_1$ , and z, since it is the integral with respect to  $\tau_2$  of terms that involve  $\partial_x \phi_1$ ,  $\partial_x u_1$ ,  $\phi_2$ ,  $\phi_1$ , and  $u_1$ , which are all  $\mathcal{C}^0$  in x,  $\tau_1$ , and z. Consequently, the vector field  $\bar{h}$  is  $C^0$  in all its arguments. In addition, since the vector field  $\bar{f}$  is the integral with respect to  $\tau_1$  of  $\bar{h}$ , it follows that  $\bar{f}$  is also  $\mathcal{C}^0$  in all its arguments. The conclusion of the lemma follows from the fact that the set K is compact and that all functions are periodic in  $\tau_1$ , and therefore  $\bar{h}$  is uniformly Lipschitz continuous and bounded in  $(K \cap C_{\delta}) \times \mathbb{R}_{>0}$ , and the vector field  $\overline{f}$  is uniformly Lipschitz continuous on  $K \cap C_{\delta}$ . 

Next, for each  $(\theta, \tau) \in C_{\delta} \times \mathbb{R}^2_+$ , we define

$$\begin{split} u_{2}(\theta,\tau) &:= \int_{0}^{\tau_{2}} \left( \phi_{2}(\theta,\tau_{1},s_{2}) + \psi_{m}(\theta,\tau_{1},s_{2}) \right. \\ &+ \psi_{p}(\theta,\tau_{1},s_{2}) - \bar{h}(\theta,\tau_{1},s_{2}) \right) ds_{2} \end{split}$$

 $\square$ 

 $\square$ 

as well as the auxiliary functions

$$\sigma_1(\theta,\tau) := u_1(\theta,\tau) \tag{25a}$$

$$\sigma_2(\theta,\tau) := u_2(\theta,\tau) - \int_0^\tau \partial_{\tau_1} u_1(\theta,\tau_1,s_2) \, ds_2 - \partial_x u_1(\theta,\tau) \cdot u_1(\theta,\tau)$$
(25b)

$$\bar{\sigma}(\theta,\tau_1) := \int_0^{\tau_1} \left( \bar{h}(\theta,s_1) - \bar{f}(\theta) \right) ds_1.$$
(25c)

The functions  $(\sigma_k, \bar{\sigma}), k \in \{1, 2\}$ , will play an important role in our analysis. We state some of their regularity properties. Lemma 3: Let  $K \subset \mathbb{R}^n$  be a compact set. Then, there exist  $L_k, \bar{L} > 0$  such that for  $k \in \{1, 2\}$ :

$$|\sigma_k(\theta,\tau)| \le L_k, \quad |\bar{\sigma}(\theta,\tau_1)| \le \bar{L},\tag{26a}$$

$$|\sigma_k(\theta,\tau) - \sigma_k(\hat{\theta},\hat{\tau})| \le L_k(|\theta - \hat{\theta}| + |\tau - \hat{\tau}|), \tag{26b}$$

$$\left|\bar{\sigma}(\theta,\tau_1) - \bar{\sigma}(\hat{\theta},\hat{\tau}_1)\right| \le L(\left|\theta - \hat{\theta}\right| + \left|\tau_1 - \hat{\tau}_1\right|),\tag{26c}$$

 $\forall \ \theta, \hat{\theta} \in K \cap C_{\delta} \ \tau, \hat{\tau} \in \mathbb{R}^2_{\geq 0}, \text{ and } \tau_1, \hat{\tau}_1 \in \mathbb{R}_{\geq 0}.$ 

*Proof:* By Assumption 3, the vector field  $\phi_1$  is continuous with respect to  $\tau_2$ , and is  $C^1$  with respect to x and  $\tau_1$ , i.e. continuously differentiable and its differential (the jacobian matrix  $[\partial_x \phi_1 \ \partial_{\tau_1} \phi_1]$ ) is locally Lipschitz continuous. Since  $u_1$  is the integral of  $\phi_1$  with respect to  $\tau_2$ , it follows that  $u_1, \partial_x u_1$ , and  $\partial_{\tau_1} u_1$  are  $C^0$  in all arguments. In addition, we note that  $\phi_2$  is  $C^0$  in x and  $\tau_1$ , and continuous with respect to  $\tau_2$ . Therefore,  $u_2$  is the integral with respect to  $\tau_2$  of terms that are locally Lipschitz continuous in x and  $\tau_1$ , and continuous in  $\tau_2$ . Consequently,  $u_2$  is also  $C^0$  in all arguments. Moreover, since all terms are periodic in  $\tau_1$  and  $\tau_2$ , we obtain that all terms are globally Lipschitz in  $\tau_1$  and  $\tau_2$ . This establishes the inequalities for the maps  $\sigma_k$  for  $k \in \{1, 2\}$ . An identical argument establishes the inequality for the map  $\bar{\sigma}$ .

The following technical Lemma will be key for our results. The proof of the first items leverages the Lipschitz extension Lemma of [13, Lemma 2].

Lemma 4: Let  $K \subset \mathbb{R}^n$  be a compact set, and for  $k \in \{1, 2\}$  let  $\sigma_k, \bar{\sigma}$  be given by (25), and  $L_k, \bar{L} > 0$  be given by Lemma 3. Consider the closed sets

$$C|_{K,\delta} = (K \cap C_{\delta}) \times \mathbb{R}^2_+$$
(27a)

$$D|_{K} = \left(K \cap \overline{D}\right) \times \mathbb{R}^{2}_{+}.$$
(27b)

Then, there exist functions  $\tilde{\sigma}_k : \mathbb{R}^n \times \mathbb{R}^2_+ \to \mathbb{R}^{n_1}$ ,  $\tilde{\sigma} : \mathbb{R}^n \times \mathbb{R}^2_+ \to \mathbb{R}^{n_1}$  such that the following holds: (a) For all  $(\theta, \tau) \in C|_{K,\delta}$ :

 $\widetilde{\sigma}_k(\theta, \tau) = \sigma_k(\theta, \tau), \quad \widetilde{\sigma}(\theta, \tau_1) = \overline{\sigma}(\theta, \tau_1).$ 

(b) For all  $(\theta, \tau) \in \mathbb{R}^{n+2}$ :

$$|\widetilde{\sigma}_k(\theta,\tau)| \le L_k, \quad |\widetilde{\sigma}(\theta,\tau_1)| \le \bar{L}.$$
(28)

(c) For all  $(\theta, \tau) \in \mathbb{R}^{n+2}$  and  $(\theta', \tau') \in \mathbb{R}^{n+2}$ :

$$\widetilde{\sigma}_{k}(\theta,\tau) - \widetilde{\sigma}_{k}(\theta',\tau') \leq L_{k} \left( |\theta - \theta'| + |\tau - \tau'| \right), \\ \widetilde{\sigma}(\theta,\tau_{1}) - \widetilde{\sigma}(\theta',\tau'_{1}) \leq \sqrt{n} \overline{L} \left( |\theta - \theta'| + |\tau_{1} - \tau'_{1}| \right)$$

(d) For all  $(\theta, \tau) \in C|_{K,\delta}$ :

$$\begin{aligned}
\alpha_1(\theta,\tau) &:= \phi_1(\theta,\tau) - \partial_{\tau_2} \widetilde{\sigma}_1(\theta,\tau) = 0, \\
\alpha_2(\theta,\tau) &:= \phi_2(\theta,\tau) - \partial_{\tau_2} \widetilde{\sigma}_2(\theta,\tau) \\
&\quad - \partial_x \widetilde{\sigma}_1(\theta,\tau) \phi_1(\theta,\tau) - \partial_{\tau_1} \widetilde{\sigma}_1(\theta,\tau) \\
&\quad = \overline{h}(\theta,\tau_1).
\end{aligned}$$
(29)

# (e) There exists $M_3 > 0$ such that for all $(\theta, \tau) \in C|_{K,\delta}$ , $\alpha_3(\theta, \tau) \subset M_3\mathbb{B}$ , where

$$\alpha_{3}(\theta,\tau) := \left\{ X \phi_{1}(\theta,\tau) + Z \zeta + \partial_{x} \widetilde{\sigma}_{1}(\theta,\tau) \phi_{2}(\theta,\tau) \\
+ \partial_{\tau_{1}} \widetilde{\sigma}_{2}(\theta,\tau) : \zeta \in \Phi(z), Z \in \partial_{z} \widetilde{\sigma}_{1}(\theta,\tau), \\
X \in \partial_{x} \widetilde{\sigma}_{2}(\theta,\tau) \right\},$$
(31)

(f) There exists  $M_4 > 0$  such that for all  $(\theta, \tau) \in C|_{K,\delta}$ ,  $\alpha_4(\theta, \tau) \subset M_4\mathbb{B}$ , where

$$\begin{aligned}
\alpha_4(\theta,\tau) &:= \left\{ X \,\phi_2(\theta,\tau) + Z \,\zeta : \,\zeta \in \Phi(z), \\
Z &\in \partial_z \widetilde{\sigma}_1(\theta,\tau), X \in \partial_x \widetilde{\sigma}_2(\theta,\tau) \right\}.
\end{aligned}$$
(32)

*Proof:* By invoking [13, Lemma 2], we get the existence of functions  $\tilde{\sigma}_k, \tilde{\sigma}$ , constructed using the saturation function as in [13, Lemma 2], such that, due to Lemma 3, the properties in items (a), (b), and (c) hold.

