# MATRIX INVERTIBLE EXTENSIONS OVER COMMUTATIVE RINGS. PART III: HERMITE RINGS 

GRIGORE CĂLUGĂREANU, HORIA F. POP, ADRIAN VASIU

#### Abstract

We reobtain and often refine prior criteria due to Kaplansky, McGovern, Roitman, Shchedryk, Wiegand, and Zabavsky-Bilavska and obtain new criteria for a Hermite ring to be an EDR. We mention three criteria: (1) a Hermite ring $R$ is an $E D R$ iff for all pairs $(a, c) \in R^{2}$, the product homomorphism $U(R / R a c) \times U(R / R c(1-a)) \rightarrow U(R / R c)$ between groups of units is surjective; (2) a reduced Hermite ring is an EDR iff it is a pre-Schreier ring and for each $a \in R$, every zero determinant unimodular $2 \times 2$ matrix with entries in $R / R a$ lifts to a zero determinant matrix with entries in $R$; (3) a Bézout domain $R$ is an $E D D$ iff for all triples $(a, b, c) \in R^{3}$ there exists a unimodular pair $(e, f) \in R^{2}$ such that $(a, e)$ and ( $b e+a f, 1-a-b c$ ) are unimodular pairs. We use these criteria to show that each Bézout ring $R$ that is an $(S U)_{2}$ ring (as introduced by Lorenzini) such that for each nonzero $a \in R$ there exists no nontrivial self-dual projective $R / R a$-module of rank 1 generated by 2 elements (e.g., all its elements are squares), is an $E D R$.

## 1. Introduction

Let $R$ be a commutative ring with identity. Let $U(R), N(R), J(R), Z(R)$ and $\operatorname{Pic}(R)$ be its group of units, its nilpotent radical, its Jacobson radical, its set of zero divisors, and its Picard group (respectively). For $a \in R$, let $\operatorname{Ann}_{R}(a)$ be its annihilator in $R$. For $n \in \mathbb{N}=\{1,2, \ldots\}$, let $\mathbb{M}_{n}(R)$ be the $R$-algebra of $n \times n$ matrices with entries in $R$. Let $G L_{n}(R)$ be the general linear group of units of $\mathbb{M}_{n}(R)$. Let $S L_{n}(R):=\left\{M \in G L_{n}(R) \mid \operatorname{det}(M)=1\right\}$ be the special linear subgroup of $G L_{n}(R)$. Let $U m(F)$ be the set of unimodular elements of a free $R$-module $F$. We say that $A, B \in \mathbb{M}_{2}(R)$ are congruent modulo an ideal $I$ of $R$ if $A-B \in \mathbb{M}_{2}(I)$.

In this paper we study Bézout rings, i.e., rings whose finitely generated ideals are principal. Each Bézout ring is an arithmetical ring, i.e., its lattice of ideals is distributive and all its localizations at prime ideals are valuation rings (see [10], Thms. 1 and 2). The ring $R$ is a Bézout ring iff each diagonal matrix with entries in $R$ admits diagonal reduction (see [11, Thm. (3.1)). Each Hermite ring $R$ in the sense of Kaplansky, i.e., defined by the identity $R^{2}=R U m\left(R^{2}\right)$, is a Bézout ring but the converse does not hold (see [6], Ex. 3.4, [20], Ex. 3.3, or [2], Prop. 8). However, a Hermite domain is the same as a Bézout domain. Bézout domains are $G C D$ (greatest common divisors exist) domains and hence pre-Schreier domains with trivial Picard groups. As $R$ is a Hermite ring iff each $1 \times 2$ matrix with entries in $R$ admits diagonal reduction, each $E D R$ is a Hermite ring. We will use the tools

[^0]of Parts I and II in order to obtain necessary and sufficient criteria for a Hermite ring (or domain) to be an $E D R$ (or an $E D D$, i.e., an elementary divisor domain).

Let $A \in \operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$. Recall that $A$ is called extendable if it is obtained from a matrix $A^{+} \in S L_{3}(R)$ by removing its third row and its third column (see [3], Def. 1.1). If we can choose $A^{+}$such that its $(3,3)$ entry is 0 , then $A$ is called simply extendable. Recall that $A$ is called determinant liftable (resp. weakly determinant liftable) if there exists $B \in U m\left(\mathbb{M}_{2}(R)\right)$ (resp. $B \in \mathbb{M}_{2}(R)$ ) congruent to $A$ modulo $R \operatorname{det}(A)$ and with $\operatorname{det}(B)=0$ (see [3], Def. 1.1). The only general implications between these 4 notions on $A$ are the ones in the diagram

(see [4], Thm. 1.3 for the vertical ones; for the fact that their converses do not hold and that there exist no implications between extendable and determinant liftable see [3], Exs. 5.3 and 6.2 and [4, paragraph after Thm. 1.3 and Ex. 1.9). Recall that a matrix $B \in \mathbb{M}_{2}(R)$ is caled non-full if it is the product of a $2 \times 1$ and a $1 \times 2$ matrix with entries in $R$.

Recall from [3], Def. 1.2 that $R$ is called a $\Pi_{2}$ ring if each matrix in $\operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$ of zero determinant is extendable, equivalently it is simply extendable by [3], Lem. $4.1(1)$ and that $R$ is called an $E_{2}$ (resp. an $\left.S E_{2}\right)$ ring if each matrix in $\operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$ is extendable (resp. simply extendable). If $\operatorname{Pic}(R)$ is trivial (say, $R$ is a Bézout domain), then $R$ is a $\Pi_{2}$ ring (see [3], paragraph after Thm. 1.4).

See [3], Def. 1.5 for stable ranges notation. If $R$ is a Hermite ring, then $\operatorname{sr}(R) \leq 2$ (see [14], Prop. 8(i) or [21], Cor. 2.1.1). In fact, a Bézout ring $R$ is a Hermite ring iff $\operatorname{sr}(R) \leq 2$ (see [21], Thm. 2.1.2). Bézout domains that have stable range 1 or 1.5 were also studied in [16] and respectively [18, 19] and 1]. For Hermite rings, Parts I and II get summarized in an example and a theorem as follows.

Example 1.1. For Hermite rings $R$, simply extendable and extendable properties on a matrix in $\operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$ are equivalent (see [3], Thm. 1.6). For Hermite rings $R$ that are $\Pi_{2}$ rings, simply extendable, extendable and determinant liftable properties on a matrix in $\operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$ are equivalent (see [4, Cor. 1.5). For Hermite rings $R$ such that zero determinant matrices in $\operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$ are non-full, the 4 notions on a matrix in $\operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$ are equivalent (see [4], Cor. 1.8).

Theorem 1.2. For a Hermite ring $R$ the following statements are equivalent:
(1) The ring $R$ is an $E D R$.
(2) The ring $R$ is an $S E_{2}$ ring.
(3) The ring $R$ is an $E_{2}$ ring.
(4) For each $a \in R, R / R a$ is a $\Pi_{2}$ ring (equivalently, every projective $R / R a$ module of rank 1 generated by 2 elements is free).
(5) Each matrix in $\operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$ is determinant liftable and $R$ is a $\Pi_{2}$ ring.

If all zero determinant matrices in $\mathbb{M}_{2}(R)$ are non-full, then these five statements are also equivalent to:
(6) Each matrix in $\operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$ is weakly determinant liftable.

See [3], Cor. 1.8 for $(1) \Leftrightarrow(2) \Leftrightarrow(3)$, see [3], Cors. 2.5 and 4.2 for $(3) \Leftrightarrow(4)$, see [3] Thm. 1.4 for the equivalence of (4), and see [4], Thm. 1.4 for (2) $\Leftrightarrow$ (5). See [4] Thm. 1.7 for $(3) \Leftrightarrow(6)$. The equivalence $(1) \Leftrightarrow(4)$ can be viewed as a more practical way to check that a Hermite ring is an EDR than [20], Thm. 2.1 (which does not restrict to only 2 generators) or [23], Thms. 3 and 5 (which work with finitely generated projective modules over all quotients of $R$ ).

Recall that $R$ is a Hermite ring iff for all $p, q \in \mathbb{N}$ and each $p \times q$ matrix $B$ with entries in $R$, there exist $M \in G L_{p}(R)$ and $N \in G L_{q}(R)$ such that $M B$ and $B N$ are both lower (equivalently, upper) triangular (see [7], Thm. 3). Thus, in Theorem 1.2(4) or (5) it suffices to consider only upper triangular matrices, and it is part of the goals of this paper to show that in fact one can restrict to specific upper triangular matrices (e.g., see Propositions 2.2 and 2.3).
Example 1.3. For a ring $R$ (resp. a ring $R$ with $N(R)=0$ ) and ( $a, b, c) \in U m\left(R^{3}\right)$, $A:=\left[\begin{array}{ll}a & b \\ 0 & c\end{array}\right] \in \operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$ is determinant (resp. weakly determinant) liftable iff there exists $(x, y, z, w) \in R^{4}$ such that $a x+b y+c w=1$ and $x w=y z$ (resp. such that $1-a x-b y-c w+a c(x w-y z)=0$ ), see [4], Thm. 1.2 (resp. Thm. 5.1(2) and (3)). Note that $1-a x-b y-c w+a c(x w-y z)=(1-a x)(1-c w)-(b+a c z) y$ (cf. [4], Eq. (II)), hence $A$ is weakly determinant liftable iff there exists $(x, z, w) \in R^{3}$ such that $b+a c z$ divides $(1-a x)(1-c w)$.

Based on Example 1.3 and $(1) \Leftrightarrow(5)$ of Theorem 1.2 it follows directly:
Corollary 1.4. Assume $R$ is a Hermite ring and $a \Pi_{2}$ ring. Then $R$ is an EDR iff for each $(a, b, c) \in U m\left(R^{3}\right)$ there exists $(x, y, z, w) \in R^{4}$ such that $a x+b y+c w=1$ and $x w=y z$ (i.e., there exists $(x, y, w) \in R^{3}$ such that $a x+b y+c w=1$ and $x w \in R y)$.

For Hermite rings, to get necessary and/or sufficient conditions to be EDRs that involve units, one would like to get unit interpretations that would characterize the inequality $s r(R) \leq 2$ in some way similar to [3], Prop. 2.4. As a progress in this direction we introduce using units the following class of rings.
Definition 1.5. We say that $R$ is a $U_{2}$ ring if for each $(a, b) \in U m\left(R^{2}\right)$ and $c \in R$, the natural product homomorphism

$$
v_{a, b, c}: U(R / R a c) \times U(R / R b c) \rightarrow U(R / R c)
$$

is surjective, i.e., the functorial commutative diagram

whose arrows are natural reductions, is not only a pullback but is also a pushout.
For $(a, b) \in U m\left(R^{2}\right)$, if $\left(a^{\prime}, b^{\prime}\right) \in R^{2}$ is such that $a a^{\prime}+b b^{\prime}=1$, then $v_{\left(a a^{\prime}, 1-a a^{\prime}, c\right)}$ factors through $v_{a, b, c}$. Hence $R$ is a $U_{2}$ ring iff $v_{a, 1-a, c}$ is surjective for all $(a, c) \in R^{2}$. The fact that a unit in $U(R / R c)$ does or does not belong to $\operatorname{Im}\left(v_{a, 1-a, c}\right)$ relates to a certain zero determinant matrix being or not being non-full (see Example 3.1).
Example 1.6. Assume $\operatorname{asr}(R)=1$, i.e., $R$ has almost stable range 1. We show that $R$ is a $U_{2}$ ring. Let $(a, b) \in U m\left(R^{2}\right)$ and $c \in R$. If $c \in J(R)$, then $U(R)$ surjects
onto $U(R / R c)$. If $c \notin J(R)$, then, as $c$ is a linear combination of $a c$ and $b c$, either $a c \notin J(R)$ or $b c \notin J(R)$. Hence either $U(R / R a c) \rightarrow U(R /(R a c+R c))=U(R / R c)$ or $U(R / R b c) \rightarrow U(R /(R b c+R c))=U(R / R c)$ is a surjective homomorphisms (see [3], Prop. 2.4(3)). We incur that $v_{a, b, c}$ is surjective.

