Computing thermal transport from first-principles in UO_2 is complicated due to the challenges associated with Mott physics. Here we use irreducible derivative approaches to compute the cubic and quartic phonon interactions in UO_2 from first-principles, and we perform enhanced thermal transport computations by evaluating the phonon Green's function via self-consistent diagrammatic perturbation theory. Our predicted phonon lifetimes at $T = 600$ K agree well with our inelastic neutron scattering measurements across the entire Brillouin zone, and our thermal conductivity predictions agree well with previous measurements. Both the changes due to thermal expansion and self-consistent contributions are nontrivial at high temperatures, though the effects tend to cancel, and interband transitions yield a substantial contribution.

Uranium dioxide (UO_2) has attracted a great deal of research interest since the 1950s, both as a standard nuclear fuel and as a fundamental system of rich physics induced by the partially filled f shell [1, 2]. As thermal transport is critical in nuclear fuels, phonon thermal transport in UO_2 has been extensively studied both by experiments [3–7] and from first-principles [8–14]. However, wide-ranging results were obtained from first-principles computations, and a robust consensus has not yet merged (see Sec. II in Supplemental Material (SM) [15] for a detailed discussion of the different approaches). While low-temperature thermal conductivity is substantially complicated by magnons, defects, and boundary effects, room temperature and beyond should be dominated by phonon thermal transport. However, accurately computing phonon interactions in UO_2 from first-principles is complicated due to the complex interplay of Mott physics, magnetic order, and spin-orbit coupling (SOC). Here we circumvent these technical challenges by employing f -orbital occupation matrix control (OMC) [16–19] and the $3\mathbf{k}$ antiferromagnetic (AFM) ground state obtained by our previous study [20], which provides a robust description of the ground state and phonons as compared to experiment.

Phonon thermal conductivity has been reliably computed in band insulators by solving the linearized phonon Peierls-Boltzmann transport equation (BTE) from first-principles using scattering rates computed within leading order perturbation theory [21–24]. This *de facto* standard approach for computing phonon thermal conductivity, as implemented by multiple publicly available software packages [25–28], solves the BTE using cubic phonon interactions and the imaginary part of the bare bubble diagram. Naturally, non-trivial inaccuracy will occur under extreme conditions (e.g., high temperatures) where perturbation theory is inadequate. More recently, quartic phonon interactions have been incorporated us-

ing the imaginary part of the sunset diagram [29, 30], and the contribution of interband phonon transitions has been addressed by a generalization of the BTE, known as the Wigner transport equation (WTE) [31, 32]. Here, we go beyond the current state of the art for computing thermal conductivity, which only uses the imaginary parts of the bubble and sunset diagrams, by using self-consistent diagrammatic perturbation theory to compute the single phonon Green's function [33].

In the present work, we use density functional theory plus U (DFT+ U) [34] to compute the cubic and quartic phonon interactions, which are then used to compute the inelastic neutron scattering (INS) function and thermal conductivity. Both the scattering function and the thermal conductivity are computed using increasingly sophisticated levels of theory, including bare perturbation theory and self-consistent perturbation theory [33]. For the latter, two different levels of self-consistency are employed: the Hartree-Fock (HF) approximation for phonons and quasiparticle perturbation (QP) theory. The former is the traditional variational approach of Hooton [35], where the four phonon loop diagram is evaluated self-consistently, and the latter self-consistently evaluates both the four phonon loop diagram and the real part of the three phonon bubble diagram [33]. Following Ref. [33], the self-consistency scheme and the subsequent diagrams evaluated to construct the phonon self-energy are indicated by the notation $S_{ijk...}^A$, where $A \in \{o, HF, QP\}$ labels the self-consistency scheme and i, j, k, \dots indicate all diagrams evaluated post self-consistency (see Figure 1 and S1 of Ref [33] for schematics of diagrams). The colloquial diagram names bubble, loop, and sunset are abbreviated as b , l , and s , respectively, while the self-consistency schemes o , HF , and QP correspond to the bare, Hartree-Fock, and quasiparticle Green's function, respectively. For example, the imaginary part of the phonon self-

FIG. 1. (a) The unfolded phonon dispersion at $T = 0$ K, computed using GGA+ U +SOC ($U = 4$ eV) in the $3\mathbf{k}$ AFM state. The hollow points were directly computed using DFT, while the corresponding curves are Fourier interpolations. The width of the line shading represents the FWHM computed at $T = 600$ K using S_b^o . (b) $S(\mathbf{Q}, \omega)$ at $\mathbf{Q} = [0.6, 0.6, 6.6]$ and $T = 600$ K, computed using S_b^o . For direct comparison, the INS instrumental energy resolution (ER) is accounted for in the solid curves [39]. The q -voxel dimensions used in both the measurement and computation are 0.075, 0.2, and 0.2 reciprocal lattice units (r.l.u.) along the $[L, L, L]$, $[0, 0, L]$, and $[-H, H, 0]$ directions, respectively.

