Manydepth2: Motion-Aware Self-Supervised Monocular Depth Estimation in Dynamic Scenes with Attention

Kaichen Zhou¹, Jia-Wang Bian¹, Jian-Qing Zheng¹, Jiaxing Zhong¹, Qian Xie¹, Niki Trigoni¹, Andrew Markham¹

Abstract—Despite advancements in self-supervised monocular depth estimation, challenges persist in dynamic scenarios due to the dependence on assumptions about a static world. In this paper, we present Manydepth2, to achieve precise depth estimation for both dynamic objects and static backgrounds, all while maintaining computational efficiency. To tackle the challenges posed by dynamic content, we incorporate optical flow and coarse monocular depth to create a pseudo-static reference frame. This frame is then utilized to build a motionaware cost volume in collaboration with the vanilla target frame. Furthermore, to improve the accuracy and robustness of the network architecture, we propose an attentionbased depth network that effectively integrates information from feature maps at different resolutions by incorporating both channel and non-local attention mechanisms. Compared to methods with similar computational costs, Manydepth2 achieves a significant reduction of approximately five percent in root-mean-square error for self-supervised monocular depth estimation on the KITTI-2015 dataset. The code could found https://github.com/kaichen-z/Manydepth2.

Index Terms-Monocular Depth Estimation, Self-Supervised.

I. INTRODUCTION

The role of vision-based depth estimation (VDE) has become increasingly important in computer vision due to its ability to understand the 3D geometry of a scene based on 2D observation, which serves as the foundation for various high-level 3D tasks, such as scene reconstruction [1], object detection [2] and navigation [3]. Moreover, VDE has enabled state-of-the-art applications ranging from autonomous driving [4] to augmented reality [4], [5].

Recently, self-supervised depth estimation has emerged as a viable approach for training depth estimation methods, aiming to alleviate the dependency on extensive training data and reduce high computational demands. These methods learn depth maps from either monocular images [6] or stereo image pairs [7]. Despite the significant advancements made in self-supervised monocular vision-based depth estimation, a notable performance gap persists when comparing selfsupervised monocular VDEs to self-supervised stereo VDEs. The disparity in performance can be mainly ascribed to the capability of stereo methods to utilize multiple views for constructing a feature volume, thereby incorporating a greater amount of 3D camera frustum information. While multi-frame monocular VDEs, as presented in [8], have the ability to construct a feature volume based on adjacent frames, the presence of dynamic elements in these adjacent frames can potentially disrupt the construction of the feature volume.

Fig. 1: **Qualitative comparison on Cityscapes.** The first row presents the RGB images. The second row shows the error maps of the depth estimates produced by ManyDepth. The third row displays the error maps of the depth estimates generated by Manydepth2.

Taking the aforementioned concern into account, this paper strives to enhance the performance of multi-frame monocular VDEs by integrating motion information during the inference process and adeptly managing the influence of dynamic objects in the construction of the cost volume. Experimental results indicate that our method could effectively handle dynamic objects, as demonstrated in Fig. 1.

Specifically, in light of recent advancements in optical flow estimation and its successful application in motion detection and estimation tasks, we propose Manydepth2. Manydepth2 is a self-supervised monocular vision-based depth estimation system that leverages motion information through a motionaware cost volume constructed with an attention mechanism. The attention mechanism is chosen due to its demonstrated outstanding performance in representation learning and effective fusion of diverse information. Our main contributions are summarized as follows:

- We utilize estimated optical flow alongside prior depth information to generate a pseudo-static reference frame. This reference frame effectively neutralizes the influence of dynamic elements within the original frame.
- By incorporating the pseudo-static reference frame, the target frame, and the initial reference frame, we construct a novel motion-aware volume that captures the dynamics of moving objects.
- Building on the High-Resolution Network (HRNet),

Fig. 2: Illustration for the structure of Manydepth2. During Stage 1, target and reference frame I_t and I_r are processed Flow Net, Pose Net, and Depth Net to generate optical flow $f_{r\leftarrow t}$, transformation matrix $[\mathbf{R}|\mathbf{t}]_{rt}$, and coarse depth D_t^c . During Stage 2, the outputs are used to generate the motion-aware cost volume \mathcal{V}_m . Finally, the motion-aware cost volume \mathcal{V}_m and the target frame I_t are used by Attention-Based Depth Net to produce the refined depth D_t .

we propose a novel depth estimation architecture that combines non-local and channel attention, enabling the integration of multi-scale features for accurate pixelwise dense predictions.

