ABSTRACT

This paper presents a neural vocoder based on a denoising diffusion probabilistic model (DDPM) incorporating explicit periodic signals as auxiliary conditioning signals. Recently, DDPM-based neural vocoders have gained prominence as non-autoregressive models that can generate high-quality waveforms. The neural vocoders based on DDPM have the advantage of training with a simple time-domain loss. In practical applications, such as singing voice synthesis, there is a demand for neural vocoders to generate high-fidelity speech waveforms with flexible pitch control. However, conventional DDPM-based neural vocoders struggle to generate speech waveforms under such conditions. Our proposed model aims to accurately capture the periodic structure of speech waveforms by incorporating explicit periodic signals. Experimental results show that our model improves sound quality and provides better pitch control than conventional DDPM-based neural vocoders.

Index Terms— Speech synthesis, singing voice synthesis, neural vocoder, diffusion probabilistic model, pitch controllability

1. INTRODUCTION

A neural vocoder is a deep neural network (DNN) that generates speech waveforms from acoustic features and have been used in various speech applications, including speech synthesis [1], singing voice synthesis [2], and voice conversion. The success of these applications depends heavily on the capabilities of the neural vocoder, such as generated sound quality, inference speed, and controllability.

There are several types of neural vocoders, such as autoregressive (AR) [3–6] and non-AR ones [7–12]. Notably, non-AR neural vocoders leveraging generative adversarial networks (GANs) [13] have gained popularity in generating high-quality speech waveforms at high speed [10–12]. These methods are usually challenging to train with only adversarial loss and need to be combined with multiple auxiliary losses with weighting parameters, leading to complicated training procedures.

In recent advances in image generation, denoising diffusion probabilistic models (DDPMs) [14–17] have emerged as promising generative models that outperforms traditional GAN-based models [18, 19]. Several studies [20, 21] have successfully incorporated DDPMs into neural vocoders, which can be trained with a simple time-domain loss function while achieving generated sound quality comparable to AR neural vocoders. However, DDPMs involve an iterative denoising process during inference, resulting in a tradeoff between performance and speed. Later studies have proposed data-dependent adaptive priors [22, 23], improved modeling frameworks [24, 25], and better training strategies [26] to reduce the number of iterations while maintaining sound quality.

Since neural vocoders are data-driven approaches, they present challenges in controllability compared with conventional signalprocessing-based vocoders [27]. In particular, the controllability of the fundamental frequency (F_0) is an essential issue for neural vocoders in practical applications such as speech and singing voice synthesis. As an extension to GAN-based neural vocoders, several methods inputting sinusoidal signals corresponding to the pitch of the speech waveform as explicit periodic signals have been proposed to achieve superior pitch controllability [28-30]. Another effect of using periodic signals is the capability to generate speech waveforms with higher sampling rates, such as 48 kHz, without increasing the model size or changing the model structure [28]. Such pitch-controllable, high-sampling-rate speech waveform generation models are in demand for professional use cases such as music production. Nevertheless, despite this, DDPM-based neural vocoders suitable for these practical use cases have not been sufficiently investigated. Tackling these challenges will broaden the range of applications of DDPM-based neural vocoders.

In this paper, we introduce a novel DDPM-based neural vocoder conditioned by explicit periodic signals, following previous pitchrobust neural vocoders. The proposed model is based on Prior-Grad [22], which can generate speech waveforms with reasonable inference cost. The experimental results show that the proposed model improves the sound quality of speech waveforms at high sampling rates and F_0 controllability.

2. DDPM-BASED NEURAL VOCODER

Let $\mathbf{x}_0 = (x_1, x_2, \dots, x_N)$ be a speech waveform corresponding to the acoustic feature sequence $\mathbf{c} = (\mathbf{c}_1, \mathbf{c}_2, \dots, \mathbf{c}_K)$, where N is the number of samples of the speech waveform and K is the number of frames of the acoustic feature. A neural vocoder is defined as a DNN that generates a sample sequence of the speech waveform \mathbf{x}_0 corresponding to the acoustic feature sequence \mathbf{c} .