Recall that a ring $R$ is called pre-Schreier if each $x \in R$ is primal, i.e., if $x$ divides $y z$, with $(y, z) \in R^{2}$, then there exists $(u, v) \in R^{2}$ such that $x=u v, u$ divides $y$ and $v$ divides $z$. The next two examples underline the relevance of this class of rings.

Example 1.7. Let $R$ be such that each zero determinant matrix $B \in \mathbb{M}_{2}(R)$ is non-full. We show that $R$ is a pre-Schreier ring. Let $(x, y, z) \in R^{3}$ be such that $x$ divides $y z$. Let $w \in R$ be such that $x w=y z$. Let $C:=\left[\begin{array}{cc}x & y \\ z & w\end{array}\right] \in \mathbb{M}_{2}(R)$. As $\operatorname{det}(C)=0$, there exists $(l, m, o, q) \in R^{4}$ such that $C=\left[\begin{array}{c}l \\ m\end{array}\right]\left[\begin{array}{ll}o & q\end{array}\right]$. Hence $x=l o$ with $l$ dividing $y=l q$ and $o$ dividing $z=m o$. Thus $R$ is a pre-Schreier ring.
Example 1.8. Assume $N(R)=0$. Let $B \in \mathbb{M}_{2}(R)$ with $\operatorname{det}(B)=0$. We check that if $B$ admits diagonal reduction, then $B$ is non-full. Let $M, N \in G L_{2}(R)$ be such that $M B N=\left[\begin{array}{cc}a & 0 \\ 0 & a b\end{array}\right]$ with $(a, b) \in R^{2}$. As $\operatorname{det}(B N)=\operatorname{det}(M) \operatorname{det}(B) \operatorname{det}(N)=$ $0=a^{2} b$, it follows that $(a b)^{2}=0$ and thus, as $N(R)=0$, we have $a b=0$. So, $B=M^{-1}\left[\begin{array}{ll}a & 0 \\ 0 & 0\end{array}\right] N^{-1}=M^{-1}\left[\begin{array}{l}a \\ 0\end{array}\right]\left[\begin{array}{ll}1 & 0\end{array}\right] N^{-1}$ is non-full.

From Examples 1.7 and 1.8 we get directly:
Corollary 1.9. If $R$ is an $E D R$ with $N(R)=0$, then $R$ is a pre-Schreier ring.
Section 3 proves the following theorem.
Theorem 1.10. We assume that one of the following conditions holds:
(1) for each $(a, b, c) \in U m\left(R^{3}\right)$ there exists $(x, y, z, w) \in R^{4}$ such that $1-a x-$ $b y-c w+a c(x w-y z)=0$ and $R$ is a pre-Schreier ring;
(2) each upper triangular matrix in $\operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$ is simply extendable and $R$ is either a $\Pi_{2}$ ring or an integral domain (e.g., $R$ is an $S E_{2}$ ring).

Then $R$ is a $U_{2}$ ring.
Example 1.11. Assume each upper triangular matrix in $\operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$ is weakly determinant liftable (e.g., this holds if $R$ is a $W J_{2,1}$ ring in the sense of [4], Def. $1.10(1)$, see [4], Thm. $1.11(1))$. If $R$ is also a pre-Schreier ring with $N(R)=0$, then condition (1) of Theorem 1.10 holds by Example 1.3 hence $R$ is a $U_{2}$ ring.

Each Dedekind domain is a $U_{2}$ ring by Example 1.6. Hence Dedekind domains which are not PIDs are $U_{2}$ rings which are not $\Pi_{2}$ rings (see [3], Thm. 1.7(4)).

In Section 4 we prove the following 'units supplement' to Theorem 1.2
Theorem 1.12. For a Hermite ring $R$ the following statements are equivalent:
(1) The ring $R$ is an EDR.
(2) The ring $R / N(R)$ is a pre-Schreier ring and each matrix in $\operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$ is weakly determinant liftable.
(3) The ring $R$ is a $U_{2}$ ring.
(4) Given two unimodular pairs $(a, b),(c, d) \in U m\left(R^{2}\right)$, there exists $t \in R$ such that we can factor $d+c t=d_{1} d_{2}$ with $\left(a, d_{1}\right),\left(b, d_{2}\right) \in U m\left(R^{2}\right)$.
(5) Given $(a, d) \in R^{2}$ and $c \in 1+R d$, there exists $t \in R$ such that we can factor $d+c t=d_{1} d_{2}$ with $\left(a, d_{1}\right),\left(1-a, d_{2}\right) \in U m\left(R^{2}\right)$.

Example 1.13. Let $R$ be a Hermite ring which is not an $E D R$ (see [6], Sect. 4 and Ex. 4.11 and [2], Prop. 8). From Theorems 1.2 and 1.12 it follows that $R$ is neither an $E_{2}$ ring nor a $U_{2}$ ring and there exists $a \in R$ such that the Hermite ring $R / R a$ is not a $\Pi_{2}$ ring.

Theorem 1.12 implies directly the following result 1
Corollary 1.14. Assume $R$ is a Hermite ring and a pre-Schreier ring with $N(R)=$ 0 . Then $R$ is an EDR iff each matrix in $\operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$ is weakly determinant liftable and iff for each $(a, b, c) \in U m\left(R^{3}\right)$ there exists $(x, y, z, w) \in R^{4}$ such that

$$
\begin{equation*}
(1-a x)(1-c w)=(b+a c z) y \tag{III}
\end{equation*}
$$

If $\operatorname{asr}(R)=1$, then $R$ is an $U_{2}$ ring (see Example 1.6), thus McGovern's theorem reproved as [3], Cor. 1.9(2) follows from the equivalence (1) $\Leftrightarrow(3)$ of Theorem 1.12

In Section 5 we prove the following ' $\Pi_{2}$ supplement' to Theorem 1.2 ,
Theorem 1.15. Assume $R$ is a Hermite ring with $N(R)=0$. Then $R$ is an $E D R$ iff for each $a \in R$ the quotient ring $R / \operatorname{Ann}_{R}(a)$ is a $\Pi_{2}$ ring and each matrix in $\operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$ is weakly determinant liftable (equivalently, and for every $(a, b, c) \in$ $U m\left(R^{3}\right)$ there exists $(x, y, z, w) \in R^{4}$ such that Equation (III) holds).

Lorenzini introduced 3 classes of rings that are 'between' Hermite rings and $E D R s$ (see [12], Prop. 4.11). For the first class, called $J_{2,1}$ (see [12], Def. 4.6), it was proved in [4, Thm. $1.11(2)$ that each $J_{2,1}$ ring which is a $\Pi_{2}$ ring is an EDR. We recall the last 2 classes of rings (see [12], Def. 2.1) in a slightly different way.

Definition 1.16. For $n \geq 2$ we say that $R$ is:
(1) a $\left(W S U^{\prime}\right)_{n}\left(\right.$ resp. $\left.(W S U)_{n}\right)$ ring if for each $A \in U m\left(\mathbb{M}_{n}(R)\right)$ there exists $N \in S L_{n}(R)$ (resp. $\left.N \in G L_{n}(R)\right)$ such that $A N$ is symmetric;
(2) an $\left(S U^{\prime}\right)_{n}\left(\right.$ resp. $\left.(S U)_{n}\right)$ ring if it a Hermite ring and a $\left(W S U^{\prime}\right)_{n}$ (resp. $\left.(W S U)_{n}\right)$ ring.

In Definition 2.1(1), the existence of $N$ is equivalent to the existence of $M \in$ $S L_{n}(R)\left(\right.$ resp. $\left.M \in G L_{n}(R)\right)$ such that $M A$ is symmetric and equivalent to the existence of $M, N \in S L_{n}(R)$ (resp. $\left.M, N \in G L_{n}(R)\right)$ such that $M A N$ is symmetric. This follows via conjugation from the fact that for each symmetric matrix $O \in$ $\mathbb{M}_{n}(R)$ and every $M \in G L_{n}(R), M O M^{T}$ is symmetric.

Each $\left(W S U^{\prime}\right)_{n}$ ring is a $(W S U)_{n}$ ring. A $(W S U)_{2}$ ring is an $E_{2}$ (resp. $S E_{2}$ ring) iff each symmetric matrix in $\operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$ is extendable (resp. simply extendable). Section 6 proves basic properties of $\left(W S U^{\prime}\right)_{n}$ and $(W S U)_{n}$ rings; e.g., our definition of $\left(S U^{\prime}\right)_{n}$ or $(S U)_{n}$ rings is equivalent to the one in [12] by Proposition 6.1. In Section 7 we prove the following theorem.

[^1]Theorem 1.17. Let $R$ be $a(W S U)_{2}$ ring. Then the following properties hold:
(1) For each $(a, b) \in U m\left(R^{2}\right)$ and $c \in R$, $\operatorname{Coker}\left(v_{a, b, c}\right)$ is a Boolean group, i.e., we have an inclusion $\left\{x^{2} \mid x \in U(R / R c)\right\} \subset \operatorname{Im}\left(v_{a, b, c}\right)$.
(2) If $\operatorname{sr}(R) \leq 4$, then for each $d \in R$, every projective $R / R d$-module of rank 1 generated by 2 elements is self-dual.
(3) Assume that each element of $R$ is the square of an element of $R$ (e.g., this holds if $R$ is an integrally closed domain with an algebraically closed field of fractions or is a perfect ring of characteristic 2 ). Then $R$ is a $U_{2}$ ring. If moreover $R$ is a Hermite ring, then $R$ is an EDR.

In Section 8 we prove the following theorem.
Theorem 1.18. Let $R$ be a Hermite ring with the property that for each $(a, b) \in$ $U m\left(R^{2}\right)$ and $c \in R$, $\operatorname{Coker}\left(v_{a, b, c}\right)$ is a Boolean group. Then for each $d \in R$, every projective $R / R d$-module of rank 1 generated by 2 elements is self-dual.

To connect with Pell-type equations and provide more examples of $(W S U)_{2}$ rings that are EDRs, we first prove in Section 9 the following non-full Pell-type criterion.
Criterion 1.19. Let $A=\left[\begin{array}{ll}a & b \\ b & c\end{array}\right] \in \operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$ be symmetric and with zero determinant. Then the following properties hold:
(1) The matrix $A$ is simply extendable if there exists $(e, f) \in R^{2}$ such that $a e^{2}-c f^{2} \in U(R)$, and the converse holds if $R$ has characteristic 2 .
(2) Assume that $R$ is a Hermite ring of characteristic 2 with $N(R)=0$. If $b$ is not a zero divisor, then $A$ is simply extendable.

By combining Theorem 1.17(1) with Criterion 1.19, we obtain the following Pelltype criterion proved in Section 9
Criterion 1.20. Let $R$ be a $(S U)_{2}$ ring. Then $R$ is an $E D R$ if for all $(a, b, c) \in$ $U m\left(R^{3}\right)$ there exists $(e, f) \in R^{2}$ such that $\left(a e^{2}-c f^{2}, a c-b^{2}\right) \in U m\left(R^{2}\right)$, and the converse holds if $R$ has characteristic 2 .

