ABSTRACT

Existing learned video compression models employ flow net or deformable convolutional networks (DCN) to estimate motion information. However, the limited receptive fields of flow net and DCN inherently direct their attentiveness towards the *local* contexts. *Global* contexts, such as large-scale motions and global correlations among frames are ignored, presenting a significant bottleneck for capturing accurate motions. To address this issue, we propose a joint *local* and *global* motion compensation module (LGMC) for leaned video coding. More specifically, we adopt flow net for *local* motion compensation. To capture *global* context, we employ the cross attention in feature domain for motion compensation. In addition, to avoid the quadratic complexity of vanilla cross attention, we divide the softmax operations in attention into two independent softmax operations, leading to linear complexity. To validate the effectiveness of our proposed LGMC, we integrate it with DCVC-TCM and obtain learned video compression with joint *local* and *global* motion compensation (LVC-LGMC). Extensive experiments demonstrate that our LVC-LGMC has significant rate-distortion performance improvements over baseline DCVC-TCM.

Index Terms— Motion estimation, neural video compression

1. INTRODUCTION

The rapid development of social media and video applications triggers the increases of the video date volume, bringing challenges to video compression [\[1,](#page-4-0) [2\]](#page-4-1). In recent years, learned video compression has attracted lots of attentions. Most learned video compression models [\[1,](#page-4-0) [2,](#page-4-1) [3,](#page-4-2) [4\]](#page-4-3) are based on predictive coding paradigm, which employs a flow net or Deformable Convolutional Networks (DCN) [\[5\]](#page-4-4) to predict the motion information between the reference frame and current frame. Subsequently, a motion codec is cooperated to compress the motion information. Meanwhile, residual codec [\[1\]](#page-4-0) or a contextual codec [\[2\]](#page-4-1) is used to compress the residuals or contexts. To enhance the compression perfor-mance, advanced entropy models [\[6\]](#page-5-0) and flow coding techniques [\[7\]](#page-5-1) are investigated in recent years. Some models [\[8\]](#page-5-2) even outperform the Versatile Video Coding (VVC) under the Low Delay configuration.

Traditional video coding is block-based, which is capable of search over a predefined region for motion estimation. Flow-based or DCN-based motion estimation can only handle small motions due to the limited receptive field of Convolution Neural Networks (CNN), which can only capture *local* redundancy. *Global* redundancies are existed even in the scenario of small motions, which has not been sufficiently explored in learned video compression.

To address above issues, we propose a novel mixed flowattention based motion estimation and motion compensation module in feature space for joint *local* and *global* redundancy capturing. Our module is built upon the conditional coding paradigm [\[2,](#page-4-1) [9\]](#page-5-3). We integrate the proposed joint *local* and *global* module to DCVC-TCM to obtain the learned video compression model LVC-LGMC. In the LVC-LGMC, multiscale motion compensation is adopted. More specifically, when compressing the current P-frame x_t , we use a flow net to estimate the motion offset. By warping the multi-scale features using the decoded estimated offset, the local redundancies between frames can be well captured. To achieve global motion estimation, we propose to employ the cross attention between the propagated features and middle features of current frame for the long-range modeling. The attention map contains the global similarity between frames without consuming additional bits for representation. However, the quadratic complexity of vanilla attention impedes the compression of high-resolution videos. To address this issue, we propose to divide the softmax in vanilla attention into two softmax operations [\[10\]](#page-5-4). The dot product features after two independent softmax operations is treated as the similarity metric. Such division of softmax operation makes the complexity increases linearly with the resolution, leading the operation more efficient. When compared with the baseline DCVC-TCM [\[9\]](#page-5-3), the proposed LVC-LGMC reduces 10% bit-rates on MCL-JCV test sequences [\[11\]](#page-5-5).

The contributions of this paper are summarized as follows:

• We propose a novel attention-based motion compensation module to handle large-scale movements and cap-

Fig. 1. Overall frame work of the proposed LVC-LGMC. E_C is the contextual encoder, and D_C is the contextual decoder. E_M is the MV encoder, and D_M is the MV decoder. LGMC is the proposed joint local and global motion compensation module.

ture global redundancy between frames but with linear complexity and without extra bits. To our knowledge, this is the first attempt to use cross attention for motion compensation.

• We incorporate proposed attention-based motion compensation with flow-based motion compensation for joint local and global motion compensation. The proposed method significantly boosts the model performance.

2. THE PROPOSED LVC-LGMC METHOD

The paradigm of the proposed LVC-LGMC is illustrated in Fig. [1.](#page-1-0) We reproduce the DCVC-TCM [\[9\]](#page-5-3) and build LVC-LGMC on top of it. Following DCVC-TCM, we adopt temporal propagated multi-scale features for local compensation.