energy used in the standard thermal conductivity approach [22] is obtained from S_b^o ; and the approach in Ref. [30], which employs quartic phonon interactions using the imaginary part of the sunset diagram, is obtained from S_{bs}^o . For each scheme we employ, both BTE and WTE are applied within the relaxation time approximation (RTA). For S_b^o , the full solution to the BTE is also obtained, yielding results very close to the RTA (see Sec. III of SM [15]), as is consistent with previous results for ThO_2 [36] and CaF_2 [36, 37]. To include the effects of the thermal expansion, the phonons and phonon interactions are computed at three expanded volumes, according to the experimental thermal expansion coefficients at $T = 360$, 600 , and 1000 K [38]. These computed results are linearly interpolated or extrapolated to temperatures from 0 to 1400 K.

Our DFT+ U calculations were carried out using the projector augmented-wave (PAW) method [40, 41], as implemented in the Vienna ab initio Simulation Package (VASP) code [42, 43]. The exchange correlation functional employed in our DFT+ U calculations was the

generalized gradient approximation (GGA) as formulated by Perdew, Burke, and Ernzerhof (PBE) [44], due to its overall better accuracy for phonons in UO_2 (see Sec. IX of SM [15]). We used the rotationally invariant DFT+ U approach of Dudarev *et al.* [45], which only employs a single effective interaction, and $U = 4$ eV was used throughout. SOC was included in all calculations. We customized the VASP code to initialize and monitor the occupation matrices during the calculations [20], and the initial values of the occupation matrices were taken from our previous work (i.e., \mathbb{S}_0) [20]. The cubic and quartic phonon interactions were calculated via the bundled irreducible derivative (BID) approach [46]. More information on the phonon interaction calculations, including supercell size, k -point mesh, and Born effective charges, is provided in Sec. III of SM [15]. Details of the thermal conductivity calculations are also provided in Sec. III of SM [15].

The scattering function $S(\mathbf{Q}, \omega)$ at $T = 600$ K was measured using the Angular Range Chopper Spectrometer (ARCS) with an incident neutron energy $E_i = 120$ meV and ARCS-100-1.5-AST Fermi chopper [47]. Further details of the UO_2 crystal and ARCS measurements have been reported previously [48]. The ARCS energy resolution functions [47] were used in fitting the phonon peaks, and the reported widths are the intrinsic full-width half-maximum (FWHM) values that have been corrected for the instrument contribution. The ARCS instrument measures a large volume in \mathbf{Q} and \mathbf{E} , which contains many Brillouin zones, and the data analysis allows for an adjustable size of q -voxel, a finite volume in reciprocal space associated with some q -point, in all crystallographic directions. The q -voxel size is normally chosen to be as small as possible, with the minimum being dictated by having sufficient counting statistics, and the resulting scattering function is normally inherently broadened due to this issue [36]. To make a meaningful comparison against experiment, the usage of the experimental q -voxel must be accounted for within theory. Details of the computation are reported in Ref. [36], and the q -voxel information is included in Sec. V of SM [15].

We begin by considering the INS scattering function, which was measured at $T = 600$ K. The scattering function can be decomposed into components from n -phonon contributions, and the dominant peaks in the spectra arise from the one phonon contributions. The one phonon scattering function can be obtained from the phonon self-energy, which can be computed using standard tools from many-body physics [36]. Given that $T = 600$ K is still a modest temperature, we will demonstrate that the bare bubble and loop diagrams are still sufficient to reasonably capture the INS scattering function peak width.

We begin by plotting the phonon linewidths computed using S_b^o , which are overlaid on the phonon dispersion (see Fig. 1 (a)). The branch naming convention follows Ref. [49]. Generally, the acoustic branches have a much smaller FWHM than the optical branches, as is expected. For the INS scattering function, we first consider

FIG. 2. FWHMs of the $S(\mathbf{Q}, \omega)$ peaks as a function of \mathbf{q} in various zones for UO_2 at $T = 600$ K. The S_{lb}^0 q -point and q -voxel results are shown as blue and red curves, respectively. INS results are shown as black points.

the particular example of $\mathbf{Q} = [0.6, 0.6, 6.6]$, where we individually illustrate the effects of the q -voxel and energy resolution (see Fig. 1 (b)). The peak at approximately 12 meV corresponds to the TA mode, whereas the LA mode at approximately 20 meV is barely observable due to the weighting factors in the scattering function. Clearly, both the q -voxel and energy resolution must be considered to make a meaningful comparison with INS measurements. The favorable agreement suggests that the level of theory we are using is robust, but a detailed comparison across the entire Brillouin zone is still needed.