We recall that, if the characteristic of $R$ if a prime, then its perfection $R_{p e r f}$ is the inductive limit of the inductive system indexed by $n \in \mathbb{N}$ whose all transition homomorphisms are the Frobenius endomorphism of $R$. If $R$ is Hermite (or a Bézout) ring, then so is $R_{\text {per } f} \cong(R / N(R))_{\text {perf }}$.
Example 1.21. Assume $R$ has characteristic 2. If for all $(a, c) \in R^{2}, \operatorname{Coker}\left(v_{a, 1-a, c}\right)$ is a Boolean group, then $R_{\text {perf }}$ is a $U_{2}$ ring. From this and Theorem 1.17(3) it follows that perfections of $(W S U)_{2}$ rings of characteristic 2 are $U_{2}$ rings. Thus perfections of $(S U)_{2}$ rings of characteristic 2 are EDRs by Theorem 1.12,

As an application of Corollary 1.14 in Section 10 we prove:
Criterion 1.22. For a Bézout domain $R$ the following statements are equivalent:
(1) The ring $R$ is an EDD.
(2) For each $(a, b, s) \in R^{3}$, there exists $(q, r) \in R^{2}$ such that by defining $y:=$ $r+s-a s q-b q r$ and $t:=1+q-a q-b r$ we have $t \in R y+$ Rat (equivalently, there exists a product decomposition $y=y_{1} y_{2}$ such that $y_{1}$ divides $t$ and $\left(a, y_{2}\right) \in U m\left(R^{2}\right)$ ).
(3) For each $(a, b, s) \in R^{3}$ there exists $(e, f) \in U m\left(R^{2}\right)$ such that $(a, e),(b e+$ $a f, 1-b s-a) \in U m\left(R^{2}\right)$.
E.g., statement (3) holds if $(a, s) \in U m\left(R^{2}\right)$ as we can take $(e, f):=(s, 1)$, if $(1-a, b) \in U m\left(R^{2}\right)$ as we can take $(e, f):=(1,0)$, or if there exists $q \in R$ such that $(b+a q, 1-b s-a) \in U m\left(R^{2}\right)$ as we can take $(e, f):=(1-a, q+b)$. So, each Bézout domain $R$ with the property that for all $(a, b, s) \in R^{3}$ with $(a, s),(b, 1-a) \notin U m\left(R^{2}\right)$ there exists $q \in R$ such that $(b+a q, 1-b s-a) \in U m\left(R^{2}\right)$, is an EDD.

The implicit and explicit questions raised in the literature, such as, "Is a Bézout domain of finite Krull dimension [at least 2] an EDD?" (see [5], Ch. III, Probl. 5, p. 122), and, 'What classes of Bézout domains which are not EDDs exist?', remain unanswered. However, the above results reobtain or can be easily used to reobtain multiple other criteria existing in the literature of when a Hermite ring is an $E D R$. The equivalence $(1) \Leftrightarrow(4)$ of Theorem 1.12 was proved for Bézout domains in [17], Thm. 5 and a variant of it was proved for Hermite rings in [15], Prop. 2.9. Equation (III) generalizes and refines the equation one would get based on [15], Rm. 2.8. The last two references were reinterpreted in terms of neat stable range (see [22], Def. 21) 1 in [22], Thms. 31 and 33 ; see [13] for clean and neat rings.

## 2. Test matrices

Definition 2.1. Let $A \in U m\left(\mathbb{M}^{2}(R)\right)$. An upper triangular matrix $B \in U m\left(\mathbb{M}^{2}(R)\right)$ will be called a companion test matrix for $A$ if there exists $\left(a, b, c, a^{\prime}, c^{\prime}\right) \in R^{5}$ such that $A$ is equivalent to $\left[\begin{array}{ll}a & b \\ 0 & c\end{array}\right]$ and $B=\left[\begin{array}{cc}a a^{\prime} & b \\ 0 & c c^{\prime}\end{array}\right]$.

Let $\mathcal{P}$ be one of the 4 notions extendable, simply extendable, determinant liftable and weakly determinant liftable. Definition 2.1 is justified by the next proposition.
Proposition 2.2. If $\mathcal{P}$ is weakly determinant liftable we assume that $N(R)=0$. If $A \in U m\left(\mathbb{M}^{2}(R)\right)$ has a companion test matrix $B$ which is $\mathcal{P}$, then $A$ is $\mathcal{P}$.
Proof. As $\mathcal{P}$ property depends only on equivalence classes (see [3], Lem. 4.3(1) for the case of extendable and simply extendable notions), it suffices to show that if $B=\left[\begin{array}{cc}a a^{\prime} & b \\ 0 & c c^{\prime}\end{array}\right]$ is $\mathcal{P}$, then so is $C=\left[\begin{array}{ll}a & b \\ 0 & c\end{array}\right]$.

First we assume that $\mathcal{P}$ is extendable (resp. simply extendable). From [3], Cor. 4.7 (resp. [3], Thm. 4.3) it follows that there exists $(e, g) \in R^{2}$ (resp. $(e, g) \in$ $\left.U m\left(R^{2}\right)\right)$ such that $\left(a a^{\prime} e, b e+c c^{\prime} g, a a^{\prime} c c^{\prime}\right) \in U m\left(R^{3}\right)\left(\right.$ resp. $\left(a a^{\prime} e, b e+c c^{\prime} g\right) \in$ $U m\left(R^{2}\right)$ ). Denoting $f:=c^{\prime} g \in R$, as $\left(a a^{\prime} e, b e+c f, a a^{\prime} c c^{\prime}\right) \in U m\left(R^{3}\right)$ (resp. $\left.\left(a a^{\prime} e, b e+c f\right) \in U m\left(R^{2}\right)\right)$, it follows that $(a e, b e+c f, a c) \in U m\left(R^{3}\right)$ (resp. $(a e, b e+$ $\left.c f) \in U m\left(R^{2}\right)\right)$. Thus $C$ is $\mathcal{P}$ by [3], Cor. 4.7 (resp. [3], Thm. 4.3).

Next we assume that $\mathcal{P}$ is determinant liftable (resp. weakly determinant liftable). From [4, Thm. 1.2 (resp. 4], Thm. $5.1(2)$ and 3) it follows that there exists $(x, y, z, w) \in R^{4}$ such that $1-a a^{\prime} x-b y-c c^{\prime} w=0$ and $x w=y z$ (resp. such that $\left.1-a a^{\prime} x-b y-c c^{\prime} w+a a^{\prime} c c^{\prime}(x w-y z)=0\right)$. If $\left(x^{\prime}, y^{\prime}, z^{\prime}, w^{\prime}\right):=\left(a^{\prime} x, y, a^{\prime} c^{\prime} z, c^{\prime} w\right) \in R^{4}$, then $1-a x^{\prime}-b y^{\prime}-c w^{\prime}=0$ and $x^{\prime} w^{\prime}=y^{\prime} z^{\prime}\left(\right.$ resp. $1-a x^{\prime}-b y^{\prime}-c w^{\prime}+a c\left(x^{\prime} w^{\prime}-y^{\prime} z^{\prime}\right)=$ 0 ), so $C$ is $\mathcal{P}$ by [4], Thm. 1.2 (resp. Thm. 5.1(2) and 3 ).

Until Proposition 2.3 below we assume that $R$ is a Hermite ring, i.e., for every pair $(p, q) \in R^{2}$ there exists $(r, s, t) \in R^{3}$ such that $p=r s, q=r t$ and $(s, t) \in U m\left(R^{2}\right)$. If moreover $R$ is an integral domain (i.e., if $R$ is a Bézout domain), then $r$ is unique up to a multiplication with a unit of $R$ and is called the greatest common divisor of $p$ and $q$ and one writes $r=\operatorname{gcd}(x, y)$. Our convention is $\operatorname{gcd}(0,0)=0$ (so that we can still write $0=0 \cdot 1$ with $\operatorname{gcd}(1,1)=1$ ).

Let $A \in U m\left(\mathbb{M}_{2}(R)\right)$ and $M \in S L_{2}(R)$ be such that $B:=M A=\left[\begin{array}{ll}g & u \\ 0 & h\end{array}\right]$ is upper triangular. We write $g=a c$ and $h=b c$ with $(a, b) \in U m\left(R^{2}\right)$ and $c \in R$. As $B \in U m\left(\mathbb{M}_{2}(R)\right)$ and $R g+R h=R c$, we have $(c, u) \in U m\left(R^{2}\right)$. Let $a^{\prime}, b^{\prime}, c^{\prime}, u^{\prime} \in R$ be such that $a a^{\prime}+b b^{\prime}=c c^{\prime}+u u^{\prime}=1$. For $d \in R, A$ and $B$ are equivalent to

$$
C:=\left[\begin{array}{cc}
1 & d b^{\prime} \\
0 & 1
\end{array}\right] B\left[\begin{array}{cc}
1 & d a^{\prime} \\
0 & 1
\end{array}\right]=\left[\begin{array}{cc}
a c & u+c d\left(a a^{\prime}+b b^{\prime}\right) \\
0 & b c
\end{array}\right]=\left[\begin{array}{cc}
a c & u+c d \\
0 & b c
\end{array}\right]
$$

Here the role of $u+c d$ is that of an arbitrary element of $R$ whose reduction modulo $R c$ is the 'fixed' unit $u+R c \in U(R / R c)$. Note that each matrix $D_{a^{\prime}, b^{\prime}, d}:=$ $\left[\begin{array}{cc}a a^{\prime} c c^{\prime} & u+c d \\ 0 & b b^{\prime} c c^{\prime}\end{array}\right] \in \operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$ is a companion test matrix for $A$ and that $D_{a^{\prime}, b^{\prime}, 0}$ is the image of the 'first universal test matrix for Hermite rings'

$$
\mathcal{D}:=\left[\begin{array}{cc}
x(1-y z) & y \\
0 & (1-x)(1-y z)
\end{array}\right] \in \operatorname{Um}\left(\mathbb{M}_{2}(\mathbb{Z}[x, y, z])\right)
$$

via the ring homomorphism $\mathbb{Z}[x, y, z] \rightarrow R$ that maps $x, y$, and $z$ to $a a^{\prime}, u$, and $u^{\prime}$ (respectively); so $1-x$ maps to $b b^{\prime}=1-a a^{\prime}$ and $1-y z$ maps to $1-u u^{\prime}=c c^{\prime}$. We also note that $\mathcal{D}$ is equivalent to the matrix

$$
\mathcal{E}:=\left[\begin{array}{cc}
1 & 0 \\
z(x-1)(1-y z) & 1
\end{array}\right] \mathcal{D}\left[\begin{array}{cc}
1 & 0 \\
x z & 1
\end{array}\right]=\left[\begin{array}{cc}
x & y \\
0 & (1-x)(1-y z)^{2}
\end{array}\right]
$$

which is the image of the 'second universal test matrix for Hermite rings'

$$
\mathcal{F}:=\left[\begin{array}{cc}
x & y \\
0 & (1-x)(1-y z)
\end{array}\right] \in \operatorname{Um}\left(\mathbb{M}_{2}(\mathbb{Z}[x, y, z])\right)
$$

via the endomorphism of $\mathbb{Z}[x, y, z]$ that fixes $x$ and $y$ and maps $z$ to $2 z-y z^{2}$. See Corollary 4.2 for the usage of universal test matrix in this paragraph.

The 'universal test upper triangular matrix for all rings' is

$$
\mathcal{G}:=\left[\begin{array}{cc}
x & y \\
0 & 1-x-y z
\end{array}\right] \in \operatorname{Um}\left(\mathbb{M}_{2}(\mathbb{Z}[x, y, z])\right)
$$

Proposition 2.3. If $\mathcal{P}$ is weakly determinant liftable we assume that $N(R)=0$. Then the following properties hold:
(1) Each upper triangular matrix in $\operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$ is $\mathcal{P}$ iff for each homomorphism $\phi: \mathbb{Z}[x, y, z] \rightarrow R$, the image of $\mathcal{G} \in \operatorname{Um}\left(\mathbb{M}_{2}(\mathbb{Z}[x, y, z])\right)$ in $\operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$ via $\phi$ is $\mathcal{P}$.
(2) Each zero determinant upper triangular matrix in $\operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$ is $\mathcal{P}$ iff for each homomorphism $\phi: \mathbb{Z}[x, y, z] \rightarrow R$ with $x(1-x-y z) \in \operatorname{Ker}(\phi)$, the image of $\mathcal{G} \in \operatorname{Um}\left(\mathbb{M}_{2}(\mathbb{Z}[x, y, z])\right)$ in $\operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$ via $\phi$ is $\mathcal{P}$.

