Atilla Aras

## **Proofs for the New Definitions in Financial Markets**

## **Abstract**

Constructing theorems can help to determine the shape of certain utility curves that make up the new definitions in financial markets. The aim of this study was to present proofs for these theorems. Basic thoughts of new alternative definitions emerge from the decision-making under uncertainty in economics and finance. Shape of the certain utility curve is central to standard definitions in determining risk attitudes of investors. Shape alone determines risk behavior of investors in standard theory. Although the terms "risk-averse," "risk-loving," and "risk-neutral" are equivalent to "strict concavity," "strict convexity," and "linearity," respectively, in standard theory, strict concavity or strict convexity, or linearity are valid for certain new definitions, not being the same as standard theory. Hence, it can be stated that new alternative definitions are broader than standard definitions from the viewpoint of shape. For instance, the certain utility curve of a risk-averse investor can be strictly concave or strictly convex, or linear in alternative definitions.

*Keywords*: certain utility curve, risk-averse, risk-loving, risk-neutral *JEL classification*: D11, D15, G11

#### **Proofs for the New Definitions in Financial Markets**

#### **1. Background**

Aras (2022, 2023) has recently formulated new definitions to determine the risk attitudes of investors in financial markets. Aras (2023) has provided empirical evidence to support the validity of these definitions and divided them in two groups. The new definitions differ from those in the standard theory on the assumptions concerning the certain utility curves of the investors. The aim of this study is to determine the shape of the certain utility curves of investors for the new definitions. The theorems detailed herein were constructed to achieve this aim.

Certain utility curves describing investors are strictly concave, strictly convex, or linear, for the risk-averse, risk-loving, and risk-neutral investors, respectively, in standard theory. Now, we can know that some new definitions in Aras's work may satisfy strict concavity or strict convexity, or linearity, but not in the same way as standard theory. For instance, the shape of the certain utility curve of a risk-averse investor can be strictly concave or strictly convex, or linear in the new definitions. Although the shape of the certain utility curve of investors is a must in standard theory, some new definitions by Aras (2022, 2023) satisfy the aforementioned shapes one by one. Hence it can be concluded that new alternative definitions have broader content than standard definitions when shape of the certain utility curve is taken into account.

The motivation of the study is that all risk attitudes of investors in financial markets (i.e., not enough risk-aversity) cannot be included to the existing theorems in most cases by standard theory. For instance, some risk attitudes of investors cannot be determined in the problem of equity premium puzzle by using standard theory. Hence, constructing the shapes of the certain utility curves in the new definitions is a first step to determine all risk attitudes of investors in financial markets for most problems in finance theory.

PROOFS 4

## **2. Literature Review**

New definitions of Aras (2022, 2023) are based on decision-making under risk. Decision-making under risk depends on the shape of certain utility curve in standard theory.

There is a vast amount of literature about decision-making under risk. Many scientists have been working on this topic and new theories are still being formulated. The Expected Utility Theory (EUT) is the oldest of these. It was first proposed by Bernoulli (1738) to address the problem of how much a rational person pays when gambling. The answer is the expected monetary value of the gamble. Bernoulli gave a counterexample, known as the St. Petersburg paradox. It is as follows: although the expected payoff of a lottery approaches infinity, the lottery itself is worth a very small amount to the game's players.

Von Neumann and Morgenstern (1944) addressed the same problem and developed the EUT theory. The theory depends on preferences and axioms. Savage (1954) proposed another theory, the Subjective Expected Utility Theory (SEUT), about decision-making under risk. It builds on the basic ideas of Ramsey (1931), de Finetti (1937), and von Neumann and Morgenstern (1944). The main difference between the EUT and SEUT is how the theories treat probability. In the EUT, probability is based on objective information, whereas in the SEUT, it is perceived subjectively by decision-makers.

Economists have tried to separate the decision-making under risk theories into different categories (Suhonen, 2007). The separation of normative and descriptive theories is one of these. Normative theories are interested in how people should behave in risky environments. Descriptive theories, by contrast, are focused on how people make decisions in real environments. The Weighted Utility Theory (Chew & MacCrimmon, 1979) and Generalized Expected Utility Theory (Machina, 1982) are examples of the descriptive theory. Starmer (2000) explains the common features of these theories as follows:

1. Preferences are defined over prospects.

- 2. Their functions satisfy continuity and ordering.
- 3. The principle of monotonicity is followed.

Regret theory is another example of a descriptive theory. It was proposed simultaneously by Bell (1982), Fishburn (1982), and Loomes and Sugden (1982, 1987). The theory states that the fear of regret may preclude people from taking action, or it may lead a person take action. Investors in financial markets are affected so that they become unnecessarily risk-adverse or risk-loving.

Kahneman and Tversky (1992, 2013) formulated the Prospect Theory, which is another example of descriptive theory. Their approach to decision-making under risk was to refer to traditional behavioral sciences. Their experimental findings (1981, 1986) were the backbones for their theory. They posited that people value losses and gains differently and make decisions based on perceived gains, rather than perceived losses.

Hey and Orme (1994), Harless and Camerer (1994), and Loomes and Sugden (1995) developed the models in the Theory of Stochastic Preference. This is another alternative descriptive theory. Models of this theory have common features; for instance, they share deterministic core theories of preference.

EUT has been heavily criticized by scientists since the early 1950s. Scientists criticize it because decision-makers systematically violate the rationality axioms. Allais' paradox (1953) is one criticism of the EUT. Other problems and paradoxes against EUT are preference reversal, as explained by Lichtentestein and Slovic (1971); Ellsberg's paradox, by Ellsberg (1961); and other experiments that indicate that decision-makers violate rationality axioms.