We now proceed to comprehensively compare the computational and experimental results for the FWHMs of the scattering function peaks across the Brillouin zone (see Fig. 2). Following standard INS conventions, the energy resolution is removed from the peak width, and the theoretical results are presented for both the q -point and the q -voxel that was used in INS. Overall, there is favorable agreement across all modes and q -paths, indicating that the cubic phonon interactions computed using DFT+ U and the bubble diagram used to evaluate the self-energy are sufficient to describe experiment at $T = 600$ K. We reevaluated Fig. 2 using S_{lb}^{HF} and S_{lb}^{QP} , while accounting for thermal expansion, and the net changes are found to be modest at $T = 600$ K (see Sec. VIII in SM [15]).

The thermal conductivity will first be explored at up to $T = 1400$ K using bare perturbation theory (see Fig. 3(a)), where the imaginary parts of the bubble and sunset diagrams will be considered. Recall that we are not

accounting for magnons, defects, or boundary effects, and thus our results will not describe experiment below $T \approx 400$ K. The S_b^0 BTE results using the imaginary part of the bubble diagram are reasonable above $T = 400$ K as compared to experiment [4–7]. This favorable agreement is anticipated from our preceding favorable comparison with INS. However, the result systematically underpredicts experiment at high temperatures, and therefore it is compelling to include the quartic phonon interactions. We begin by using the imaginary parts of both the bare bubble and sunset diagrams (S_{bs}^0), where the latter purely uses quartic interactions, and the result is pushed further away from experiment by a small amount. This same effect was previously observed in Ref. [14] (see SM [15], Fig. S1), though the value of their results are strongly underpredicted relative to our own (see Sec. II in SM [15]). Interestingly, above room temperature, roughly 30% of the thermal conductivity arises from phonon modes with energies above 26 meV, which are predominantly optical modes, and therefore the optical modes do play a nontrivial role in thermal transport (see Sec. VI in SM [15]). We proceed by including interband phonon contributions via the WTE, which increases the thermal conductivity monotonically with temperature, yielding good agreement with experiment. At $T = 1400$ K, the interband portion contributes about 30% of the total thermal conductivity, which is non-trivial.

While the current approximation yields reasonable agreement with experiment, it is important to use a logically consistent approach where the real portion of the self-energy is not discarded and the effects of thermal expansion are included (see Fig. 3(b)). When thermal expansion is included in the thermal conductivity calculation, a non-trivial decrease in thermal conductivity is observed: at $T = 1400$ K, the decrease of the S_{bs}^0 BTE result due to thermal expansion is nearly 50%. This strong decrease may explain the relatively low predicted thermal conductivity in Ref. [49], which used S_b^0 BTE and included thermal expansion. While the interband contribution contained in the S_{bs}^0 WTE result increases the predicted value, the thermal conductivity is still underpredicted as compared to experiment. However, it is still necessary to account for the real part of the phonon self-energy, and explore the possibility of accounting for higher order diagrams via self-consistent perturbation theory [33].

Nominally, we would expect the QP result to be better than HF as it sums additional diagrams which are known to be relevant [33]. We first consider S_{bs}^{HF} WTE, which notably increases the thermal conductivity at high temperatures. This result is anticipated, given that the HF approximation nominally increases the effective harmonic frequencies, decreasing the phonon lifetime contribution from the bubble. The S_{bs}^{QP} WTE result is shifted downwards from the HF result, slightly above the bare perturbation theory result using the bubble and sunset diagrams. The underestimation of the experimental thermal conductivity by S_{bs}^{QP} might be accounted for by including

FIG. 3. Thermal conductivity computed using GGA+*U*+SOC (*U* = 4 eV) and comparing with experiments [4–7]. Panel (a) presents the bare perturbation theory results without including thermal expansion. Panel (b) presents the results with thermal expansion and self-consistent perturbation theory.

more diagrams, possibly requiring diagrams with phonon interactions beyond fourth order. Ideally, one would sum all possible diagrams and obtain the exact phonon self-energy, which can be done in the classical limit using molecular dynamics [33]. Another possibility for the discrepancy is that the PBE exchange correlation functional is not sufficiently describing the phonon interactions.