2.1. Overview of DDPM

A DDPM is a deep generative model defined by two Markov chains: the *forward* and *reverse* processes. The *forward process* gradually diffuses the data \mathbf{x}_0 to standard noise \mathbf{x}_T as follows:

$$q(\mathbf{x}_{1:T}|\mathbf{x}_0) = \prod_{t=1}^T q(\mathbf{x}_t|\mathbf{x}_{t-1}), \tag{1}$$

where T is the number of steps of DDPMs, and $q(\mathbf{x}_t|\mathbf{x}_{t-1}) = \mathcal{N}(\mathbf{x}_t; \sqrt{1-\beta_t}\mathbf{x}_{t-1}, \beta_t \mathbf{I})$ is a transition probability that adds small Gaussian noise in accordance with a predefined noise schedule $\{\beta_1, ..., \beta_T\}$. This formulation enables us to sample $\mathbf{x}_t \sim q(\mathbf{x}_t|\mathbf{x}_0)$ at an arbitrary timestep t in a closed form as

$$\mathbf{x}_t = \sqrt{\bar{\alpha}_t} \mathbf{x}_0 + \sqrt{1 - \bar{\alpha}_t} \boldsymbol{\epsilon},\tag{2}$$

where $\alpha_t = 1 - \beta_t$, $\bar{\alpha}_t = \prod_{s=1}^t \alpha_s$, and $\boldsymbol{\epsilon} \sim \mathcal{N}(\mathbf{0}, \mathbf{I})$.

The *reverse process* is a denoising process that gradually generates data \mathbf{x}_0 from standard noise $p(\mathbf{x}_T)$ as follows:

$$p_{\theta}(\mathbf{x}_{0:T}) = p(\mathbf{x}_T) \prod_{t=1}^T p_{\theta}(\mathbf{x}_{t-1} | \mathbf{x}_t),$$
(3)

where $p_{\theta}(\mathbf{x}_{t-1}|\mathbf{x}_t)$ is modeled by a DNN with parameters θ . As both forward and reverse processes have the same function form when β_t is small, the transition probability of the reverse process is parameterized as $p_{\theta}(\mathbf{x}_{t-1}|\mathbf{x}_t) = \mathcal{N}(\mathbf{x}_{t-1}; \boldsymbol{\mu}_{\theta}(\mathbf{x}_t, t), \gamma_t \mathbf{I})$, where $\gamma_t = \frac{1 - \bar{\alpha}_{t-1}}{1 - \bar{\alpha}_t} \beta_t$ and $\gamma_1 = 0$. The mean $\boldsymbol{\mu}_{\theta}(\mathbf{x}_t, t)$ is defined as

$$\boldsymbol{\mu}_{\theta}(\mathbf{x}_{t},t) = \frac{1}{\sqrt{a_{t}}} \left(\mathbf{x}_{t} - \frac{\beta_{t}}{\sqrt{1 - \bar{\alpha}_{t}}} \boldsymbol{\epsilon}_{\theta}(\mathbf{x}_{t},\mathbf{c},t) \right), \qquad (4)$$

where $\epsilon_{\theta}(\mathbf{x}_t, \mathbf{c}, t)$ is a DNN for predicting noise contained in \mathbf{x}_t .

A DDPM can be regarded as a latent variable model with $\mathbf{x}_{1:T}$ as the latent variable. The model $\epsilon_{\theta}(\mathbf{x}_t, \mathbf{c}, t)$ can be optimized by maximizing the evidence lower bound (ELBO) of the log-likelihood $p(\mathbf{x}_0)$. However, DDPM-based neural vocoders [20, 21] generally use a simplified loss $L_{\text{DDPM}}(\theta)$, following [15], as

$$L_{\text{DDPM}}(\theta) = \mathbb{E}_{q} \left[||\boldsymbol{\epsilon} - \boldsymbol{\epsilon}_{\theta}(\mathbf{x}_{t}, \mathbf{c}, t)||_{2}^{2} \right],$$
(5)

where $|| \cdot ||_p$ is the L_p norm.

2.2. PriorGrad

The pioneer DDPM-based neural vocoders, WaveGrad [20] and DiffWave [21], require over 200 iterations to achieve sufficient quality comparable to AR neural vocoders. PriorGrad introduces an adaptive prior $\mathcal{N}(\mathbf{0}, \Sigma_{\mathbf{c}})$, where the diagonal variance $\Sigma_{\mathbf{c}}$ is computed from \mathbf{c} as $\Sigma = \text{diag}[(\sigma_1^2, \sigma_2^2, \ldots, \sigma_N^2)]$, where σ_n^2 represents the power at the *n*-th sample obtained by interpolating the normalized frame-level energy calculated from \mathbf{c} . The loss function is also modified to use the Mahalanobis distance in accordance with $\Sigma_{\mathbf{c}}$, as

$$L_{\text{Prior}}(\theta) = \mathbb{E}_{q} \left[\left| \left| \boldsymbol{\epsilon} - \boldsymbol{\epsilon}_{\theta}(\mathbf{x}_{t}, \mathbf{c}, t) \right| \right|_{\boldsymbol{\Sigma}_{\mathbf{c}}^{-1}}^{2} \right],$$
(6)

where $||\mathbf{x}||_{\boldsymbol{\Sigma}^{-1}}^2 = \mathbf{x}^\top \boldsymbol{\Sigma}^{-1} \mathbf{x}$. Intuitively, as the power envelope of the adaptive prior is closer to that of the target speech waveform than that of the standard Gaussian prior, PriorGrad achieves faster model convergence and inference with better denoising performance.