To establish item (d), we note that since  $\tilde{\sigma}_1 = \sigma_1$  in the set  $C|_{K,\delta}$ , and by using the construction of  $\sigma_1$  in (25a) and the definition of  $u_1$  in (15a), we directly obtain  $\partial_{\tau_2} u_1 = \phi_1$ , which establishes (29). Similarly, since

$$\partial_{\tau_2} \widetilde{\sigma}_2 = \phi_2 + \psi_m + \psi_p - \bar{h} - \partial_{\tau_1} u_1 - \partial_{\tau_2} (\partial_x u_1 \cdot u_1)$$
(33a)

$$\partial_x \widetilde{\sigma}_1 \phi_1 = \partial_x u_1 \cdot \phi_1, \quad \partial_{\tau_1} \widetilde{\sigma}_1 = \partial_{\tau_1} u_1, \tag{33b}$$

and since  $\partial_{\tau_2}(\partial_x u_1 \cdot u_1) = \partial_{\tau_2}(\partial_x u_1) \cdot u_1 + \partial_x u_1 \cdot \phi_1$ , and

$$\partial_{\tau_2} \left( \partial_x \int_0^{\tau_2} \phi_1(\bar{\theta}, \tau_1, s_2) \, ds_2 \right) = \partial_{\tau_2} \left( \int_0^{\tau_2} \partial_x \phi_1(\bar{\theta}, \tau_1, s_2) \, ds_2 \right)$$
$$= \partial_x \phi_1, \tag{34}$$

we can combine (33)-(34) to obtain (30). To establish items (e) and (f), let  $M_k > 0$  satisfy

$$|\phi_k(\theta,\tau)| \le M_k, \quad k \in \{1,2\},$$

for all  $(\theta, \tau) \in C|_{K,\delta} \times \mathbb{R}^2_{\geq 0}$ , which exists due to the continuity of  $\phi_k$ , the compactness of  $C|_{K,\delta}$  and the periodicity of  $\phi_k$ with respect to  $\tau$ . In addition, since  $\Phi$  is LB, there exist  $M_z > 0$  such that  $\Phi(C|_{K,\delta}) \subset M_z \mathbb{B}$ . Moreover, since  $\tilde{\sigma}_1$  and  $\tilde{\sigma}_2$  are globally Lipschitz by construction, it follows that the generalized Jacobians  $\partial_z \tilde{\sigma}_1$  and  $\partial_x \tilde{\sigma}_2$  are OSC, compact, convex, and bounded [26]. Therefore,  $\forall(\theta, \tau) \in C|_{K,\delta} \times \mathbb{R}^2_{>0}$ ,  $\forall a_3 \in \alpha_3(\theta, \tau)$ ,  $\forall a_4 \in \alpha_4(\theta, \tau)$ , we have

$$|a_3| \le L_2 M_1 + L_1 M_z + L_1 M_2 + L_1 =: M_3,$$
  
 $|a_4| \le L_2 M_2 + L_2 M_z =: M_4.$ 

Continuing with the proof of Theorem 1, let

$$\varepsilon_1^* := \delta \left( \sqrt{n} \bar{L} M_s + M_3 + M_4 + 0.5 \bar{L}_{\bar{h}} \right)^{-1} \tag{35a}$$

$$\varepsilon_2^* := \delta \left( 2\bar{L}(0.5\sqrt{n}+1) \right)^{-1} \tag{35b}$$

$$\varepsilon_3^* := \delta \left( 2(L_1 + L_2) + 1 \right)^{-1} \tag{35c}$$

$$\varepsilon_4^* := \rho \left( 2(L_1 + L_2 + (0.5\sqrt{n} + 1)\bar{L}) \right)^{-1}, \tag{35d}$$

and  $\varepsilon^* := \min \{\varepsilon_0, \varepsilon_1, \varepsilon_2, \varepsilon_3, \varepsilon_4\}$ , which satisfies  $\varepsilon^* \in (0, 1)$  due to (35c). Let  $\varepsilon \in (0, \varepsilon^*)$  and consider the restricted HDS:

$$(\theta,\tau) \in C|_{K}, \quad \begin{cases} \dot{\theta} \in F_{\varepsilon}(\theta,\tau_{1},\tau_{2}) \\ \dot{\tau}_{1} = \varepsilon^{-1} \\ \dot{\tau}_{2} = \varepsilon^{-2} \end{cases}$$
(36a)

$$(\theta,\tau) \in D|_{K}, \quad \begin{cases} \theta^{+} \in G(\theta) \cap K \\ \tau_{1}^{+} = \tau_{1} \\ \tau_{2}^{+} = \tau_{2} \end{cases}$$
(36b)

with  $\theta = (x, z)$ ,  $\tau = (\tau_1, \tau_2)$ , and flow set  $C|_K$  and jump set  $D|_K$  defined in (27), with K given by (21a). We divide the rest of proof into four main steps:

Step 1: Construction and Properties of Auxiliary Functions: Using the compact set  $\tilde{K} := K + \frac{\delta}{2}\mathbb{B}$  and the functions  $\sigma_k, \bar{\sigma}$  given by (25), let Lemmas 2-3 generate  $L_{\bar{h}}, L_{\bar{f}}, M_{\bar{h}}, L_k, \bar{L} > 0$ . Using these constants, the set K, and the functions  $(\sigma_k, \bar{\sigma})$ , let Lemma 4 generate the functions  $(\tilde{\sigma}_k, \tilde{\sigma})$ . Then, for each  $(\theta, \tau) \in \mathbb{R}^n \times \mathbb{R}^2_+$  and each  $\varepsilon \in (0, \varepsilon^*)$ , we define

$$\hat{\theta} := \theta - \gamma_{\varepsilon}(\theta, \tau), \quad \tilde{\theta} := \hat{\theta} - \lambda_{\varepsilon}(\hat{\theta}, \tau_1), \tag{37}$$

where

$$\gamma_{\varepsilon}(\theta,\tau) := \begin{pmatrix} \sum_{k=1}^{2} \varepsilon^{k} \tilde{\sigma}_{k}(\theta,\tau) \\ 0 \end{pmatrix},$$
(38a)

$$\lambda_{\varepsilon}(\hat{\theta},\tau_1) := \begin{pmatrix} \varepsilon \tilde{\sigma}(\hat{\theta},\tau_1) \\ 0 \end{pmatrix}.$$
(38b)

Using the inequalities in (28), we have

$$|\gamma_{\varepsilon}(\theta,\tau)| = \left|\sum_{k=1}^{2} \varepsilon^{k} \widetilde{\sigma}_{k}(\theta,\tau)\right| \le \varepsilon (L_{1} + \varepsilon L_{2}),$$
(39)

11

for all  $(\theta, \tau) \in \mathbb{R}^n \times \mathbb{R}^2_+$ . Similarly, due to items (b)-(c) of Lemma 4, the definition of  $\hat{\theta}$  in (37), and inequality (39),

$$\begin{aligned} \lambda_{\varepsilon}(\hat{\theta},\tau_{1}) &| \leq \varepsilon \left| \tilde{\sigma}(\hat{\theta},\tau_{1}) - \tilde{\sigma}\left(\theta,\tau_{1}\right) \right| + \varepsilon \left| \tilde{\sigma}\left(\theta,\tau_{1}\right) \right| \\ &\leq \varepsilon \sqrt{n} \bar{L} \left| \hat{\theta} - \theta \right| + \varepsilon \left| \tilde{\sigma}(\theta,\tau_{1}) \right| \\ &\leq \varepsilon \sqrt{n} \bar{L} \left| \gamma_{\varepsilon}(\theta,\tau) \right| + \varepsilon \left| \tilde{\sigma}(\theta,\tau_{1}) \right|, \end{aligned}$$

$$\tag{40}$$

for all  $(\theta, \tau) \in \mathbb{R}^n \times \mathbb{R}^2_+$ . Also, note that due to item (a) of Lemma 4, the functions  $\gamma_{\varepsilon}$  and  $\lambda_{\varepsilon}$  satisfy  $\gamma_{\varepsilon}(\theta, \tau) = \left(\sum_{k=1}^2 \varepsilon^k \sigma_k(\theta, \tau), 0\right)$  and  $\lambda_{\varepsilon}(\hat{\theta}, \tau_1) = \left(\varepsilon \bar{\sigma}(\hat{\theta}, \tau_1), 0\right)$  for all  $(\theta, \tau), (\hat{\theta}, \tau) \in \left(\tilde{K} \cap C_{\delta}\right) \times \mathbb{R}^2_+$ , with  $(\sigma_k, \bar{\sigma})$  given by (26). Step

2: Construction of First Auxiliary Solution: Let  $(\theta, \tau)$  be a solution to the HDS (36) with  $\theta(0,0) \in K_0$ . By construction, we have that

$$\theta(t,j) \in K \subset K, \quad \forall \ (t,j) \in \operatorname{dom}(\theta,\tau).$$
(41)

Using (26a), (28), (39), and the choice of  $\varepsilon^*$ , we have

$$|\gamma_{\varepsilon}(\theta(t,j),\tau(t,j))| \le \frac{\delta}{2}, \quad \forall \ (t,j) \in \operatorname{dom}(\theta,\tau).$$
(42)

For each  $(t, j) \in \text{dom}(\theta, \tau)$ , let  $\hat{\theta}$  be defined via (37). It follows that  $\hat{\theta}$  is a hybrid arc, and due to (41) and (42) it satisfies

$$\hat{\theta}(t,j) \in K + \frac{\delta}{2} \mathbb{B} = \tilde{K}, \quad \forall \ (t,j) \in \operatorname{dom}(\hat{\theta},\tau).$$
(43)

Therefore, using (26a), (28), and (40), we also have

$$|\lambda_{\varepsilon}(\hat{\theta}(t,j),\tau_1(t,j))| \le \varepsilon \bar{L}\left(\frac{1}{2}\sqrt{n}+1\right) \le \frac{\delta}{2},\tag{44}$$

for all  $(t, j) \in \operatorname{dom}(\hat{\theta}, \tau)$ .