Many alternative models to EUT have been developed since the mid to late twentieth century, and many scientists expect this to continue. Because none of the alternative theories presented to date have been able to express all paradoxes and to overcome the aforementioned problems, the EUT cannot be rejected and replaced. At the same time, it would be illogical to reject all alternative theories. Hence, scientists propose that there should be one core theory (i.e., EUT) with alternative theories (Suhonen, 2007).

## **3. Materials & Methods**

## **3.1 Definitions**

Aras (2022, 2023) has provided some definitions concerning the financial markets. These differ on the assumption of the certain utility curve of the investors. While he (2022) assumed a concave curve for all types of investors (i.e., apart from a not enough risk-averse investor), he also assumed concavity and convexity for risk-averse and risk-loving investors for the certain utility curve of the investors, respectively in his next article. His definitions in that paper were as shown below (2023):

*A risk-averse investor* allocates negative utility to uncertain wealth value at time *t*, owing to the insufficient model used and future uncertainties. Consequently, the following inequality holds true:

$$
u(w_t) > \beta \eta_t E_t[u(w_{t+1})]
$$
\n(1)

By contrast, *a not enough risk-loving investor* allocates positive utility to uncertain wealth value at time *t*, owing to the insufficient model used and future uncertainties. However, the following inequality holds true, assuming the certain utility curve is a continuously differentiable concave curve: (p. 8)

$$
u(w_t) > \beta \eta_t E_t[u(w_{t+1})]
$$
\n(2)

In addition, Aras (2023) states the following:

*a risk-loving investor* allocates positive utility to uncertain wealth value at time *t*, owing to the insufficient model used and future uncertainties. Consequently, the following inequality holds true:

$$
u(w_t) < \beta \eta_t E_t \left[ u(w_{t+1}) \right] \tag{3}
$$

Moreover, *a not enough risk-averse investor* allocates negative utility to uncertain wealth value at time *t*, because of the insufficient model used and future uncertainties. However, the following inequality holds true when the certain utility curve is an increasingly continuously differentiable convex curve: (pp. 8-9)

$$
u(w_t) < \beta \eta_t E_t[u(w_{t+1})] \tag{4}
$$

Finally, Aras (2023) indicates the following:

*a risk-neutral investor* allocates negative or positive utility to uncertain wealth value at time *t*, owing to the insufficient model used and future uncertainties. Consequently, the following inequality holds true when the certain utility curve is a continuously differentiable concave, convex, or linear curve: (p. 9)

$$
u(w_t) = \beta \eta_t E_t[u(w_{t+1})]
$$
\n(5)

In these equations,  $u, t, u(w_t), E_t[u(w_{t+1})], \beta$  and  $\eta_t$  denote a continuously differentiable utility curve, the time the investor compares the utilities of certain and uncertain wealth values, the certain utility of a wealth value at time  $t$ , the predicted uncertain utility gained from future wealth value  $(w_{t+1})$  with the information set available at time *t*, the subjective time discount factor, and *the sufficiency factor of the model at time t*, respectively.

 $\eta_t$  is a coefficient that is selected for the utility curve of the uncertain value, that is,  $E_t[u(w_{t+1})]$ . According to Aras (2022), it can be calculated as follows:

 $\eta_t E_t[u(w_{t+1})] = E_t[u(w_{t+1})] +$  negative utility allocated by the investor at time *t*, owing to the insufficient model used and future uncertainties,  $\eta_t E_t[u(w_{t+1})] = E_t[u(w_{t+1})] +$  positive utility allocated by the investor at time *t*,

because of the insufficient model used and future uncertainties, and

 $\eta_t E_t[u(w_{t+1})] = E_t[u(w_{t+1})] +$  zero utility allocated by the investor at time *t*, because of insufficient model and future uncertainties. (p. 616)

## **3.2 Theorems**

The first three theorems are standard in theory. However, I constructed the last five theorems (Theorems 4, 5, 6, 7, and 8) and two propositions.

**Theorem 1.** Suppose that  $u(w)$  is an increasing curve.

The agent is risk-averse in standard form  $\Leftrightarrow u(w)$  is strictly concave.

**Theorem 2.** Suppose that  $u(w)$  is an increasing curve.

The agent is risk-loving in standard form  $\Leftrightarrow u(w)$  is strictly convex.

**Theorem 3.** Suppose that  $u(w)$  is an increasing curve.

The agent is risk-neutral in standard form  $\Leftrightarrow u(w)$  is linear.

**Proposition 1.** Suppose that  $u(w)$  is an increasing strict convex utility curve for the agent on a given interval and variable  $w_{t+1}$  denotes the wealth at current time. Let  $w_{t+2}$  -  $w_{t+1}$  be less than ∞. Inequality  $Eu(w_{t+2}) > u(w_{t+1})$  holds true for the agent.

*Proof.* Let  $u(w)$  be an increasing strict convex utility curve for the agent. Because the utility curve is an increasing strict convex curve, inequalities  $w_{t+2} > w_{t+1}$  and  $u(w_{t+2}) < Eu(w_{t+2})$ hold true. Hence, we possess  $u(w_{t+2}) - u(w_{t+1})/\infty < u(w_{t+2}) - u(w_{t+1})/w_{t+2} - w_{t+1} <$  $Eu(w_{t+2}) - u(w_{t+1})/w_{t+2} - w_{t+1}$ . Thus,  $Eu(w_{t+2}) - u(w_{t+1})/w_{t+2} - w_{t+1} > 0$ . Because  $w_{t+2} - w_{t+1} > 0$ ,  $Eu(w_{t+2}) - u(w_{t+1}) > 0$ . Therefore,  $Eu(w_{t+2}) > u(w_{t+1})$  holds true for the agent.