Proof. The 'only if' parts are clear. For the 'if' part of (1), let $A=\left[\begin{array}{ll}a & b \\ 0 & c\end{array}\right] \in$ $\operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$. Let $\left(a^{\prime}, b^{\prime}, c^{\prime}\right) \in R^{3}$ be such that $a a^{\prime}+b b^{\prime}+c c^{\prime}=1$. Let $\phi: \mathbb{Z}[x, y, z] \rightarrow$ $R$ be the homomorphism that maps $x, y$ and $z$ to $a a^{\prime}, b$ and $b^{\prime}$ (respectively). The image $\left[\begin{array}{cc}a a^{\prime} & b \\ 0 & c c^{\prime}\end{array}\right]$ of $\mathcal{G}$ via $\phi$ is $\mathcal{P}$, so $A$ is $\mathcal{P}$ by Proposition 2.2. The 'if' part of (2) is proved similarly as $a c=0$ implies $a a^{\prime} c c^{\prime}=0$ and $x(1-x-y z) \in \operatorname{Ker}(\phi)$.

## 3. Proof of Theorem 1.10

Let $(a, b) \in U m\left(R^{2}\right)$ and $c \in R$. For a fixed unit $\bar{u} \in U(R / R c)$, let $u \in R$ be such that $\bar{u}=u+(c)$ and consider the matrix $A=\left[\begin{array}{cc}a c & u \\ 0 & b c\end{array}\right] \in \operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$.

Assume $R$ is a pre-Schreier ring and for $(a c, u, b c) \in U m\left(R^{3}\right)$ there exists $(x, y, z, w) \in$ $R^{4}$ such that $1-a c x-u y-b c w+a b c^{2}(x w-y z)=0$; so $(1-a c x)(1-b c w)=$ $y\left(u+a b c^{2} z\right)$ (cf. Example 1.3). As $u+a b c^{2} z$ divides $(1-a c x)(1-b c w)$ and $R$ is a preSchreier ring, we will only use the existence of a nonuple ( $\left.x, y, z_{1}, z_{2}, w, q, r, s, t\right) \in$ $R^{9}$, e.g., $\nu:=(x, y, b c z, 0, w, 1,1,1,1) \in R^{9}$, such that $(a c, s q),(b c, r t) \in U m\left(R^{2}\right)$ and we can decompose $q r u+a c z_{1}+b c z_{2}=u_{a} u_{b}$, with $u_{a} \in R$ dividing $s-a c x$ and $u_{b} \in R$ dividing $t-b c w$. Hence $(q+R a c)^{-1} \cdot\left(u_{a}+R a c\right) \in U(R / R a c)$ and $(r+R b c)^{-1} \cdot\left(u_{b}+R b c\right) \in U(R / R b c)$ are such that the product of their images in $U(R / R c)$ is $\bar{u}$. Thus $R$ is a $U_{2}$ ring.

Assume $R$ is a $\Pi_{2}$ ring and $A$ is simply extendable. So $A$ is determinant liftable. Let $(x, y, z, w) \in R^{4}$ be such that $(1-a c x)(1-b c w)=\left(u+a b c^{2} z\right) y$ and $x w=y z$ (see Example 1.3). Clearly, $(1-a c x, y, 1-b c w) \in U m\left(R^{3}\right)$. We will only use the existence of a nonuple ( $\left.x, y, z_{1}, z_{2}, w, q, r, s, t\right) \in R^{9}$, e.g., $\nu$ above, such that

$$
D:=\left[\begin{array}{cc}
s-a c x & q r u+a c z_{1}+b c z_{2} \\
y & t-b c w
\end{array}\right] \in \operatorname{Um}\left(\mathbb{M}_{2}(R)\right)
$$

has zero determinant, $(a c, s q),(b c, r t) \in U m\left(R^{2}\right)$ and $(s-a c x, y, t-b c w) \in U m\left(R^{3}\right)$. As $R$ is a $\Pi_{2}$ ring, $D$ is non-full (see [3, Thm. 1.4) and thus we can decompose $q r u+a c z_{1}+b c z_{2}=u_{a} u_{b}$, with $u_{a} \in R$ dividing $s-a c x$ and $u_{b} \in R$ dividing $t-b c w$. As in the previous paragraph we argue that $R$ is a $U_{2}$ ring.

In this paragraph we assume that $R$ is an integral domain and $A$ is simply extendable. To prove that $v_{a, b, c}$ is surjective we can assume that $a b c \neq 0$. As $A$ is simply extendable, from [3], Prop. 5.1(1) it follows that its reduction modulo Rabc ${ }^{2}$ is non-full and hence the system of congruences
$x y \equiv a c \bmod a b c^{2}, x w \equiv u \bmod a b c^{2}, y z \equiv 0 \quad \bmod a b c^{2}, z w \equiv b c \bmod a b c^{2}$
has a solution $(x, y, z, w) \in R^{4}$. From the second congruence it follows that $(c, x w) \in$ $U m\left(R^{2}\right)$. From this and the first and fourth congruences, it follows that there exists $\left(y^{\prime}, z^{\prime}\right) \in R^{2}$ such that $y=c y^{\prime}$ and $z=c z^{\prime}$. Thus, as $R$ is an integral domain, the above first system of congruences is equivalent to a second one

$$
x y^{\prime} \equiv a \quad \bmod a b c, x w \equiv u \quad \bmod a b c^{2}, y^{\prime} z^{\prime} \equiv 0 \quad \bmod a b, \quad z^{\prime} w \equiv b \quad \bmod a b c .
$$

As $(a, b) \in U m\left(R^{2}\right)$, from the last two congruences it follows firstly that $\left(a, z^{\prime}\right) \in$ $U m\left(R^{2}\right)$ and secondly that there exists $y^{\prime \prime} \in R$ such that $y^{\prime}=a y^{\prime \prime}$. Thus the second system of congruences is equivalent to a third one

$$
x y^{\prime \prime} \equiv 1 \quad \bmod b c, x w \equiv u \quad \bmod a b c^{2}, \quad y^{\prime \prime} z^{\prime} \equiv 0 \quad \bmod b, \quad z^{\prime} w \equiv b \quad \bmod a b c .
$$

From the first and third congruences it follows firstly that $\left(b, y^{\prime \prime}\right) \in U m\left(R^{2}\right)$ and secondly that there exists $z^{\prime \prime} \in R$ such that $z^{\prime}=b z^{\prime \prime}$. Thus the third system of congruences is equivalent to a fourth one that has only three congruences

$$
x y^{\prime \prime} \equiv 1 \quad \bmod b c, \quad x w \equiv u \quad \bmod a b c^{2}, \quad z^{\prime \prime} w \equiv 1 \quad \bmod a c .
$$

Thus $x \in U(R / R b c)$ and $w+R a c \in U(R / R a c)$ are such that the product of their images in $U(R / R c)$ is $\bar{u}$. Hence $R$ is a $U_{2}$ ring. Thus Theorem 1.10 holds.

Example 3.1. Let $(a, c) \in R^{2}$ be such that $\operatorname{Rac} \cap R(1-a) c=0$ and let $u \in R$ be such that $(c, u) \in U m\left(R^{2}\right)$; so $a(1-a) c=0$ and $A=\left[\begin{array}{cc}a c & u \\ 0 & (1-a) c\end{array}\right] \in$ $\operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$ has zero determinant. The reduction of $A$ modulo $R a c$ is $A_{1}:=$ $\left[\begin{array}{ll}0 & u \\ 0 & c\end{array}\right]$ and modulo $R(1-a) c$ is $A_{2}:=\left[\begin{array}{cc}c & u \\ 0 & 0\end{array}\right]$. Both $A_{1}$ and $A_{2}$ are non-full. For $i \in\{1,2\}$, to solve the matrix equation $A_{i}=\left[\begin{array}{c}l_{i} \\ m_{i}\end{array}\right]\left[\begin{array}{cc}o_{i} & q_{i}\end{array}\right]$ is the same as solving the system of equations $l_{i} o_{i}=c \delta_{i 1}, l_{i} q_{i}=u, m_{i} o_{i}=0, m_{i} q_{i}=c \delta_{i 2}$, where $\delta_{i 1}$ and $\delta_{i 2}$ are Kronecker deltas. As $(c, u) \in U m\left(R^{2}\right)$, we have $l_{1} \in U(R / R a c)$ and $q_{2} \in U(R / R(1-a) c)$. So the solution sets are $\left\{\left(l_{1}, 0, c l_{1}^{-1}, u l_{1}^{-1}\right) \mid l_{1} \in U(R / R a c)\right\}$ for $i=1$ and $\left\{\left(u q_{2}^{-1}, c q_{2}^{-1}, 0, q_{2}\right) \mid q_{2} \in U(R / R(1-a) c)\right\}$ for $i=2$. As $R c=R a c+R(a-$ $a) c$, the matrix $A$ is non-full iff there exists $\left(o_{1}, q_{2}\right) \in U(R / R a c) \times U(R / R(1-a) c)$ such that $l_{2} o_{1}+R c=u+R c$ and iff $u+R f \in \operatorname{Im}\left(v_{a, 1-a, c}\right)$.

## 4. Proof of Theorem 1.12 and applications

To prove Theorem 1.12 let $S:=R / N(R)$. We show that $(1) \Rightarrow(2)$. As $R$ is an $E D R$, each matrix in $\operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$ is determinant liftable by Theorem 1.2 and so it is weakly determinant liftable. From [9, Thm. 3 it follows that $S$ is an $E D R$ and hence it is a pre-Schreier ring by Example 1.8. So $(1) \Rightarrow(2)$ holds.

We show that $(2) \Rightarrow(3)$ if $N(R)=0$. As $N(R)=0$, from Example 1.3 it follows that condition (1) of Theorem 1.12 holds, hence $R$ is a $U_{2}$ ring. We have $(3) \Leftrightarrow(4)$, as for $(a, b),(c, d) \in U m\left(R^{2}\right),(4)$ only translates what means that the unit $d+R c \in U(R / R c)$ is in the image of $v_{a, b, c}$. Clearly, (4) $\Rightarrow(5)$ (with $\left.b=1-a\right)$.

To check that $(5) \Rightarrow(4)$, let $(a, b),(c, d) \in U m\left(R^{2}\right)$. If $(e, f, s, t) \in R^{4}$ is such that $a e+b f=c s+d t=1$, then by applying (5) to $(a e, d)$ and $s c \in 1+R d$ it follows that there exists $t_{1} \in R$ such that we can decompose $d+t_{1} s c=d_{1} d_{2}$ with $\left(a e, d_{1}\right),\left(1-a e, d_{2}\right)=\left(b, d_{2}\right) \in U m\left(R_{2}\right)$ and thus $\left(a, d_{1}\right),\left(b, d_{2}\right) \in U m\left(R_{2}\right)$ and statement (4) holds by taking $t:=t_{1} s$.

We show that $(3) \Rightarrow(1)$. As $R$ is an $E D R$ iff it is an $E_{2}$ ring (see Theorem 1.2), it suffices to show that if $R$ is a $U_{2}$ ring, then each $A \in U m\left(\mathbb{M}_{2}(R)\right)$ is extendable. Based on [3], Lem. 4.1(3), we can assume that $A$ is upper triangular, and hence we can write $A=\left[\begin{array}{cc}a c & u \\ 0 & b c\end{array}\right]$ where $(a, b, c, u) \in R^{4}$ is $\operatorname{such}$ that $\operatorname{det}(A)=a b c^{2}$ and $(a, b) \in U m\left(R^{2}\right)$ and $u$ in $R$ is (up to equivalence, see Section 2) an arbitrary representative of a fixed unit $u+R c \in U(R / R c)$. As $R$ is a $U_{2}$ ring, based on the arbitrariness part we can assume there exists $(d, e) \in R^{2}$ such that $u=d e$, $d+R a c \in U(R / R a c)$ and $e+R b c \in U(R / R b c)$. Let $d^{\prime}, e^{\prime} \in R$ be such that $d^{\prime}+R a c$ is the inverse of $d+R a c$ and $e^{\prime}+R a c$ is the inverse of $e+R b c$. Let $f, g \in R$ be such that $d d^{\prime}=1+a c f$ and $e e^{\prime}=1+b c g$. The non-full matrix

$$
B:=\left[\begin{array}{cc}
a c(1+b c g) & u \\
a b c^{2} d^{\prime} e^{\prime} & b c(1+a c f)
\end{array}\right]=\left[\begin{array}{cc}
a c e e^{\prime} & d e \\
a b c^{2} d^{\prime} e^{\prime} & b c d d^{\prime}
\end{array}\right] \in \mathbb{M}_{2}(R)
$$

is congruent to $A$ modulo $R \operatorname{det}(A)$. So $A$ modulo $R \operatorname{det}(A)$ is non-full, thus simply extendable (see [3], Prop. 5.1(2)). Hence $A$ is extendable by [3, Lem. 4.1(1).

