# Abstract

Within the framework of  $SU(3)$  flavor symmetry, we investigate two-body doubly charmful baryonic  $B \to \mathbf{B}_c \bar{\mathbf{B}}'_c$  decays, where  $\mathbf{B}_c \bar{\mathbf{B}}'_c$  represents the anti-triplet charmed dibaryon. We determine the  $SU(3)_f$  amplitudes and calculate  $\mathcal{B}(B^- \to \Xi_c^0 \bar{\Xi}_c^-) = (3.4^{+1.0}_{-0.9}) \times 10^{-5}$  and  $\mathcal{B}(\bar{B}^0_s \to \Lambda_c^+ \bar{\Xi}_c^-) = (3.9^{+1.2}_{-1.0}) \times 10^{-5}$  induced by the single W-emission configuration. We find that the W-exchange amplitude, previously neglected in studies, needs to be taken into account. It can cause a destructive interfering effect with the W-emission amplitude, alleviating the significant discrepancy between the theoretical estimation and experimental data for  $\mathcal{B}(\bar{B}^0 \to \Lambda_c^+ \bar{\Lambda}_c^-)$ . To test other interfering decay channels, we calculate  $\mathcal{B}(\bar{B}^0_s \to \Xi_c^{0(+)} \bar{\Xi}_c^{0(+)}) = (3.0^{+1.4}_{-1.1}) \times 10^{-4}$  and  $\mathcal{B}(\bar{B}^0 \to \bar{B}^0)$  $\Xi_{c}^{0}\overline{\Xi}_{c}^{0}$  =  $(1.5_{-0.6}^{+0.7}) \times 10^{-5}$ . We estimate non-zero branching fractions for the pure W-exchange decay channels, specifically  $\mathcal{B}(\bar{B}^0_s \to \Lambda_c^+ \bar{\Lambda}_c^-) = (8.1^{+1.7}_{-1.5}) \times 10^{-5}$  and  $\mathcal{B}(\bar{B}^0 \to \Xi_c^+ \bar{\Xi}_c^-) = (3.0 \pm 0.6) \times 10^{-6}$ . Additionally, we predict  $\mathcal{B}(B_c^+ \to \Xi_c^+ \overline{\Xi}_c^0) = (2.8^{+0.9}_{-0.7}) \times 10^{-4}$  and  $\mathcal{B}(B_c^+ \to \Lambda_c^+ \overline{\Xi}_c^0) = (1.6^{+0.5}_{-0.4}) \times 10^{-5}$ , which are accessible to experimental facilities such as LHCb.

<span id="page-0-0"></span><sup>∗</sup> [Email address: yukuohsiao@gmail.com](mailto:Email address: yukuohsiao@gmail.com)

#### I. INTRODUCTION

The tree-level dominated two-body charmless baryonic B meson decays,  $B \to \mathbf{B} \mathbf{B}'$ , can proceed through the W-boson exchange  $(W_{ex})$ , W-boson annihilation  $(W_{an})$ , and W-boson emission  $(W_{\rm em})$  decay configurations. In analogy with leptonic B decay, where the  $W_{\rm an}$ amplitude  $\mathcal{M}_{\text{wan}}(B \to \ell \bar{\nu}) \propto m_{\ell} \bar{u}_{\ell} (1 + \gamma_5) v_{\bar{\nu}}$  involves a tiny lepton mass  $m_{\ell}$  corresponding to helicity suppression [\[1](#page-8-0), [2](#page-8-1)],  $\mathcal{M}_{wex(wan)}(B \to \mathbf{B}\mathbf{B}') \propto m_{-}\langle \mathbf{B}\mathbf{B}'|\bar{q}q' |0\rangle + m_{+}\langle \mathbf{B}\mathbf{B}'|\bar{q}\gamma_{5}q' |0\rangle$ with  $m_{\mp} = m_q \mp m_{q'}$  is considered to be more suppressed than  $\mathcal{M}_{\text{wem}}(B \to \mathbf{B}\mathbf{B}')$  [\[3\]](#page-8-2). Hence, it raises the debate if one can really neglect the  $W_{\text{ex(an)}}$  contribution to the branching fractions [\[3](#page-8-2)[–10\]](#page-8-3).