**Proposition 2.** Suppose that  $u(w)$  is an increasing strict concave utility curve for the agent on a given interval and variable  $w_{t+1}$  denotes the wealth at current time. Let  $w_{t+2}$  -  $w_{t+1}$  be less than  $\infty$ . Inequalities  $Eu(w_{t+2}) > u(w_{t+1})$ ,  $Eu(w_{t+2}) < u(w_{t+1})$ , or  $Eu(w_{t+2}) = u(w_{t+1})$  hold true for the agent.

*Proof.* Let  $u(w)$  be an increasing strict concave utility curve for the agent. Because the utility curve is an increasing strict concave curve, inequalities  $w_{t+2} > w_{t+1}$  and  $u(w_{t+2}) > Eu(w_{t+2})$ hold true. Hence, we possess the following inequality.  $Eu(w_{t+2}) - u(w_{t+1})/\infty <$  $Eu(w_{t+2}) - u(w_{t+1})/w_{t+2} - w_{t+1} < u(w_{t+2}) - u(w_{t+1})/w_{t+2} - w_{t+1}$ . Thus, inequalities  $Eu(w_{t+2}) > u(w_{t+1}), Eu(w_{t+2}) < u(w_{t+1}),$  or  $Eu(w_{t+2}) = u(w_{t+1})$  hold true for the agent. Q.E.D.

**Theorem 4.** Suppose that  $u(w)$  is an increasing utility curve on a given interval and the agent's subjective time discount factor ( $\beta$ ) has an acceptable value. Variable  $w_{t+1}$  denotes the wealth at current time. The agent is allocating negative utility for the uncertain wealth value (i.e.,  $\eta_{t+1}$  $<$  1)

The following holds true on the given interval for nontrivial lotteries with some  $\beta \eta_{t+1} < 1$ values.

The agent is risk-averse or risk-loving, or risk-neutral in standard forms  $\Leftrightarrow \beta \eta_{t+1} E u(w_{t+2})$ 

$$
\langle u(w_{t+1})
$$

*Proof.*  $(\Rightarrow)$ 

Suppose that  $u(w)$  is an increasing utility curve with some  $\beta \eta_{t+1} < 1$  values.

*Case 1*. Suppose that  $Eu(w_{t+1}) < u[E(w)] = u(w_{t+1})$  on the given interval with some  $\beta \eta_{t+1}$  < 1 values. Inequality  $Eu(w_{t+1})$  <  $u[E(w)] = u(w_{t+1})$  is equal to strict concavity. Thus, choose an arbitrary probability value p with  $0 < p < 1$  for the expected value. We have three alternatives for the increasing utility curve by proposition 2.

*Alternative 1.* We have  $Eu(w_{t+2}) > u(w_{t+1})$  by proposition 2. Because there exist some  $\beta \eta_{t+1}$  < 1 values, such that  $\beta \eta_{t+1} E u(w_{t+2}) < E u(w_{t+1}) < u[E(w)] = u(w_{t+1})$  $Eu(w_{t+2})$  holds true,  $Eu(w_{t+1}) < u[E(w)] = u(w_{t+1})$  implies  $\beta \eta_{t+1} Eu(w_{t+2}) < u(w_{t+1})$ with some  $\beta \eta_{t+1}$  < 1 values.

*Alternative 2.* We have  $Eu(w_{t+2}) < u(w_{t+1})$  by proposition 2. Because there exist some  $\beta \eta_{t+1} < 1$  values, such that  $\beta \eta_{t+1} E u(w_{t+2}) < E u(w_{t+1}) < E u(w_{t+2}) < u[E(w)] =$  $u(w_{t+1})$  holds true,  $Eu(w_{t+1}) < u[E(w)] = u(w_{t+1})$  implies  $\beta \eta_{t+1} Eu(w_{t+2}) < u(w_{t+1})$ with some  $\beta \eta_{t+1}$  < 1 values.

*Alternative 3.* We have  $Eu(w_{t+2}) = u(w_{t+1})$  by proposition 2. Because there exist some  $\beta \eta_{t+1} < 1$  values, such that  $\beta \eta_{t+1} E u(w_{t+2}) < E u(w_{t+1}) < E u(w_{t+2}) = u[E(w)] =$  $u(w_{t+1})$  holds true,  $Eu(w_{t+1}) < u[E(w)] = u(w_{t+1})$  implies  $\beta \eta_{t+1} Eu(w_{t+2}) < u(w_{t+1})$ with some  $\beta \eta_{t+1}$  < 1 values.

*Case 2.* Suppose that  $u[E(w)] = u(w_{t+1}) < Eu(w_{t+1})$  on the given interval with some  $\beta \eta_{t+1}$  < 1 values. Inequality  $u[E(w)] = u(w_{t+1})$  <  $Eu(w_{t+1})$  is equal to strict convexity. Thus, choose an arbitrary probability value p with  $0 < p < 1$  for the expected value. We have  $u(w_{t+1}) < Eu(w_{t+2})$  for the increasing utility curve by proposition 1. Because there exist some  $\beta \eta_{t+1} < 1$  values, such that  $\beta \eta_{t+1} E u(w_{t+2}) < u[E(w)] = u(w_{t+1}) < Eu(w_{t+1}) <$  $Eu(w_{t+2})$  holds true,  $u[E(w)] = u(w_{t+1}) < Eu(w_{t+1})$  implies  $\beta \eta_{t+1} Eu(w_{t+2}) < u(w_{t+1})$ with some  $\beta \eta_{t+1}$  < 1 values.

*Case 3.* Suppose that  $u[E(w)] = u(w_{t+1}) = Eu(w_{t+1})$  on the given interval with some  $\beta \eta_{t+1}$  < 1 values. Inequality  $u[E(w)] = u(w_{t+1}) = Eu(w_{t+1})$  is equal to linearity. Thus, choose an arbitrary probability value p with  $0 \le p \le 1$  for the expected value. There are three conditions to examine.