• Our proposed model outperforms existing single and multi-frame methods on the KITTI, Cityscapes, and Odometry datasets. Additionally, our model can be trained efficiently using only a single NVIDIA RTX 3090 graphics card within a reasonable timeframe.

II. RELATED WORKS

A. Monocular Depth Estimation

Self-supervised techniques for monocular depth prediction have gained notable traction due to their independence from labeled data and their versatility across various scenarios. Broadly, monocular VDEs fall into two categories: one relies on the present frame for depth estimation, while the other employs multiple frames to achieve depth prediction. Singleframe Monocular Depth Estimation: Within the realm of depth estimation methodologies, the initial category has witnessed the emergence of notable frameworks that have set benchmarks in terms of reliability and performance. A prime example from this category is Monodepth, as highlighted in the study by [9]. This model distinguishes itself with a bifurcated network architecture: one part is dedicated explicitly to pose estimation, while another part focuses on depth estimation tasks. A pivotal aspect of the Monodepth architecture lies in the collaborative synergy between these two networks. They operate by leveraging the warping connection intrinsic to depth and image transformations. This collaboration results in creating a photometric loss function, which is a key part of why it works so well. Further elevating the landscape of depth estimation methodologies, DevNet, in [10], takes a comprehensive approach by embedding 3D geometric consistency. Multi-frame Monocular Depth Estimation: The premise of the second category rests on the notion that integrating temporal information during inference-by employing multiple neighboring frames as

inputs-can enhance the accuracy of the final depth estimation. Initially, this is accomplished by employing testtime refinement techniques [11], along with recurrent neural networks (RNNs) as evidenced in studies like [12]. The test-time refinement method adopts a monocular strategy to leverage temporal data during testing, whereas the recurrent neural network integrates with a monocular depth estimation network to analyze continuous frame sequences. Nonetheless, models utilizing recurrent neural networks often entail high computational costs and lack a distinct geometric inference approach. Recently, Manydepth [8] and MonoRec [13] have made notable advancements in performance and real-time efficiency by incorporating cost volumes from stereo-matching tasks for geometric-based reasoning [14]. These models rely on a photometric loss function, where temporally neighboring frames are mapped onto the current image plane using predetermined depth bins. Within the cost volume framework, the inferred depth with the minimal value corresponds closely to the actual depth. Nevertheless, these approaches are grounded in static assumptions regarding scenarios and struggle with dynamic foreground elements. To tackle this limitation, we introduce Manydepth2, a technique adept at managing dynamic foreground by integrating temporal data into the cost volume and implementing a motionaware photometric loss function.

B. Self-supervised VDE for Dynamic Objects

Owing to the unique attributes of dynamic objects, there has been a focused effort among researchers to handle these objects distinctively throughout both the training and inference stages within self-supervised vision-based depth estimation (VDE) techniques. In [15], a deliberate decision was made to exclude dynamic objects from the analysis. This exclusion was aimed at preventing any potential interference with the optimization process, thereby ensuring the precision and accuracy of the depth estimation results. On the other hand, in [16], a more nuanced approach was adopted. Dynamic objects were first identified and segmented from the scene. Subsequent to this segmentation, these objects were treated distinctively within the framework of the photometric loss function. Such a strategy facilitates the integration of dynamic objects into the depth learning mechanism, ensuring that they contribute meaningfully without merely being sidelined or excluded. Furthermore, recent research efforts, as seen in [17], have ventured into predicting motion information at the object level. This predictive capability is then harnessed to establish more refined constraints, thereby enhancing the efficacy of self-supervised depth learning methodologies. Despite these advancements, it's noteworthy that many of these approaches either grapple with intensive computational requirements or demonstrate only marginal enhancements in performance metrics. Recognizing these challenges, our novel approach, termed Manydepth2, seeks to overcome these constraints. We introduce a motion-aware cost volume framework that seamlessly integrates forecasted optical flow insights, all achieved through a sophisticated attention mechanism.