2.1. Flow-based Local Compensation

When compressing the t -th frame x_t , first, we conduct the local compensation [\[9\]](#page-5-3). In particular, multi-scale features $\hat{\bm{f}}^{0}_t$ $_t^0, \hat{\boldsymbol{f}}_t^1$ $\hat{\bm{f}}_t^1, \hat{\bm{f}}_t^2$ $\hat{\boldsymbol{r}}_t$ are extracted from propagated feature $\hat{\boldsymbol{F}}_{t-1}$. Motion vector \hat{v}_t is employed to warp the multi-scale features to multi-scale local contexts \hat{l}_t^0 $\stackrel{0}{t}, \hat{\bm{l}}_t^1$ $\begin{matrix} 1\ \, \boldsymbol{t} \end{matrix}, \hat{\boldsymbol{l}}_{t}^{2}$ $\hat{\bm{l}}_t^2$. The $\hat{\bm{l}}_t^0$ $\stackrel{0}{t}, \hat{\bm{l}}_t^1$ $\hat{\bm{l}}_t^1, \hat{\bm{l}}_t^2$ \overline{t} are concatenated with the current frame x_t , middle-feature y_t^1 and middle-feature \hat{y}_t^2 respectively. As such, the network could well understand how to conduct conditional coding. During decoding, the multi-scale contexts are also concatenated to recover the frame. The overall process can be formulated as: First. Due of the reduced by the limit of the proposed LVC-LGMC. Every **Fig.** 2. Illustration competes and D₆ is the contextual decoder. The and is the proposed ioni local and global motion compensation competes is the

$$
\hat{\boldsymbol{x}}_t = D_C \left(\left[E_C(\boldsymbol{x}_t | \hat{\boldsymbol{l}}_t^0, \hat{\boldsymbol{l}}_t^1, \hat{\boldsymbol{l}}_t^2) \right] | \hat{\boldsymbol{l}}_t^0, \hat{\boldsymbol{l}}_t^1, \hat{\boldsymbol{l}}_t^2 \right), \tag{1}
$$

where E_C and D_C are the contextual encoder and the contextual decoder.

2.2. Attention-based Global Compensation

The *vanilla* approach for global compensation is introduced

Fig. 2. Illustration of the joint local and global motion compensation module (LGMC) at encoder side.

Fig. 3. Illustration of the joint local and global motion compensation module (LGMC) at decoder side.

tion, global motion compensation is utilized for learned video compression. It has been recognized that the CNN has limited receptive fields, such that global attention is adopted for global motion compensation. Regarding the compression of x_t , given multi-scales features $\hat{\boldsymbol{f}}_t^{\bar{0}}$ $\frac{\tilde{0}}{t}, \hat{\boldsymbol{f}}_t^1$ $\frac{1}{t}, \hat{\hat{\pmb{f}}}^2_t$ \bar{t} , current frame x_t , and middle features y_t^1, y_t^2 , we take y_t^2 \in $\mathbb{R}^{C \times \frac{L}{16}}, \hat{\boldsymbol{f}}_t^1$ \in $\mathbb{R}^{C\times L}$ as an example. where C is the channel number, and $L = H \cdot W$, H is the height and W is the width of the frame. The y_t^2 and $\hat{\boldsymbol{f}}_t^2$ \overline{t} are first fed into a Depth Residual Bottleneck [\[12\]](#page-5-6) for nonlinear embedding. The *vanilla* approach adopts cross attention $[13, 14]$ $[13, 14]$ $[13, 14]$, which is formulated as:

$$
\hat{g}_t^2 = \underbrace{\text{softmax}\left(y_t^2 \left(\hat{f}_t^2\right)^\top\right)}_{\text{non-negative}} \hat{f}_t^2. \tag{2}
$$

The softmax $\left(y_t^2\left(\hat{\boldsymbol{f}}_t^2\right)\right)$ $\left(\begin{array}{c} 2 \\ t \end{array} \right)^{\top}$ $\Big\{ \in \mathbb{R}^{\frac{L}{16} \times \frac{L}{16}} \geq 0$, and it can be treated as the similarity metric. It computes the similarity between a symbol and all other symbols, such that the similarity can be captured. The attention and y_t^2 are then concatenated to conduct conditional coding on the basis of global dependency.

