# Popular astronomy and other science articles in glossy magazines – outreaching to those who do not care to be reached

#### Abstract

The target auditory of scientific outreach efforts is often limited to the small enthusiastic subset of the society that value science and actively seeks knowledge. However, the vast majority is usually indifferent or in some cases may even be opposed to sciences. To bring these people around to support sciences, we have to double and triple our efforts. I describe my personal experience how I reach out to them by means of popular articles in glossy magazines – not the most common outreach venue, at least in Bulgaria. Four years of writing have though me that the key for success is to turn the science into and engaging human story that will keep the readers curious until the revelation of the riddle at the end of the last paragraph. Next, come the spectacular visuals – for the modern reader, spoiled by eye candies of Internet and Hollywood they are almost as important as the written words. The final requirement is accessibility – an article should explain well only two or three concepts; I am not calling for simplicity but for measuring and structuring of the information content - it is better to give the readers two understandable pieces that they would enjoy instead one impenetrable article that would turn them away from popular science for good.

# 1 Introduction: communication scenarios

In the best outreach scenario educators in the STEM (science, technology, education and mathematics) fields face enthusiastic audiences, often with some relevant background and with inane interest in the discussed topic, asking thoughtful questions and absorbing the material with understanding. These people have made a conscious effort to learn, and in the case of astronomy – they did come for the planets, stars and galaxies. This is usually true for high profile events by scientist that are popular household names and planetarium shows or at dedicated camps for amateur scientists (astronomy camps are one example, see [7]). On the knowledge sharing side are scientists, who are motivated to focus the popular attention upon their work, seeking public and/or financial support. The communication vehicle is the media itself – either traditional or of the new social variety, – that is driven by completely different motivation and occasionally may slip into sensationalism [16].

Many outreach situations are far from the ideal described at the beginning. In the common case of the high school classroom the teachers have to deal with indifferent pupils, lacking interest in the natural sciences. The mass media is another, even more challenging outreach channel and the specifics are rarely discussed in the literature [12, 11]: while the students may be somewhat motivated to pay attention by the

impending test or a final exam, nothing prevents the readers, watchers or listeners from switching their attention to other pieces that may – seemingly or for real – refer to much more pressing matters with immediate effect on their lives; or are just easier to enjoy. Here the popular science is competing directly, on an even field with politics, various kinds of entertainment and sports. In general, educators must deal with people who may have randomly encountered a popular science piece, just leafing though a magazine, surfing TV channels or may be attending a special event just to ask a question or two about UFOs or aliens.

In reality, the situation is probably a combination of these two scenarios, where we have to work with diverse audience, applying different techniques to capture people's attention. These techniques may even contradict each other and we have to find the optimal compromise.

Hoping that it may be useful for other educators, I share here my experience of doing outreach via short articles, usually up to 1800 words, in mostly but not exclusively Bulgarian newspapers and glossy magazines. These are part of the general media that is not specialized in popular science, and have their own language specifics ([5]; for other countries in Eastern Europe see [1]). Furthermore, they belong to the traditional media outlets, that despite the increasing role of the social media, still remain an important source of science news for a significant fraction of the population. Indeed, in a 2023 poll for UK 52% of the responders refer to the TV as their main source of such news, 29% — to national newspapers and 24% - to radio<sup>1</sup>, motivating scientists to use these channels for outreach activities (for the challenges in the science-media interface see [14]). Finally, I discuss specific popular pieces and that I have written and describe what I consider the best practices.

## 2 Basic principles

I build my presentations on a few basic principles, defining the what, how, how much and why questions that each presentation must answer, always adding a human element to make the story more emotionally tangible.

**Accessibility** defines the difficulty level of the offered material. Perhaps, this is the most critical choice the presenter has to made, because it requires to adjust the material to the expected level of the audience that may be varied from junior high school [3, 9] to advanced amateurs [7, 10], it may be mixed and the level may not be known in advance. Our goal is to explain complex concepts, but unlike the classroom, in the general media we don't have the luxury to gradually build up knowledge. Some rare exceptions to this rule are the regular columns and serialized publications, but even they are not too powerful in this regard, if the publications are separated by months, and if there is a significant fluidity of the reader's base. Therefore, every material must be independent and to provide enough background information to be self-sufficient.

Understandability defines the manner of presentation and aims to bring successfully the intended message to the audience. The general public, that is likely to access the general media we discussed here, does not have a significant scientific background, implying that enough information must be incorporated in the material to make the understanding possible. This often requires including strong visual component and if the volume of the presentation permits, repeating some concepts twice, explaining them in different ways, giving different examples or analogies. Gradual build up, from the simple and more basic concepts to more complex may help – this often means to follow the historical development of the subject, which usually evolves toward higher level of sophistication.