In summary, we have computed the scattering function and thermal conductivity of UO₂ from first-principles using various levels of self-consistent perturbation theory and compared to our own INS experiments and existing thermal conductivity experiments. The relevant contributions of this work include accurately describing the phonon interactions in UO₂ from first principles and illustrating the effects of improving the quality of the single particle phonon Green's function on the thermal conductivity. Favorable agreement between our theory and INS experiment is obtained for the FWHM of the scattering function across the Brillouin zone. In terms of quantitatively computing the thermal conductivity at high temperatures, we find that thermal expansion decreases the thermal conductivity while interband transitions increases the thermal conductivity, and these effects are of similar magnitude. Including quartic phonon interactions at the level of the bare sunset diagram causes

a small decrease in thermal conductivity, while the self-consistent perturbation theory yielded moderate and appreciable increases for the quasiparticle and Hartree-Fock procedures, respectively. Aside from low temperatures where magnons and defects play important roles, phonon thermal transport in UO₂ is now well characterized from first-principles.

This work is supported by the Center for Thermal Energy Transport under Irradiation, an Energy Frontier Research Center funded by the U.S. Department of Energy (DOE) Office of Basic Energy Sciences. This research used resources at the Spallation Neutron Source, a DOE Office of Science User Facility operated by the ORNL. This research made use of Idaho National Laboratory computing resources, which are supported by the DOE Office of Nuclear Energy and the Nuclear Science User Facilities under contract no. DE-AC07-05ID14517. This research also used resources of the National Energy Research Scientific Computing Center, a DOE Office of Science User Facility supported by the Office of Science of the U.S. Department of Energy under Contract No. DE-AC02-05CH11231. The unfolding of phonons and phonon interactions was supported by grant DE-SC0016507 funded by the U.S. Department of Energy, Office of Science.

I. LISTS OF ABBREVIATIONS AND LABELS

TABLE S1: List of abbreviations in this work.

Abbreviation	Definition
AFM	antiferromagnetic
ARCS	the Angular Range Chopper Spectrometer
BID	the bundled irreducible derivative approach
BTE	the linearized phonon Peierls-Boltzmann transport equation
DFT	density functional theory
ER	energy resolution
FWHM	full-width half-maximum
GGA	the generalized gradient approximation
HF	the Hartree-Fock approximation
INS	the inelastic neutron scattering
OMC	occupation matrix control
PAW	the projector augmented-wave method
PBE	GGA as formulated by Perdew, Burke, and Ernzerhof
QP	quasiparticle perturbation theory
RTA	the relaxation time approximation
SM	supplemental material
SOC	spin-orbit coupling
VASP	the Vienna ab initio Simulation Package code
WTE	the Wigner transport equation

TABLE S2: List of labels in this work.

Labels	Definition
E	energy
$\mathcal{S}_{ijk\dots}^A$	the self-consistent perturbation theory scheme, where $A \in \{o, HF, QP\}$ labels the self-consistency scheme and i, j, k, \dots indicate all diagrams evaluated post self-consistency. The colloquial diagram names bubble, loop, and sunset are abbreviated as b , l , and s , respectively, while the self-consistency schemes o , HF , and QP correspond to the bare, Hartree-Fock, and quasiparticle Green's function, respectively.
$S(\mathbf{Q}, \omega)$	the scattering function, where \mathbf{Q} is the reciprocal lattice vector, and ω is the angular frequency.
$\hat{\mathbf{S}}_{BZ}$	the invertible matrix of integers which yields the supercell
T	temperature
U	the U value in DFT+ U approximation

II. PREVIOUS DFT+U STUDIES ON THERMAL CONDUCTIVITY OF UO₂

Extensive DFT+U studies have computed the thermal conductivity of UO₂, covering various exchange correlation functionals, including LDA+U [1, 2], PBE+U [3–5], and PBEsol+U [6, 7]. The phonon interactions are computed at different orders as well: Ref. [1, 2, 4] only computed the Gruneisen parameters, while all other studies computed the cubic phonon interactions. Additionally, Ref. [3] includes the thermal expansion using the quansiharmonic method, and Ref. [5] computed the quartic phonon interactions. From all the aforementioned studies, the computed thermal conductivity results are collected in Fig. S1. Note that we only present results that are directly comparable to our own (e.g. results with boundary effects are excluded, etc). Clearly, there are wide ranging results among the existing data in the literature.

FIG. S1. Thermal conductivity of UO₂ in previous DFT+U studies [1–7], comparing with experiments [8–11].