Next, for each  $(t, j) \in \text{dom}(\hat{\theta}, \tau)$  such that  $(t, j + 1) \in \text{dom}(\hat{\theta}, \tau)$ , we have that:

$$\theta(t,j) = \hat{\theta}(t,j) + \gamma_{\varepsilon}(\theta(t,j),\tau(t,j)) \in D \cap K \subset D \cap \tilde{K}.$$

Using (42) and the construction of the inflated jump set (2b), we conclude that  $\hat{\theta}(t, j) \in D_{\delta/2}$ . Thus, using (36b) and (42), we obtain:

$$\hat{\theta}(t, j+1) = \theta(t, j+1) - \gamma_{\varepsilon}(\theta(t, j+1), \tau(t, j+1))$$

$$\in G(\theta(t, j) \cap D) \cap K + \frac{\delta}{2}\mathbb{B}$$

$$\subset G(\theta(t, j) \cap D) + \frac{\delta}{2}\mathbb{B}$$

$$= G\left(\left(\hat{\theta}(t, j) + \gamma_{\varepsilon}(\theta(t, j), \tau(t, j))\right) \cap D\right) + \frac{\delta}{2}\mathbb{B}$$

$$\subset G\left(\left(\hat{\theta}(t, j) + \frac{\delta}{2}\mathbb{B}\right) \cap D\right) + \frac{\delta}{2}\mathbb{B}.$$
(45)

Similarly, from (37), for all  $j \in \mathbb{Z}_{\geq 0}$  such that  $I_j = \{t : (t, j) \in \text{dom}(\hat{\theta})\}$  has a nonempty interior, we have:

$$\theta(t,j) = \hat{\theta}(t,j) + \gamma_{\varepsilon}(\theta(t,j),\tau(t,j)) \in C \cap K \subset C_{\delta} \cap \tilde{K},$$
(46)

for all  $t \in I_j$ . Therefore, using the construction of the inflated flow set (2a), and the bound (42), we have that  $\hat{\theta}(t, j) \in C_{\delta/2}$ . Since  $\gamma_{\varepsilon}$  is Lipschitz continuous due to Lemma 4,  $\hat{\theta}(\cdot, j)$  is locally absolutely continuous, and it satisfies

$$\dot{\hat{\theta}}(t,j) = \dot{\theta}(t,j) - \overbrace{\gamma_{\varepsilon}(\theta(t,j),\tau(t,j))}^{:}$$

$$= F_{\varepsilon}(\theta,\tau) - \overbrace{\gamma_{\varepsilon}(\theta(t,j),\tau(t,j))}^{:}, \text{ for a.a. } t \in I_j.$$
(47)

$$\begin{split} \varepsilon \tilde{\sigma}_{1} &\in \varepsilon \partial_{\theta} \tilde{\sigma}_{1} \theta + \varepsilon \partial_{\tau} \tilde{\sigma}_{1} \dot{\tau} \\ &= \varepsilon \partial_{x} \tilde{\sigma}_{1} \dot{x} + \varepsilon \partial_{z} \tilde{\sigma}_{1} \dot{z} + \varepsilon \partial_{\tau_{1}} \tilde{\sigma}_{1} \dot{\tau}_{1} + \varepsilon \partial_{\tau_{2}} \tilde{\sigma}_{1} \dot{\tau}_{2} \\ &\subset \partial_{x} \tilde{\sigma}_{1} \sum_{k=1}^{2} \varepsilon^{k-1} \phi_{k} + \partial_{\tau_{1}} \tilde{\sigma}_{1} + \frac{1}{\varepsilon} \partial_{\tau_{2}} \tilde{\sigma}_{1} + \varepsilon \partial_{z} \tilde{\sigma}_{1} \Phi, \\ \varepsilon^{2} \dot{\tilde{\sigma}}_{2} &\in \varepsilon^{2} \partial_{\theta} \tilde{\sigma}_{2} \dot{\theta} + \varepsilon^{2} \partial_{\tau} \tilde{\sigma}_{2} \dot{\tau} \\ &= \varepsilon^{2} \partial_{x} \tilde{\sigma}_{2} \dot{x} + \varepsilon^{2} \partial_{z} \tilde{\sigma}_{2} \dot{z} + \varepsilon^{2} \partial_{\tau_{1}} \tilde{\sigma}_{2} \dot{\tau}_{1} + \varepsilon^{2} \partial_{\tau_{2}} \tilde{\sigma}_{2} \dot{\tau}_{2} \\ &\subset \partial_{x} \tilde{\sigma}_{2} \sum_{k=1}^{2} \varepsilon^{k} \phi_{k} + \varepsilon \partial_{\tau_{1}} \tilde{\sigma}_{2} + \partial_{\tau_{2}} \tilde{\sigma}_{2} + \varepsilon^{2} \partial_{z} \tilde{\sigma}_{2} \Phi, \end{split}$$

where we used (12), the structure of (13), and (36). Therefore, using the definition of  $\gamma_{\varepsilon}$ , we have that (47) can be written as

$$\dot{\hat{\theta}}(t,j) \in \left(\begin{array}{c} \sum_{k=1}^{4} \varepsilon^{k-2} \alpha_{k}(\theta(t,j),\tau(t,j)) \\ \Phi(z(t,j)) \end{array}\right), \text{ for a.a. } t \in I_{j},$$

Using the last containment in (46), and items (a), (d), (e), and (f) of Lemma 4, we obtain that for all  $t \in I_i$ :

$$\begin{aligned} \alpha_1(\theta(t,j),\tau(t,j)) &= 0\\ \alpha_2(\theta(t,j),\tau(t,j)) &= \bar{h}(\theta(t,j),\tau_1(t,j))\\ \alpha_k(\theta(t,j),\tau(t,j)) &\subset M_k \mathbb{B}, \quad k \in \{3,4\}. \end{aligned}$$

Therefore,  $\forall \ \varepsilon \in (0, \varepsilon^*)$  and for a.a.  $t \in I_j, \ \hat{\theta}(\cdot, j)$  satisfies

$$\dot{\hat{\theta}}(t,j) \in \left(\begin{array}{c} \bar{h}(\theta(t,j),\tau_{1}(t,j)) \\ \Phi(z(t,j)) \end{array}\right) + \chi_{\varepsilon}(\theta(t,j),\tau(t,j))$$

$$\chi_{\varepsilon}(\theta,\tau) := \left(\begin{array}{c} \sum_{k=1}^{2} \varepsilon^{k} \alpha_{k+2}(\theta(t,j),\tau(t,j)) \\ 0 \end{array}\right).$$
(48)

where

$$\chi_{\varepsilon}(\theta,\tau) := \left( \begin{array}{c} \sum_{k=1}^{2} \varepsilon^{k} \alpha_{k+2}(\theta(t,j),\tau(t,j)) \\ 0 \end{array} \right).$$

Finally, using the equality in (46), we can write (48) as:

$$\dot{\hat{\theta}}(t,j) \in \begin{pmatrix} \bar{h}\left(\hat{\theta}(t,j) + \gamma_{\varepsilon}(\theta(t,j),\tau(t,j)),\tau_{1}(t,j)\right) \\ \Phi(z(t,j)) \\ + \chi_{\varepsilon}(\theta(t,j),\tau(t,j)). \end{cases}$$
(49)

which holds for a.a.  $t \in I_j$ .

Step 3: Construction of Second Auxiliary Solution: Using the solution  $(\theta, \tau)$  to the restricted HDS (36) considered in Step 2, as well as the hybrid arc  $\hat{\theta}$ , we now define a new auxiliary solution. In particular, for each  $(t, j) \in \text{dom}(\theta, \tau)$ , using (37) we define:

$$\tilde{\theta}(t,j) := \hat{\theta}(t,j) - \lambda_{\varepsilon} \left( \hat{\theta}(t,j), \tau_1(t,j) \right).$$
(50)

By construction,  $\tilde{\theta}$  is a hybrid arc. Since, by combining equation (37) and inequalities (42) and (44) we have that

$$|\gamma_{\varepsilon}(\theta(t,j),\tau(t,j)) + \lambda_{\varepsilon}(\hat{\theta}(t,j),\tau_1(t,j))| \le \delta,$$
(51)

for all  $(t, j) \in \text{dom}(\theta, \tau)$ , and for all  $(t, j) \in \text{dom}(\hat{\theta}, \tau)$ , it follows that the hybrid arc (50) satisfies  $\tilde{\theta}(0, 0) \in K_0 + \delta \mathbb{B}$ . Now, for each  $(t, j) \in \text{dom}(\tilde{\theta})$  such that  $(t, j + 1) \in \text{dom}(\tilde{\theta})$  it satisfies

$$\theta(t,j) = \tilde{\theta}(t,j) + \gamma_{\varepsilon}(\theta(t,j),\tau(t,j)) + \lambda_{\varepsilon}(\hat{\theta}(t,j),\tau_1(t,j))$$
  
$$\in D \cap K \subset D \cap \tilde{K},$$

where we used (37) and (50). Therefore, using the construction of the inflated jump set (2b), we conclude that  $\tilde{\theta}(t, j) \in D_{\delta}$ , and using (44)-(45) we have:

$$\begin{aligned} \theta(t,j+1) &= \hat{\theta}(t,j+1) - \lambda_{\varepsilon}(\hat{\theta}(t,j+1),\tau_{1}(t,j+1)) \\ &\in G\left(\left(\hat{\theta}(t,j) + \frac{\delta}{2}\mathbb{B}\right) \cap D\right) + \delta\mathbb{B} \\ &= G\left(\left(\tilde{\theta}(t,j) + \lambda_{\varepsilon}(\hat{\theta}(t,j),\tau_{1}(t,j)) + \frac{\delta}{2}\mathbb{B}\right) \cap D\right) \\ &+ \delta\mathbb{B}, \\ &\subset G_{\delta}(\tilde{\theta}(t,j)), \end{aligned}$$

where we also used (50) and the definition of the inflated jump map  $G_{\delta}$  in (2d).