We are left to show that $(2) \Rightarrow(3)$ in general (i.e., without assuming that $N(R)=0)$. For $A \in U m\left(\mathbb{M}_{2}(R)\right)$, let $\bar{A} \in U m\left(\mathbb{M}_{2}(S)\right)$ be its reduction modulo $N(R)$. If $B \in \operatorname{Um}\left(\mathbb{M}_{2}(S)\right)$, we choose $A$ such that $B=\bar{A}$. As $A$ is weakly
determinant liftable, there exists $C \in \mathbb{M}_{2}(R)$ congruent to $A$ modulo $R \operatorname{det}(A)$ and $\operatorname{det}(C)=0$. Hence $\bar{C} \in \mathbb{M}_{2}(S)$ is congruent to $B \operatorname{modulo} S \operatorname{det}(B)$ and $\operatorname{det}(\bar{C})=0$. So $S$ has the same properties as $R$ (note that $N(S)=0$ and $S=S / N(S)=R / N(R)$ is a pre-Schreier ring). As we proved that $(2) \Rightarrow(3)$ if $N(R)=0$, it follows that $S$ is a $U_{2}$ ring. As $(3) \Rightarrow(1)$, we incur that $S$ is an $E D R$. It is well-known that this implies that $R$ is an EDR: e.g., see [9, Thm. 3; this also follows from Theorem 1.2 via the fact that $A$ is (simply) extendable iff $\bar{A}$ is so as one can easily check based on [3], Cor. 4.7. As $R$ is an $E D D$, it is an $S E_{2}$ ring (see Theorem 1.2) and hence a $U_{2}$ ring (see Theorem 1.12(2)). Thus (2) $\Rightarrow$ (3). Hence Theorem 1.12 holds.

Corollary 4.1. Assume $R$ is a Bézout domain such that for each $(a, b) \in U m\left(R^{2}\right)$ and $c \in R$, the image of the functorial homomorphism $U(R / R a b c) \rightarrow U(R / R a b) \cong$ $U(R / R a) \times U(R / R b)$ is the product of the images of the functorial homomorphisms $U(R / R a b c) \rightarrow U(R / R a)$ and $U(R / R a b c) \rightarrow U(R / R b)$. Then $R$ is an $E D R$.

Proof. Based on Theorem 1.12, it suffices to show that $R$ is a $U_{2}$ ring. Given a unit $u+R c \in U(R / R c)$ and $(a, b) \in U m\left(R^{2}\right)$, let $a^{\prime}:=\operatorname{gcd}(a, c)$ and $b^{\prime}:=\operatorname{gcd}(b, c)$. As $\operatorname{gcd}(a, b)=1$, there exists $c^{\prime} \in R$ such that $c=a^{\prime} b^{\prime} c^{\prime}$. From our hypothesis applied to $\left(a^{\prime}, b^{\prime}\right) \in U m\left(R^{2}\right)$ and $c^{\prime} \in R$ it follows that there exist units $e+R c, f+R c \in$ $U(R / R c)$ such that their images in $U\left(R / R a^{\prime}\right) \times U\left(R / R b^{\prime}\right)$ are $\left(u+R a^{\prime}, 1+R b^{\prime}\right)$ and $\left(1+R a^{\prime}, u+R b^{\prime}\right)$ (respectively). Then $(u+R a, 1+R b) \in R / R a b \cong R / R a \times R / R b$ and $e+R c \in R / R c$ (resp. $(1+R a, u+R b) \in R / R a b \cong R / R a \times R / R b$ and $f+R c \in R / R c$ ) map to the same element in $R / R a^{\prime} b^{\prime} \cong R / R a^{\prime} \times R / R b^{\prime}$ and hence, as $a b c^{\prime}$ is the least common multiple of $c$ and $a b$, there exists $(g, h) \in R^{2}$ such that $g+R a b c^{\prime}$ (resp. $\left.h+R a b c^{\prime}\right)$ reduces to both of them. As $g+R b c \in U(R / R b c)$ and $h+R a c \in$ $U(R / R a c)$, it follows that $(e+R c)(f+R c) \in \operatorname{Im}\left(v_{a, b, c}\right)$. Hence to show that $v_{a, b, c}$ is surjective, by replacing $u+R c$ with $(u+R c)[(e+R c)(f+R c)]^{-1}$ we can assume that $u-1 \in R a^{\prime} b^{\prime}$, i.e., the images of $u+R c$ and $1+R a b$ in $R a^{\prime} b^{\prime}$ are equal, which implies that $u+R c$ belongs to $\operatorname{Im}\left(U\left(R / R a b c^{\prime}\right) \rightarrow U(R / R c)\right)$. As $a b c^{\prime}+R a b c \in R / R a b c$ has square 0 , the homomorphism $U(R / R a b c) \rightarrow U\left(R / R a b c^{\prime}\right)$ is surjective and thus $u+R c$ belongs also to $\operatorname{Im}(U(R / R a b c) \rightarrow U(R / R c))$ and hence to $\operatorname{Im}\left(v_{a, b, c}\right)$.

Corollary 4.2. Let $R$ be a Hermite ring. Then $R$ is an EDR iff for all homomorphisms $\phi: \mathbb{Z}[x, y, z] \rightarrow R$, the image of $\mathcal{D} \in \operatorname{Um}\left(\mathbb{M}_{2}(\mathbb{Z}[x, y, z])\right.$ ) (equivalently, $\mathcal{F} \in \operatorname{Um}\left(\mathbb{M}_{2}(\mathbb{Z}[x, y, z])\right)$, see Section (2) in $\operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$ via $\phi$ is extendable.

Proof. The 'only if' part is obvious. To prove the 'if' part, based on Theorem 1.12, it suffices to prove that $R$ is a $U_{2}$ ring, i.e., for all $a, c \in R$ and every $(u, c) \in U m\left(R^{2}\right)$, we have $u+R c \in \operatorname{Im}\left(v_{a, 1-a, c}\right)$. Let $s, t \in R$ be such that $c s+u t=1$. As $u+R c s \in$ $U(R / R c s)$, it suffices to prove that $u+R c s \in \operatorname{Im}\left(v_{a, 1-a, c s}\right)$. Thus by replacing $c$ with $c s$ we can assume that $c=1-u t$. Hence $A=\left[\begin{array}{cc}a(1-u t) & u \\ 0 & (1-a)(1-u t)\end{array}\right] \in$ $\operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$ is the image of $\mathcal{D}$ via the homomorphism $\phi: \mathbb{Z}[x, y, z] \rightarrow R$ that maps $x, y$, and $z$ to $a, u$, and $t$ (respectively) and so $A$ is extendable. As $\mathcal{D}$ is equivalent to $\mathcal{E}$ (see Section 2), it follows that $A$ is equivalent to the matrix $B:=\left[\begin{array}{cc}a & u \\ 0 & (1-a)(1-u w)\end{array}\right] \in \operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$, where $w:=2 t-u t^{2}$. From [3], Lem. $4.1(3)$ it follows that $B$ is extendable and hence its reduction modulo $\operatorname{det}(B)=$ $R a(1-a)(1-u w)=R a(1-a) c^{2}$ is non-full (see [3], Prop. 5.1(2)). We will denote by $\bar{*}$ the reduction modulo $R a(1-a) c^{2}$ of $*$, where $*$ is either $R$ or an element of
$R$. We have a product decomposition $\bar{u}=\overline{u_{1}} \bar{u}_{2}$ with $\bar{u}_{1}=u_{1}+R a(1-a) c^{2} \in \bar{R}$ dividing $\bar{a}$ and $\bar{u}_{2}=u_{2}+R a(1-a) c^{2} \in \bar{R}$ dividing $(1-\bar{a})(1-\bar{w} \bar{u})$ and hence also $1-\bar{a}$; here $\left(u_{1}, u_{2}\right) \in R^{2}$. Thus there exists a triple $(d, e, f) \in R^{3}$ such that $u_{1} u_{2}=u+a(1-a) c^{2} d, u_{1}$ divides $a+a(1-a) c^{2} e$ and $u_{2}$ divides $1-a+a(1-a) c^{2} f$. It follows that $\left(u_{1},(1-a) c\right),\left(u_{2}, a c\right) \in U m\left(R^{2}\right)$, and therefore we have an identity $u+R c=u_{1} u_{2}+R c=v_{a, 1-a, c}\left(u_{2}+R a c, u_{1}+R(1-a) c\right)$.
Corollary 4.3. Let $R$ be a Bézout domain. Then $R$ is an EDD iff for all $(a, u, t) \in$ $R^{3}$ with $u \neq 0$ there exists $(s, l, z) \in R^{3}$ such that
(IV)

$$
(1-u s-a l)^{2}+l-u s l-a l^{2}-(s+t-u s t) z=0
$$

Proof. The Hermite ring $R$ is an $E D R$ iff for all $(a, u, t) \in R^{3}$ the matrix $A=$ $\left[\begin{array}{cc}a(1-u t) & u \\ 0 & (1-a)(1-u t)\end{array}\right] \in \operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$ is extendable (see Corollary 4.2) iff it is determinant liftable (see Example 1.1(1)) and hence (see [4, Thm. 1.2) iff there exists $(x, y, z, w) \in R^{4}$ such that

$$
1-a(1-u t) x-u y-(1-a)(1-u t) w=0=x w-y z
$$

If $u=0$, then $A$ is diagonal and hence simply extendable (see [3], Ex. 4.9(3)). Thus we can assume $u \neq 0$. The equation $1-a(1-u t) x-u y-(1-a)(1-u t) w=0$ can be rewritten as $1-u y=(1-u t)(a x-a w+w)$ and working modulo $R u$ with $u \neq 0$ it follows that its general solution is $a x+(1-a) w=1-u s$ and $y=s+t-u s t$ with $s \in R$. As $R$ is an integral domain, the general solution of $a x+(1-a) w=1-u s$ is $x=1-u s+(1-a) l$ and $w=1-u s-a l$ and the equation $x w-y z=0$ becomes $[1-u s+(1-a) l](1-u s-a l)-(s+t-u s t) z=0$ and the corollary follows.

## 5. Proof of Theorem 1.15

For $(a, b) \in R^{2}$, let $\operatorname{Diag}(a, b)$ be the diagonal matrix whose $(1,1)$ and $(2,2)$ entries are $a$ and $b$ (respectively). We first prove the following general lemmas.
Lemma 5.1. Let $(d, e) \in R^{2}$ be such that $R d=R e$. Then there exists $N \in S L_{2}(R)$ such that $N \operatorname{Diag}(d, 0)=\operatorname{Diag}(e, 0)($ so $\operatorname{Diag}(d, 0)$ and $\operatorname{Diag}(e, 0)$ are equivalent $)$.
Proof. Let $(u, v) \in R^{2}$ be such that $(d, e)=(e u, d v)$. As $1-u v \in \operatorname{Ann}_{R}(d)$, for $N:=\left[\begin{array}{cc}v & -1 \\ 1-u v & u\end{array}\right] \in S L_{2}(R)$ one computes $\operatorname{Niag}(d, 0)=\operatorname{Diag}(e, 0)$.
Lemma 5.2. Let $e \in R$ be such that for $m \in\{2,4\}$ the reduction map $\operatorname{Um}\left(R^{m}\right) \rightarrow$ $\operatorname{Um}\left(\left(R / \operatorname{Ann}_{R}(e)\right)^{m}\right)$ is surjective2. Assume $N(R)=0$. Then all zero determinant matrices in eUm $\left(\mathbb{M}_{2}(R)\right)$ admit diagonal reduction iff $R / \mathrm{Ann}_{R}(e)$ is a $\Pi_{2}$ ring.
Proof. For $* \in R \cup \mathbb{M}_{2}(R)$, let $\bar{*}$ be the reduction of $*$ modulo $\operatorname{Ann}_{R}(e)$. We compute

$$
\left[\begin{array}{ll}
m_{11} & m_{12}  \tag{V}\\
m_{21} & m_{22}
\end{array}\right] \operatorname{Diag}(e, 0)\left[\begin{array}{ll}
l_{11} & l_{12} \\
l_{21} & l_{22}
\end{array}\right]=\left[\begin{array}{ll}
e m_{11} l_{11} & e m_{11} l_{12} \\
e m_{21} l_{11} & e m_{21} l_{12}
\end{array}\right]
$$

The right hand side of Equation (V) depends only on the pairs $\left(m_{11}, m_{21}\right),\left(l_{11}, l_{12}\right)$ in $R^{2}$. Given such two pairs, we have $\left(m_{11}, m_{21}\right),\left(l_{11}, l_{12}\right) \in U m\left(R^{2}\right)$ iff there exists $\left(m_{12}, m_{22}, l_{21}, l_{22}\right) \in R^{4}$ such that $\left[\begin{array}{ll}m_{11} & m_{12} \\ m_{21} & m_{22}\end{array}\right],\left[\begin{array}{ll}l_{11} & l_{12} \\ l_{21} & l_{22}\end{array}\right] \in S L_{2}(R)$.