Given that phonon interactions are not normally tabulated in publications, and are not provided in the aforementioned publications, it is not possible to directly scrutinize them. However, we can assess the phonon frequencies, which are far more straightforward to compute. The phonons computed by the aforementioned studies are collected and compared with experiment (see Fig. S2) (note that Ref. [2]’s phonons are provided by Ref. [12]), with the exception of Ref. [5, 6]. Ref. [6] only provides folded phonon dispersion in a supercell, and Ref. [5] does not provide phonon dispersion calculated by DFT+U. All other studies provide phonon dispersion calculated by DFT+U at zero temperature, except Ref. [3] which computes the phonons at the volume corresponding to $T = 295$ K. Multiple nontrivial anomalies can be identified, such as the inversion of the acoustic modes between Γ and L [1, 3], the overestimation of the LO1 and TO1 branches [1, 3, 7], the breaking of cubic symmetry [1, 4], and large oscillations in the highest optical branch [3, 12]. Given these nontrivial discrepancies in the phonon frequencies, it would not be unexpected to find corresponding discrepancies in the phonon interactions.

FIG. S2. Phonon dispersion of UO_2 in previous DFT+ U studies [1, 3, 4, 7, 12], comparing with experiments [3, 13].

III. COMPUTATIONAL DETAILS AND CONVERGENCE OF THERMAL CONDUCTIVITY

In DFT calculations, a plane-wave cutoff energy of 550 eV was used, and the energy convergence criterion was 10^{-6} eV. The phonons were calculated in our previous work [13], while in this work we increased the supercell size (see Sec. III of the Supplemental Materials). The cubic and quartic irreducible derivatives were computed at six finite displacement amplitudes which were then used to construct quadratic error tails, ensuring that the discretization error was properly extrapolated to zero. Above the Néel temperature T_N , the space group of UO_2 is $Fm\bar{3}m$ and the point group symmetry of the uranium site is O_h . The face-centered cubic lattice vectors are encoded in a 3×3 row stacked matrix $\hat{\mathbf{a}} = \frac{a_0}{2}(\hat{\mathbf{J}} - \hat{\mathbf{1}})$, where $\hat{\mathbf{1}}$ is the identity matrix and $\hat{\mathbf{J}}$ is a matrix in which each element is 1. The Brillouin zone is discretized using a real space supercell $\hat{\mathbf{S}}_{BZ}\hat{\mathbf{a}}$, where $\hat{\mathbf{S}}_{BZ}$ is an invertible matrix of integers which produces superlattice vectors that satisfy the point group [14]. Below T_N , the $3\mathbf{k}$ AFM ordering breaks the symmetry of the $Fm\bar{3}m$ space group, and has a primitive cell of $\hat{\mathbf{S}}_C\hat{\mathbf{a}}$, where $\hat{\mathbf{S}}_C$ generates the conventional cubic cell (multiplicity of 4) and is defined as $\hat{\mathbf{S}}_C = \hat{\mathbf{J}} - 2\hat{\mathbf{1}}$. When computing third order irreducible derivatives (ID), we use the supercell $\hat{\mathbf{S}}_O\hat{\mathbf{a}}$ and extract all third order IDs consistent with the supercell, where $\hat{\mathbf{S}}_O = \hat{\mathbf{S}}_C\hat{\mathbf{S}}_C = 4\hat{\mathbf{1}} - \hat{\mathbf{J}}$. The supercell $\hat{\mathbf{S}}_O\hat{\mathbf{a}}$ has a multiplicity of 16 (48 atoms). When computing fourth order IDs, we use the primitive cell $\hat{\mathbf{S}}_C\hat{\mathbf{a}}$ and extract all fourth order IDs consistent with the primitive cell. For a $3\mathbf{k}$ AFM calculation with a primitive cell $\hat{\mathbf{S}}_C\hat{\mathbf{a}}$, a $12\hat{\mathbf{1}}$ Γ -centered k -point mesh was applied; for larger supercell calculations, the k -point density was approximately held constant. In order to compare with the INS scattering function, we unfold the $3\mathbf{k}$ AFM IDs back to the original primitive unit cell $\hat{\mathbf{a}}$, averaging any translational symmetry breaking due to the antiferromagnetism. The Born effective charges ($Z_U^* = 5.54$ and $Z_O^* = -2.77$) of the U and O ions and the dielectric constant ($\epsilon = 5.69$) were used to account for LO-TO splitting [15, 16].

We test the convergence of thermal conductivity calculations by varying the interpolation grid from $6\hat{\mathbf{1}}$ to $12\hat{\mathbf{1}}$ in BTE calculations (see Fig. S3). Both \mathcal{S}_b^o and \mathcal{S}_s^o results are approximately converged using $12\hat{\mathbf{1}}$ interpolation grid, which is used in all calculations in the main manuscript. The linearized Boltzmann transport equation (BTE) is also solved for \mathcal{S}_b^o , and yields approximately identical results to the RTA with different interpolation grids (see Fig. S4).

FIG. S3. Calculated thermal conductivity using GGA+U+SOC, \mathcal{S}_b^o or \mathcal{S}_s^o with BTE (RTA), and different interpolation grids, comparing with experiments [8–11].