*Condition 1.* Choose  $p = 1$  for the expected value. Moreover,  $u[E(w)] =$  $u(w_{t+1}) = Eu(w_{t+1})$  holds true. Because there exist all  $\beta \eta_{t+1} < 1$  values, such that

 $\beta \eta_{t+1} E u(w_{t+2}) < u(w_{t+1}) = u[E(w)] = E u(w_{t+1}) = E u(w_{t+2}) = u(w_{t+2})$  holds true,  $u[E(w)] = u(w_{t+1}) = Eu(w_{t+1})$  implies  $\beta \eta_{t+1} Eu(w_{t+2}) < u(w_{t+1})$  with some  $\beta \eta_{t+1} < 1$ values.

*Condition 2.* Choose p with  $0 < p < 1$  for the expected value. Then, we have  $u[E(w)] =$  $u(w_{t+1}) = Eu(w_{t+1}) < Eu(w_{t+2})$  for the increasing utility curve. Because there exist some  $\beta \eta_{t+1}$  < 1 values, such that  $\beta \eta_{t+1} E u(w_{t+2}) < u[E(w)] = u(w_{t+1}) = E u(w_{t+1})$  <  $Eu(w_{t+2})$  holds true,  $u[E(w)] = u(w_{t+1}) = Eu(w_{t+1})$  implies  $\beta \eta_{t+1} Eu(w_{t+2}) < u(w_{t+1})$ with some  $\beta \eta_{t+1}$  < 1 values.

*Condition 3.* Choose  $p = 0$  for the expected value. Then,  $u[E(w)] = u(w_{t+1})$  $= Eu(w_{t+1}) = u(w_t) = Eu(w_t) < Eu(w_{t+2})$  for the increasing utility curve. Because there exist some  $\beta \eta_{t+1} < 1$  values, such that  $\beta \eta_{t+1} E u(w_{t+2}) < u[E(w)] = u(w_{t+1}) = E u(w_{t+1}) =$  $u(w_t) = Eu(w_t) < Eu(w_{t+2})$  holds true,  $u[E(w)] = u(w_{t+1}) = Eu(w_{t+1})$  implies  $\beta \eta_{t+1} E u(w_{t+2}) < u(w_{t+1})$  with some  $\beta \eta_{t+1} < 1$  values.

Since we know  $Eu(w_{t+1}) < u[E(w)] = u(w_{t+1}), u[E(w)] = u(w_{t+1}) < Eu(w_{t+1}),$  or  $u[E(w)]$  $= u(w_{t+1}) = Eu(w_{t+1})$  with some  $\beta \eta_{t+1} < 1$  values, these cases cover all the possibilities, so we can conclude that  $\beta \eta_{t+1} E u(w_{t+2}) < u(w_{t+1})$  holds true with some  $\beta \eta_{t+1} < 1$  values.

$$
(\Longleftarrow)
$$

Suppose that  $\beta \eta_{t+1} E u(w_{t+2}) < u(w_{t+1})$  holds true on the given interval with some  $\beta \eta_{t+1}$  < 1 values and  $u(w)$  is an increasing curve.

*Case 1*. Then, we have  $\beta \eta_{t+1} E u(w_{t+2}) < u(w_{t+1}) = u[E(w)]$  for the increasing utility curve. Some  $\beta \eta_{t+1} < 1$  values can be chosen, such that  $\beta \eta_{t+1} E u(w_{t+2}) < E u(w_{t+1}) <$  $Eu(w_{t+2}) < u(w_{t+1}) = u[E(w)]$  holds true. Inequality  $Eu(w_{t+1}) < u(w_{t+1}) = u[E(w)]$  is equal to strict concavity. Hence,  $\beta \eta_{t+1} E u(w_{t+2}) < u(w_{t+1})$  implies  $E u(w_{t+1}) < u(w_{t+1}) =$  $u[E(w)]$  with some  $\beta \eta_{t+1} < 1$  values.

*Case 2.* Then, we have  $\beta \eta_{t+1} E u(w_{t+2}) < u(w_{t+1}) = u[E(w)]$  for the increasing utility curve. Some  $\beta \eta_{t+1} < 1$  values can be chosen, such that  $\beta \eta_{t+1} E u(w_{t+2}) < u(w_{t+1}) =$  $u[E(w)] < Eu(w_{t+1}) < Eu(w_{t+2})$  holds true. Inequality  $u(w_{t+1}) = u[E(w)] < Eu(w_{t+1})$  is equal to strict convexity. Hence,  $\beta \eta_{t+1}Eu(w_{t+2}) < u(w_{t+1})$  implies  $u(w_{t+1}) = u[E(w)] <$  $Eu(w_{t+1})$  with some  $\beta \eta_t < 1$  values.

*Case 3.* Then, we have  $\beta \eta_{t+1} E u(w_{t+2}) < u(w_{t+1}) = u[E(w)]$  for the increasing utility curve. There are three alternatives to consider.

*Condition 1*. Choose  $p = 1$  for the expected value. All  $\beta \eta_{t+1} < 1$  values can be chosen, such that  $\beta \eta_{t+1} E u(w_{t+2}) < u(w_{t+1}) = u[E(w)] = E u(w_{t+1}) = E u(w_{t+2}) = u(w_{t+2})$  holds true. Hence,  $\beta \eta_{t+1} E u(w_{t+2}) < u(w_{t+1})$  implies  $u(w_{t+1}) = u[E(w)] = Eu(w_{t+1})$  with some  $\beta \eta_{t+1}$  < 1 values.