[^2]Let $A=\left[\begin{array}{ll}a & b \\ c & d\end{array}\right] \in U m\left(\mathbb{M}_{2}(R)\right)$ be such that $\operatorname{det}(e A)=0$; so $e^{2} \operatorname{det}(A)=0$ and as $N(R)=0$ it follows that $e \operatorname{det}(A)=0$. Thus $\operatorname{det}(A) \in \operatorname{Ann}_{R}(e)$ and hence $\operatorname{det}(\bar{A})=0$. The matrix $e A$ admits diagonal reduction iff it is equivalent to $(f, 0)$ (see Example (1.8) with $R e=R f$ and hence iff it is equivalent to $(e, 0)$ (see Lemma 5.1). From this and the previous paragraph it follows that $e A$ admits diagonal reduction iff there exists $\left(m_{11}, m_{21}\right),\left(l_{11}, l_{12}\right) \in U m\left(R^{2}\right)$ such that $(e a, e b, e c, e d)$ is equal to $\left(e m_{11} l_{11}, e m_{11} l_{12}, e m_{21} l_{11}, e m_{21} l_{12}\right)$ and, as the map $U m\left(R^{2}\right) \rightarrow U m\left(\left(R / \operatorname{Ann}_{R}(e)\right)^{2}\right)$ is surjective, iff $\bar{A}=\left[\begin{array}{l}\overline{m_{11}} \\ \overline{m_{21}}\end{array}\right]\left[\begin{array}{ll}\overline{l_{11}} & \overline{l_{12}}\end{array}\right]$ is non-full. Each $C \in U m\left(\mathbb{M}_{2}\left(R / \operatorname{Ann}_{R}(e)\right)\right)$ is $\bar{B}$ for some $B \in U m\left(\mathbb{M}_{2}(R)\right)$; if $\operatorname{det}(C)=0$, then $\operatorname{det}(B) \in \operatorname{Ann}_{R}(e)$ and hence $\operatorname{det}(e B)=0$. Thus we conclude that all zero determinant matrices in $a U m\left(\mathbb{M}_{2}(R)\right)$ admit diagonal reduction iff all zero determinant matrices in $\operatorname{Um}\left(\mathbb{M}_{2}\left(R / \operatorname{Ann}_{R}(e)\right)\right)$ are non-full (equivalently, are simply extendable by [3], Prop. 5.1(1)) and iff $R / \operatorname{Ann}_{R}(e)$ is a $\Pi_{2}$ ring.

We prove Theorem 1.15. If $R$ is an $E D R$ then all zero determinant matrices in $\mathbb{M}_{2}(R)$ admit diagonal reduction. If for each $a \in R, R / A n n_{R}(a)$ is a $\Pi_{2}$ ring, then all zero determinant matrices in $R U m\left(\mathbb{M}_{2}(R)\right)=\mathbb{M}_{2}(R)$ admit diagonal reduction by Lemma 5.2. In the last two sentences we can replace 'admit diagonal reduction' by 'are non-full' by Example 1.8, hence Theorem 1.15 follows from Theorem 1.2 ,

$$
\text { 6. On }\left(W S U^{\prime}\right)_{n} \text { AND }(W S U)_{n} \text { RINGS }
$$

For $F \in \mathbb{M}_{n}(R)$, let $F^{T}$ be its transpose and let $\operatorname{Ker}_{F}$ and $\operatorname{Im}_{F}$ be the kernel and the image (respectively) of the $R$-linear map $L_{F}: R^{n} \rightarrow R^{n}$ defined by it.

Proposition 6.1. A ring $R$ is an $\left(S U^{\prime}\right)_{n}\left(\right.$ resp. $\left.(S U)_{n}\right)$ ring in the sense of Definition 2.1(2) iff it is so in the sense of [12], Def. 2.1.

Proof. For the 'only if' part, let $B \in \mathbb{M}_{n}(R)$. As $R$ is a Hermite ring, there exist $e \in R$ and $C \in U m\left(\mathbb{M}_{n}(R)\right)$ such that $B=e C$. As $R$ is an $\left(S U^{\prime}\right)_{n}\left(\operatorname{resp} .(S U)_{n}\right)$ ring, there exists $N \in S L_{n}(R)$ (resp. $N \in G L_{n}(R)$ ) such that $A N$ is symmetric. Hence $B N=e(A C)$ is symmetric, thus $R$ is an $\left(S U^{\prime}\right)_{n}$ (resp. $\left.(S U)_{n}\right)$ ring in the sense of [12], Def. 2.1. For the 'if part, clearly $R$ is a $\left(W S U^{\prime}\right)_{n}\left(\operatorname{resp} .(W S U)_{n}\right)$ ring and it is a Hermite ring by [12], Prop. 3.1.

As in [12], Sect. 2, if $U(R)$ is a 2-divisible abelian group, $R$ is a $\left(W S U^{\prime}\right)_{n}$ ring iff it is a $(W S U)_{n}$ ring. For $(W S U)_{n}$ rings we have the following general result.

Theorem 6.2. Assume $R$ is a $(W S U)_{n}$ ring. Then the following properties hold:
(1) Each unimodular matrix $A \in U m\left(\mathbb{M}_{n}(R)\right)$ is equivalent to its transpose $A^{T}$.
(2) If $n=2$, then every projective $R$-module of rank 1 and generated by 2 elements is self-dual.
(3) If $\operatorname{sr}(R) \leq n^{2}$, then for each $d \in R, R / R d$ is a $(W S U)_{n}$ ring.

Proof. If $N \in G L_{n}(R)$ is such that $A N$ is symmetric, then $\left(N^{T}\right)^{-1} A N=A^{T}$ and hence part (1) holds. To check part (2), let $P$ be a projective $R$-module of rank 1 generated by 2 elements. We consider an isomorphism $P \oplus Q \cong R^{2}$ to be viewed as an identification. Taking determinants it follows that $Q$ is the dual of
$P$. Let $B \in U m\left(\mathbb{M}_{2}(R)\right)$ be such that $\operatorname{Ker}_{B}=Q$ and $\operatorname{Im}_{B}=P$. As $B^{T}$ and $B$ are equivalent by part (1), the $R$-modules $P$ and $Q$ are isomorphic, so $P$ is selfdual. Thus part (2) holds. To check part (3) for $d \in R$, let $\bar{A} \in U m\left(\mathbb{M}_{n}(R / R d)\right)$. As $s r(R) \leq n^{2}$, there exists $A \in U m\left(\mathbb{M}_{n}(R)\right)$ such that its reduction modulo $R d$ is $\bar{A}$ (see [3], Prop. 2.4(1)). Let $N \in G L_{n}(R)$ be such that $A N$ is symmetric. If $\bar{N} \in G L_{n}(R / R a)$ is the reduction of $N$ modulo $R d$, then $\bar{A} \bar{N}$, being the reduction of $A N$ modulo $R d$, is symmetric. Thus $R / R d$ is a $(W S U)_{n}$ ring; so part (3) holds.

Remark 6.3. If $R$ is an integral domain such that for each $d \in R$, every projective $R / R d$-module of rank 1 and generated by 2 elements is self-dual, then each $A \in$ $\operatorname{Um}\left(\mathbb{M}_{n}(R)\right)$ is equivalent to its transpose $A^{T}$.

## 7. Proof of Theorem 1.17 and applications

Let Spec $R$ be the spectrum of $R$ and let Max $R$ be its subset of maximal ideals.
To prove part (1), it suffices to show that for all $(u, c) \in U m\left(R^{2}\right)$ and $a \in R$, we have $u^{2}+R c \in \operatorname{Im}\left(v_{a, 1-a, c}\right)$. To check this we can assume that $c \neq 0$. As in the proof of Corollary4.2, we can assume that there exists $t \in R$ such that $c=1-u t$. As we are assuming that $R$ is a $(W S U)_{2}$ ring, there exists $M=\left[\begin{array}{cc}x & y \\ z & w\end{array}\right] \in G L_{2}(R)$ such that $M\left[\begin{array}{cc}a c & u \\ 0 & (1-a) c\end{array}\right]$ is a symmetric matrix, i.e., we have an identity

$$
\begin{equation*}
a c z=u x+(1-a) c y \tag{VI}
\end{equation*}
$$

As $c$ divides $u x$ and $(u, c) \in U m\left(R^{2}\right), c$ divides $x$. Let $s \in R$ be such that $x=c s$.
Let $\mu:=\operatorname{det}(M)=c s w-y z \in U(R)$. Thus $(c s, y z) \in U m\left(R^{2}\right)$.
We first assume that $c \notin Z(R)$. Dividing Equation (VI) by $c$ it follows that

$$
\begin{equation*}
a z+(a-1) y=u s \tag{VII}
\end{equation*}
$$

We check that the assumption $(a, s) \notin U m\left(R^{2}\right)$ leads to a contradiction. This assumption implies that there exists $\mathfrak{m} \in \operatorname{Max} R$ such that $R a+R s \subseteq \mathfrak{m}$. From this and Equation (VII) it follows that $(a-1) y \in \mathfrak{m}$. As $a-1 \notin \mathfrak{m}$, it follows that $y \in \mathfrak{m}$, hence $(s, y z) \notin U m\left(R^{2}\right)$, a contradiction. As $(a, s) \in U m\left(R^{2}\right), s+R a \in U(R / R a)$.

From Equation (VII) it follows that the images of $(-y+R c)(u+R c)^{-1} \in$ $U(R / R c)$ and $s+R a \in U(R / R a)$ in $U(R /(R a+R c))$ are equal. Thus there exists a unit of the quotient ring $R /(R a \cap R c)$ that maps to $(-y+R c)(u+R c)^{-1} \in U(R / R c)$. As $(R a \cap R c) / R a c$ is a square 0 ideal of $R / R a c$, the homomorphism $U(R / R a c) \rightarrow$ $U(R /(R a \cap R c))$ is surjective, hence $(-y+R c)(u+R c)^{-1} \in \operatorname{Im}\left(v_{a, 1-a, c}\right)$.

Due to the symmetry of Equation (VII) in $a z$ and $(a-1) y$, similar arguments give $s+R(1-a) \in U(R / R(1-a))$ and $(z+R c)(u+R c)^{-1} \in \operatorname{Im}\left(v_{a, 1-a, c}\right)$. Clearly $\mu+R c \in \operatorname{Im}\left(v_{a, 1-a, c}\right)$. As $\mu+R c=(-y+R c)(z+R c)$, it follows that
$(u+R c)^{2}=\left[(-y+R c)(u+R c)^{-1}\right]^{-1}\left[(z+R c)(u+R c)^{-1}\right]^{-1}(\mu+R c) \in \operatorname{Im}\left(v_{a, 1-a, c}\right)$.
We use a trick with annihilators to show that an analogue of Equation (VII) holds even if $c \in Z(R)$. As $(c, u),(c, y z) \in U m\left(R^{2}\right)$, it follows that $(c, u y z) \in U m\left(R^{2}\right)$. This implies that $\operatorname{Ann}_{R}(c) \subset R u y z$. From this and the identity $c[a z+(a-1) y-u s]=$ 0 it follows that there exists $q \in R$ such that $a z+(a-1) y-s u=u y z q$. If $s_{1}:=s+y z q$, then $\left(s_{1}, y z\right) \in U m\left(R^{2}\right)$ and the identity $a z+(a-1) y=u s_{1}$ holds. Thus, using $s_{1}$ and the last identity instead of $s$ and Equation (VII), as above we argue that $(u+R c)^{2} \in \operatorname{Im}\left(v_{a, 1-a, c}\right)$. So part (1) holds.