FIG. S4. Calculated thermal conductivity using GGA+U+SOC, S_b^o , and different interpolation grids. Blue and red curves present BTE (RTA) and BTE (full solution) results, respectively.

IV. PHONON DISPERSION CALCULATIONS

The computational details of phonon dispersion calculations were already reported in our previous work [13], and in this work we increased the supercell from $\hat{\mathbf{S}}_{BZ} = 2\hat{\mathbf{S}}_C$ to $\hat{\mathbf{S}}_{BZ} = 4\hat{\mathbf{1}}$ (see Fig. S5 for a comparison). When $\hat{\mathbf{S}}_{BZ} = 4\hat{\mathbf{1}}$, the q -point $(0.25, 0.25, 0.25)$ is directly computed. The good agreement between $\hat{\mathbf{S}}_{BZ} = 2\hat{\mathbf{S}}_C$ and $\hat{\mathbf{S}}_{BZ} = 4\hat{\mathbf{1}}$ means the supercell size is sufficient to converge the phonon dispersion.

FIG. S5. Unfolded phonons of $3\mathbf{k}$ AFM UO_2 computed by GGA+ U +SOC ($U = 4$ eV) (lines), compared with inelastic neutron scattering data from Ref. [3] at $T = 300$ K (grey squares) and Ref. [13] at $T = 600$ K (black triangles). Lines with different colors represent interpolations from different supercells $\hat{\mathbf{S}}_{BZ}$. The hollow points were directly computed using DFT+ U , while the corresponding lines are Fourier interpolations.

V. q -VOXEL DIMENSION INFORMATION

The q -voxel dimensions used in Fig. 3 in main text are listed in Tables S3, S4, and S5. In all of the aforementioned tables, the first column specifies the phonon branch; the second column specifies a line segment in reciprocal space; the third, fourth, and fifth columns specify the three voxel dimensions in reciprocal lattice units.

(001) direction	path	$\Delta_{[0,0,L]}$	$\Delta_{[H,H,0]}$	$\Delta_{[\bar{H},H,0]}$

VI. THE SPECTRAL AND CUMULATIVE THERMAL CONDUCTIVITY IN BTE CALCULATIONS

In this section, we report the calculated spectral and cumulative thermal conductivity as functions of phonon energy at $T = 300$ K, 600 K, and 1200 K in S_{bs}^o BTE calculations, shown in Fig. S6. At all three temperatures, roughly 70% of thermal conductivity arises from phonon modes with energies below 24 meV, and therefore the optical modes do play a nontrivial role in thermal transport. Our GGA+ U +SOC phonon dispersion has very good agreement with experiment [13], except for a small offset in the highest optical phonon branch, but Fig. S6 indicates that this branch has a negligible influence on the thermal conductivity.

FIG. S6. Spectral and cumulative thermal conductivity of UO_2 as a function of phonon energy, computed using GGA+ U +SOC ($U = 4$ eV) at $T = 300$, 600, and 1200 K in S_{bs}^o BTE calculations.

VII. COMPARISON BETWEEN BARE AND SELF-CONSISTENT PERTURBATION THEORY

Here the calculated thermal conductivity using self-consistent perturbation theory, HF and QP, is analyzed separately for the bubble diagram and the bubble plus the sunset diagram. Note that for S_b^{HF} and S_b^{QP} , the quartic phonon interactions still have a contribution due to the fact that the self-consistent Green's function is evaluated using the loop diagram. The effect of thermal expansion is not included in this section.

FIG. S7. Thermal conductivity, computed using GGA+U+SOC ($U = 4$ eV) within (a) bare perturbation theory, (b) HF self-consistent perturbation theory, and (c) QP self-consistent perturbation theory, and comparing with experiments [8–11]. Thermal expansion is not included.

VIII. THE EFFECT OF THERMAL EXPANSION ON THERMAL CONDUCTIVITY

To address the effect of thermal expansion on thermal conductivity of UO_2 , the irreducible derivatives are computed at four different cell volumes, where the lattice parameters $a = 5.5461, 5.5602, 5.5717$, and 5.5942\AA are used, corresponding to the experimental percentage change in the lattice parameter at $T = 0, 360, 600$, and 1000 K [17], respectively. These computed results are linearly interpolated or extrapolated to temperatures from 0 to 1400 K .

We first present the phonon linewidth at $T = 600\text{ K}$, and compare with INS experiment (see Fig S8 for S_{lb}^o , Fig S9 for S_{lb}^{HF} , and Fig S10 for S_{lb}^{QP} results). The differences between bare and self-consistent perturbation theory are modest. Finally, the thermal conductivity is calculated using bare perturbation theory and self-consistent perturbation theory (see Fig S11). While the thermal conductivity increase due to interband transition and the decrease due to thermal expansion are both non-trivial, they tend to cancel, thus combining both effects only slightly decrease the thermal conductivity in UO_2 .