*Condition 2.* Choose p with  $0 < p < 1$  for the expected value. Some  $\beta \eta_{t+1} < 1$  values can be chosen, such that  $\beta \eta_{t+1} E u(w_{t+2}) < u(w_{t+1}) = u[E(w)] = E u(w_{t+1}) <$  $Eu(w_{t+2})$  holds true. Hence,  $\beta \eta_{t+1} Eu(w_{t+2}) < u(w_{t+1})$  implies  $u(w_{t+1}) = u[E(w)] =$  $Eu(w_{t+1})$  with some  $\beta \eta_{t+1} < 1$  values.

*Condition 3*. Choose  $p = 0$  for the expected value. Some  $\beta \eta_{t+1} < 1$  values can be chosen, such that  $\beta \eta_{t+1} E u(w_{t+2}) < u(w_{t+1}) = u[E(w)] = E u(w_{t+1}) = E u(w_t) = u(w_t) <$  $Eu(w_{t+2})$  holds true. Hence,  $\beta \eta_{t+1}Eu(w_{t+2}) < u(w_{t+1})$  implies  $u(w_{t+1}) = u[E(w)] =$  $Eu(w_{t+1})$  with some  $\beta \eta_{t+1} < 1$  values.

We can conclude that the agent is risk-averse or risk-loving, or risk-neutral in standard forms with some  $\beta \eta_{t+1}$  < 1 values.

$$
Q.E.D.
$$

**Theorem 5.** Suppose that  $u(w)$  is an increasing utility curve on a given interval. The agent's subjective time discount factor ( $\beta$ ) has an acceptable value. Variable  $w_{t+1}$  denotes the wealth The following holds true on the given interval for nontrivial lotteries with some  $\beta \eta_{t+1} \geq 1$ values.

The agent is risk-averse or risk-loving, or risk-neutral in standard forms  $\Leftrightarrow u(w_{t+1})$ 

$$
\beta\eta_{t+1}Eu(w_{t+2}).
$$

*Proof.*  $(\Rightarrow)$ 

That the agent is allocating positive utility for the uncertain wealth value is equivalent to  $\beta \eta_{t+1}$ ≥ 1 values. Suppose that  $u(w)$  is an increasing utility curve with some  $βη_{t+1} ≥ 1$  values.

*Case 1.* Suppose that  $Eu(w_{t+1}) < u[E(w)] = u(w_{t+1})$  on the given interval with some  $\beta \eta_{t+1} \geq 1$  values. Then there exist some  $\beta \eta_{t+1} \geq 1$  values, such that there is one condition to examine.

*Condition 1.* Choose  $0 < p < 1$ . Then,  $Eu(w_{t+1}) < u[E(w)] = u(w_{t+1})$ , which is equal to strict concavity, implies three alternatives by proposition 2.

*Alternative 1.* We have  $Eu(w_{t+2}) > u(w_{t+1})$  by proposition 2. Because there exist all  $\beta \eta_{t+1} \geq$ 1 values,  $Eu(w_{t+1}) < u[E(w)] = u(w_{t+1}) < Eu(w_{t+2}) \leq \beta \eta_{t+1} Eu(w_{t+2})$  holds true. Thus  $Eu(w_{t+1}) < u[E(w)] = u(w_{t+1})$  implies  $u(w_{t+1}) < \beta \eta_{t+1} Eu(w_{t+2})$  with some  $\beta \eta_{t+1} \ge 1$ values.

*Alternative 2.* We have  $Eu(w_{t+2}) < u(w_{t+1})$  by proposition 2. Because there exist some  $\beta \eta_{t+1}$  $\geq 1$  values,  $Eu(w_{t+1}) < Eu(w_{t+2}) \leq u[E(w)] = u(w_{t+1}) \leq \beta \eta_{t+1} Eu(w_{t+2})$  holds true. Moreover, former inequality implies  $Eu(w_{t+1}) < Eu(w_{t+2}) < u[E(w)] = u(w_{t+1}) <$  $\beta \eta_{t+1} E u(w_{t+2})$ . Thus,  $E u(w_{t+1}) < u[E(w)] = u(w_{t+1})$  implies  $u(w_{t+1}) < \beta \eta_{t+1} E u(w_{t+2})$ with some  $\beta \eta_{t+1} \geq 1$  values.

*Alternative 3.* We have  $Eu(w_{t+2}) = u(w_{t+1})$  by proposition 2. Because there exist all  $\beta \eta_{t+1} \geq$ 1 values,  $Eu(w_{t+1}) < Eu(w_{t+2}) = u(w_{t+1}) = u[E(w)] \leq \beta \eta_t Eu(w_{t+2})$  holds true.

Moreover, former inequality implies  $Eu(w_{t+1}) < Eu(w_{t+2}) = u(w_{t+1}) = u[E(w)]$  <  $\beta \eta_t E u(w_{t+2})$  Thus,  $E u(w_{t+1}) < u[E(w)] = u(w_{t+1})$  implies  $u(w_{t+1}) < \beta \eta_t E u(w_{t+2})$  with some  $\beta \eta_{t+1} \geq 1$  values.

*Case 2.* Suppose that  $u[E(w)] = u(w_{t+1}) < Eu(w_{t+1})$  on the given interval with some  $\beta \eta_{t+1} \ge 1$  values. Inequality  $u[E(w)] = u(w_{t+1}) < Eu(w_{t+1})$  is equal to strict convexity. Then,  $u(w_{t+1}) = u[E(w)] \leq Eu(w_{t+2})$  holds true by proposition 1. We can choose all  $\beta \eta_{t+1}$ ≥ 1 values, such that  $u(w_{t+1}) = u[E(w)] < Eu(w_{t+1}) < Eu(w_{t+2}) \leq βη_{t+1} Eu(w_{t+2})$  holds true. Thus,  $u[E(w)] = u(w_{t+1}) < Eu(w_{t+1})$  implies  $u(w_{t+1}) < \beta \eta_{t+1} Eu(w_{t+2})$  with some  $\beta \eta_{t+1} \geq 1$  values.