In the study of singly charmful baryonic  $B \to \mathbf{B}_c \mathbf{B}'$  decays, the  $W_{\text{ex(an)}}$  amplitude was also neglected [\[11,](#page-8-4) [12\]](#page-8-5). Nonetheless, it has been found that  $\mathcal{M}_{wex(wan)}(B \to B_c\bar{B}') \propto$  $m_c \langle \mathbf{B}_c \mathbf{B}' | \bar{c} (1 + \gamma_5) q | 0 \rangle$  with  $m_c \gg m_q$  can alleviate the helicity suppression [\[13](#page-8-6)]. This results in  $\mathcal{B}_{\text{wex}}(\bar{B}^0_s \to \Lambda_c^+\bar{p})$  and  $\mathcal{B}_{\text{wex}}(\bar{B}^0 \to \Xi_c^+\bar{\Sigma}^-)$  being predicted to be of order  $10^{-5}$ , much more reachable than  $\mathcal{B}(B \to \mathbf{B}\bar{\mathbf{B}}') \sim 10^{-8} - 10^{-7}$  for the test of a non-negligible  $W_{\text{ex(an)}}$ contribution. However, until very recently, these observations have not been reported.

It is worth noting that two-body doubly charmful baryonic  $B$  decays,  $B \to \mathbf{B}_c \bar{\mathbf{B}}'_c$ , have provided a possible experimental indication of a non-negligible contribution from the  $W_{\text{ex}}$ term. The measured branching fractions for  $B \to \mathbf{B}_c \bar{\mathbf{B}}'_c$  are reported as follows:

<span id="page-1-0"></span>
$$
\mathcal{B}(\bar{B}^0 \to \Xi_c^+ \bar{\Lambda}_c^-) = (1.2 \pm 0.8) \times 10^{-3} [14],
$$
  
\n
$$
\mathcal{B}(B^- \to \Xi_c^0 \bar{\Lambda}_c^-) = (9.5 \pm 2.3) \times 10^{-4} [14],
$$
  
\n
$$
\mathcal{B}(\bar{B}^0 \to \Lambda_c^+ \bar{\Lambda}_c^-) < 1.6 \times 10^{-5} [14, 15]
$$
  
\n
$$
= (2.2^{+2.2}_{-1.6} \pm 1.3) \times 10^{-5} [16],
$$
  
\n
$$
\mathcal{B}(\bar{B}_s^0 \to \Lambda_c^+ \bar{\Lambda}_c^-) < 9.9 \times 10^{-5} [14, 15].
$$
 (1)

Initially, it was considered that  $B \to \mathbf{B}_c \bar{\mathbf{B}}_c'$  receives a single contribution from the  $W_{\text{em}}$ topology [\[16,](#page-8-9) [17](#page-8-10)]. In Eq. [\(1\)](#page-1-0),  $\mathcal{B}(\bar{B}^0 \to \Xi_c^+\bar{\Lambda}_c^-) \simeq \mathcal{B}(\bar{B}^0 \to \Lambda_c^+\bar{\Lambda}_c^-)$  seemly supporting this assumption. Nonetheless, it also leads to an estimation of  $\mathcal{B}(\bar{B}^0 \to \Lambda_c^+\bar{\Lambda}_c^-) \simeq$  $(V_{cd}/V_{cs})^2(\tau_{\bar{B}^0}/\tau_{B^-})\mathcal{B}(B^- \to \Xi_c^0 \bar{\Lambda}_c^-) = (4.7 \pm 1.1) \times 10^{-5}$  by utilizing the  $\mathcal{B}(B^- \to \Xi_c^0 \bar{\Lambda}_c^-)$ value from Eq. [\(1\)](#page-1-0). This clearly shows a significant deviation from the experimental upper limit of  $1.6 \times 10^{-5}$  by around 3 standard deviations. Therefore, it is reasonable to infer that the  $W_{\text{ex}}$  topology, overlooked in  $\bar{B}^0 \to \Lambda_c^+ \bar{\Lambda}_c^-$ , should be taken into account. It can