Relevance explains why a given scientific concept is important to the people. In most general terms, this is the old question why the humanity should spend resources on fundamental studies, especially astronomy whose subjects are billions of kilometers away. Many answers can be given here, my personal favorite is that the astronomy and other fundamental sciences are part of the general scientific education that gives young people the background tools like the scientific method and the inquisitive way of thinking, necessary to work not just in the STEM fields, but in

<sup>1</sup>https://pressgazette.co.uk/comment-analysis/science-neceshpoint/ IT, etc., and even to deal better with the

challenges of everyday life like decision at elections when applying the inquisitive thinking have significantly more immediate consequences. Another – and very obvious – line of arguing the usefulness of science is that it makes our lives easier (even though the science has its dark side; the recent movie Oppenheimer is a good illustration of this dichotomy) and we can follow up with examples like mathematical methods, various image processing and recognition techniques that have very broad applications. They may not necessarily have been invented by astronomers and for astronomy, but together with other fundamental sciences astronomy has creates a broad field for testing and refinement of these methods, for creating easily accessible well tested and user friendly push-button solutions that facilitate their wider spread adoption.

Measure determines the quantity of the offered information content to something that the reader or the user can absorb in the limited amount of time that people usually devote to mass media. Today, a large fraction of the audience is "trained" to expect short message in a burst of visual or audiovisual form; in the extreme cases it may last merely seconds. While we can think of popular science messages with similar duration – aimed mostly to rise awareness of a scientific subject rather to explain that subject in detail – the glossy magazines I refer to here allow for longer messages. Based on personal observations only, I assume that people who bought or picked up a free magazine would spend at least 10-15 minutes, if they find it attractive enough. Still, this allows for no more that 2-3 new or complex concepts that need explanation, e.g. the triangulation and parallax or spectrum and color, or redhsift and Universe's expansion.

Attractivity it a quality of the material that would ensure capturing the attention of the readers or watchers. In practical terms this means to convert – as the professional journalists know well – even the dullest scientific explanation into a relatable human story, with struggles and surprise turns, not unlike any good detective story might contain. This is actually easier than it may sound, because the scientific investigation closely resembles the detective work described in a crime novels (hopefully, without the violence): collecting evidence, creating

a theory/hypothesis and testing to see if it fits all the data. Not surprisingly, this is a description of the scientific method, known from the ancient Greek times. Rather, the danger here is to overdo the human struggle element, causing repulse or even derision. The attractivity is boosted also by subjects of intrinsically high public interest, like the existence of life and intelligence in the Universe – [8], to give an example of our own work.

Some direct implications of these principle were already mentioned: taking advantage of the explanatory power that illustrations offer, relating the scientific ideas to the lives and efforts of their authors. Many more can be added to this list, like the careful structure of the material (I typically break the text for the magazines into 5-6 self-contained sections) that helps to make explicit the connections between the historic steps leading to a particular discovery, or that would explain better the relations between the components of a scientific method that led to that discovery: collecting observations, building a hypothesis, and verification of the predictions of this hypothesis.

The volume of a material is yet another important element of the presentation. If it is too long we may "loose" the audience, if it is too short we will not have enough room to bring across more complex ideas. Often, the volume is set by the adopted "format" for the given media. Here the editors or producers – the people who have more experience with the particular media – usually know better, having learned form the previous experience what works best.

My own experience with the glossy magazines suggest that 1600-1800 words (in Bulgarian, the English equivalent is usually somewhat more compact at 1300-1500 words) is a reasonable volume, that allows to explain 2-3 concepts. This translates into 5-6 A4  $(8-1/4 \, \text{inch} \times 11-3/4 \, \text{inch}$  or  $21.0 \, \text{cm} \times 29.7 \, \text{cm})$  pages. Typically, two of the pages amount to illustrations with their own captions. The text is layered into 2 or 3 columns, with some separate blocks.

These blocks deserve specialized attention. They are used to elaborate a specific and stand-alone part of the topic that is important, but if it is included in the main text may divert the reader form the

understanding the main point of the presentation. Some examples are: parallax, polarization of light, and correction of the atmospheric turbulence with adaptive optics – these were included in publications on stellar evolution, on the search for biosignatures (based on the hirality of life's building blocks) or on brown dwarfs and exoplanets. The blocks may also be devoted to biographical notes of scientists, history of space missions, examples from the literature and movies – usually science fiction but not always – where a particular scientific concept or relevant historic event was mentioned [2, 13, 15].

