Abstract. Synthesizing healthy brain scans from diseased brain scans offers a potential solution to address the limitations of general-purpose algorithms, such as tissue segmentation and brain extraction algorithms, which may not effectively handle diseased images. We consider this a 3D inpainting task and investigate the adaptation of 2D inpainting methods to meet the requirements of 3D magnetic resonance imaging (MRI) data. Our contributions encompass potential modifications tailored to MRI-specific needs, and we conducted evaluations of multiple inpainting techniques using the BraTS2023 Inpainting datasets to assess their efficacy and limitations.

Keywords: Brain tumor · inpainting · MRI.

### 1 Introduction

Numerous algorithms for automated analysis of brain magnetic resonance imaging MRI images exist to aid clinical decision-making. It is, however, challenging to perform automatic image processing for patients with brain tumors as many algorithms are intended for analyzing healthy brains and may not effectively handle images with lesions. Examples of such algorithms include brain anatomy parsing, tissue segmentation, and brain extraction. We propose that synthesizing healthy brain scans from diseased brain scans could potentially address this challenge, and the problem is formulated as a 3D inpainting task [\[1\]](#page-6-0).

Inpainting, a fundamental task in computer vision, has undergone significant advancements over the years. Its primary objective is to realistically fill in missing regions within 2D natural images, enabling various applications, including image restoration, object removal, and image completion. The computer vision community has developed numerous sophisticated algorithms that excel in addressing inpainting challenges in the context of two-dimensional images, achieving impressive results, and driving the state-of-the-art in this field.

Despite the remarkable progress made in 2D inpainting, the adaptation of these algorithms to the realm of 3D, especially in the context of medical imaging, remains an open problem. This paper aims to explore the challenges associated with 3D inpainting of MRI scans and investigate the feasibility of adapting 2 R. Zhu et al.

existing 2D inpainting algorithms to the MRI data. In this study, we put forth the following contributions:

- 1) An exploration of potential modifications and adaptations of existing 2D inpainting techniques to better suit the requirements of 3D MRI data.
- 2) Presentation of experimental results and a comparative evaluation of different inpainting methods, assessing their efficacy and limitations on the BraTS2023 Inpainting datasets [\[2\]](#page-6-1).

# 2 Methods

Given images with brain tumors and tumor masks or with masks that simulates brain tumors, we input the masked image into an inpainting model, and the model is expected to output a healthy-looking brain where the tumor region is filled. We selected three image synthesis models, namely pGAN [\[3\]](#page-6-2), ResViT [\[4\]](#page-6-3), and Palette [\[5\]](#page-6-4), for our experiments. pGAN and ResViT are originally developed for brain MRI data, and we adapted the architecture of the Palette model to accommodate 3D data as input.

### 2.1 pGAN

Preprocessing Initially, we apply z-Score standardization to normalize the intensity. Subsequently, we slice the MRI data based on the slice dimension and save each slice as an individual 2D npy file.

Network pGAN [\[3\]](#page-6-2) is a conditional generative adversarial network composed of a generator G, a pre-trained VGG16 network, and a discriminator D. The generator G learns to create target images that correspond to the healthy region. Simultaneously, the discriminator  $D$  assesses the authenticity of the synthetic and real images. All subnetworks are trained jointly, where the generator  $G$  aims to minimize pixel-wise, perceptual, and adversarial losses ( $\mathcal{L}_{pix}$ ,  $\mathcal{L}_{per}$ , and  $\mathcal{L}_{adv}$ , respectively), and the discriminator  $D$  aims to maximize the adversarial loss. The complete loss is

$$
\mathcal{L}_{pGAN} = \lambda_{pix} \mathcal{L}_{pix} + \lambda_{per} \mathcal{L}_{per} + \lambda_{adv} \mathcal{L}_{adv},\tag{1}
$$

where  $\lambda_{pix}$ ,  $\lambda_{per}$ , and  $\lambda_{adv}$  are the weights of the pixel-wise, perceptual, and adversarial losses, respectively.

#### 2.2 ResViT

Preprocessing Preprocessing for ResViT is the same as that of pGAN.