<span id="page-2-1"></span>FIG. 1. Feynman diagrams of  $B_q \to \mathbf{B}_c \bar{\mathbf{B}}'_c$  and  $B_c^+ \to \mathbf{B}_c \bar{\mathbf{B}}'_c$  decays.

cause a destructive interfering effect, thus reducing the overestimated branching fraction. Additionally, the  $W_{ex}$  topology can induce a non-zero  $\mathcal{B}(\bar{B}^0_s \to \Lambda_c^+ \bar{\Lambda}_c^-)$ , warranting further examination.

For clarification, a careful study of  $B \to \mathbf{B}_c \mathbf{B}'_c$  is necessary. The  $SU(3)$  flavor symmetry can be a useful theoretical tool [\[3](#page-8-2), [8](#page-8-11), [18](#page-8-12)[–31\]](#page-9-0), allowing us to parameterize the amplitudes without involving the complexity of model calculations. Hence, we propose using the  $SU(3)<sub>f</sub>$ approach to specifically explore the  $W_{\text{ex}}$  and  $W_{\text{em}}$  contributions to  $B \to \mathbf{B}_c \bar{\mathbf{B}}'_c$ . The first observation of  $B_c^+ \to J/\Psi p \bar{p} \pi^+$  by LHCb [\[32\]](#page-9-1) indicates a potential test-bed for the baryonic phenomena in  $B_c^+$  decays, such as the branching fraction [\[33](#page-9-2)[–41](#page-9-3)], direct  $CP$  asymmetry [\[42,](#page-9-4) [43\]](#page-9-5), triple product asymmetry [\[44\]](#page-9-6), angular distribution [\[45\]](#page-9-7), and exotic states [\[46](#page-9-8)[–48\]](#page-9-9) as studied in baryonic B decays. Therefore, we will estimate  $\mathcal{B}(B_c^+ \to \mathbf{B}_c \bar{\mathbf{B}}_c')$  to initiate a theoretical investigation.

## II. FORMALISM

To study the two-body doubly charmful baryonic  $B_{(c)} \to \mathbf{B}_c \bar{\mathbf{B}}'_c$  decays with  $B_c$  denoting  $B_c^+(b\bar{c})$ , the quark-level effective Hamiltonians for the  $b \to c\bar{q}q'$  weak transitions are required, given by  $[49, 50]$  $[49, 50]$ 

<span id="page-2-0"></span>
$$
\mathcal{H}_{eff}^{b \to c\bar{q}q'} = \frac{G_F}{\sqrt{2}} V_{cb} V_{qq'}^* \Big[ c_1(\bar{q}'q)(\bar{c}b) + c_2(\bar{q}'_{\beta}q_{\alpha})(\bar{c}_{\alpha}b_{\beta}) \Big], \qquad (2)
$$

where  $G_F$  is the Fermi constant,  $V_{cb}$  and  $V_{qq'}$  with  $q = (u, c)$  and  $q' = (s, d)$  the Cabibbo-Kobayashi-Maskawa (CKM) matrix elements. In Eq. [\(2\)](#page-2-0), we define  $(\bar{q}_1q_2) = \bar{q}_1\gamma_\mu(1-\gamma_5)q_2$ ,

and the subscripts  $(\alpha, \beta)$  denote the color indices; moreover,  $c_{1,2}$  are the scale  $(\mu)$ -dependent Wilson coefficients with  $\mu = m_b$  for the b decays. In the  $SU(3)_f$  representation,  $\mathcal{H}_{eff}^{b \to c\bar{c}q'}$  and  $\mathcal{H}_{eff}^{b\to c\bar{u}q'}$  by omitting Lorentz structure are reduced as  $H^i$  and  $H^i_j$ , respectively, where i and  $j$  run from 1 to 3 to represent the flavor indices. Explicitly, the nonzero entries are given by [\[27](#page-9-10)]