#### 3 Attention magnets

The "tools" to capture the attention of the audience are a part of the principles discussed in the previous section, but they are sufficiently critical for the success of the communication, to merit more attention, because if the reader gets bored after a paragraph or two, all our efforts to explain, structure and illustrate some scientific concept would be lost.

The most effective of these tools is the introduction of the human elements/stories/achievements, that can touch the readers emotionally. I refrain from asking to bring into a popular scientific article elements of fiction, but we should never forget that that science is a human activity and scientists are driven by human curiosity and other usual emotions, that we posses good and bad qualities as any other human being. Our audience can related to these, one way or another. Of course, I have always tried in these articles to point at the best in scientists (and in people). One example is Arthur Eddington, mentioned in a piece about the 2019 Nobel price laureates. It is well known that he helped to confirm and promote Einstein's general relativity, but he opened up as a completely different personality in some the personal letters he sent to his mother. Yet, Eddington was a devoted follower of the scientific truth and in the time of a grave war he gave a chance to a scientific theory by a German physicist – Einstein – and went to great length in order to confirm it.

Another example along the same line comes from an article about exoplanets – it is the long, multiyear effort of the teams behind the Kepler space telescope and the team leader William J. (Bill) Borucki to demonstrate the feasibility of ultra high precision stabilization of the future spacecraft. It was necessary to minimize the photomitric errors due to intrapixel sensitivity variations. This required building a physical model to show - on the ground - that the technological challenges are surmountable. Omitting the fine technical details while keeping in the readers' sights the scientific goals of this space telescope, allows us to offer the audience a relatable and understandable story of human struggle, persistence and devotion, ending in a scientific triumph – the discovery of thousands of planets that let us for the first time to glimpse the planetary population of in the Milky Way as a whole, and to derive meaningful statistical estimates of the number of planets around different types of stars.

References to cultural mainstays are other ways to keep the attention of the audience. Two popular science publications – a weekly newspaper "Orbita" and a monthly magazine "Kosmos" - were popular in Bulgaria in 1980's and memories of editors and authors that were associated with them are still alive in the general public's mind. One of these people is Dimitar Peev (1919-1996; [4]). He held a degree in Law but worked for nearly his entire life as a science journalist, leaving behind hundred of popular articles, books and science fiction novels. Among those was a piece about our knowledge of the planet Saturn, published in 1965. This was a good starting point, when I revisited this enticing object in a new article that reported how our view of the Solar system has changed and has been enriched by the astronomical and astronautical progress in the intervening nearly six decades.

The question how scientific discoveries affect people's lives is a powerful magnet of public attention. The examples are numerous and well-known – from the celestial calendar that told the Egyptians when to plant to the mid-infrared astronomical all-sky surveys that may save us from the next big asteroid primed to hit the Earth.

## Conclusions: the best prac- man story to show the social side of natural sciences. tices

We must use every opportunity to reach out and to widen our audience. This becomes increasingly important in an age when fake news and "alternative" facts have become a mainstay in the information space. Sadly, the Internet is no longer a source of reliable information, and instead it reinforces illogical believes, prejudices and biases. The algorithms of search engines often tend to boost self-confirmation and support these distortions. This creates a difficult, if not outright hostile environment for science outreach and popularization [6]. If these tendencies survive on long term they may lead to slowing the progress in fundamental sciences like astronomy, that depend on public support and funding.

An astronomer – or any other scientist – can no longer enjoy doing science in a "ivory tower", regardless of whether this is an observatory on a mountain top above the clouds or a friendly lecture room full of interested students. We can not leave behind the mundane everyday concerns; reaching out to the general public, including via the general media, is one of the potent channels that helps to broaden the audience beyond what specialized popular science outlets can do. This is not to confront the usage of general and specialized media or the targeted lobbying – for a better effect they all should be used together, as Karl Sagan did.

Astronomy has an advantage over most other fundamental sciences – it generates a visually appealing products and has easier time creating science friendly social environment. I described here my somewhat limited effort in this direction. It amounts to some two dozen popular articles, most of them in Bulgarian magazines, published over the course of nearly six years. In terms of best practices, confirmed by the continued interest of the editors (and presumably and most importantly, of the readers), I can put forward a short list the ideas that I have followed: making even the most complex ideas accessible and understandable to the general reader, offering them in selfsufficient bits that can be absorbed in one reading, and finally, packaging these concepts with enough hu-