Network ResViT [\[4\]](#page-6-3) is a conditional generative adversarial model built upon the self-attention Transformer architecture. The generator subnetwork adheres to the encoder-information bottleneck-decoder pathway, with the incorporation of a Transformer to explicitly leverage nonlocal contextual information. Meanwhile, the discriminator subnetwork is formulated based on a conditional Patch-GAN architecture. The generator's bottleneck comprises a stack of novel *ag*gregated residual transformer (ART) blocks. Each ART block is organized as a cascade of a transformer module responsible for extracting hidden contextual features, along with a convolutional module that captures hidden local features from the input feature maps. The loss function incorporates both a pixel-wise L1 loss and an adversarial loss. The complete loss is

$$
\mathcal{L}_{ResViT} = \lambda_{pix} \mathcal{L}_{pix} + \lambda_{adv} \mathcal{L}_{adv},
$$
\n(2)

where  $\lambda_{pix}$  and  $\lambda_{adv}$  are the weights of the pixel-wise and adversarial losses, respectively.

### 2.3 3D Palette

Preprocessing To accommodate GPU memory limitations, we adopt the crop method utilized by the baseline model 3D Pix2Pix, cropping the image to a size of  $96 \times 96 \times 96$  centered on the mask region. Additionally, the data normalization procedure aligns with that of the baseline model.

Network Palette [\[5\]](#page-6-4) is a conditional diffusion model that employs the Unet architecture [\[6,](#page-6-5)[7\]](#page-6-6). The diffusion model transforms samples from a standard Gaussian distribution into samples from an empirical data distribution using an iterative denoising process. The conditional diffusion model tailors the denoising process based on the input signal. The model employs the L2 loss function to capture the distribution of the output.

## 3 Results

#### 3.1 Qualitative evaluation

We visually inspected the inpainting results of random samples for each of the three models and the baseline model. The cross-sectional views of the results are shown in Figs. [1](#page-3-0) and [2](#page-4-0) for slices without and with brain tumors, respectively.

Both pGAN and ResViT use the same 2D slice as input. However, the results clearly indicate that ResViT generates output with substantially higher levels of detail. Likewise, when employing 3D MRI data as input, 3D Palette demonstrates greater potential than 3D pix2pix.

#### 3.2 Quantitative evaluation

Following the evaluation guidelines of the MICCAI-BraTS2023 Inpainting Challenge, we quantitatively assessed our inpainting results with the *structural sim*ilarity index measure (SSIM) [\[8\]](#page-6-7), peak-signal-to-noise-ratio (PSNR), and meansquare-error (MSE).

Considering the slow inference speed of 3D Palette, we conducted evaluations on only ten samples, whereas pGAN, ResViT, and the baseline model were evaluated on 250 samples in addition to the ten samples. The results are shown in Tables [1](#page-5-0) and [2.](#page-5-1)

<span id="page-5-0"></span>Table 1. Quantitative comparison (mean±standard deviation) of inpainting results on 250 samples.

Model	<b>SSIM</b>	<b>PSNR</b>	MSE
3D Pix2Pix	$0.8072 \pm 0.1292$	$19.2986 + 2.4886$	$0.0111 \pm 0.0068$
pGAN	$0.7679 \pm 0.1531$	$18.0701 \pm 2.7323$	$0.0159 \pm 0.0132$
ResViT	$0.7454 \pm 0.1521$	$16.9280 \pm 2.0234$	$0.0192 \pm 0.0088$

<span id="page-5-1"></span>Table 2. Quantitative comparison (mean±standard deviation) of inpainting results on ten samples.

Model	<b>SSIM</b>	<b>PSNR</b>	MSE
3D Pix2Pix	$0.7209 \pm 0.0955$	$18.9827 \pm 2.1998$	$0.0143 \pm 0.0071$
pGAN	$0.6746 \pm 0.1044$	$17.5363 \pm 2.9347$	$0.0219 \pm 0.0141$
ResViT	$0.6260 \pm 0.1105$	$17.8071 \pm 1.8430$	$0.0181 \pm 0.0079$
3D Palette	$0.6222 + 0.1218$	$16.6225 \pm 2.4153$	$0.0259 \pm 0.0177$

An intriguing observation is that while ResViT produces results with more realistic details than pGAN, its performance measured by the metrics does not surpass that of pGAN.

# 4 Discussion

Based on the results of the qualitative evaluation, it is evident that for the inpainting tasks considered in this work, the models often experience a loss of detailed structure. For the inferior outcome metrics of ResViT in quantitative evaluation compared to 3D Pix2Pix, one possible reason could be related to slice continuity issues. The objective of our upcoming work is to modify the model structure of ResViT to enable its compatibility with 3D data. Furthermore, the combination of inpainting results from multiple models to achieve better inpainting quality may be explored in future.