On the other hand, for each  $j \in \mathbb{Z}_{\geq 0}$  such that  $I_j = \{t : (t, j) \in \text{dom}(\tilde{\theta})\}$  has a nonempty interior, we must have:

$$\begin{aligned}
\theta(t,j) &= \hat{\theta}(t,j) + \gamma_{\varepsilon}(\theta(t,j),\tau(t,j)) + \lambda_{\varepsilon}(\hat{\theta}(t,j),\tau_{1}(t,j)) \\
&= \hat{\theta}(t,j) + \lambda_{\varepsilon}(\hat{\theta}(t,j),\tau_{1}(t,j)) \\
&\in C \cap K,
\end{aligned}$$
(52)

and therefore, due to (44), the inclusion in (52), and the definition of inflated flow set (2a):

$$\hat{\theta}(t,j) \in C_{\delta/2} \cap K \subset C_{\delta/2} \cap \tilde{K} \subset C_{\delta} \cap \tilde{K}, \quad \forall \ t \in I_j.$$
(53)

Since  $\tilde{\sigma}$  is Lipschitz continuous in all arguments due to Lemma 4, it follows that  $\tilde{\theta}(\cdot, j)$  is locally absolutely continuous and satisfies:

$$\dot{\tilde{ heta}}(t,j) = \dot{\hat{ heta}}(t,j) - rac{d\lambda_{arepsilon}( heta(t,j), au_1(t,j))}{dt}, ext{ for a.a. } t \in I_j.$$

Using the definition of  $\lambda_{\varepsilon}$  in (38b), as well as (53), item (a) of Lemma 4, and (25c), we obtain:

$$\begin{aligned} \dot{\lambda}_{\varepsilon} &\in \left(\varepsilon\partial_{\hat{\theta}}\tilde{\sigma}(\hat{\theta},\tau_{1})\dot{\hat{\theta}} + \varepsilon\partial_{\tau_{1}}\tilde{\sigma}(\hat{\theta},\tau_{1})\dot{\tau}_{1},0\right) \\ &= \left(\varepsilon\partial_{\hat{\theta}}\tilde{\sigma}(\hat{\theta},\tau_{1})\dot{\hat{\theta}} + \partial_{\tau_{1}}\tilde{\sigma}(\hat{\theta},\tau_{1}),0\right) \\ &= \left(\varepsilon\partial_{\hat{\theta}}\tilde{\sigma}(\hat{\theta},\tau_{1})\dot{\hat{\theta}} + \bar{h}(\hat{\theta},\tau_{1}) - \bar{f}(\hat{\theta}),0\right) \end{aligned}$$

Therefore, using (49) we have that for almost all  $t \in I_j$ :

$$\dot{\tilde{\theta}}(t,j) \in \begin{pmatrix} \bar{f}(\hat{\theta}(t,j)) \\ \Phi(z(t,j)) \end{pmatrix} + \begin{pmatrix} p\left(\theta(t,j),\hat{\theta}(t,j),\tau(t,j)\right) \\ 0 \end{pmatrix},$$
(54)

where the last term can be written in compact form as

$$p(\theta, \hat{\theta}, \tau) = \varepsilon \partial_{\hat{\theta}} \tilde{\sigma}(\hat{\theta}, \tau_1) \dot{\hat{\theta}} + \sum_{k=1}^2 \varepsilon^k \alpha_{k+2}(\theta, \tau) + \bar{h} \left( \hat{\theta} + \gamma_{\varepsilon}(\theta, \tau), \tau_1 \right) - \bar{h}(\hat{\theta}, \tau_1).$$

Using (50), (52), (53) and Lemma 2, we have:

$$\left| \bar{h} \left( \hat{\theta} + \gamma_{\varepsilon}(\theta, \tau), \tau_{1} \right) - \bar{h} \left( \hat{\theta}, \tau_{1} \right) \right| \leq L_{\bar{h}} |\gamma_{\varepsilon}(\theta, \tau)|$$

$$\left| \bar{h}(\theta, \tau_{1}) \right| \leq M_{\bar{h}}.$$
(55b)

for all  $t \in I_j$  and all  $\varepsilon \in (0, \varepsilon^*)$ , where we omitted the time arguments to simplify notation. Using  $\hat{\theta} = (\hat{x}, z)$ , we have that  $\partial_{\hat{a}} \tilde{\sigma} \cdot \hat{\theta}$  satisfies:

$$\begin{aligned} \partial_{\hat{\theta}} \tilde{\sigma}(\hat{\theta}, \tau_1) \hat{\theta} &= \partial_{\hat{x}} \tilde{\sigma}(\hat{\theta}, \tau_1) \dot{\hat{x}} + \partial_z \tilde{\sigma}(\hat{\theta}, \tau_1) \dot{z} \\ &\subset \partial_{\hat{x}} \tilde{\sigma}(\hat{\theta}, \tau_1) \left( \bar{h}(\theta, \tau_1) + \sum_{k=1}^2 \varepsilon^k \alpha_{k+2}(\theta, \tau) \right) \\ &+ \partial_z \tilde{\sigma}(\hat{\theta}, \tau_1) \Phi(z), \end{aligned}$$

where the inclusion follows from (49), and  $\alpha_i$  are defined in (29), (30), (31), and (32). Since  $\tilde{\sigma}$  is globally Lipschitz continuous by Lemma 4, it follows that  $\partial_{\hat{x}}\tilde{\sigma} \subset \bar{L}\mathbb{B}$ ,  $\partial_{\hat{z}}\tilde{\sigma} \subset \bar{L}\mathbb{B}$ . Using (52), (53), items (c), (e) and (f) of Lemma 4, as well as (55b), we obtain for all  $t \in I_j$  and all  $\varepsilon \in (0, \varepsilon^*)$ :

$$\partial_{\hat{\theta}}\tilde{\sigma}(\hat{\theta}(t,j),\tau_1(t,j))\hat{\theta}(t,j) \subset \sqrt{n}\bar{L}M_s\mathbb{B},\tag{56}$$

where  $M_s := M_{\bar{h}} + M_3 + M_4 + M_z$ , the constant  $M_z$  comes from the proof of items (e)-(f) in Lemma 4, and where we used the fact that  $\varepsilon < 1$ . Therefore, using the above bounds, as well as (42) to bound (55a), we conclude that for all  $t \in I_j$  and all  $\varepsilon \in (0, \varepsilon^*)$ :

$$p(\theta(t,j), \hat{\theta}(t,j), \tau(t,j)) \subset \varepsilon \widetilde{M} \mathbb{B} \subset \delta \mathbb{B},$$

where  $\widetilde{M} = \sqrt{n}\overline{L}M_s + M_3 + M_4 + \frac{\delta \overline{L}_{\overline{h}}}{2}$ , and we used the fact that  $\delta < 1$  and the choice of  $\varepsilon$ . Using (44), (50), and (54), we conclude that for almost all  $t \in I_j$ :

$$\dot{\tilde{\theta}}(t,j) \in \begin{pmatrix} \bar{f}\left(\tilde{\theta}(t,j) + \frac{\delta}{2}\mathbb{B}\right) \\ \Phi(z(t,j)) \end{pmatrix} + \delta\mathbb{B} \subset F_{\delta}(\tilde{\theta}(t,j)),$$

where  $F_{\delta}$  is the inflated average flow map in (20). It follows that  $\tilde{\theta}$  is  $(T, \rho/2)$ -close to some solution  $\bar{\theta}$  of the average system (17), with  $\bar{\theta}(0,0) \in K_0$ . Using (37), (50), and the fact that (51) also holds with  $\delta = \frac{\rho}{2}$  due to the fact that  $\varepsilon < \varepsilon_4$ , we conclude that  $\theta$  is  $(T, \rho)$ -close to  $\bar{\theta}$ .

Step 4: Removing K from the HDS (36). We now study the properties of the solutions to the unrestricted system (11) from  $K_0$ , based on the properties of the solutions of the restricted system (36) initialized also in  $K_0$ . Let  $(\theta, \tau)$  be a solution of (11) starting in  $K_0$ . We consider two scenarios:

- (a) For all  $(t, j) \in \text{dom}(\theta, \tau)$  such that  $t + j \leq T$  we have  $\theta(t, j) \in K$ . Then, it follows that  $\theta$  is  $(T, \rho)$ -close to  $\overline{\theta}$ .
- (b) There exists  $(t, j) \in \text{dom}(\theta, \tau)$  such that  $\theta(s, k) \in K$  for all  $(s, k) \in \text{dom}(\theta, \tau)$  such that  $s + k \le t + j$  and either:
  - (1) there exists sequence  $\{\ell_i\}_{i\in\mathbb{Z}}$  satisfying  $\lim_{i\to\infty}\ell_i = t$  such that  $(\ell_i, j) \in \operatorname{dom}(\theta, \tau)$  and  $\theta(\ell_i, j) \notin K$  for each i, or else
  - (2)  $(t, j+1) \in \operatorname{dom}(\theta, \tau)$  and  $\theta(t, j+1) \notin K$ .

Then, we must have that the solution  $(\theta, \tau)$  agrees with a solution to (36) up to time (t, j), which implies that  $\theta(t, j) \in \mathcal{R}_T(K_0) + \rho \mathbb{B}$ . But, since  $\rho \in (0, 1)$ , and due to the construction of K in (21a), we have that  $\mathcal{R}_T(K_0) + \rho \mathbb{B}$  is contained in the interior of K, so neither of the above two cases can occur.

Since item (b) cannot occur, we obtain the desired result.

#### B. Proof of Theorem 2

The proof proceeds in a similar manner to the proof of Theorem 1 and the proof of [13, Theorem 2].