$$
H_1^2 = \lambda_{ud}, \ H_1^3 = \lambda_{us}, \ H^2 = \lambda_{cd}, \ H^3 = \lambda_{cs}, \tag{3}
$$

with  $\lambda_{qq'} \equiv V_{cb}V_{qq'}^*$ . Accordingly, we present the B meson and  $\mathbf{B}_c$  baryon in the  $SU(3)_f$ forms:

$$
B(B_i) = (B^-, \overline{B}^0, \overline{B}_s^0),
$$
  

$$
\mathbf{B}_c(\mathbf{B}_c^{ij}) = \begin{pmatrix} 0 & \Lambda_c^+ & \Xi_c^+ \\ -\Lambda_c^+ & 0 & \Xi_c^0 \\ -\Xi_c^+ & -\Xi_c^0 & 0 \end{pmatrix},
$$
 (4)

whereas  $B_c$  is a singlet. By connecting the flavor indices of the initial state to those of the effective Hamiltonian and final states, the  $SU(3)_f$  approach yields the amplitudes to be

<span id="page-3-0"></span>
$$
\mathcal{M}(B \to \mathbf{B}_c \bar{\mathbf{B}}_c') = e B_i H^i \mathbf{B}_{cjk} \bar{\mathbf{B}}_c'^{jk} + c' B_i H^j \mathbf{B}_{cjk} \bar{\mathbf{B}}_c'^{ik} ,
$$
  

$$
\mathcal{M}(B_c \to \mathbf{B}_c \bar{\mathbf{B}}_c') = \bar{c}' H^i_j \mathbf{B}_{cik} \bar{\mathbf{B}}_c'^{jk} ,
$$
 (5)

where the parameter e and  $c'(\bar{c}')$  correspond to the  $W_{\rm ex}$  and  $W_{\rm em}$  configurations in Fig. [1a](#page-2-1) and Fig.  $1b(c)$ , respectively. For a later numerical analysis, we use the equation  $[14]$ :

$$
\mathcal{B}(B_{(c)} \to \mathbf{B}_c \bar{\mathbf{B}}_c') = \frac{G_F^2 |\vec{p}_{\rm cm}| \tau_{B_{(c)}}}{16\pi m_{B_{(c)}}^2} |\mathcal{M}(B_{(c)} \to \mathbf{B}_c \bar{\mathbf{B}}_c')|^2,
$$
  

$$
|\vec{p}_{cm}| = \frac{\sqrt{(m_{B_{(c)}}^2 - M_+^2)(m_{B_{(c)}}^2 - M_-^2)}}{2m_{B_{(c)}}},
$$
 (6)

to compute the branching fractions, where  $M_{\pm} \equiv m_{\mathbf{B}_c} \pm m_{\mathbf{\bar{B}}'_c}$ ,  $\vec{p}_{cm}$  is the three-momentum of the  $B_c$  baryon in the  $B_{(c)}$  meson rest frame, and  $\tau_{B_{(c)}}$  stands for the  $B_{(c)}$  lifetime. The amplitude  $\mathcal{M}(B_{(c)} \to \mathbf{B}_c \bar{\mathbf{B}}'_c)$  can be found in Table [I.](#page-4-0)

#### III. NUMERICAL RESULTS

In the numerical analysis, the CKM matrix elements are adopted from PDG [\[14\]](#page-8-7):

$$
(V_{cb}, V_{cs}, V_{ud}, V_{us}, V_{cd}) = (A\lambda^2, 1 - \lambda^2/2, 1 - \lambda^2/2, \lambda, -\lambda),
$$
\n(7)

where  $A = 0.826$  and  $\lambda = 0.225$  in the Wolfenstein parameterization. In Eq. [\(5\)](#page-3-0), the parameters  $e$  and  $c'$  are complex numbers, which we present as

$$
|c'|, |e|e^{i\delta_e},\tag{8}
$$

with  $\delta_e$  a relative phase. By using the experimental data in Table [II,](#page-5-0) we solve the parameters as

<span id="page-4-1"></span>
$$
|c'| = (1.29 \pm 0.18) \text{ GeV}^3, |e| = (0.19 \pm 0.03) \text{ GeV}^3, \delta_e = 180^\circ.
$$
 (9)

Moreover, we assume  $\bar{c}' = c'$  due to the similarity of the Feynman diagrams in Figs. [1b](#page-2-1) and [1c](#page-2-1). Subsequently, we calculate the branching fractions as provided in Table [II](#page-5-0) using the determination in Eq. [\(9\)](#page-4-1).