FIG. S8. FWHMs of the $S(\mathbf{Q}, \omega)$ peaks as a function of q in various zones for UO_2 at $T = 600\text{ K}$. Thermal expansion is included when computing the irreducible derivatives. The S_{lb}^o q -point and q -voxel results are shown as blue and red curves, respectively. INS results are shown as black points.

FIG. S9. FWHMs of the $S(\mathbf{Q}, \omega)$ peaks as a function of q in various zones for UO_2 at $T = 600$ K. Thermal expansion is included when computing the irreducible derivatives. The S_{lb}^{HF} q -point and q -voxel results are shown as blue and red curves, respectively. INS results are shown as black points.

FIG. S10. FWHMs of the $S(\mathbf{Q}, \omega)$ peaks as a function of q in various zones for UO_2 at $T = 600$ K. Thermal expansion is included when computing the irreducible derivatives. The S_{ib}^{QP} q -point and q -voxel results are shown as blue and red curves, respectively. INS results are shown as black points.

FIG. S11. Thermal conductivity, computed using GGA+ U +SOC ($U = 4$ eV) within (a) bare perturbation theory, (b) HF self-consistent perturbation theory, and (c) QP self-consistent perturbation theory, and comparing with experiments [8–11]. Thermal expansion is included when computing the irreducible derivatives.

IX. ENERGY, STRUCTURE, AND PHONON CALCULATIONS USING PBESOL

In our previous work [13], we presented the results of energy difference between different magnetic ordering, in addition to the lattice parameter, oxygen cage distortion, and phonon dispersion in $3\mathbf{k}$ AFM state, using both PBE+ U and LDA+ U . Recent studies [6, 7] reported that PBESol+ U predicts a more accurate lattice parameter than PBE+ U or LDA+ U . Therefore, we performed PBESol+ U +SOC calculations for aforementioned energetic, structural, and phonon properties, and made a comparison with PBE+ U +SOC and LDA+ U +SOC.

We first compare the energies of $1\mathbf{k}$ AFM and $3\mathbf{k}$ AFM states using PBESol+ U +SOC calculation. The occupation matrix \mathbb{S}_0 , computed by PBE [13], is used to initialize the PBESol calculation. Unsurprisingly, during PBESol calculations, the resulting occupation matrix only slightly changes from the initial value. The energy differences between $1\mathbf{k}$ AFM and $3\mathbf{k}$ AFM ordering are computed using $U = 2 - 5$ eV (see Fig. S12). In PBESol+ U , the $3\mathbf{k}$ AFM state has the lowest energy when $U < 3.6$ eV, and the $1\mathbf{k}$ AFM state has the lowest energy when $U > 3.6$ eV. At $U = 4$ eV, the $1\mathbf{k}$ AFM and the $3\mathbf{k}$ AFM state are essentially degenerate, as the energy difference is only 1 meV.

FIG. S12. Calculated energy difference of UO_2 for FM and $1\mathbf{k}$ AFM relative to $3\mathbf{k}$ AFM using LDA+ U , PBE+ U , and PBESol+ U with SOC, as a function of the Hubbard U .

Additionally, the lattice parameter and oxygen cage distortion are computed in the $3\mathbf{k}$ AFM state (see Fig. S13). Generally, the predictions of the lattice parameter and oxygen cage distortion from PBESol are very close to LDA and PBE. For the lattice parameter, PBESol's prediction is between PBE and LDA, and $U = 3$ eV gives excellent agreement with experiment. The oxygen cage distortion of PBESol is slightly larger than both LDA and PBE for $U = 4 - 5$ eV, and $U = 5$ eV gives favorable agreement with experiment. Finally, the phonon dispersion is computed in the $3\mathbf{k}$ AFM state using $U = 4$ eV and $\hat{\mathbf{S}}_{BZ} = 2\hat{\mathbf{S}}_C$ (see Fig. S14). The phonons computed by PBESol are also between PBE and LDA phonons, mainly due to the different cell volume. For acoustic branches, LDA, PBE, and PBESol have close predictions, however, for optical branches, PBE still has the overall best agreements except the highest optical branch. Therefore, we consider PBE to have the overall best description of the phonons for UO_2 , and all results in the main text are computed using PBE.

FIG. S13. Calculated (a) lattice parameter and (b) $\langle 111 \rangle$ oxygen cage distortion in the $3\mathbf{k}$ AFM state, using LDA+ U +SOC, PBE+ U +SOC, and PBEsol+ U +SOC, as a function of the Hubbard U . The horizontal dashed lines represent the experimental values of the lattice parameter from Ref. [18] and the distortion from Ref. [19].