Let  $\omega : \mathcal{B}_{\mathcal{A}} \to \mathbb{R}_{\geq 0}$  be a proper indicator for  $\mathcal{A}$  on  $\mathcal{B}_{\mathcal{A}}$ , and let  $\beta \in \mathcal{KL}$  such that each solution  $\overline{\theta}$  of the averaged HDS (17) starting in  $\mathcal{B}_{\mathcal{A}}$  satisfies

$$\forall \left(\bar{\theta}(t,j)\right) \leq \beta \left(\omega(\bar{\theta}(0,0)), t+j\right), \qquad \forall (t,j) \in \operatorname{dom} \bar{\theta}.$$

Let  $K_0 \subset \mathcal{B}_{\mathcal{A}}$  be compact, and let

$$K_{1} = \left\{ \theta \in \mathcal{B}_{\mathcal{A}} : \, \omega(\theta) \leq \beta \left( \max_{\tilde{\theta} \in K_{0}} \omega(\tilde{\theta}), 0 \right) + 1 \right\},\tag{57}$$

$$K = K_1 \cup G(K_1 \cap D). \tag{58}$$

By construction, the continuity of  $\omega$ ,  $\beta$ , and the OSC property of G, the set K is compact and satisfies  $K \subset \mathcal{B}_A$ . Let  $\nu \in (0, 1)$ and observe that, due to the robustness properties of well-posed HDS [11, Lemma 7.20], there exists  $\delta \in (0, \delta^*)$  such that all solutions  $\tilde{\theta}$  to the inflated averaged HDS (20) that start in  $K_0 + \delta \mathbb{B}$  satisfy for all  $(t, j) \in \text{dom } \tilde{\theta}$ :

$$\omega(\tilde{\theta}(t,j)) \le \beta \left( \omega(\tilde{\theta}(0,0)), t+j \right) + \frac{\nu}{3}.$$
(59)

Without loss of generality we may assume that  $\delta < 1$ , and we define  $\tilde{K} = K + \frac{\delta}{2}\mathbb{B}$ . Using  $\tilde{K}$  we let Lemmas 2 and 3 generate the constants  $L_{\bar{h}}, L_{\bar{f}}, M_{\bar{h}}, \bar{L}, L_k, L > 0$  so that the bounds (24) and (26) hold for all  $\theta, \theta' \in \tilde{K} \cap C_{\delta}$  and all  $\tau_1, \hat{\tau}_1 \in \mathbb{R}_{\geq 0}$ . Using these constants, we define  $\varepsilon_i$  as in (35) for all  $i \in \{1, 2, 3, 4\}$ . Since  $\omega$  and  $\beta$  are continuous, and  $\beta(r, \cdot)$  converges to zero as the argument grows unbounded, there exists  $\varepsilon_5^* \in \left(0, \frac{\delta}{2(L_1 + L_2 + \bar{L})}\right)$  such that for all  $\theta \in \tilde{K}$  and  $\tilde{\theta} \in \tilde{K} + \varepsilon_5^*(L_1 + L_2 + \bar{L})\mathbb{B}$  satisfying  $|\theta - \tilde{\theta}| \leq \varepsilon_5^*(L_1 + L_2 + \bar{L})$  and all  $s \geq 0$ :

$$\omega(\theta) \le \omega(\tilde{\theta}) + \frac{\nu}{3}, \qquad \beta(\omega(\tilde{\theta}), s) \le \beta(\omega(\theta), s) + \frac{\nu}{3}. \tag{60}$$

Then, we let  $\varepsilon^* = \min_{k=1,\dots,5} \varepsilon_k$  and fix  $\varepsilon \in (0, \varepsilon^*)$ . As in the proof of Theorem 1, we define the restricted HDS:

$$(\theta, \tau) \in C|_{K} \begin{cases} \theta \in F_{\varepsilon}(\theta, \tau_{1}, \tau_{2}) \\ \dot{\tau}_{1} = \varepsilon^{-1} \\ \dot{\tau}_{2} = \varepsilon^{-2} \end{cases}$$
(61a)

$$(\theta, \tau) \in D|_{K} \begin{cases} \theta^{+} \in G(\theta) \cap K \\ \tau_{1}^{+} = \tau_{1} \\ \tau_{2}^{+} = \tau_{2} \end{cases}$$
(61b)

and we let  $(\theta, \tau)$  denote a solution to (61) starting in  $K_0$ . As in the proof of Theorem 1, using (37), we define for each  $(t, j) \in \text{dom}(\theta, \tau)$ :

$$\tilde{\theta} := \theta - \gamma_{\varepsilon}(\theta, \tau) - \lambda_{\varepsilon}(\theta - \gamma_{\varepsilon}(\theta, \tau), \tau_1),$$

which, as shown in the proof of Theorem 1, is a hybrid arc that is a solution to the inflated HDS (20), and therefore satisfies (59) for all  $(t, j) \in \text{dom }\tilde{\theta}$ . We can now use (60) to obtain:

$$\omega(\theta(t,j)) \le \omega(\tilde{\theta}(t,j)) + \frac{\nu}{3} \le \beta(\omega(\tilde{\theta}(0,0)), t+j) + \frac{2\nu}{3} \le \beta(\omega(\theta(0,0)), t+j) + \nu,$$
(62)

for all  $(t, j) \in \text{dom}(\theta)$ . Since  $\beta \in \mathcal{KL}$ ,  $\theta$  remains in the set

$$K_{\nu} = \left\{ \theta \in \mathcal{B}_{\mathcal{A}} : \, \omega(\theta) \leq \beta \left( \max_{\tilde{\theta} \in K_{0}} \omega(\tilde{\theta}), 0 \right) + \nu \right\},\$$

which is compact and satisfies  $K_v \subset K_1$  due to the fact that  $\nu < 1$ . We can now use the exact same argument of Step 4 in the proof of Theorem 1 to establish that the bound (62) also holds for every solution that starts in  $K_0$  of the original unrestricted HDS (11).

#### VI. APPLICATIONS TO HYBRID MODEL-FREE CONTROL AND OPTIMIZATION

We present different applications to illustrate the generality of the results of Section IV. In all our examples, we will consider a HDS of the form (11), where  $f_{\varepsilon}$  is allowed to switch between a finite number of vector fields, some of which might not necessarily have a stabilizing second-order average HDS. Specifically, the main state x of the system will evolve in an application-dependent closed set  $M \subset \mathbb{R}^{n_1}$  via dynamics

$$\dot{x} = f_{\varepsilon}(x, z, \tau_1, \tau_2) = \sum_{k=1}^{2} \varepsilon^{k-2} \phi_{z_1, k}(x, \tau_1, \tau_2),$$
(63)

where  $z_1$  is a logic mode allowed to switch between values in the set  $Q = \{1, ..., N\}$ , where  $N \in \mathbb{Z}_{\geq 2}$ . The switching behavior can be either *time-triggered* (using the automaton (6)) or *state-triggered* (using a hysteresis-based mechanism). In both cases, Zeno behavior will be precluded by design. Since for each  $z_1 \in Q$ , the functions  $\phi_{z_1,k}$  will be designed to satisfy Assumption 3, for each mode  $z_1 \in Q$  the 2nd-order average mapping can be directly computed using (16). In this case, we directly get:

$$\bar{f}_{z_1} = \frac{1}{T_1 T_2} \int_0^{T_1} \int_0^{T_2} \phi_{z_1,2} \, d\tau_2 \, d\tau_1 + \frac{1}{T_1 T_2} \int_0^{T_1} \int_0^{T_2} \frac{1}{2} \left[ \int_0^{\tau_2} \phi_{z_1,1} \, ds_2, \phi_{z_1,1} \right] \, d\tau_2 \, d\tau_1.$$
(64)

To guarantee that  $\bar{f}_{z_1}$  is well-defined, we will let the functions  $\phi_{z_1,k}$  depend on a vector of frequencies  $w = (w_1, w_2, \dots, w_r)$ , for some  $r \in \mathbb{Z}_+$ , which satisfies the following assumption, which is standard in vibrational control [8] and extremum seeking [6], [20], [31], [35], [36].

Assumption 4:  $w_i \in \mathbb{Q}_{>0}$  and  $w_i \neq w_j, \forall i \neq j \in \mathbb{N}$ .

#### A. Switching Model-Free Optimization and Stabilization

In the first two applications, the set of logic modes satisfies  $Q = Q_s \cup Q_u$ , where  $Q_s \cap Q_u = \emptyset$ , and  $Q_s$  indicates "stable" modes, and  $Q_u$  indicates "unstable" modes. The switching signal  $z_1 : \text{dom}(z_1) \to Q$  is generated by the hybrid automaton (6) studied in Section III, with state  $z = (z_1, z_2, z_3)$ , which induces the average dwell-time constraint (8a) and the average activation-time constraint (8b) on the switching, effectively ruling out Zeno behavior. Using the data  $(C_z, \mathcal{T}_F, D_z, \mathcal{T}_G)$  of system (6), the closed-loop switched system with highly oscillatory vector fields has the form of (11), with sets

$$C = M \times C_z, \quad D = M \times D_z, \tag{65}$$

flow map  $F_{\varepsilon} = \{f_{\varepsilon}\} \times \Phi$ , with  $f_{\varepsilon}$  given by (63),  $\Phi(z) = \mathcal{T}_F(z)$ , and jump map:

$$G(x,z) = \{x^+\} \times \mathcal{T}_G(z). \tag{66}$$

Fig. 3: Graphs defining the network topology in Example 1.