III. METHODOLOGY

A. Overview

Firstly, as a foundational step, we utilize the potential of both optical flow information and pre-training depth data. By combining these insights, we construct a pseudostatic reference frame. This innovative approach ensures that the depth estimation process remains robust and relevant, even when confronted with dynamic elements within the scene. Our methodology further integrates the pseudo-static reference frame alongside the original target frame and vanilla reference frame to create a carefully designed motionaware cost volume. This volume could improve the depth estimation by considering the detailed movement and space relationships in the scene. Finally, We are introducing a depth net structure that utilizes attention mechanisms for processing cost volume. This structure is meticulously crafted to effectively combine feature maps that come from different resolutions, all originating from a high-resolution network.

B. Framework

Our objective is to estimate the depth map D_t and the rigid transformation $[\mathbf{R}|\mathbf{t}]_{rt}$ between the target frame I_t and a reference frame I_r . To create the constraint for self-supervision, we can first reconstruct target frame I'_t in the following manner:

$$\mathbf{I}_{t}' = \phi(\mathbf{I}_{r}, \mathbf{D}_{t}, \mathbf{K}_{t}, \mathbf{K}_{r}, [\mathbf{R}|\mathbf{t}]_{rt}).$$
(1)

Here, K_t, K_r represents the intrinsic matrices of the target and reference frames, and $\phi(.)$ denotes the projection process based on the image warping. The ultimate photometric loss function, denoted as \mathcal{L}_p , is computed as the discrepancy between the transformed image I'_t and the reference image I_t . This loss function serves as the optimization objective for the proposed neural network.

The structure of Manydepth2 is demonstrated in Fig. 2. At the outset, Manydepth2 employs a trained optical flow network denoted by θ_f and a pose network denoted by

Fig. 3: Relationship between optical flow and depth in the dynamic scenario. This figure demonstrates that in a dynamic scenario, there is a discrepancy between the static optical flow and the real optical flow.

 θ_p to predict the optical flow $f_{r\leftarrow t}$ and the transformation matrix $[\mathbf{R}|\mathbf{t}]_{rt}$ from the target frame to reference frame. Concurrently, a prior depth network denoted by θ_{cd} is utilized to estimate the coarse depth map D_t^c for the target frame. Subsequently, the target frame denoted as I_t , the reference frame represented by I_r , the coarse depth map denoted as D_t , the transformation matrix $[\mathbf{R}|\mathbf{t}]_{rt}$, and the optical flow $f_{r\leftarrow t}$ are utilized collaboratively to construct a motion cost volume denoted as \mathcal{V}_m . The motion-aware cost volume \mathcal{V}_m and the target frame I_t are used in unison as inputs to the attention-based depth network θ_{ad} with the objective of predicting the final depth map D_t . Subsequently, this predicted depth map D_t is utilized in the construction of the ultimate photometric loss denoted as \mathcal{L}_p .

C. Pseudo-Static Reference Frame

To address the depth estimation of moving objects with monocular video, we leverage the estimation of flow $f_{r\leftarrow t}$, transformation matrix $[\mathbf{R}|\mathbf{t}]_{rt}$, and coarse depth D_t^c . Using the image warping relationship between I_t and I_r , we can calculate a depth-based flow (static flow) $f'_{r\leftarrow t}$ according to the following expression:

$$\boldsymbol{f}_{r\leftarrow t}' = \frac{1}{\boldsymbol{D}_r} (\boldsymbol{K}_r) (\boldsymbol{R}_{rt} (\boldsymbol{K}_t)^{-1} \boldsymbol{D}_t^c \boldsymbol{p}_t + \boldsymbol{t}_{rt}) - \boldsymbol{p}_t, \quad (2)$$

where p_t are pixels in the frame I_t ; $K_r \& K_t$ are intrinsic matrix for frames $I_r \& I_t$. As illustrated in Fig. 3, in static scenarios, the static flow $f'_{r\leftarrow t}$ aligns with the real optical flow $f_{r\leftarrow t}$. In scenarios involving moving objects, the real optical flow $f_{r\leftarrow t}$ can be decomposed into static optical flow $f'_{r\leftarrow t}$ and dynamic optical flow $f^d_{r\leftarrow t}$. Then the dynamic flow can be calculated as $f^d_{r\leftarrow t} = f_{r\leftarrow t} - f'_{r\leftarrow t}$.