Part (2) follows from Theorem 6.2(2) and (3). The first part of part (3) follows from part (1) and definitions. Based on it, the second part of part (3) follows from Theorem 1.12 Thus Theorem 1.17 holds.
Remark 7.1. If $(a, y) \in U m\left(R^{2}\right)\left(\right.$ resp. $\left.(1-a, z) \in U m\left(R^{2}\right)\right)$, then $-y+R a c \in$ $U(R / R a c)($ resp. $z+R / R(1-a) c \in U(R / R(1-a) c))$, hence $u+R c \in \operatorname{Im}\left(v_{a, 1-a, c}\right)$.
Corollary 7.2. For a Bézout domain the following statements are equivalent:
(1) The ring $R$ is an $(W S U)_{2}$ (resp. $\left.\left(W S U^{\prime}\right)_{2}\right)$ ring.
(2) For all $(a, b),(c, u) \in U m\left(R^{2}\right)$ with abc $\neq 0$, if $\left(a^{\prime}, b^{\prime}\right) \in R^{2}$ such that $a a^{\prime}+b b^{\prime}=1$ is given, then there exists a triple $(s, l, w) \in R^{3}$ with the property that $c s w+\left(a^{\prime} u s-b l\right)\left(b^{\prime} u s+a l\right) \in U(R)\left(\right.$ resp. $\left.c s w+\left(a^{\prime} u s-b l\right)\left(b^{\prime} u s+a l\right)=1\right)$.
Proof. If $A_{1}, A_{2} \in \mathbb{M}_{2}(R)$ are equivalent, then there exists $M_{1} \in G L_{2}(R)$ such that $M_{1} A_{1}$ is symmetric iff there exists $M_{2} \in G L_{2}(R)$ such that $M_{2} A_{2}$ is symmetric. This is so, as for $M, N, M_{1} \in G L_{2}(R)$ such that $A_{2}=M A_{1} N$ and $M_{1} A_{1}$ is symmetric, by denoting $M_{2}:=N^{T} M_{1} M^{-1} \in G L_{2}(R), M_{2} A_{2}=N^{T}\left(M_{1} A_{1}\right) N$ is symmetric. Also, if $M, N, M_{1} \in S L_{2}(R)$, then $M_{2} \in S L_{2}(R)$.

Based on the previous paragraph and Section 2, the ring $R$ is a $(W S U)_{2}$ (resp. $\left.\left(W S U^{\prime}\right)_{2}\right)$ ring iff for all $(a, b),(c, u) \in U m\left(R^{2}\right)$ there exists $M=\left[\begin{array}{cc}x & y \\ z & w\end{array}\right]$ in $G L_{2}(R)$ (resp. in $S L_{2}(R)$ ) such that the matrix $M\left[\begin{array}{cc}a c & u \\ 0 & b c\end{array}\right]$ is symmetric, i.e., the equation $a c z=u x+b c y$ holds. If $a b c=0$, then $\left[\begin{array}{cc}a c & u \\ 0 & b c\end{array}\right]$ is simply extendable (see [3], Ex. 4.9(3)) and hence equivalent to a diagonal matrix (see [3], Thm. 4.3) and from the previous paragraph we get that $M$ exists. Thus we can assume that $a b c \neq 0$. So $c \notin Z(R)$ and hence as in the proof of Theorem 1.17 we write $x=c s$ with $s \in R$ and the identity $a z=u s+b y$ holds. The general solution of the equation $a z-b y=u s$ in the indeterminates $y, z$ is $z=a^{\prime} u s-b l$ and $y=-b^{\prime} u s-a l$ with $l \in R$. As $\operatorname{det}(M)=x w-y z=c s w+\left(a^{\prime} u s-b l\right)\left(b^{\prime} u s+a l\right)$, the corollary hods.

Remark 7.3. Referring to Corollary 7.2 (2) with $b=1-a$, we can take $a^{\prime}=1=b^{\prime}$, and one is searching for $(s, l, w) \in R^{3}$ such that $c s w+(u s+a l-l)(u s+a l) \in U(R)$ $($ resp. and $c s w+(u s+a l-l)(u s+a l)=1$, which for $c=1-u t$ with $t \in R$ is closely related to Equation (IV) via a substitution of the form $z:=-w)$.
Remark 7.4. A symmetric matrix $A=\left[\begin{array}{ll}a & b \\ b & d\end{array}\right] \in \operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$ is determinant liftable iff there exists $(x, w)^{2} \in R$ such that $b$ divides $1-a x-d w$ and for a suitable $s \in R$ such that $b s=1-a x-c w$, the equation $X^{2}+s X+x w=0$ has two solutions $y, z \in R$ (so $x w-y z=0$ and $1-a x-b y-b z-d w=0$ ).

Recall from [24], Sect. 1 that $R$ is said to have square stable range 1 , and one writes $\operatorname{ssr}(R)=1$, if for each $(a, b) \in U m\left(R^{2}\right)$, there exists $r \in R$ such that $a^{2}+b r \in U(R)$. Clearly, if $s r(R)=1$, then $\operatorname{ssr}(R)=1$.
Example 7.5. Assume $\operatorname{ssr}(R)=1$. Then for each $c \in R$, the cokernel of the reduction homomorphism $U(R) \rightarrow U(R / R c)$ is a Boolean group and hence for all $(a, b) \in U m\left(R^{2}\right), \operatorname{Coker}\left(v_{a, b, c}\right)$ is a Boolean group. If $(c, u) \in U m\left(R^{2}\right)$, let $w \in R$ be such that $u^{2}+c w \in U(R)$. Then $M:=\left[\begin{array}{cc}c & -u \\ u & w\end{array}\right] \in G L_{2}(R)$ and the
product matrix $M\left[\begin{array}{cc}a c & u \\ 0 & (1-a) c\end{array}\right]$ is symmetric. Hence, if $R$ is also a Hermite ring, then each upper triangular matrix in $\operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$ has a companion test matrix equivalent to a symmetric matrix; thus, from this, Theorem 1.2 and Proposition 2.2 it follows that $R$ is an $E D R$ iff each symmetric matrix in $\operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$ is extendable.

## 8. Proof of Theorem 1.18

Let $P$ be a projective $R / R d$-module of rank 1 generated by 2 elements. We consider an isomorphism $P \oplus Q \cong(R / R d)^{2}$. Let $D \in U m\left(\mathbb{M}_{2}(R / R d)\right)$ be such that $\operatorname{Ker}_{D}=Q$ and $\operatorname{Im}_{D}=P$. As $\operatorname{sr}(R) \leq 2$, there exists $A \in U m\left(\mathbb{M}_{2}(R)\right)$ such that its reduction modulo $R d$ is $D$ (see 3, Prop. 2.4(1)). Let $\bar{R}:=R / R \operatorname{det}(A)$ and let $\bar{A} \in U m\left(\mathbb{M}_{2}(\bar{R})\right)$ be the reduction of $A$ modulo $R \operatorname{det}(A)$. We have $\operatorname{det}(A) \in R d$. We know that $\operatorname{Ker}_{\bar{A}}$ and $\operatorname{Im}_{\bar{A}}$ are dual projective $\bar{R}$-modules of rank 1 generated by 2 elements (see [3], Sect. 3) and their reductions modulo the ideal $R d / R \operatorname{det}(A)$ of $\bar{R}$ are $Q$ and $P$. Thus, to end the proof, it suffices to show that the classes of $\operatorname{Ker}_{\bar{A}}$ and $\operatorname{Im}_{\bar{A}}$ in $\operatorname{Pic}(\bar{R})$ are equal (equivalently, have orders 1 or 2 or equivalently, $\operatorname{Ker}_{\bar{A}}^{2}$ and $\operatorname{Im}_{\bar{A}}^{2}$ are free $R$-modules of rank 2 ). So, $d$ and $D$ will not be mentioned again.

Based on Section2, we can assume that $A=\left[\begin{array}{cc}a c & u \\ 0 & b c\end{array}\right] \in \mathbb{M}_{2}(R)$ with $(a, b, c) \in$ $R^{3}$ such that $(a, b),(c, u) \in U m\left(R^{2}\right)$ and we will only use that $\operatorname{Coker}\left(v_{a, b, c}\right)$ is a Boolean group. As $\operatorname{Coker}\left(v_{a, b, c}\right)$ makes sense for $R / R a b c$ and as two finitely generated projective $R / R a b c^{2}$-modules are isomorphic if and only if their reductions modulo the square 0 ideal $R a b c / R a b c^{2}$ are isomorphic, by reducing modulo $R a b c$ we can assume that $a b c=0$. Hence $(R, A)=(\bar{R}, \bar{A})$ and we will only use $(R, A)$.

Let $(s, t) \in R^{2}$ be such that $c s+u t=1$. By [3], Ex. 5.2 we have $\operatorname{Ker}_{A}=$ $R v_{1}+R v_{2}$, where $v_{1}:=\left[\begin{array}{c}-u \\ a c\end{array}\right]$ and $v_{2}:=\left[\begin{array}{c}-b c \\ 0\end{array}\right]$. As $(a, b) \in \operatorname{Um}\left(R^{2}\right)$, we have Spec $R=$ Spec $R_{a} \cup S$ Sec $R_{b}$. Note $\left(\operatorname{Ker}_{A}\right)_{a}=R_{a} v_{1}$ and $\left(\operatorname{Ker}_{A}\right)_{b}=R_{b}\left(t v_{1}+\frac{s}{b} v_{2}\right)$. Over $R_{a b}$ we have $c=0$ and hence $v_{1}=u\left(t v_{1}+\frac{s}{b} v_{2}\right)$. Thus $\left(\operatorname{Ker}_{A}^{\otimes 2}\right)_{a}=R\left(v_{1} \otimes v_{1}\right)$, $\left(\operatorname{Ker}_{A}^{\otimes 2}\right)_{b}=R\left(\left(t v_{1}+\frac{s}{b} v_{2}\right) \otimes\left(t v_{1}+\frac{s}{b} v_{2}\right)\right)$, and over $R_{a b}$ we have an identity $v_{1} \otimes v_{1}=$ $u^{2}\left(\left(t v_{1}+\frac{s}{b} v_{2}\right) \otimes\left(t v_{1}+\frac{s}{b} v_{2}\right)\right)$. As $u^{2}+R c \in \operatorname{Im}\left(v_{a, b, c}\right)$, there exists $u_{a} \in U(R / R b c)$ and $u_{b} \in U(R / R a c)$ such that the product of their images in $U(R / R c)$ is $u^{2}+R c$. As $R_{a}$ is a localization of $R / R b c$ and $R_{b}$ is a localization of $R / R a c$, we will denote also by $u_{a}$ and $u_{b}$ their images in $R_{a}$ and $R_{b}$ (respectively). Thus $u_{a}^{-1}\left(v_{1} \otimes v_{1}\right)$ and $u_{b}^{-1}\left(\left(t v_{1}+\frac{s}{b} v_{2}\right) \otimes\left(t v_{1}+\frac{s}{b} v_{2}\right)\right)$ coincide over $R_{a b}$ and hence there exists an element $v \in \operatorname{Ker}_{A}^{\otimes 2}{ }_{s}$ whose images in $\left(\operatorname{Ker}_{A}^{\otimes 2}\right)_{a}$ and $\left(\operatorname{Ker}_{A}^{\otimes 2}\right)_{b}$ are equal to $u_{a}^{-1}\left(v_{1} \otimes v_{1}\right)$ and $u_{b}^{-1}\left(\left(t v_{1}+\frac{s}{b} v_{2}\right) \otimes\left(t v_{1}+\frac{s}{b} v_{2}\right)\right)$ (respectively). Thus $R v=\operatorname{Ker}_{A}^{\otimes 2}$, hence $\operatorname{Ker}_{A}^{\otimes 2} \cong R$.
Corollary 8.1. Let $R$ be a Hermite ring such that for each $a \in R$, every selfdual projective $R / R a$-module of rank 1 generated by 2 elements is free. Then the following properties hold:
(1) The ring $R$ is an EDR iff for all $(a, b) \in U m\left(R^{2}\right)$ and $c \in R$, $\operatorname{Coker}\left(v_{a, b, c}\right)$ is a Boolean group.
(2) If $R$ is a $(W S U)_{2}$ ring, then $R$ is an $E D R$.