*Case 3.* Suppose that  $u(w_{t+1}) = u[E(w)] = Eu(w_{t+1})$  on the given interval with some  $\beta \eta_{t+1} \ge 1$  values. Inequality  $u[E(w)] = u(w_{t+1}) = Eu(w_{t+1})$  is equal to linearity. We can choose all  $\beta \eta_{t+1} \geq 1$  values, such that  $u(w_{t+1}) = u[E(w)] = Eu(w_{t+1}) < Eu(w_{t+2}) \leq$  $\beta \eta_{t+1} E u(w_{t+2})$  holds true. Thus,  $u(w_{t+1}) = u[E(w_{t+1})] = Eu(w_{t+1})$  implies  $u(w_{t+1})$  $\beta \eta_{t+1} E u(w_{t+2})$  with some  $\beta \eta_{t+1} \ge 1$  values.

Since we know  $Eu(w_{t+1}) < u(w_{t+1}) = u[E(w)]$ ,  $u(w_{t+1}) = u[E(w)] < Eu(w_{t+1})$ , or  $u(w_{t+1}) = u[E(w)] = Eu(w_{t+1})$  with some  $\beta \eta_{t+1} \ge 1$  values, these cases cover all the possibilities, so we can conclude that  $u(w_{t+1}) < \beta \eta_{t+1} E u(w_{t+2})$  holds true with some  $\beta \eta_{t+1}$  $\geq$  1 values.

$$

$$

Suppose that  $u(w)$  is an increasing utility curve with some  $\beta \eta_{t+1} \ge 1$  values.

*Case 1*. Suppose that  $u(w_{t+1}) < \beta \eta_{t+1} E u(w_{t+2})$  with some  $\beta \eta_{t+1} \ge 1$  values. We can choose all  $\beta \eta_{t+1} \geq 1$  values, such that  $Eu(w_{t+1}) < u(w_{t+1}) = u[E(w)] < Eu(w_{t+2}) \leq$  $\beta \eta_{t+1} E u(w_{t+2})$  holds true. Hence,  $E u(w_{t+1}) < u(w_{t+1}) = u[E(w)]$  which is equal to strict concavity holds true with some  $\beta \eta_{t+1} \geq 1$  values.

*Case 2.* Suppose that  $u(w_{t+1}) < \beta \eta_{t+1} E u(w_{t+2})$  with some  $\beta \eta_{t+1} \ge 1$  values. We can choose all  $\beta \eta_{t+1} \geq 1$  values, such that  $u(w_{t+1}) = u[E(w)] < Eu(w_{t+1}) < Eu(w_{t+2}) \leq$  $\beta \eta_{t+1} E u(w_{t+2})$  holds true. Hence,  $u(w_{t+1}) = u[E(w)] < Eu(w_{t+1})$  which is equal to strict convexity holds true with some  $\beta \eta_{t+1} \geq 1$  values.

*Case* 3. Suppose that  $u(w_{t+1}) < \beta \eta_{t+1} E u(w_{t+2})$  with some  $\beta \eta_{t+1} \ge 1$  values. We can choose all  $\beta \eta_{t+1} \geq 1$  values, such that  $Eu(w_{t+1}) = u(w_{t+1}) = u[E(w)] < Eu(w_{t+2}) \leq$  $\beta \eta_{t+1} E u(w_{t+2})$  holds true. Hence,  $u(w_{t+1}) = u[E(w)] = Eu(w_{t+1})$  which is equal to linearity holds true with some  $\beta \eta_{t+1} \geq 1$  values.

We can conclude that the agent is risk-averse or risk-loving, or risk-neutral in standard forms with some  $\beta \eta_{t+1} \geq 1$  values.

$$
Q.E.D.
$$

**Theorem 6.** Suppose that  $u(w)$  is an increasing utility curve on a given interval. The agent's subjective time discount factor ( $\beta$ ) has an acceptable value. Variable  $w_{t+1}$  denotes the wealth at current time. The agent is allocating positive utility for the uncertain wealth value  $(i.e., \eta_{t+1} > 1).$ 

The following holds true on the given interval for nontrivial lotteries with some  $\beta \eta_{t+1} \leq 1$ values.

The agent is risk-loving or risk-neutral in standard forms  $\Leftrightarrow u(w_{t+1}) < \beta \eta_{t+1} E u(w_{t+2})$ .

*Proof.* 
$$
(\Rightarrow)
$$

That the agent is allocating positive utility for the uncertain wealth value is equivalent to  $\beta \eta_{t+1} \leq 1$ . Suppose that  $u(w)$  is an increasing utility curve some  $\beta \eta_{t+1} \leq 1$  values.

*Case 1*. Suppose that  $u(w_{t+1}) = u[E(w)] < Eu(w_{t+1})$  on the given interval. Inequality  $u(w_{t+1}) = u[E(w)] < Eu(w_{t+1})$  is equal to strict convexity. There exist some  $\beta \eta_{t+1} \leq 1$ values, such that  $u(w_{t+1}) = u[E(w)] < Eu(w_{t+1}) < \beta \eta_{t+1} Eu(w_{t+2}) \le Eu(w_{t+2})$  holds true. Thus,  $u(w_{t+1}) = u[E(w)] < Eu(w_{t+1})$  implies  $u(w_{t+1}) < \beta \eta_{t+1} Eu(w_{t+2})$  with some  $\beta \eta_{t+1} \leq 1$  values.