3. PROPOSED METHOD: PERIODGRAD

Speech waveforms are strongly autocorrelated signals, a characteristic that makes them inherently different from other tasks where DDPMs have been successful, such as image generation. Existing DDPM-based neural vocoders need to learn the periodic structure of speech in an entirely data-driven manner, which may limit the flexibility of F_0 control during inference. Additionally, it may also be challenging to generate periodic speech even with a limited amount of training data and high sampling rates. Using explicit periodic information may be helpful for DDPM-based neural vocoder in generating speech waveforms.

We propose PeriodGrad, a DDPM-based neural vocoder that leverages explicit periodic signals as conditions. In PeriodGrad, the extended noise estimation model $\epsilon_{\theta}(\mathbf{x}_t, \mathbf{c}, \mathbf{e}, t)$ denoises the noise from the input signal \mathbf{x}_t conditioned on the auxiliary feature \mathbf{c} and the periodic signal $\mathbf{e} = [\mathbf{e}_1, \mathbf{e}_2, \dots, \mathbf{e}_N]$. PeriodGrad uses the sinebased periodic signal, which consists of sample-level signals concatenated with sine waves and voiced/unvoiced (V/UV) signals as the periodic signal \mathbf{e} , as in the previous study [28]. Any model structure can be used, by simply introducing an additional condition embedding layer. PeriodGrad can be trained using the same training criterion as conventional DDPM-based neural vocoders, such as Eq. (5) or Eq. (6). According to PriorGrad [22], we adopt the energy-based adaptive prior, and the model is trained using the following loss function:

$$L_{\text{Period}}(\theta) = \mathbb{E}_q \left[||\boldsymbol{\epsilon} - \boldsymbol{\epsilon}_{\theta}(\mathbf{x}_t, \mathbf{c}, \mathbf{e}, t)||_{\boldsymbol{\Sigma}_{\mathbf{c}}^{-1}}^2 \right].$$
(7)

4. EXPERIMENT

4.1. Experimental conditions

We conducted experiments using 70 Japanese children's songs by one single female singer. Sixty songs (approx. 70 min.) were used for training, and the remaining ten songs (approx. 6 min.) were used for testing. The sampling frequency of the audio waveform was 48kHz, and the quantization bit was 16 bits. We used two types of acoustic feature sets: voc: 50-dimensional mel-cepstral coefficients, a continuous $\log F_0$ value, 25-dimensional aperiodicity, and a V/UV binary flag, and ms+F0: 80-dimensional log mel-spectrograms, a continuous $\log F_0$ value, and a V/UV binary flag. Note that ms+F0 is the same configuration employed in several singing voice synthesis approaches [31]. Mel-cepstral coefficients were extracted by WORLD [27]. Mel-spectrograms were extracted with 2048-point fast Fourier transform using a 25-ms Hanning window. Voting results from three different $\log F_0$ extractors were used to reduce the impact of extraction errors [32]. The $\log F_0$ was interpolated before being fed into neural vocoders. All feature vectors were extracted with a 5-ms shift, and the features were normalized to have zero mean and unit variance before training. The explicit periodic signal used as the input to the neural vocoders was generated based on the glottal closure instants extracted from the natural waveform during training and based on non-interpolated $\log F_0$ during inference.

We compared PeriodGrad with two neural vocoders: PriorGrad, as a DDPM-based baseline model [22], and PeriodNet, as a pitch-controllable GAN-based model [28]. These methods were trained with two auxiliary feature sets: **voc** and **ms+F0**.

In PriorGrad, we used the same model architecture with 30 layers of non-causal dilated convolutions with three dilation cycles as in the original settings [22], except that the upsampling scale was adjusted to a 5 ms frame shift. The number of iterations during training and inference was set to 50 and 12, respectively. The noise schedule was set to linspace (1e-4, 0.05, 50) during training and [0.0001, 0.0005, 0.0008, 0.001, 0.005, 0.008, 0.01, 0.05, 0.08, 0.1, 0.2, 0.5] during inference, by following the official implementation¹. In the case of **ms+F0**, the normalized energy was calculated according to the original paper [22]. In the case of **voc**, the normalized energy was derived from the impulse response calculated from the mel-cepstrum coefficients.