Proof. For part (1), its 'only if' part follows from Theorem 1.12. To check the 'if' part, from Theorem 1.18 it follows that for each $A \in U m\left(\mathbb{M}_{2}(R)\right)$, the reduction $\bar{A}$ of $A$ modulo $R \operatorname{det}(A)$ is such that $\operatorname{Im}_{\bar{A}} \cong R / R \operatorname{det}(A)$, hence $\bar{A}$ is non-full and thus extendable (see [3], Prop. 5.1(2)). Hence $R$ is an $E_{2}$ ring and thus an EDR by Theorem [1.2, Thus Corollary 8.1(1) holds. Corollary 8.1(2) follows from Corollary 8.1(1) and Theorem 1.17(1) (it also follows from Theorems 6.2(2) and 1.2).

## 9. Proof of Criteria 1.19 and 1.20

We first prove Criterion 1.19 (1). If there exists $(e, f) \in R^{2}$ such that $a e^{2}-c f^{2} \in$ $U(R)$, then from the identity $a e^{2}-c f^{2}=e(a e+b f)-f(b e+c f)$ it follows that $(a e+b f, b e+c f) \in U m\left(R^{2}\right)$, so $A$ is simply extendable by [3], Thm. 4.3. For the converse, assume $\operatorname{char}(R)=2$ and $A$ is simply extendable. Let $(e, f) \in U m\left(R^{2}\right)$ be such that $(a e+b f, b e+c f) \in U m\left(R^{2}\right)$ by loc. cit. To prove that $a e^{2}-c f^{2} \in U(R)$ it suffices to show that the assumption that there exist $\mathfrak{m} \in M a x R$ such that $a e^{2}-c f^{2} \in \mathfrak{m}$, leads to a contradiction. By replacing $R$ with $R / \mathfrak{m}$, we can assume that $R$ is a field and we know that either $a \neq 0$ or $c \neq 0$, either $a e+b f \neq 0$ or $b e+c f \neq 0, a c=b^{2}$ and $a e^{2}=c f^{2}$; hence either $e \neq 0$ or $f \neq 0$. If acef $=0$, then by the symmetry in $(a, c)$ and $(e, f)$ we can assume that $a e=0$; if $a=0$, then $b=0, c \neq 0$, and hence $f=0$, thus $a e+b f=b e+c f=0$, a contradiction, and if $e=0$, then $f \neq 0$, hence $c=0$, and by the symmetry in the pair $(a, c)$, we similarly reach a contradiction. Thus we can assume that acef $\neq 0$, hence $b^{2}=a c=e^{-2} c^{2} f^{2}=f^{-2} a^{2} e^{2}$; as $\operatorname{char}(R)=2$ and $R$ is a field, it follows that $b=e^{-1} c f=f^{-1} a e$, thus $a e+b f=b e+c f=0$, a contradiction. So part (1) holds.

To prove part (2), as $b \notin Z(R)$, for each $\mathfrak{m} \in \operatorname{Max} R, b$ is a nonzero element of $R_{\mathfrak{m}}$. As $R$ is a Hermite ring and $N(R)=0$, each $R_{\mathfrak{m}}$ is a valuation domain (e.g., see [4], Ex. 2.4). Let $d \in R$ and $\left(a^{\prime}, b^{\prime}\right) \in U m\left(R^{2}\right)$ be such that $a=d a^{\prime}$ and $b=d b^{\prime}$. As $d$ divides $a$ and $(a, c) \in U m\left(R^{2}\right)$, we have $(d, c) \in U m\left(R^{2}\right)$. Thus also $\left(d^{2}, c\right) \in U m\left(R^{2}\right)$. From this, as $d^{2}$ divides $a c$, it follows that $d^{2}$ divides $a$; let $u \in R$ be such that $a=d^{2} u$. As $b \in R_{\mathfrak{m}} \backslash\{0\}$, it is easy to see that the image of $u$ in $R_{\mathfrak{m}}$ is a unit for all $\mathfrak{m} \in \operatorname{Max} R$. Hence $u \in U(R)$. By symmetry, there exist $g \in R$ and $v \in U(R)$ such that $c=g^{2} v$. As $b \notin Z(R)$, we have $d, g \notin Z(R)$.

To complete the proof that the matrix $A$ is extendable, based on part (1) it suffices to show that there exists $(e, f) \in R^{2}$ such that $a e^{2}-c f^{2}=a e^{2}+c f^{2} \in U(R)$. Replacing $A$ by $u^{-1} A$ (see [3], Lem. 4.1(3)), we can assume that $u=1$. Thus $a=d^{2}$. From this and the identities $a c=b^{2}$ and $c=g^{2} v$, the element $w:=\frac{b}{g d}$ of the total ring of fractions of $R$ has the property that $w^{2}=v$ in each valuation domain $R_{\mathfrak{p}}$ with $\mathfrak{p} \in \operatorname{Spec} R$, hence $w \in R_{\mathfrak{p}}$, and we conclude that $w \in R$ and $v=w^{2}$. By replacing $(v, g)$ with $(1, g w)$, we can assume that $v=1$ and $c=g^{2}$. As $(a, c)=\left(d^{2}, g^{2}\right) \in U m\left(R^{2}\right)$, it follows that $(d, g) \in U m\left(R^{2}\right)$, hence there exists $(e, f) \in U m\left(R^{2}\right)$ such that $d e+g f=1$, and so $a e^{2}+c f^{2}=1 \in U(R)$. Thus part (2) holds and so Criterion 1.19 holds.

We prove Criterion 1.20. As $R$ is an $(S U)_{2}$ ring, it is a Hermite ring, and, as the extendability is preserved under equivalence (see [3], Lem. 4.1(3)), it is an $E_{2}$ ring iff each symmetric matrix in $\operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$ is extendable. Thus $R$ is an $E D R$ iff each symmetric matrix in $\operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$ is extendable by Theorem 1.2, Let $A=\left[\begin{array}{ll}a & b \\ b & c\end{array}\right] \in \operatorname{Um}\left(\mathbb{M}_{2}(R)\right)$. Based on [3], Lem. 4.1(1) and Criterion 1.19(1)
applied to $A$ modulo $R\left(a c-b^{2}\right), A$ is extendable if there exists $(e, f) \in R^{2}$ such that $a e^{2}-c f^{2}+R\left(a c-b^{2}\right) \in U\left(R /\left[R\left(a c-b^{2}\right)\right]\right)$, equivalently, if $\left(a e^{2}-c f^{2}, a c-b^{2}\right) \in$ $U m\left(R^{2}\right)$, and the converse holds if $\operatorname{char}(R)=2$; hence Criterion 1.20 holds.

## 10. Proof of Criterion 1.22

As $R$ is a Bézout domain, $R$ is an $E D D$ iff for all $(a, b, s) \in R^{3}$, the equation

$$
\begin{equation*}
[1-(1-a-b s) w-b y](1-a x)=a y[(1-a-b s) z+b x] \tag{VIII}
\end{equation*}
$$

in the indeterminates $x, y, z$ and $w$ has a solution in $R^{4}$ (see Corollary 1.14 and Proposition [2.3(1)). To solve this equation, we note that, as $(a, 1-a x) \in \operatorname{Um}\left(R^{2}\right)$, $a$ divides $1-(1-a-b s) w-b y$. Thus, as $R$ is an integral domain, Equation (IX) has a solution in $R^{4}$ iff the system of two equations

$$
\begin{equation*}
1-(1-a-b s) w-b y=t a \text { and } t(1-a x)=y[(1-a-b s) z+b x] \tag{IX}
\end{equation*}
$$

in the indeterminates $t, x, y, z$ and $w$ has a solution in $R^{5}$ (this holds even if $a=0$ !).
The first equation of System (IX), rewritten as $w=1+a(w-t)+b(s w-y)$, has the general solution given by $w=1-a q-b r, t=q+w=1+q-a q-b r$ and $y=r+s w=r+s(1-a q-b r)$, where $(q, r) \in R^{2}$ can be arbitrary.

The second equation of System (IX), rewritten as $t=(a t+b y) x+(1-a-b s) y z$, has a solution iff $t \in R(a t+b y)+R(1-a-b s) y$. As $1=(1-a-b s) w+(a t+b y)$, we have $t \in R(a t+b y)+R(1-a-b s) y$ iff $t \in R(a t+b y)+R y=R a t+R y$.

From the last two paragraphs it follows that System (IX) has a solution in $R^{5}$ iff there exists $(q, r) \in R^{2}$ as mentioned in statement (2). Thus (1) $\Leftrightarrow(2)$.

If $(1-a, b) \in U m\left(R^{2}\right)$, then we can choose $(q, r) \in U m\left(R^{2}\right)$ such that $t=$ $1+q(1-a)+r b=0$, hence $t=0 \in R a t+R y=R y$, and for $e:=1$ and $f:=0$, we have $(a, e),(b e+a f, 1-b s-a) \in U m\left(R^{2}\right)$. Thus to prove that (2) $\Leftrightarrow$ (3) we can assume that $(1-a, b) \notin U m\left(R^{2}\right)$, and hence always $t \neq 0$.

For $t_{1}:=\operatorname{gcd}(r-q s, t)$ we write $t=t_{1} t_{2}$ and $r-q s=\alpha t_{1}$ with $\left(\alpha, t_{2}\right) \in U m\left(R^{2}\right)$; thus $y=r+s(t-q)=s t+\alpha t_{1}$. We would like to find $(q, r) \in R^{2}$ such that there exists $(g, h) \in R^{2}$ with the property that $g y+a h t=t$, equivalently, $g s t+g \alpha t_{1}+a h t=$ $t$, and thus we must have $g \in R t_{2}$. Writing $g=t_{2} \beta$ with $\beta \in R$, we want to find $(q, r) \in R^{2}$ such that there exists $(\beta, h) \in R^{2}$ satisfying $1=\beta\left(s t_{2}+\alpha\right)+a h$, equivalently, such that $\left(a, s t_{2}+\alpha\right) \in U m\left(R^{2}\right)$. Replacing $r=q s+\alpha t_{1}$ in $t$, it follows that $t=1+q-b q s-b \alpha t_{1}-a q$, hence there exists $\gamma \in R$ such that $1+q(1-b s-a)=t_{1} \gamma$; we have $t_{2}=\gamma-b \alpha$ and thus $e:=s t_{2}+\alpha=s \gamma+(1-b s) \alpha$. As $\left(\alpha, t_{2}\right) \in U m\left(R^{2}\right)$, it follows that $(\alpha, \gamma) \in U m\left(R^{2}\right)$. There exists a unique $f \in R$ such that $\alpha=e-f s$ and $\gamma=b e+f(1-b s)$; in fact we have $f=t_{2}=\gamma-b \alpha$ and thus $R=R \alpha+R \gamma=R e+R f$, i.e., $(e, f) \in U m\left(R^{2}\right)$. There exists $q \in R$ such that $b e+f(1-b s)$ divides $1+q(1-b s-a)$ iff $(b e+f(1-b s), 1-b s-a) \in U m\left(R^{2}\right)$ and hence iff $(b e+a f, 1-b s-a) \in U m\left(R^{2}\right)$. Thus $(2) \Leftrightarrow(3)$. So Criterion 1.22 holds.

Acknowledgement. The third author would like to thank SUNY Binghamton for good working conditions. Competing interests: the authors declare none.