## IV. DISCUSSION AND CONCLUSIONS

The  $SU(3)_f$  approach enables us to explore all possible  $B \to \mathbf{B}_c\bar{\mathbf{B}}'_c$  decays, as summarized in Table [I.](#page-4-0) Furthermore, it helps in deriving constraints on  $SU(3)_f$  relations, facilitating the decomposition of amplitudes into  $e$  and  $c'$  terms. These terms parameterize the  $W_{ex}$  and  $W_{\text{em}}$  topologies depicted in Fig[.1a](#page-2-1) and Fig[.1b](#page-2-1)(c), respectively.

In  $b \to c\bar{c}s$  induced decays, the  $SU(3)<sub>f</sub>$  symmetry unequivocally establishes that both  $\bar{B}^0 \to \Xi_c^+ \bar{\Lambda}_c^-$  and  $B^- \to \Xi_c^0 \bar{\Lambda}_c^-$  solely proceed through the  $W_{\text{em}}$  topology, supporting earlier considerations [\[16,](#page-8-9) [17\]](#page-8-10). The nearly identical branching fractions, as shown in Eq. [\(1\)](#page-1-0), also provide consistent evidence. In our latest findings, we unveil additional insights. For

TABLE I. Amplitudes of  $B_{(c)} \to \mathbf{B}_c \bar{\mathbf{B}}'_c$  with the  $SU(3)_f$  parameters e and  $c'(\bar{c}')$ .

 $\bar{B}^0_s \to \Xi_c^{0(+)} \bar{\Xi}_c^{0(-)}$ , the interference of the  $W_{\rm ex}$  amplitude with the  $W_{\rm em}$  amplitude adds a new contribution to the decay process. Furthermore,  $\bar{B}_s^0 \to \Lambda_c^+ \bar{\Lambda}_c^-$  represents a pure  $W_{\text{ex}}$  decay, offering a clear and distinct case for experiments to clarify if the  $W_{\text{ex}}$  contribution can be neglected.

The  $b \to c\bar{c}d$  induced decays with  $|V_{cd}/V_{cs}| \simeq 0.05$  are more suppressed. Unlike  $\mathcal{M}(\bar{B}^0_s \to 0.05$  $\Xi_c^0(\bar{\Xi}_c^0) = \mathcal{M}(\bar{B}_s^0 \to \Xi_c^+ \bar{\Xi}_c^-), \ \bar{B}^0 \to \Xi_c^+ \bar{\Xi}_c^-$  as a pure  $W_{ex}$  decay does not share an isospin relation with  $\bar{B}^0 \to \Xi_c^0 \bar{\Xi}_c^0$ , which is against our naive expectation. Instead, the equality relation arises from  $M(\bar{B}^0 \to \Lambda_c^+ \bar{\Lambda}_c^-) = M(\bar{B}^0 \to \Xi_c^0 \bar{\Xi}_c^0)$ . Moreover, an interesting triangle relation exists:

<span id="page-5-2"></span>
$$
\mathcal{M}(\bar{B}^0 \to \Xi_c^+ \bar{\Xi}_c^-) + \mathcal{M}(B^- \to \Xi_c^0 \bar{\Xi}_c^-) = \mathcal{M}(\bar{B}^0 \to \Xi_c^0 \bar{\Xi}_c^0). \tag{10}
$$

If the  $W_{\text{ex}}$  contribution is negligible, the relation is simplified to  $\mathcal{M}(B^- \to \Xi_c^0 \bar{\Xi}_c^-) \simeq$  $\mathcal{M}(\bar{B}^0 \to \Xi_c^0 \bar{\Xi}_c^0)$ , resulting in nearly equal branching fractions.