FIG. S14. Phonons of $3\mathbf{k}$ AFM UO_2 . (a) The unfolded phonon dispersion curves and (b) density of states of LDA+ U +SOC, PBE+ U +SOC, and PBEsol+ U +SOC ($U = 4$ eV) (solid lines), compared with inelastic neutron scattering data from Ref. [3] at $T = 300$ K (grey squares), Ref. [13] at $T = 600$ K (black triangles), Ref. [13] at $T = 77$ K (dashed black curves), and Ref. [20] at $T = 10$ K (dashed green curves). The hollow points were directly computed using DFT+ U , while the corresponding lines are Fourier interpolations.

X. PHONON THERMAL CONDUCTIVITY CALCULATIONS USING GGA ($U = 0$)

It is interesting to explore the thermal conductivity using GGA (i.e., $U = 0$) in the FM state, despite the fact that it is incorrectly predicted to be a metal (though we still apply LO-TO splitting). In the Supplemental Materials of our previous work [13], the phonon dispersion computed by GGA using $\hat{\mathbf{S}}_{BZ} = 2\hat{\mathbf{1}}$ is reported. Here the supercell is increased to $\hat{\mathbf{S}}_{BZ} = 4\hat{\mathbf{1}}$ (see Fig. S15). Notably, comparing with experiments, the highest acoustic phonon branch is slightly underestimated, and the highest optical branch is largely underestimated and has large oscillations. These anomalies clearly show that $U = 0$ is not adequate to accurately capture the phonons of UO_2 .

FIG. S15. Phonon dispersion of FM UO_2 , calculated by GGA (i.e., $U = 0$ without SOC), compared with inelastic neutron scattering data from Ref. [3] at $T = 300$ K (grey squares) and Ref. [13] at $T = 600$ K (black triangles). The hollow points were directly computed using DFT, while the corresponding lines are Fourier interpolations.

The third order IDs are computed using supercell $\hat{\mathbf{S}}_{BZ} = \hat{\mathbf{S}}_O$, and the thermal conductivity is computed using the RTA with \mathcal{S}_b^o . Surprisingly, the thermal conductivity computed by GGA is very close to GGA+ U (see Fig. S16). However, a significant difference between GGA and GGA+ U is observed in both the spectral and cumulative thermal conductivity at $T = 300$ K (see Fig. S17). For both \mathcal{S}_b^o and \mathcal{S}_{bs}^o with GGA+ U , the optical phonons have a substantial contribution, quantified by phonon energies greater than 24 meV, accounting for $\sim 30\%$ of the total thermal conductivity, while the corresponding contribution is $\sim 50\%$ in GGA. Though the prediction of thermal conductivity using GGA at first seems accurate, it is achieved due to cancelling errors, rather than accurate descriptions of phonons and phonon interactions.

FIG. S16. Thermal conductivity of UO_2 , computed using GGA+ U +SOC ($U = 4$ eV) and GGA ($U = 0$ without SOC), and comparing with experiments [8–11].

FIG. S17. Spectral and cumulative thermal conductivity of UO_2 as functions of phonon energy at $T = 300\text{K}$, computed using GGA+ U +SOC ($U = 4$ eV) and GGA ($U = 0$ without SOC).

XI. THERMAL CONDUCTIVITY CONTRIBUTION OF ELECTRONS AND PHOTONS

In experiments above room temperature, thermal conductivity of UO_2 decreases with increasing temperature until around $T = 2000\text{K}$, then increases until the melting temperature [8]. As phonon thermal conductivity due to phonon-phonon interactions normally only decreases with increasing temperature, the increasing thermal conductivity at high temperature must be produced by other mechanisms. The potentially observable contributions from photon and electron (i.e., polaron, a thermally activated quasiparticle) are suggested [21]. Semi-classical models have been applied to the thermal conductivity of UO_2 , accounting for contributions of polarons [22–24] and photons [23], and their results are collected (see Fig. S18). The total thermal conductivity is presented by Ref. [8], fitting to experiments. Above $T = 2000\text{ K}$, Ref. [22, 24] claim the polaron contribution is significant, meanwhile [23] claims the photon contribution is critical. A common understanding has not yet emerged, and modeling beyond the semi-classical theory level is still lacking.

FIG. S18. Modeled electron and photon thermal conductivity in UO_2 by Ref. [22–24], comparing to fitted total thermal conductivity by Ref. [8]

XII. COMPUTED IRREDUCIBLE DERIVATIVES

This section contains all computed irreducible derivatives, and all information required to specify the irreducible derivatives.