It follows that Assumption 2 is satisfied by construction, and the corresponding 2nd-order average HDS  $\mathcal{H}_2^{\text{ave}}$  can be directly obtained using (17):

$$(\bar{x}, \bar{z}) \in C, \ \left\{ \left( \begin{array}{c} \dot{\bar{x}} \\ \dot{\bar{z}} \end{array} \right) \in F(\bar{x}, \bar{z}),$$
(67a)

$$(\bar{x}, \bar{z}) \in D, \ \left\{ \left( \begin{array}{c} \bar{x}^+\\ \bar{z}^+ \end{array} \right) \in G(\bar{x}, \bar{z}),$$
(67b)

where  $F(\bar{x}, \bar{z}) = \{\bar{f}_{z_1}(\bar{x})\} \times \mathcal{T}_F(\bar{z})$ . We consider two different problems where this model is applicable:

1) Synchronization of Network Oscillators with Switching Control Directions and Network Topologies: Consider a collection of  $r \in \mathbb{Z}_{\geq 2}$  oscillators evolving on the *r*-torus  $M = \mathbb{S}^1 \times \cdots \times \mathbb{S}^1 = \mathbb{T}^r \subset \mathbb{R}^{2r}$ , which is an embedded (and compact) submanifold in the Euclidean space. Let  $x^i = (x_1^i, x_2^i) \in \mathbb{S}^1$  be the state of the *i*<sup>th</sup> oscillator, for  $i \in \{1, \ldots, r\}$ , and denote its input by  $u_i$ . Moreover, let  $\alpha := (\alpha_1, \ldots, \alpha_r) \in \mathcal{J}$ , where  $\mathcal{J} \subseteq \{+1, -1\}^r$ ,  $|\mathcal{J}| = N_1 \in \mathbb{N}$ , such that  $\alpha_i \in \{+1, -1\}$  for all *i*. The dynamics of the network can be written in vector form as:

$$\begin{pmatrix} \dot{x}^1\\ \vdots\\ \dot{x}^r \end{pmatrix} = \begin{pmatrix} (1+\alpha_1 u_1) S x^1\\ \vdots\\ (1+\alpha_r u_r) S x^r \end{pmatrix}, \quad S := \begin{pmatrix} 0 & 1\\ -1 & 0 \end{pmatrix}, \tag{68}$$

Let  $x = (x^1, \ldots, x^r) \in M$ , and note that M is invariant under the dynamics in (68). The connectivity between oscillators is dictated by the network topology which, at any given instant, is defined by a unique element from a collection of undirected graphs  $\{\mathcal{G}_1, \ldots, \mathcal{G}_{N_2}\}, \mathcal{G}_k = (\mathcal{V}, \mathcal{E}_k)$ , where  $\mathcal{V} = \{1, \ldots, r\}$  is the set of nodes representing the oscillators, and  $\mathcal{E}_k$  is the edge set representing the interconnections. To simplify our presentation, we make the following assumption.

Assumption 5: For each  $k \in \{1, 2, ..., N_2\}$  the graph  $\mathcal{G}_k$  is connected.

Our goal is to achieve decentralized synchronization of the oscillators under switching communication topologies and unknown control directions. To solve this model-free control problem, we consider the feedback law

$$u_{i} = u_{i,k}(x,\tau_{2}) = \varepsilon^{-1} \sqrt{2w_{i}} \cos\left(w_{i}\tau_{2} + J_{i,k}(x)\right),$$
(69)

where  $J_{i,k}(x) = \frac{1}{2} \sum_{j \in \mathcal{N}_k^i} |x^i - x^j|^2$ . In (69), the set  $\mathcal{N}_k^i = \{j \in \mathcal{V} : (i, j) \in \mathcal{E}_k\} \subset \mathcal{V}$  indicates the neighbors of the  $i^{\text{th}}$  agent according to the topology of the graph  $\mathcal{G}_k$ . We consider a model where both the network topology  $\mathcal{G}_k$  and the control directions  $\alpha$  are allowed to switch in (68) and (69). To capture this behavior, let  $\mathcal{Q} = \{1, \ldots, N_1N_2\}$ , and fix a choice of all possible bijections  $\varrho : \mathcal{Q} \ni z_1 \mapsto (k(z_1), \alpha(z_1)) \in \{1, \ldots, N_2\} \times \mathcal{J}$ . In this way, for each  $z_1 \in \mathcal{Q}$  there is a particular control direction  $\alpha(z_1)$  and graph  $\mathcal{G}_{k(z_1)}$  acting in (68) and (69). To study this system, we define the coordinates:

$$x_1^i = -\cos(\xi_i), \qquad \qquad x_2^i = \sin(\xi_i), \qquad \qquad \forall i \in \mathcal{V},$$

where  $\xi_i \in [0, 2\pi)$ , and  $\xi := (\xi_1, \dots, \xi_r)$ . In this way, we obtain the polar representation of (68):

$$\begin{pmatrix} \dot{\xi}_1 \\ \vdots \\ \dot{\xi}_r \end{pmatrix} = \begin{pmatrix} 1 + \alpha_1 u_{1,k}(\xi, \tau_2) \\ \vdots \\ 1 + \alpha_r u_{r,k}(\xi, \tau_2) \end{pmatrix},$$
(70)

where the feedback law  $u_{i,k}$  becomes:

$$u_{i,k}(\xi,\tau_2) = \varepsilon^{-1} \sqrt{2w_i} \cos(w_i \tau_2 + J_{i,k}(\xi)),$$
(71)

with distance function  $J_{i,k}(\xi) = \sum_{j \in \mathcal{N}_k^i} (1 - \cos(\xi_i - \xi_j))$ . The averaged vector field can be obtained using (64):

$$\dot{\bar{\xi}} = \mathbb{1} - \nabla V_{z_1}(\bar{\xi}),\tag{72}$$

Fig. 4: Simulation results of the first case in Example 1 for  $\varepsilon = 1/\sqrt{60\pi}$  and a randomly generated initial condition.

where  $1 = (1, 1, ..., 1), V_{z_1}(\bar{\xi}) = \sum_{i=1}^r J_{i,k(z_1)}(\bar{\xi})$ , and  $\nabla V_{z_1}$  is given by

$$\nabla V_{z_1}(\bar{\xi}) = \begin{pmatrix} \sum_{j \in \mathcal{N}_{k(z_1)}^1} \sin(\bar{\xi}_1 - \bar{\xi}_j) \\ \vdots \\ \sum_{j \in \mathcal{N}_{k(z_1)}^r} \sin(\bar{\xi}_r - \bar{\xi}_j) \end{pmatrix},$$

which is the well-known Kuramoto model over the graph  $\mathcal{G}_{k(z_1)}$  [22], [23]. In particular, the subset S that characterizes synchronization has the simple polar coordinate representation  $S = \{(\xi_1, \ldots, \xi_r) \in [0, 2\pi)^r : \xi_1 = \cdots = \xi_r\}$ . Now observe that the vector field in (68) under the feedback law (69), or equivalently the vector field in (70) under the feedback law (71), has the same structure as the vector fields  $f_{\varepsilon}$  in (63) with trivial dependence on the intermediate timescale  $\tau_1 = \varepsilon^{-1}t$ . Moreover, using (6) with  $Q_u = \emptyset$  to generate the  $z_1$ , the closed-loop system has the form (11) with  $C = M \times C_z$  and  $D = M \times D_z$ given by (65), and jump map G given by (66). For this system, we study the stability properties of the set  $\mathcal{A} = S \times C_z$  using two tunable parameters (c.f. Remark 4).

Proposition 1: Under Assumptions 4-5, the HDS (11) renders the set  $\mathcal{A}$  SGPAS as  $(\varepsilon, \eta_1) \to 0^+$  with some basin of attraction  $\mathcal{B}_{\mathcal{A}}$ , and every maximal solution is complete.

Proof: Since  $Q_u = \emptyset$ ,  $\eta_2 > 0$  and  $T_o \ge 0$  can be arbitrary. For a fixed  $z_1 \in Q$ , the averaged vector field (72) is simply the Kuramoto model over the graph  $\mathcal{G}_{k(z_1)}$ . Assumption 5 guarantees that the subset S is UAS for the averaged vector field (5) for each fixed  $z_1 \in Q$ . Equivalently, the compact set  $\mathcal{A}$  is UAS for the hybrid system (6a) when  $\eta_1 = 0$  with respect to some basin of attraction  $\mathcal{B}_{\mathcal{A}}$ . Hence, since system (6a) satisfies Assumption 1, and  $\mathcal{A}$  is compact, by [11, Thm. 7.12 and Lemma 7.20] we have that when  $\eta_1 > 0$  the set  $\mathcal{A}$  is SGPAS as  $\eta_1 \to 0^+$  with respect to  $\mathcal{B}_{\mathcal{A}}$ . Therefore, by Theorem 2, we conclude that  $\mathcal{A}$  is also SGPAS as  $(\varepsilon, \eta_1) \to 0^+$  for the original HDS (11) with respect to  $\mathcal{B}_{\mathcal{A}}$ .

*Example 1:* We first consider the scenario where the topology is static and the control directions are switching. Let r = 2, i.e. two oscillators, which implies  $N_2 = 1$ . We let  $N_1 = 4$ ,  $\mathcal{A} = \{(+1, +1), (-1, +1), (+1, -1), (-1, -1)\}$ , and we consider the bijection  $\rho$  that satisfies  $\rho(1) = (1, (+1, +1)), \rho(2) = (1, (-1, +1)), \rho(3) = (1, (+1, -1)), \rho(4) = (1, (-1, -1))$ . Numerical simulation results, shown in Fig. 4, show that (local) practical synchronization is achieved. Next, we allow the topology to also switch in time. We let r = 4,  $N_1 = 4$ ,  $N_2 = 3$ , the set  $\mathcal{A} = \{(+1, +1, -1, +1), (-1, +1, +1, +1), (-1, +1, -1, -1), (-1, -1, -1), (-1, -1, +1), (-1, +1, +1), (-1, +1, +1), (-1, +1, -1, -1), (-1, -1, +1), (-1, +1, +1), (-1, +1, +1), (-1, +1, +1), (-1, +1, +1), (-1, +1, +1), (-1, +1, +1), (-1, +1, +1), (-1, +1, +1), (-1, +1, +1)$ 

(-1, -1, +1, +1)}, and the collection of graphs  $\{\mathcal{G}_1, \mathcal{G}_2, \mathcal{G}_3\}$  shown in Fig. 3. The numerical simulation results are shown in Fig. 5, and demonstrate that (local) practical synchronization is achieved despite simultaneous switches happening in the network topology and the control directions.