It can be challenging to compute the  $W_{\text{ex}}$  and  $W_{\text{em}}$  amplitudes. For example, the factorization approach derives the  $W_{\text{ex}}$  amplitude as  $\mathcal{M}_{\text{wex}} \propto f_B q^{\mu} \langle \mathbf{B}_c \mathbf{B}_c' | \bar{c} \gamma_{\mu} (1 - \gamma_5) c | 0 \rangle^{-1}$  $\mathcal{M}_{\text{wex}} \propto f_B q^{\mu} \langle \mathbf{B}_c \mathbf{B}_c' | \bar{c} \gamma_{\mu} (1 - \gamma_5) c | 0 \rangle^{-1}$  $\mathcal{M}_{\text{wex}} \propto f_B q^{\mu} \langle \mathbf{B}_c \mathbf{B}_c' | \bar{c} \gamma_{\mu} (1 - \gamma_5) c | 0 \rangle^{-1}$ , where

TABLE II. Branching fractions of  $B_{(c)} \to \mathbf{B}_c \bar{\mathbf{B}}'_c$  decays.

<span id="page-5-1"></span><sup>&</sup>lt;sup>1</sup> Please consult the similar deviation for  $\mathcal{M}(B \to \mathbf{B}_c \bar{\mathbf{B}})$  in Ref. [\[13\]](#page-8-6).

 $f_B$  is the B meson decay constant,  $q^{\mu}$  the momentum transfer, and the matrix elements present the vacuum (0) to  $B_c \bar{B}'_c$  production. As information on the  $0 \to B_c \bar{B}'_c$  production is lacking, a model calculation is currently unavailable. For a calculation on  $\mathcal{M}_{\textrm{wem}},$  one proposes a meson propagator to provide an additional quark pair, resulting in the branching fractions to be a few times  $10^{-3}$  for  $\bar{B}^0 \to \Xi_c^+ \bar{\Lambda}_c^-$  and  $B^- \to \Xi_c^0 \bar{\Lambda}_c^-$  [\[17\]](#page-8-10). Additionally, a theoretical attempt incorporating final state interactions yields  $\mathcal{B} \simeq \mathcal{O}(10^{-3})$  [\[51\]](#page-10-2). It appears that the above approaches may overestimate the  $W_{\rm em}$  contribution.

Without invoking the model calculations, we determine  $e$  and  $c'$  with the experimental data based on the  $SU(3)_f$  symmetry. Explicitly, we use the experimental results for  $\mathcal{B}(\bar{B}^0 \to \bar{B}^0)$  $\Xi_c^+\bar{\Lambda}_c^-$  and  $\mathcal{B}(B^-\to\Xi_c^0\bar{\Lambda}_c^-)$  to fit |c'|. On the other hand, the experimental data have not been sufficient and accurate enough to simultaneously determine  $|e|$  and the relative phase  $\delta_e$ , as indicted in Table [II.](#page-5-0) For a practical determination, we fix  $\delta_e = 180^{\circ}$  to cause a maximum destructive interference, where the fitted  $|c'|$  value has been used. As a consequence, the experimental upper bounds of  $\mathcal{B}(\bar{B}^0_s \to \Lambda_c^+ \bar{\Lambda}_c^-)$  and  $\mathcal{B}(\bar{B}^0 \to \Lambda_c^+ \bar{\Lambda}_c^-)$  can sandwich an allowed range for  $|e|$ , as given in Eq. [\(9\)](#page-4-1).