In PeriodGrad, we added a fully-connected layer into each block of non-causal dilated convolution in PriorGrad to embed the periodic signal and performed training and inference under the same conditions as in PriorGrad.

In PeriodNet, we used the PeriodNet parallel model denoted as PM1 in [28], which consists of a periodic and aperiodic generator. A sine wave and V/UV signal were used as the periodic input signal of the periodic generator. The model architecture and training configuration were the same as in [28]. The generator in PeriodNet was trained using multi-resolution short-time Fourier transform (STFT)

loss and adversarial loss. The discriminator in PeriodNet adopted a multi-scale structure in the same configuration as [28].

4.2. Objective evaluation

The root mean square error (RMSE) of $\log F_0$ (F_0 -RMSE) [semitones] and the V/UV error rate (V/UV-ER) [%] were used to evaluate the pitch accuracy of generated waveforms objectively. We evaluated the normal copy-synthesis settings and the copy-synthesis with $\log F_0$ shifting by -12 to +12 semitones.

Figures 1 and 2 show examples of $\log F_0$ extracted from the generated waveforms and the results of the objective evaluation. From Fig. 2(a), in most cases, it can be seen that **PeriodGrad (voc)** has better accuracy in reproducing the given $\log F_0$ than **Prior-Grad (voc)**. This result indicates that using explicit periodic signals improves the F_0 controllability in the DDPM-based neural vocoders, similar to GAN-based ones. However, even with **PeriodGrad (voc)**, the F_0 -RMSE worsens significantly when the input F_0 is shifted upward by six semitones or more. In addition, the F_0 -RMSE did not reach the level of **PeriodNet (voc)** for any shift amount. Compared with PeriodNet, which deterministically generates periodic components from explicit periodic signals, PeriodGrad, which employs multiple sampling at inference under the DDPM framework, may have found it more challenging to generate waveforms with proper periodic structures corresponding to explicit periodic signals.

Incidentally, both **PriorGrad (ms+F0)** and **PeriodGrad (ms+F0)** could not reproduce the target $\log F_0$ when the shifted $\log F_0$ was fed into these methods, as shown in Fig 1, resulting in a significant F_0 -RMSE deterioration. **PeriodNet (ms+F0)** also has a distinctly worse F_0 -RMSE than **PeriodNet (voc)** when the $\log F_0$ was downward-shifted by more than ten semitones. The mel-spectrogram contains the pitch information of speech, unlike

the WORLD features. Even if F_0 had been explicitly used as an auxiliary feature, the neural vocoder would have modeled the speech waveform by focusing on the pitch information in the melspectrogram instead of given F_0 . We hypothesize there are two reasons why the explicitly given F_0 tends to be ignored: 1) Due to the difficulty of F_0 extraction, there are extraction errors such as octave confusion and V/UV detection error in the extracted F_0 . 2) The unvoiced regions in the extracted F_0 are linearly interpolated before being fed into the neural vocoder as a continuous feature. In these cases, there is no direct relationship between F_0 and the periodic structure of the waveform, which confuses the model. In contrast, since these problems do not exist in the pitch information embedded in the mel-spectrogram, the models tend to trust the pitch information embedded in the mel-spectrogram instead of the explicitly given F_0 .

It can also be seen from Fig. 2(b) that when the input F_0 is largely shifted upward, the V/UV-ERR becomes worse. This is because when the neural vocoder generates a waveform whose pitch is outside the range of the training data, the generated waveform becomes noisy, and the voice tends to crack, making it difficult to perform proper F_0 extraction in such cases.

4.3. Subjective evaluation

We performed 5-scale mean opinion score (MOS) tests² to evaluate the quality of the generated singing voice waveforms. In these experiments, samples were generated by each model conditioned on three different scales of log F_0 : original log F_0 , upward-shifted log F_0 by 3 semitones (300 cents), and downward-shifted log F_0 by 3 semitones (-300 cents). Thirteen participants evaluated 10 phrases randomly selected from 10 songs in the test data and evaluated a total of six methods, combining feature sets **voc** and **ms+F0** for each of **PeriodNet**, **PriorGrad**, and **PeriodGrad**. These listening tests were conducted separately. In the experiment with the original F_0 scale, the natural waveform **Natural** was also used for comparison.