However, the computational complexity of Eqn. [2](#page-1-1) is $O(L^2)$. The quadratic complexity makes it hard to employ the *vanilla* approach for high-resolution video coding. The quadratic is caused by the softmax operation, which specifies the order of matrix multiplication. To solve the quadratic complexity, we employ efficient attention [\[10,](#page-5-4) [16\]](#page-5-9), which employs the softmax operation on y_t^2 in row and the softmax

Fig. 4. Illustration of rate-distortion performance of the proposed LVC-LGMC, DCVC-TCM [\[9\]](#page-5-3), DCVC [\[2\]](#page-4-1), DVCPro [\[15\]](#page-5-10), HM-16.20 and x265 codec. The distortion is PSNR. Please zoom in for better view.

operation on $\hat{\boldsymbol{f}}_t^2$ \overline{t} in column,

$$
\hat{\boldsymbol{g}}_t^2 = \underbrace{\text{softmax}(\boldsymbol{y}_t^2) \text{ softmax} (\hat{\boldsymbol{f}}_t^2)^\top}_{\text{non-negative}} \hat{\boldsymbol{f}}_t^2. \tag{3}
$$

Since softmax $(\hat{\bm{y}}_t^2)$ softmax $(\hat{\bm{f}}_t^2)$ $\left(\begin{matrix} 2 \\ t \end{matrix} \right)^{\top} \geq 0$, which makes is can be used as a similarity metric. Larger values denotes higher similarity. In practice, softmax $(\hat{\boldsymbol{f}}_{t}^2)$ $\left(\begin{smallmatrix}2\t\end{smallmatrix}\right)^{\top}\hat{\boldsymbol{f}}_{t}^{2}$ \overline{t} is computed first, resulting in the $O(C^2L)$ complexity.

During decompression, the attention-based global compensation is also conducted. When conducting global motion Compensation, the overall process is

$$
\hat{\boldsymbol{x}}_t = D_C \left(\left[E_C(\boldsymbol{x}_t | \hat{\boldsymbol{g}}_t^0, \hat{\boldsymbol{g}}_t^1, \hat{\boldsymbol{g}}_t^2) \right] | \hat{\boldsymbol{g}}_t^0, \hat{\boldsymbol{g}}_t^1, \hat{\boldsymbol{g}}_t^2 \right). \tag{4}
$$

2.3. Joint Local and Global Motion Compensation for Learned Video Compression

Our proposed joint local and global motion compensation (LGMC) is illustrated in Fig. [2](#page-1-2) and Fig. [3.](#page-1-3) Flow is employed to warp to obtain local contexts \hat{l}_t^0 $\hat{\bm{l}}_t^1, \hat{\bm{l}}_t^1$ $\overline{\hat{\bm{l}}}_t^2, \overline{\hat{\bm{l}}}_t^2$ \overline{t} and attention is used to obtain global contexts $\hat{g}^0_t, \hat{g}^1_t, \dot{\hat{g}}^2_t$. We concatenate the local context, global context with current frames or middle feature. In this manner, local and global contexts can be utilized for

conditional coding. The overall process can be described as follows,

$$
\hat{\boldsymbol{y}}_t = [E_C(\boldsymbol{x}_t|\hat{\boldsymbol{l}}_t^0, \hat{\boldsymbol{l}}_t^1, \hat{\boldsymbol{l}}_t^2, \hat{\boldsymbol{g}}_t^0, \hat{\boldsymbol{g}}_t^1, \hat{\boldsymbol{g}}_t^2)], \n\hat{\boldsymbol{x}}_t = D_C(\hat{\boldsymbol{y}}_t|\hat{\boldsymbol{l}}_t^0, \hat{\boldsymbol{l}}_t^1, \hat{\boldsymbol{l}}_t^2, \hat{\boldsymbol{g}}_t^0, \hat{\boldsymbol{g}}_t^1, \hat{\boldsymbol{g}}_t^2),
$$
\n(5)

where \hat{y}_t is the latent representation of x_t .

3. EXPERIMENTS

3.1. Experimental Setup

We train the LVC-LGMC on Vimeo-90k dataset [\[22\]](#page-5-11). Frames are randomly cropped into 256×256 patches. The proposed models are optimized with the rate-distortion loss as follows,

$$
\mathcal{L} = \mathcal{R} + \lambda \times \mathcal{D},\tag{6}
$$

where D denotes the distortion metric Mean Square Error (MSE) or MS-SSIM [\[17\]](#page-5-12). To cover wide range of coding rates, the λ is set as $\{256, 512, 1024, 2048\}$ for MSE and ${256, 512, 1024, 2048} \times \frac{1}{50}$ for MS-SSIM. Following DCVC-TCM [\[9\]](#page-5-3), we adopt the multi-stage training strategy with the AdamW optimizer, and the batch size is set as 4.