The motion mask could be generated as following:

$$\mathcal{M}_m^t = ||\boldsymbol{f}_{r\leftarrow t} - \boldsymbol{f}_{r\leftarrow t}'||_2^2 > \epsilon, \qquad (3)$$

where ϵ is the threshold for distinguishing moving parts. The motion mask in the target mask can be used to generate the motion mask \mathcal{M}_m^r in the reference mask, utilizing $f_{r\leftarrow t}$. With \mathcal{M}_m^r , it becomes possible to reconstruct a pseudo-static reference image \hat{I}_r by eliminating the impact of dynamic

Fig. 4: **Qualitative results on KITTI Dataset.** The initial row displays the RGB images of target frames where depth information has been estimated. The subsequent rows, specifically the second, third, and fourth, showcase depth maps generated by Monodepth2 trained with stereo techniques, ManyDepth, and Manydepth2, respectively.

objects. This process can be formulated as follows:

$$\hat{\boldsymbol{I}}_{r} = \begin{cases} \boldsymbol{I}_{r} & \boldsymbol{p}_{i} \notin \boldsymbol{\mathcal{M}}_{m}^{r}; \\ \phi'(\boldsymbol{I}_{t}, \boldsymbol{D}_{t}, \boldsymbol{K}_{t}, \boldsymbol{K}_{r}, [\boldsymbol{R}|\boldsymbol{t}]_{rt}) & \boldsymbol{p}_{i} \in \boldsymbol{\mathcal{M}}_{m}^{r}. \end{cases}$$
(4)

It is important to note that $\phi'(.)$ differs from $\phi(.)$, as $\phi(.)$ is utilized to generate current frame information via sampling based on pixel correspondence between the current frame and the adjacent frame, whereas $\phi'(.)$ generates adjacent frame by shifting forward pixels of the current frame.

D. motion-aware Cost Volume

In constructing the motion-aware cost volume \mathcal{V}_m for target frame I_t , a set of parallel planes that are perpendicular to the optic axis of I_t is defined, based on the depth assumptions $\mathcal{D} = \{d_k; k = 1, ..., M\}$, where Mrepresents the number of planes. The feature extractor θ_{fe} is utilized to generate the feature maps \mathcal{F}_t and $\hat{\mathcal{F}}_r$ of I_t and $\alpha \hat{I}_r + (1-\alpha)I_r$, respectively. With the aid of \mathcal{D} and $[\mathbf{R}|t]_{rt}$, a set of wrapped feature maps $\{\hat{\mathcal{F}}_{t\leftarrow r}^{d_k}; d_k \in \mathcal{D}\}$ are generated by warping $\hat{\mathcal{F}}_r$. Considering $\mathcal{V}_m = \{\mathcal{P}_k, k = 1, ..., M\}$, it could be written as:

$$\boldsymbol{\mathcal{P}}_{k} = \frac{\sum_{i=1}^{N} |\hat{\boldsymbol{\mathcal{F}}}_{t\leftarrow r}^{d_{k}} - \boldsymbol{\mathcal{F}}_{t}|}{N}$$
(5)

Here, N denotes the number of reference frames used in construction, while in our experiment. α denotes the hyperparameters used to balance the influence of pseudo-static reference frame \hat{I}_r . Instead of directly taking the volume \mathcal{V}_m into the later depth network, we propose to construct the final feature volume \mathcal{V}_f by combining the \mathcal{V}_m with the \mathcal{F}_t though channel attention. The process of constructing the final feature volume \mathcal{V}_f is presented in Fig. 2.