*Case 2.* Suppose that  $u(w_{t+1}) = u[E(w)] = Eu(w_{t+1})$  on the given interval. Inequality  $u(w_{t+1}) = u[E(w)] = Eu(w_{t+1})$  is equal to linearity. There exist some  $\beta \eta_{t+1} \leq 1$  values, such that  $u(w_{t+1}) = u[E(w)] = Eu(w_{t+1}) < \beta \eta_{t+1} Eu(w_{t+2}) \le Eu(w_{t+2})$  holds true. Thus,  $u(w_{t+1}) = u[E(w)] = Eu(w_{t+1})$  implies  $u(w_{t+1}) < \beta \eta_{t+1} Eu(w_{t+2})$  with some  $\beta \eta_{t+1} \leq 1$ values.

Since we know  $u(w_{t+1}) = u[E(w)] < Eu(w_{t+1})$  or  $u(w_{t+1}) = u[E(w)]$  $= Eu(w_{t+1})$  with some  $\beta \eta_{t+1} \leq 1$  values, these cases cover all the possibilities, so we can conclude that  $u(w_{t+1}) < \beta \eta_{t+1} E u(w_{t+2})$  with some  $\beta \eta_{t+1} \leq 1$  values.

 $(\Leftarrow)$ 

Suppose that  $u(w)$  is an increasing utility curve

*Case 1.* Suppose that  $u(w_{t+1}) < \beta \eta_{t+1} E u(w_{t+2})$  with some  $\beta \eta_{t+1} \leq 1$  values. We can choose some  $\beta \eta_{t+1} \leq 1$  values, such that  $u(w_{t+1}) = u[E(w)] < Eu(w_{t+1})$  $\beta \eta_{t+1} E u(w_{t+2}) \leq E u(w_{t+2})$  holds true. Hence,  $u(w_{t+1}) = u[E(w)] < E u(w_{t+1})$  which is equal to strict convexity holds true with some  $\beta \eta_{t+1} \leq 1$  values.

*Case 2.* Suppose that  $u(w_{t+1}) < \beta \eta_{t+1} E u(w_{t+2})$  with some  $\beta \eta_{t+1} \leq 1$  values. Hence,  $E u(w_{t+1}) = u(w_{t+1}) = u[E(w)]$  which is equal to linearity holds true with some  $\beta \eta_{t+1} \leq 1$  values.

We can conclude that the agent is risk-loving or risk-neutral in standard forms with some  $\beta \eta_{t+1} \leq 1$  values.

$$
Q.E.D.
$$

**Theorem 7.** Suppose that  $u(w)$  is an increasing utility curve on a given interval. The agent's subjective time discount factor ( $\beta$ ) has an acceptable value. Variable  $w_{t+1}$  denotes the wealth at current time. The agent is allocating positive utility for the uncertain wealth value  $(i.e., \eta_{t+1} > 1).$ 

The following holds true on the given interval for nontrivial lotteries with some  $\beta \eta_{t+1} \leq 1$ values.

 $u(w_{t+1}) < \beta \eta_{t+1} E u(w_{t+2})$  holds true  $\Rightarrow$  The agent is risk-averse in standard form.

## *Proof.*

That the agent is allocating positive utility for the uncertain wealth value is equivalent to  $\beta \eta_{t+1} \leq 1$ . Suppose that  $u(w_{t+1}) < \beta \eta_{t+1} E u(w_{t+2})$  holds true with an increasing utility curve and some  $\beta \eta_{t+1} \leq 1$  values. We can choose some  $\beta \eta_{t+1} \leq 1$  values, such that  $Eu(w_{t+1}) < u(w_{t+1}) = u[E(w)] < \beta \eta_{t+1} Eu(w_{t+2}) \le Eu(w_{t+2})$  holds true. Hence,  $Eu(w_{t+1}) < u(w_{t+1}) = u[E(w)]$  which is equal to strict concavity holds true.

$$
Q.E.D.
$$

**Theorem 8.** Suppose that  $u(w)$  is an increasing curve on a given interval and the agent's subjective time discount factor ( $\beta$ ) has an acceptable value. Variable  $w_{t+1}$  denotes the wealth at current time. The agent is allocating positive or negative utility for the uncertain wealth value.

The following holds true on the given interval for nontrivial lotteries with some  $\beta \eta_{t+1} \leq 1$ values.

The agent is risk-averse or risk-loving, or risk-neutral in standard forms  $\Leftrightarrow \beta \eta_{t+1} E u(w_{t+2})$ 

$$
=u(w_{t+1}).
$$

*Proof.*  $(\Rightarrow)$ 

Some  $\beta \eta_{t+1} \leq 1$  values denote that the agent may allocate positive or negative utility for the uncertain wealth value. Suppose that  $u(w)$  is an increasing utility curve with some  $\beta \eta_{t+1} \leq 1$ values.

*Case 1.* Suppose that  $Eu(w_{t+1}) < u[E(w)] = u(w_{t+1})$  holds true on the given interval. Inequality  $Eu(w_{t+1}) < u[E(w)] = u(w_{t+1})$  is equal to strict concavity. Because there exist some  $\beta \eta_{t+1} \leq 1$  values, such that  $Eu(w_{t+1}) < \beta \eta_{t+1} Eu(w_{t+2}) \leq Eu(w_{t+2}) = u[E(w)] =$  $u(w_{t+1})$  holds true, smaller than or equality in this inequality implies equality. Hence,  $Eu(w_{t+1}) < u[E(w)] = u(w_{t+1})$  implies  $\beta \eta_{t+1} Eu(w_{t+2}) = u(w_{t+1})$  with some  $\beta \eta_{t+1} \leq 1$ values.