2) Lie-Bracket Extremum Seeking under Intermitence and Spoofing: Consider the following control-affine system

$$\dot{x} = \sum_{i=1}^{r} b_i(x, \tau_1) u_{i, z_1}(x, \tau_2), \quad r \in \mathbb{Z}_{\ge 1},$$
(73)

where the goal is to steer the state  $x \in \mathbb{R}^n$  towards the set of solutions of the optimization problem

min 
$$J(x)$$
, subject to  $x \in M$ , (74)

where  $M \subset \mathbb{R}^n$ , and J is a continuously differentiable cost function whose mathematical form is unknown, but which is available via measurements, which is a classic extremum seeking problem [6], [19], [35]. However, unlike traditional settings, we are interested in attaining convergence to the solutions of (74) even when the control algorithm has sporadic failures to access the measurements of J, and sporadic cost measurements collected under *malicious external spoofing* purposely designed to destabilize the system. Such types of problems can emerge in source-seeking missions operating in adversarial environments,

Fig. 5: Simulation results of the second case in Example 1 for  $\varepsilon = 1/\sqrt{60\pi}$  and a randomly generated initial condition.

such as the one described in the motivational example of Section III, see also [32], [33]. To study this scenario, we consider the following mode-dependent Lie-bracket-based control law

$$u_{i,z_1}(x,\tau_2) = \varepsilon^{-1} \sqrt{2w_i} \cos\left(w_i \tau_2 + (z_1 - 2) J(x)\right),$$
(75)

with  $z_1 \in Q = \{1, 2, 3\}$ . Note that vector field (4) considered in Section III is a particular case of the resulting system (73). Using (64), we obtain:

$$\bar{f}_{z_1}(\bar{x}) = (2 - z_1)P(\bar{x})\nabla J(\bar{x}),$$
(76)

where the matrix-valued mapping P is given by:

$$P(\bar{x}) = \frac{1}{T_1} \sum_{i=1}^r \int_0^{T_1} b_i(\bar{x}, \tau_1) \otimes b_i(\bar{x}, \tau_1) \, d\tau_1.$$

We make the following regularity assumptions on J and P:

Assumption 6: The following holds:

- 1) There exists  $\lambda_P > 0$  and  $M_P > 0$  such that  $|P(x)x| \leq M_P |x|, x^{\mathsf{T}} P(x)x \geq \lambda_P |x|^2, \forall x \in \mathbb{R}^n$ .
- 2) The cost function J is  $C^1$ , strongly convex with parameter  $\mu > 0$  and minimizer  $x^*$ , and there exist  $L_J > 0$  such that  $|\nabla J(x) \nabla J(x')| \le L_J |x x'|$ , for all  $x, x' \in \mathbb{R}^n$ .

*Remark 5:* Item (1) in Assumption 6 can be seen as a cooperative persistence of excitation condition on the vector fields  $b_i$ , see [18], [37] for similar conditions in adaptive systems. On the other hand, item (2) is common in ES.

The following result formalizes the discussions of Section III, and establishes a resilience result for the stability properties of Lie-bracket based ES algorithms with respect to intermittent measurements and spoofing when  $M = \mathbb{R}^n$ .

Proposition 2: Under Assumptions 4 and 6, for  $\eta_1 > 0$  there exist  $\eta_2 > 0$  such that for all  $\eta_2 \in (0, \eta_2^*)$  the HDS (11) renders the set  $\mathcal{A} = \{x^*\} \times C_z$  SGPAS as  $\varepsilon \to 0^+$ , and every maximal solution is complete.

*Proof:* We show that the average HDS (67) renders UGAS the set A such that Theorem 2 can be directly used. Indeed, consider the Lyapunov function  $V(\bar{x}) = J(\bar{x}) - J(x^*)$ , and note that for each  $z_1 \in Q$ , we have

$$\nabla V(\bar{x})^{\mathsf{T}} \bar{f}_{z_1}(\bar{x}) = (2 - z_1) \nabla J(\bar{x})^{\mathsf{T}} P(\bar{x}) \nabla J(\bar{x}).$$

Using strong convexity and globally Lipschitz of  $\nabla J$ :

For 
$$z_1 = 1$$
:  $\nabla V(\bar{x})^{\intercal} \bar{f}_1(\bar{x}) \leq \frac{2M_P L_J}{\mu} V(\bar{x})$   
For  $z_1 = 2$ :  $\nabla V(\bar{x})^{\intercal} \bar{f}_2(\bar{x}) \leq \frac{2M_P L_J}{\mu} V(\bar{x})$   
For  $z_1 = 3$ :  $\nabla V(\bar{x})^{\intercal} \bar{f}_3(\bar{x}) \leq -2\lambda_P \mu V(\bar{x})$ .

By [6, Proposition 3], we obtain that for  $\eta_1 > 0$  and for  $\eta_2^* > 0$  sufficiently small, the set  $\mathcal{A} = \{x^*\} \times C_z$  is UGAS for the average HDS (67). Hence, by Theorem 2,  $\mathcal{A}$  is SGPAS as  $\varepsilon \to 0^+$  for the original system (11).

## B. Switched Global Extremum Seeking on Smooth Compact Manifolds

In this section, we make full use of the tools for hybrid dynamical systems presented in this paper to solve global extremum seeking problems of the form (74) on sets M that describe a class of smooth, boundaryless, compact manifolds. This application illustrates the use of Corollary 1. As thoroughly discussed in the literature [25], [38]–[40], for such problems, no smooth algorithm with global stability bounds of the form (19) can be employed as the average system. Here, we remove this obstruction by adaptively switching between multiple ES controllers.

- (a) The set M is a smooth embedded connected compact submanifold without boundary endowed with a Riemannian structure by the metric  $\langle \cdot, \cdot \rangle_M : T_x M \times T_x M \to \mathbb{R}$  induced by the metric  $\langle \cdot, \cdot \rangle : \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}$  of the ambient Euclidean space  $\mathbb{R}^n$ .
- (b) The function J is smooth on an open set  $U \subset \mathbb{R}^n$  containing M, has a unique minimizer  $x^* \in M$  satisfying  $J(x^*) < J(x)$ ,  $\forall x \in M$  such that  $x \neq x^*$ , and there exists a known number  $\overline{J} \in (0, \infty)$  such that  $\nabla_M J(x) = 0 \iff x = x^*, \forall x \in \mathcal{L}_{\overline{J}}$ , where  $\mathcal{L}_{\bar{J}} = \{x \in M : J(x) < J(x^*) + \bar{J}\}$ , and where  $\nabla_M J$  is the orthonormal projection, defined by the metric  $\langle \cdot, \cdot \rangle$ , of  $\nabla J$  onto the tangent space  $T_x M$ ,  $\forall x \in M$ .

While Assumption 7 suffices to guarantee the local, or at best, almost-global practical asymptotic stability of the minimizer  $x^*$ for a smooth Lie Bracket-based extremum seeking controller on M [22], [23], such controllers will always generate smooth average systems having more than one critical point in M [39]. To remove this obstruction to global extremum seeking, we consider a hybrid ES algorithm that will implement state-triggered switching between certain functions introduced in the following definition:

Definition 8: Let  $N \in \mathbb{N}_{\geq 1}$ , and  $\mathcal{Q} = \{1, \dots, N\}$ . A family of functions  $\{\tilde{J}_q\}_{q \in \mathcal{Q}}$  is said to be a  $\delta$ -gap synergistic family of functions subordinate to J on M if:

- 1)  $\forall q \in \mathcal{Q}, \tilde{J}_q : U \to \mathbb{R}$  is smooth, its unique minimizer on M is  $x^*$ , and has a finite number of critical points in M, i.e.
- $\begin{aligned} &|\operatorname{Crit} \ \tilde{J}_q| \in \mathbb{N}_{\geq 1}, \text{ where } \operatorname{Crit} \ \tilde{J}_q := \{x \in M : \nabla_M \tilde{J}_q(x) = 0\}. \\ &2) \ \forall q \in \mathcal{Q}, \ J(x) < \bar{J} + J(x^*) \implies \tilde{J}_q(x) = J(x), \text{ i.e. the family } \{\tilde{J}_q\} \text{ agrees with } J \text{ on the neighborhood } \mathcal{L}_{\bar{J}} \text{ of the } \end{aligned}$ minimizer  $x^*$ ,
- 3)  $\exists \delta \in (0,\infty)$  such that

$$\delta < \Delta^* := \min_{\substack{q_1 \in \mathcal{Q} \\ x \in \operatorname{Crit} \tilde{J}_{q_1} \setminus \{x^*\}}} \max_{q_2 \in \mathcal{Q}} (\tilde{J}_{q_1}(x) - \tilde{J}_{q_2}(x)). \quad \Box$$

The constructions in Definition (8) involve families of diffeomorphisms that "warp the manifold M in sufficiently many ways so as to distinguish the minimizer  $x^*$  from other critical points of the function J". The reader is referred to [41] and [25] for the full details (and examples) of these constructions, which are leveraged in [25] for the design of *first-order* averagingbased algorithms. We emphasize that constructing these diffeomorphisms does not necessarily require exact knowledge of the mathematical form of J (although knowledge of M is required), but only a qualitative description of the costs that allows us to identify the threshold J. Such knowledge is reasonable for most practical applications where the optimal value  $J(x^*)$  is known to lie within a certain bounded region. However, our objective is to attain extremum seeking from any initial condition, ensuring that extremum seeking is accomplished regardless of where the algorithm's trajectories are initialized or land after a sudden disturbance. To design hybrid Lie-bracket-based algorithms that achieve this objective, we will rely on the following assumption:

Assumption 8: The following holds for problem (74):

(a) There exists a family of smooth vector fields  $\{b_1, \ldots, b_r\}$  on M, for which the operator  $P: M \times \mathbb{R}^n \ni (x, v) \mapsto P(x)[v] \in \mathbb{R}^n$  $T_x M$  defined by

$$P(x)[v] = \sum_{i=1}^{r} \langle b_i(x), v \rangle \, b_i(x),$$

is such that  $P(x)[v] = 0 \iff v \in (T_x M)^{\perp}$ .