E. Attention-Based Depth Network

The High-Resolution Network (HRNet) [18] is wellregarded for its ability to preserve a high level of detail in input images. The HRNet is composed of multiple branches, denoted as *B*, each generating S = b, ..., 4 features f_s^b with resolutions of $(\frac{H}{2^{b-1}}, \frac{W}{2^{b-1}})$. However, instead of exclusively utilizing the feature map from the last stage of each branch for disparity map prediction, we leverage the attention mechanism to integrate feature maps from the current branch's various stages and feature maps from deeper branches. To achieve fusion across both the channel and spatial dimensions, we introduce an innovative Depth Attention Network that leverages non-local attention \mathcal{NA} and channel attention \mathcal{CA} . Noting that the j^{th} branch of depth decoder takes the $(B - j)^{th}$ branch as input. This fusion process can be expressed as:

$$\boldsymbol{x}^{j} = \begin{cases} \mathcal{C}\mathcal{A}(\boldsymbol{f}_{B}^{B}, [\boldsymbol{f}_{s}^{B-j-1}]_{s=B-j-1}^{B}) & j == 0; \\ \mathcal{C}\mathcal{A}(\mathcal{N}\mathcal{A}(\boldsymbol{x}^{j}), [\boldsymbol{f}_{s}^{B-j-1}]_{s=B-j-1}^{B}) & j > 0. \end{cases}$$
(6)

F. Loss Function

To summarize, there are three loss functions used in updating Manydepth2's weights. The final loss function \mathcal{L} could be written as: $\mathcal{L} = \mathcal{L}_p + \mathcal{L}_s + \mathcal{L}_c$. The photometric loss \mathcal{L}_p consists of L_1 norm and SSIM regularization:

$$\mathcal{L}_p = a \sum_p \mathcal{M}_o \odot |\mathbf{I}_t - \mathbf{I}'_t| + b \frac{1 - \text{SSIM}(\mathbf{I}_t, \mathbf{I}'_t)}{2}, \quad (7)$$

where \mathcal{M}_o is the auto mask introduced in [19]. \mathcal{L}_s is the smooth loss, which could be written as:

$$\mathcal{L}_s = |\partial_x \boldsymbol{D}_t| e^{-|\partial_x \boldsymbol{I}_t|} + |\partial_y \boldsymbol{D}_t| e^{-|\partial_y \boldsymbol{I}_t|}.$$
(8)

And \mathcal{L}_c is the consistency loss introduced by [8], to preserve the consistency between prior monocular depth and final multi-frame depth, which could be written as:

$$\mathcal{L}_c = \sum \mathcal{M} \odot | \mathcal{D}_t^c - \mathcal{D}_t |, \qquad (9)$$

where \mathcal{M} is the mask introduced in [8].

IV. EXPERIMENTS

The main tests and evaluations for our study were carried out using two primary datasets: KITTI-2015 [35] and Cityscapes [36]. In our experiments, the ResNet18 [37] architecture was utilized for the pose network. The HRNet16 was used as the backbone for the attention-based depth network. The pre-trained Gmflow [38] on the Sintel dataset [39] are used as optic flow network. For testing, we set the minimum and maximum depth values to 0.1m and 80m, as in [24], [40]. In our experiment, the scale factor is computed using the median value of the ground-truth image as in [9].

A. Monocular Depth Estimation

KITTI-2015: The Tab. I presents a comparison between the performance of Manydepth2 and state-of-the-art algorithms. Overall, Manydepth2 exhibits superior performance compared to other methods, irrespective of whether monocular or multiview images are used. In particular, Manydepth2 demonstrates a significant performance advantage over Manydepth, which also employs multiview images and a cost volume structure to estimate depth. Manydepth2 outperforms Manydepth by a substantial margin of 7.2% in terms of Abs Rel. In comparison to Dynamicdepth, which employs semantic motion segmentation maps to leverage high-level computer vision information for precise depth estimation, Manydepth2 achieves a superior performance of 5.3% in terms of the Abs Rel, without the inclusion of any domain-specific information. Quantitative results are shown in Fig. 4. We also present the results for Manydepth2-NF, a version of Manydepth2 that does not use optical flow or the motion-guided cost volume. We found that our attentionbased network outperformed Manydepth by 4.1%.

Cityscapes: In contrast to the KITTI dataset, the Cityscapes dataset features a higher percentage of dynamic objects.