*Case 2.* Suppose that  $u[E(w)] = u(w_{t+1}) < Eu(w_{t+1})$  on the given interval. Inequality  $u[E(w)] = u(w_{t+1}) \leq Eu(w_{t+1})$  is equal to strict convexity. Because there exist some  $\beta \eta_{t+1} \leq 1$  values, such that  $\beta \eta_{t+1} E u(w_{t+2}) = u(w_{t+1}) = u[E(w)] \leq E u(w_{t+1}) \leq$  $Eu(w_{t+2})$  holds true, convexity in this inequality implies strict convexity. Hence,  $u[E(w)] =$  $u(w_{t+1}) < Eu(w_{t+1})$  implies  $\beta \eta_{t+1} Eu(w_{t+2}) = u(w_{t+1})$  with some  $\beta \eta_{t+1} \leq 1$  values.

Case 3. Suppose that  $u[E(w)] = u(w_{t+1}) = Eu(w_{t+1})$  on the given interval. Inequality  $u[E(w)] = u(w_{t+1}) = Eu(w_{t+1})$  is equal to linearity. Because there exist all  $\beta \eta_{t+1} \le 1$  values, such that  $\beta \eta_{t+1} E u(w_{t+2}) = u[E(w)] = u(w_{t+1}) = E u(w_{t+1}) \le E u(w_{t+2})$ holds true,  $u[E(w)] = u(w_{t+1}) = Eu(w_{t+1})$  implies  $\beta \eta_{t+1} Eu(w_{t+2}) = u(w_{t+1})$  with some  $\beta \eta_{t+1} \leq 1$  values.

Since we know  $Eu(w_{t+1}) < u[E(w)] = u(w_{t+1})$  or  $u[E(w)] = u(w_{t+1}) < Eu(w_{t+1})$ , or  $u[E(w)] = u(w_{t+1}) = Eu(w_{t+1})$  with some  $\beta \eta_{t+1} \leq 1$  values, these cases cover all the possibilities, so we can conclude that  $u(w_{t+1}) = \beta \eta_{t+1} E u(w_{t+2})$  with some  $\beta \eta_{t+1} \le 1$  values.  $(\Longleftarrow)$ 

Suppose that  $\beta \eta_{t+1} E u(w_{t+2}) = u(w_{t+1})$  on the given interval and  $u(w)$  is an increasing utility curve with some  $\beta \eta_{t+1} \leq 1$  values.

*Case 1*. There exist some  $\beta \eta_{t+1} \leq 1$  values, such that  $Eu(w_{t+1}) < \beta \eta_{t+1} Eu(w_{t+2}) =$  $u(w_{t+1}) = u[E(w)] \le Eu(w_{t+2})$  holds true. Inequality  $Eu(w_{t+1}) < u(w_{t+1}) = u[E(w)]$  is equal to concavity. Thus,  $\beta \eta_{t+1} E u(w_{t+2}) = u(w_{t+1})$  implies  $E u(w_{t+1}) < u(w_{t+1}) =$  $u[E(w)]$  with some  $\beta \eta_{t+1} \leq 1$  values

*Case 2.* There exist some  $\beta \eta_{t+1} \leq 1$  values, such that  $\beta \eta_{t+1} E u(w_{t+2}) = u(w_{t+1}) =$  $u[E(w)] < Eu(w_{t+1}) \le Eu(w_{t+2})$  holds true. Inequality  $u(w_{t+1}) = u[E(w)] < Eu(w_{t+1})$ shows convexity. Thus,  $\beta \eta_{t+1} E u(w_{t+2}) = u(w_{t+1})$  implies  $u(w_{t+1}) = u[E(w)] \le E u(w_{t+1})$ with some  $\beta \eta_{t+1} \leq 1$  values.

*Case 3*. There exist all  $\beta \eta_{t+1} \leq 1$  values, such that  $\beta \eta_{t+1} E u(w_{t+2}) = u(w_{t+1}) =$  $u[E(w)] = Eu(w_{t+1}) \le Eu(w_{t+2})$  holds true. Inequality  $u(w_{t+1}) = u[E(w)] = Eu(w_{t+1})$ shows linearity. Thus,  $\beta \eta_{t+1} E u(w_{t+2}) = u(w_{t+1})$  implies  $u(w_{t+1}) = u[E(w)] = Eu(w_{t+1})$ with some  $\beta \eta_{t+1} \leq 1$  values.

We can conclude that the agent is risk-averse or risk-loving, or risk neutral in standard forms with some  $\beta \eta_{t+1} \leq 1$  values.

Q.E.D.

# **4. Results and Discussion**

Aras (2022, 2023) formulated new definitions for the financial markets and arranged them into two groups (2023). The two groups diverge on the assumptions on the certain utility curves of investors. As Aras (2022) assumed concave certain utility curve for all investors, he also allowed different kinds of certain utility curves for investors (2023).

The shape of the certain utility curve is a necessity for determining the risk attitudes of investors in standard finance theory. This is not the case for some new definitions. For instance, the shape of the certain utility curve of a risk-loving investor may be strictly concave or strictly convex, or linear. Hence, we can conclude that new definitions are broader than standard definitions from the viewpoint of shape.

The new definitions are not equivalent to one another because each biconditional in the proofs has a different assumption (i.e., the agent is allocating extra utility differently for each biconditional). This situation is compatible with finance theory.

It is very difficult to compare certain and uncertain values at the same wealth value in one financial market in the real world as it is done in standard theory. Hence, it is much easier to determine the risk attitudes of investors in financial markets using these new definitions because there is no need to compare certain and uncertain utility curves at the same wealth value with them.

#### **5. Conclusion**

This paper has proven that certain new definitions for utility curves used by some types of investors may satisfy strict concavity or strict convexity, or linearity, which is not being the same way as standard theory. New alternative definitions contain more than standard definitions when shape is considered. Strict concavity, strict convexity, and linearity imply the risk-averse, risk-loving, and risk-neutral investors, respectively, in standard theory. By contrast, the certain utility curve of a risk-averse investor, for instance, may be strictly concave or strictly convex, or linear for new definitions. Hence, the new definitions make scientists' duties much easier in the real world.