As the numerical results, we obtain  $\mathcal{B}(\bar{B}^0 \to \Xi_c^+ \bar{\Lambda}_c^-) = (7.2^{+2.1}_{-1.9}) \times 10^{-4}$  and  $\mathcal{B}(B^- \to \Xi_c^- \bar{\Lambda}_c^-)$  $\Xi_c^0 \bar{\Lambda}_c^-$  =  $(7.8^{+2.3}_{-2.0}) \times 10^{-4}$  utilizing  $|c'| = (1.29 \pm 0.18) \text{ GeV}^3$ , in agreement with the experimental inputs. This demonstrates that  $c'$  can estimate the  $W_{\text{em}}$  contribution. Thus, we predict

$$
\mathcal{B}(B^{-} \to \Xi_{c}^{0}\bar{\Xi}_{c}^{-}) = (3.4^{+1.0}_{-0.9}) \times 10^{-5}, \n\mathcal{B}(\bar{B}_{s}^{0} \to \Lambda_{c}^{+}\bar{\Xi}_{c}^{-}) = (3.9^{+1.2}_{-1.0}) \times 10^{-5},
$$
\n(11)

which are also contributed by the single  $W_{\rm em}$  amplitude, promising to be measured by experimental facilities such as LHCb.

The previous studies have assumed that  $\bar{B}^0 \to \Lambda_c^+ \bar{\Lambda}_c^-$  receives the single  $W_{\text{em}}$  contribu-tion [\[16,](#page-8-9) [17](#page-8-10)]. Consequently, the estimated branching fraction  $\mathcal{B}(\bar{B}^0 \to \Lambda_c^+ \bar{\Lambda}_c^-) \simeq 5 \times 10^{-5}$ mentioned in the introduction significantly exceeds the experimental upper bound. In Ta-ble [I,](#page-4-0) since  $\mathcal{M}(\bar{B}^0 \to \Lambda_c^+ \bar{\Lambda}_c^-) = -\lambda_{cd}(2e+c')$  is found to include the  $SU(3)_f$  parameter e, it suggests a non-negligible  $W_{\text{ex}}$  amplitude. By newly incorporating  $e$ , a destructive interference with c' could occur, effectively reducing the branching fraction. In fact, we estimate  $|e| \simeq 0.2 \text{ GeV}^3$ , and obtain  $\mathcal{B}(\bar{B}^0 \to \Lambda_c^+ \bar{\Lambda}_c^-) = (2.1_{-0.8}^{+1.0}) \times 10^{-5}$ , thus alleviating the discrepancy.

To carefully test the  $W_{\text{ex}}$  contribution, we predict the branching fractions of the other interfering decay channels:

$$
\mathcal{B}(\bar{B}_s^0 \to \Xi_c^{0(+)} \bar{\Xi}_c^{0(+)}) = (3.0^{+1.4}_{-1.1}) \times 10^{-4}, \n\mathcal{B}(\bar{B}^0 \to \Xi_c^0 \bar{\Xi}_c^0) = (1.5^{+0.7}_{-0.6}) \times 10^{-5}.
$$
\n(12)

When  $|e| = 0$ ,  $\mathcal{B}(\bar{B}^0_s \to \Xi_c^{0(+)}\bar{\Xi}_c^{0(+)})$  would be enhanced to  $(6.3^{+1.9}_{-1.6}) \times 10^{-4}$ ; moreover,  $\mathcal{B}(\bar{B}^0 \to \Xi_c^0 \bar{\Xi}_c^0)$  would be enhanced to  $(3.1_{-0.8}^{+0.9}) \times 10^{-5}$ , making it close to  $\mathcal{B}(B^- \to \Xi_c^0 \bar{\Xi}_c^-)$ , in accordance with the description for the triangle relation in Eq. [\(10\)](#page-5-2). We also anticipate non-zero branching fractions of the pure  $W_{\text{ex}}$  decays, given by

$$
\mathcal{B}(\bar{B}_s^0 \to \Lambda_c^+ \bar{\Lambda}_c^-) = (8.1^{+1.7}_{-1.5}) \times 10^{-5}, \n\mathcal{B}(\bar{B}^0 \to \Xi_c^+ \bar{\Xi}_c^-) = (3.0 \pm 0.6) \times 10^{-6},
$$
\n(13)

which serve to test the W-exchange mechanism in the  $B \to \mathbf{B}_c \bar{\mathbf{B}}'_c$  decays.