The results of the subjective evaluation are presented in Fig. 3. Examples of spectrograms of the generated waveforms are also shown in Fig. 4. In the original F_0 scale, the proposed **Period-Grad (voc)** significantly outperformed **PriorGrad (voc)**, as shown in Fig. 3(a). The spectrogram of the waveform generated by **Prior-Grad (voc)** showed an unnatural fluctuation at the low-frequency range, as shown in the highlighted boxes at the bottom of the **Prior-Grad (voc)** in Fig. 4, which decreased the quality of the generated

²Audio samples are available at the following URL: https://www.sp.nitech.ac.jp/~hono/demos/icassp2024/

Fig. 3: Results of subjective evaluation with 95% confidence intervals. The methods annotated with * have insufficient pitch control performance. These methods are impractical, even if the subjective rating of sound quality could be better.

Fig. 4: Spectrograms of the natural and generated singing voices.

speech waveform. On the other hand, since the generated waveforms of PeriodGrad (voc) did not show such degradation, its MOS value was significantly improved compared with **PriorGrad** (voc), which suggests that the explicit periodic signal contributed significantly to the improvement of the quality of the generated speech waveform even in the DDPM-based neural vocoders. However, PeriodGrad (voc) is still not as good as PeriodNet in terms of the generated speech quality. From Fig. 4, it can be seen that Prior-Grad and PeriodGrad have a low quality of generating harmonic components contained in the natural waveform above 6 kHz. This indicates that there is still room for improvement in the quality of the generated 48 kHz sampled waveform.

On the other hand, PeriodNet (ms+F0), PriorGrad (ms+F0), and PeriodGrad (ms+F0) showed better MOS scores than Period-Net (voc), PriorGrad (voc), and PeriodGrad (voc), respectively, as shown in Fig. 3(a). Notably, in PriorGrad (ms+F0), the unnatural fluctuation in the low-frequency range was not observed unlike the spectrogram of PriorGrad (voc). In addition, the quality of Period-Grad (ms+F0) also approached that of PeriodNet (voc) and PeriodNet (ms+F0). Using the mel-spectrogram rather than vocoder parameters extracted using the WORLD vocoder improved the sound quality of the generated waveform significantly.

We discuss the results of the case of $\log F_0$ shifting in Fig. 3(b) and Fig. 3(c). First, PriorGrad (voc), PriorGrad (ms+F0), and PeriodGrad (ms+F0) were impractical since the pitch of generated sounds was not shifted properly, as mentioned in section 4.2. In particular, PriorGrad (ms+F0) showed a high score; however, this is not valuable. Since PriorGrad (ms+F0) ignores the given shifted $\log F_0$ inputs and consistently generates a waveform like the same as in the normal case, there is no conspicuous degradation due to pitch shifting. Hence, its subjective score was easily higher than most other comparisons, showing degraded sound quality due to pitch shifting. While PeriodGrad (voc) showed better performance than PriorGrad (voc), PeriodGrad (voc) did not reach PeriodNet (voc). We found that the upward-shifted waveforms generated by PeriodGrad (voc) sometimes contained noise. Another noteworthy point is that the MOS score of PeriodGrad (voc) decreased slightly with the $\log F_0$ downward shift and substantially with the $\log F_0$ upward shift, compared with **PeriodNet** (voc). PeriodGrad (voc), with multiple sampling in the DDPM inference process, may not be robust to $\log F_0$ shifting compared to the **Period**-Net (voc). Incidentally, PeriodGrad (ms+F0) showed the lowest score for both the upward and downward F_0 shifting cases. In **PeriodGrad** (ms+F0), when F_0 is shifted, both the components corresponding to the shifted and original F_0 appear in the generated waveform. This phenomenon indicates that PeriodGrad (ms+F0) also utilizes pitch information embedded in the mel-spectrogram, which does not change with F_0 shifting, along with the F_0 and the periodic signal. Note that a similar phenomenon sometimes occurred when high-pitch waveforms were generated in PeriodGrad (voc). This result suggests that the mel-cepstrum also retains some information correlated with F_0 . Appropriate disentanglement of pitch and spectrum parameters is a promising direction for future work.

5. CONCLUSION

We proposed a DDPM-based neural vocoder called PeriodGrad that uses an explicit periodic signal as an additional condition. The proposed model can generate a speech waveform while considering the periodic structure of the speech waveform explicitly in the reverse process of the DDPM. The experimental results showed that Period-Grad achieved better sound quality and F_0 controllability than the conventional DDPM-based neural vocoder in the task of generating 48-kHz singing voice waveforms. While there are still challenges in certain scenarios, PeriodGrad would mark a significant step towards providing the ability to control the pitch of the output waveform in DDPM-based neural vocoders.

Future work includes conducting experiments using various kinds of waveforms, such as speech and music, to investigate the performance of the proposed model. In addition, disentangling pitch information from spectral parameters is an important issue in building a pitch-controllable DDPM-based neural vocoder with better performance and robustness.