(b) There exists a  $\delta$ -gap synergistic family of functions  $\{\tilde{J}_q\}_{q\in\mathcal{Q}}$  subordinate to J on M, which are available for measurement.

Using the HDS (11), we consider functions  $f_{\varepsilon}$  given by

$$f_{\varepsilon}(x, z, \tau_2) = \sum_{i=1}^r \varepsilon^{-1} \sqrt{2w_i} b_i(x) \cos\left(\tilde{J}_z(x) + \omega_i \tau_2\right),$$

where  $z \in Q$  is a logic state, the sets C and D are:

$$C := \left\{ (x, z) \in M \times \mathcal{Q} : \tilde{J}_z(x) - \min_{\tilde{z} \in \mathcal{Q}} \tilde{J}_{\tilde{z}}(x) \le \delta \right\}$$
$$D := \left\{ (x, z) \in M \times \mathcal{Q} : \tilde{J}_z(x) - \min_{\tilde{z} \in \mathcal{Q}} \tilde{J}_{\tilde{z}}(x) \ge \delta \right\}$$

and the flow map in (12) uses  $\Phi(z) = \{0\}$ . Finally, the jump map in (11b) is defined as

$$G(x,z) = \{x\} \times \{z \in \mathcal{Q} : \ \tilde{J}_z(x) = \min_{\tilde{z} \in \mathcal{Q}} \tilde{J}_{\tilde{z}}(x)\},\$$

In this case, we still use equation (64) with  $z = z_1$  to obtain:

$$\bar{f}_z(\bar{x}) = -P(\bar{x})[\nabla \tilde{J}_z(\bar{x})]. \tag{78}$$

Fig. 6: Simulation results for Example 2 with  $\varepsilon = 1/\sqrt{10\pi}$ .

The following holds for the resulting HDS (11).

Proposition 3: Under Assumptions 4, 7, and 8, the set  $\mathcal{A} = \{x^*\} \times \mathcal{Q}$  is GPAS as  $\varepsilon \to 0^+$  for the HDS (11), and every maximal solution is complete.

Proof: Since the set M is compact, it suffices to show that the second-order average system  $\mathcal{H}_2^{\text{ave}}$  renders UGAS the set  $\mathcal{A}$ . To do this, we consider the Lyapunov function  $V(z) = \tilde{J}_z(x) - J(x^*)$ , which during flows satisfies

$$\dot{V} = -\sum_{i=1}^{r} \left\langle b_i(\bar{x}), \nabla \tilde{J}_{\bar{z}}(\bar{x}) \right\rangle^2 \le 0, \quad \forall \ (\bar{x}, \bar{z}) \in C.$$

$$\tag{79}$$

If  $\dot{V} = 0$  for some  $(\bar{x}, \bar{z}) \in C$ , then one of the following three situations may happen:

- 1)  $\nabla \tilde{J}_{\bar{z}}(\bar{x}) \neq 0$ , but  $P(\bar{x})[\nabla \tilde{J}_{\bar{z}}(\bar{x})] = 0$ , which implies that  $\nabla \tilde{J}_{\bar{z}}(\bar{x}) \in (T_{\bar{x}}M)^{\perp}$  due to item (a) in Assumption 8. Consequently, we must have  $\nabla_M \tilde{J}_{\bar{z}}(\bar{x}) = 0$ ; or
- 2)  $\nabla \tilde{J}_{\bar{z}}(\bar{x}) = 0$ , which again implies that  $\nabla_M \tilde{J}_z(\bar{x}) = 0$ ; or
- 3)  $\nabla \tilde{J}_{\bar{z}}(\bar{x}) \neq 0$  and  $P(\bar{x})[\nabla \tilde{J}_{\bar{z}}(\bar{x})] \neq 0$ , but  $\langle \nabla \tilde{J}_{z}(\bar{x}), P(\bar{x})[\nabla \tilde{J}_{\bar{z}}(\bar{x})] \rangle = 0$ . In that case, we can decompose  $\nabla \tilde{J}_{\bar{z}}(\bar{x}) = \nabla_{M} \tilde{J}_{\bar{z}}(\bar{x}) + \nabla_{M}^{\perp} \tilde{J}_{\bar{z}}(\bar{x})$  where  $\nabla_{M}^{\perp} \tilde{J}_{\bar{z}}(\bar{x}) \in (T_{x}M)^{\perp}$ , and therefore  $P(\bar{x})[\nabla \tilde{J}_{\bar{z}}(\bar{x})] = P(\bar{x})[\nabla_{M} \tilde{J}_{\bar{z}}(\bar{x})]$ , and  $\langle \nabla_{M} \tilde{J}_{z}(\bar{x}), P(\bar{x})[\nabla_{M} \tilde{J}_{\bar{z}}(\bar{x})] \rangle = 0$ . However, by definition of P, we have  $\sum_{i=1}^{r} \langle b_{i}(\bar{x}), \nabla_{M} \tilde{J}_{\bar{z}}(\bar{x}) \rangle^{2} = 0 \implies P(\bar{x})[\nabla_{M} \tilde{J}_{\bar{z}}(\bar{x})] = 0$ , which contradicts the assumption that  $P(\bar{x})[\nabla \tilde{J}_{\bar{z}}(\bar{x})] = P(\bar{x})[\nabla_{M} \tilde{J}_{\bar{z}}(\bar{x})] \neq 0$ . Hence, this case cannot happen.

Therefore,  $\dot{V} = 0$  for some  $(\bar{x}, \bar{z}) \in C$  implies that  $\nabla_M \tilde{J}_{\bar{z}}(\bar{x}) = 0$ . Due to item (b) in Assumption 8 and item (b) in Assumption 7, and since flows are allowed only in the set C which contains no critical points other than in  $\mathcal{A}$ , it follows that  $\dot{V} = 0$  if and only if  $(\bar{x}, \bar{z}) \in \mathcal{A}$ . Next, observe that immediately after jumps we have for all  $(\bar{x}, \bar{z}) \in D$ :

$$\Delta V = V(\bar{x}^+, \bar{z}^+) - V(\bar{x}, \bar{z}) = \tilde{J}_{\bar{z}^+}(\bar{x}) - \tilde{J}_{\bar{z}}(\bar{x}) \le -\delta < 0$$

since, by definition of the jump map we have  $\bar{z}^+ \in \{z \in Q : \tilde{J}_z(\bar{x}) = \min_{\bar{z} \in Q} \tilde{J}_{\bar{z}}(\bar{x})\}$  and, using the structure of D,

$$(\bar{x}, \bar{z}) \in D \implies \tilde{J}_{\bar{z}}(\bar{x}) - \min_{\bar{z} \in \mathcal{Q}} \tilde{J}_{\bar{z}}(\bar{x}) \ge \delta > 0.$$

By [42, Theorem 3.19], A is UGAS for the HDS (17). By Corollary 1, A is GPAS as  $\varepsilon \to 0^+$  for the HDS (11).

*Example 2:* Let  $M = \mathbb{S}^2 = \{x \in \mathbb{R}^3 : |x|^2 = 1\}$ ,  $J(x) = 1 - \langle x, e_3 \rangle$ , and define the vector fields  $b_i$  for  $i \in \{1, 2, 3\}$  by  $b_i(x) = e_i \times x$ , where  $e_i$  is the unit vector in  $\mathbb{R}^3$  with zero elements except the *i*<sup>th</sup>-element which is set to 1. Let  $\mathcal{Q} = \{1, 2\}$ , and define the family of functions  $\{\tilde{J}_1, \tilde{J}_2\}$  by  $\tilde{J}_q(x) = J(\Phi_q(x))$ , where the maps  $\Phi_q$  are defined by

$$\Phi_q(x) := \begin{cases} x, & J(x) < 1\\ \exp_{\mathbb{R}^3} \left( \frac{k_q}{2} (J(x) - 1)^2 \hat{e}_2 \right) x, & J(x) \ge 1 \end{cases}$$

the constants  $k_1 = +\frac{1}{2}$ ,  $k_2 = -\frac{1}{2}$ ,  $\exp_{\mathbb{R}^3} : \mathbb{R}^{3\times3} \to GL(3,\mathbb{R})$  is the matrix exponential where  $GL(3,\mathbb{R})$  is the group of real invertible  $3 \times 3$ -matrices, and  $\hat{e}_2$  is the skew-symmetric matrix associated with the unit vector  $e_2$ . It can be verified, see [25], that the family  $\{\tilde{J}_1, \tilde{J}_2\}$  is a  $\delta$ -gap synergistic family of functions subordinate to J on  $\mathbb{S}^2$  for any  $\delta \in (0, \frac{1}{4})$ . We use  $w_1 = 3$ ,  $w_2 = 2$ ,  $w_3 = 1$ , which completely defines the vector field  $f_{\varepsilon}$  on  $\mathbb{S}^2$ . Numerical simulation results are shown in Fig. 6 and Fig. 7. It can be observed that the trajectories converge to a neighborhood of the minimizer  $x^* = e_3$ .

Fig. 7: Trajectory on  $\mathbb{S}^2$  for Example 2 with two values of  $\varepsilon$ .

# **VII.** CONCLUSIONS

A second-order averaging result has been introduced for a class of hybrid dynamical systems that combine differential inclusions and difference inclusions. Under regularity conditions on the data of the hybrid system, this result establishes a suitable property of closeness of solution between the original dynamics and the average dynamics. This property is then leveraged to achieve semi-global practical asymptotic stability for the original dynamics whenever the average hybrid system possesses an asymptotically stable compact set. The results are illustrated through the analysis and design of various hybrid and highly-oscillatory algorithms for model-free control and optimization problems. Future research directions will focus on incorporating stochastic phenomena in the jumps via averaging tools for stochastic hybrid systems [43].