To initiate a theoretical investigation of baryonic  $B_c^+$  decays, we derive the amplitudes for  $B_c \to \mathbf{B}_c \bar{\mathbf{B}}'_c$  using the  $SU(3)_f$  symmetry. This results in two possible decay channels:  $B_c^+ \to \Xi_c^+ \bar{\Xi}_c^0$  and  $B_c^+ \to \Lambda_c^+ \bar{\Xi}_c^0$ , with  $\bar{c}'$  representing the sole contribution from the  $W_{\text{em}}$ term, as given in Table [I.](#page-4-0) Since both  $B_c \to \mathbf{B}_c \bar{\mathbf{B}}'_c$  and  $B \to \mathbf{B}_c \bar{\mathbf{B}}'_c$  involve  $c\bar{c}$  in the  $\mathbf{B}_c \bar{\mathbf{B}}'_c$ formation, it is reasonable to assume that QCD effects cannot distinguish between the topology in Fig. [1b](#page-2-1) and the one in Fig. [1c](#page-2-1) in the hadronization process. Hence, we assume  $\bar{c}' = c'$ , and predict the following branching fractions:

$$
\mathcal{B}(B_c^+ \to \Xi_c^+ \bar{\Xi}_c^0) = (2.8_{-0.7}^{+0.9}) \times 10^{-4}, \n\mathcal{B}(B_c^+ \to \Lambda_c^+ \bar{\Xi}_c^0) = (1.6_{-0.4}^{+0.5}) \times 10^{-5},
$$
\n(14)

which can be probed by the LHCb experiment.

In summary, we have explored the two-body doubly charmful baryonic  $B \to \mathbf{B}_c \mathbf{B}'_c$ decays. Here, the  $W_{\text{ex}}$  and  $W_{\text{em}}$  amplitudes have been parametrized as e and  $c'$ , respectively, using the  $SU(3)<sub>f</sub>$  approach. With the determination of the  $SU(3)<sub>f</sub>$  parameters, we have calculated the branching fractions  $\mathcal{B}(B^- \to \Xi_c^0 \bar{\Xi}_c^-) = (3.4^{+1.0}_{-0.9}) \times 10^{-5}$  and  $\mathcal{B}(\bar{B}^0_s \to \Lambda_c^+\bar{\Xi}_c^-) = (3.9^{+1.2}_{-1.0}) \times 10^{-5}$ . Considering that the single  $W_{\text{em}}$  contribution to  $\bar{B}^0 \rightarrow \Lambda_c^+ \bar{\Lambda}_c^-$  has caused the branching fraction to significantly exceed the experimental upper bound, we have added the  $W_{\text{ex}}$  amplitude (or the  $SU(3)_f$  parameter e), overlooked in previous studies, to account for a destructive interfering effect. Subsequently, we have

alleviated the discrepancy. To further test the interfering decay channels, we have predicted  $\mathcal{B}(\bar{B}^0_s \to \Xi_c^{0(+)}\bar{\Xi}_c^{0(+)}) = (3.0^{+1.4}_{-1.1}) \times 10^{-4}$  and  $\mathcal{B}(\bar{B}^0 \to \Xi_c^{0}\bar{\Xi}_c^{0}) = (1.5^{+0.7}_{-0.6}) \times 10^{-5}$ . For the pure  $W_{\text{ex}}$  decay channels, we have expected non-zero branching fractions, such as  $\mathcal{B}(\bar{B}^0_s \to \Lambda_c^+ \bar{\Lambda}_c^-) = (8.1^{+1.7}_{-1.5}) \times 10^{-5}$  and  $\mathcal{B}(\bar{B}^0 \to \Xi_c^+ \bar{\Xi}_c^-) = (3.0 \pm 0.6) \times 10^{-6}$ , promising to be observed in near-future measurements. Additionally, we have predicted  $\mathcal{B}(B_c^+\to \Xi_c^+\bar{\Xi}_c^0)$  $(2.8^{+0.9}_{-0.7}) \times 10^{-4}$  and  $\mathcal{B}(B_c^+ \to \Lambda_c^+ \bar{\Xi}_c^0) = (1.6^{+0.5}_{-0.4}) \times 10^{-5}$ , which are accessible to the LHCb experiment.