During the training phase on the Cityscapes dataset, the input resolution of Manydepth2 is set to 128×416 . The lower section of Tab. II indicates a substantial performance advantage of Manydepth2 over its competing methods. Remarkably, Manydepth2 exhibits superior performance over ManyDepth, with a margin of approximately 15.0% in the absolute relative error metric. Through the visualization of error maps generated by computing the differences between predicted depth maps and their corresponding ground truth depth maps, Fig. 1 facilitates a qualitative analysis of depth predictions. These observations indicate that Manydepth2 offers enhanced accuracy for depth estimation of both dynamic foreground and static background. Additionally, the incorporation of a pre-trained optical flow estimation model with low computational requirements has resulted in a minimal increase in parameter size and running time for Manydepth2. Quantitative results are shown in Fig. 1. Tab. III showcases the depth errors within dynamic object regions by utilizing the ground truth motion segmentation maps provided in [17], which corresponds to the qualitative results in Fig. 1.

Manydepth2	7.01	1.76	7.29	2.65

TABLE IV: Visual odometry results on Seq. 9 and Seq. 10 of the KITTI odometry dataset. The average drift in root mean square error for both translation (Tr) and rotation (R) is reported.

B. Odometry Estimation

To evaluate odometry estimation results, we follow the split used in [9], [22]. Specifically, we trained our model using Seq. 00-08 from the KITTI odometry dataset and test methods on Seq. 09-10. Tab. IV shows the results, where the translational and rotational motion were evaluated by using the root mean square error (RMSE). Manydepth2, which uses less computational resources, outperforms other learningbased techniques that use more computational resources, such as FeatDepth. The results indicate that Manydepth2 achieves a significant reduction in RMSE by approximately 24.1% for translational motion and 22.5% for rotational motion, as compared to ManyDepth, on Seq. 10. In support of this result, we present a visual depiction of the trajectory of both methods in Fig. 5, which shows that Manydepth2's trajectory exhibits considerably less drift than that of FeatDepth. The superior performance of Manydepth2 in precise pose estimation can be attributed to its use of both depth-based photometric loss and flow-based ego-motion loss, as well as the implementation of a motion-guided mask that effectively filters out dynamic foreground outliers. This combination of techniques enables Manydepth2 to achieve more reliable pose estimates compared to others.

C. Abaltion Study

In our research, we meticulously carry out ablation studies using the Cityscapes dataset. These studies are designed to dissect and showcase how effective our proposed modules are, allowing us to validate the specific design choices we've made. The detailed outcomes of these experiments are showcased in Table V. Within this table, we provide insights from experiments conducted under diverse conditions and configurations. Specifically, we assess Manydepth2's performance with variations such as the Prior Depth Net, Many-

Ablation	Abs Rel	Sq Rel	RMSE
Final Prior Depth	0.105	0.768	4.536
w/o Attention for Volume	0.100	0.709	4.298
Manydepth2-NF	0.094	0.676	4.246
Manydepth2	0.091	0.649	4.232

TABLE V: Ablation study results of depth accuracy on the KITTI 2015. The proposed Manydepth2 model was evaluated by modifying its components.

Fig. 5: **Trajectory visualization on Seq. 09. and Seq. 10.** The ground truth trajectories are represented by red lines. Trajectories generated by the FeatDepth [21] results are indicated by green lines, while our method's trajectories are depicted in blue lines.

depth2 configurations without Motion-Guided Volume and without Attention for Final Volume. A key observation from Table V is the pronounced positive impact that integrating the Attention-Based HRNet has on enhancing Manydepth2's performance. Furthermore, our findings underscore that the incorporation of both the Motion-Guided Volume and Attention for the Final Volume amplifies the capabilities of Manydepth2 even further, leading to improved outcomes.

V. CONCLUSION

We introduce Manydepth2, an innovative self-supervised multi-frame monocular depth prediction model that harnesses the synergy of optical flow-depth geometry. One of the standout features of Manydepth2 is its unique components, including a static reference frame, motion-guided cost volume, and an attention-enhanced high-resolution neural network. When benchmarked against the KITTI-2015 and Cityscapes datasets, Manydepth2 consistently delivers precise depth estimation, effectively distinguishing between dynamic foreground elements and static backgrounds. Remarkably, our model's performance is achieved using just a single RTX 3090, emphasizing its efficiency. Furthermore, Manydepth2 not only complements existing self-supervised monocular depth estimation techniques but also elevates them by integrating dynamic insights, thereby significantly enhancing accuracy.

VI. ACKNOWLEDGEMENTS

Our research is supported by Amazon Web Services in the Oxford-Singapore Human-Machine Collaboration Programme and by the ACE-OPS project (EP/S030832/1).