3.2. Rate Distortion Performance

To demonstrate the effectiveness of the proposed method, the rate-distortion performance and model complexity is eval-

Fig. 5. Illustration of rate-distortion performance of the proposed LVC-LGMC, DCVC-TCM [\[9\]](#page-5-3), DCVC [\[2\]](#page-4-1), DVCPro [\[15\]](#page-5-10), HM-16.20 and x265 codec. The distortion metric is MS-SSIM [\[17\]](#page-5-12). Please zoom in for better view.

uated. We compare our LVC-LGMC with existing video coding schemes, including DCVC-TCM [\[9\]](#page-5-3), CANF-VC [\[21\]](#page-5-13), DCVC [\[2\]](#page-4-1), MLVC [\[20\]](#page-5-14), RLVC [\[19\]](#page-5-15), DVCPro [\[15\]](#page-5-10), HM-16.20, x265. The UVG [\[18\]](#page-5-16), MCL-JCV [\[11\]](#page-5-5), and HEVC test sequences (class B, class C and class D) are all involved for performance evaluation. In particular, for learned coding schemes, we employ the official models for testing. First 96 frames in each sequences are involved in testing, and the intra period is set to 32. The height and width of frames are padded to the multiples of 64 to facilitate testing. Fig. [4,](#page-2-0) Fig. [5](#page-3-0) and Table [1](#page-4-5) present the rate-distortion performance. The proposed global and local motion compensation model LVC-LGMC outperforms the baseline DCVC-TCM model [\[9\]](#page-5-3) on all datasets, indicating the effectiveness of employing global and local motion compensation for motion estimation in learning-based video coding. Moreover, the proposed LVC-LGMC shows superior rate-distortion performance when compared with the CANF-VC, DCVC, MLVC, RLVC, DVCPro, HM-16.20, and x265. When compared with baseline model DCVC-TCM, the proposed LVC-LGMC achieves significant bit-rate savings. More specifically, the BD-rate gains on MCL-JCV are 10.09% in terms of PSNR and 9.74% BD-rate savings are obtained in terms of MS-SSIM. Moreover, it is interesting to see that we could constant achieve the rate-distortion performance improvement on different resolutions and contents, indicating the effectiveness of the proposed method. We compare the LVC-LGMC

Fig. 6. Bit allocation of LVC-LGMC and baseline model DCVC-TCM [\[9\]](#page-5-3).

with the baseline model DCVC-TCM regarding the parameter numbers, and coding complexity. The test environment is Tesla A100 GPU. The parameter numbers of the proposed LVC-LGMC and DCVC-TCM are 14.09M and 10.71M, respectively. The coding complexity increament of the LVC-LGMC is marginal, which increases the decoding time by 20% on 1080p sequences. The complexity increases of the LVC-LGMC is tolerable as the rate-distortion performance improvements are significant.

3.3. Analyses and Discussions

3.3.1. Bit Allocation

We analyze the proposed mixed attention-flow based motion estimation and compensation via bit-allocation. We take sequence BQTerrace from HEVC B as an example, where the resolution is 1920×1080 and the frame rate is 60. The average PSNR of LVC-LGMC is 33.878 dB and the average PSNR of DCVC-TCM is 33.871 dB. The associated bitrate and motion bit-rate of individual frame are presented in Fig. [6.](#page-3-1) The proposed LVC-LGMC consumes lower coding bits in motion representation, and the overall bit consumption is lower than the DCVC-TCM. It is worthy of noting that the proposed global module is bit-free for motion representation. Long-range similarities can be well estimated with the global module, such that fewer bits are required for representing the flow map. Consequently, the enhanced prediction leads to the overall bit reduction of the frame-level information coding.

3.3.2. Ablation Studies

To comprehensively evaluate the effectiveness of the proposed attention-based global context for motion compensation, we remove the global module at the encoder-side and remove the global module at the decoder-side. Removing global at the encoder-side is quite similar with distributed source coding. The results are presented in Fig. [7.](#page-4-6) Global at encoder and global at decoder both lead to performance degradation, but performs better than baseline DCVC-TCM [\[9\]](#page-5-3).

4. CONCLUSION

In this paper, we propose joint global and local motion compensation (LGMC) for learned video coding. We propose to employ the cross attention to capture global contexts for global motion compensation. To reduce the complexity, we divide the softmax operation in vanilla attention into two independent softmax operations, leading to linear complexity. We employ existing flow-based motion comprensation for local contexts. To evaluate our proposed module, we incorporate it with DCVC-TCM and we get video compression model LVC-LGMC. Extensive experiments demonstrate that our LVC-LGMC have significant improvements over corresponding baseline DCVC-TCM. Our methods are plug-andplay and can be employed in other conditional coding based models [\[2,](#page-4-1) [6,](#page-5-0) [8\]](#page-5-2) for further performance improvements.
